We report on a mother and her daughter affected by peripheral polyneuropathy and intellectual disability. The two patients referred frequent falls and walking difficulties. A motor-mixed sensory axonal-demyelinating polyneuropathy was diagnosed with electromyography (MCV: 33m/sec in the mother, 25m/sec in the daughter). Clinical features included in both patients premature ovarian failure, osteoporosis, body freckling, pes cavus and claw toes. Early hair whitening, seizures and thyroid nodular hyperplasia were observed only in the daughter.

In both subjects, a telomeric duplication at Xp22.3-11.4 was identified by array-CGH analysis. The duplicated region spanned 41 Mb and encompassed 135 genes, among which only few had previously been associated with some aspects of their clinical phenotype.

Duplications of *CDKL5* and *RPS6KA3* cause developmental delay and learning disabilities both in males and females. *SAT1* duplication is associated with a rare kind of chronic dermatitis named keratosis follicularis spinulosa decalvans. Interestingly, *PDK3* had been associated with the new X-linked dominant Charcot-Marie-Tooth type 6 (CMTX6, MIM300905) on the basis of the finding of a missense *PDK3* (p.Arg158His) gain-of-function mutation (Kennerson et al, 2013). Thus, in our patients we hypothesize an activating role of the *PDK3* duplication, in analogy with *PMP22* in the Charcot-Marie-Tooth type 1A.

In conclusion, we describe two patients with a 41-Mb Xp-telomeric duplication related to a syndromic form of polyneuropathy and intellectual disability. Clinical phenotype could be explained by a combination of duplicated genes: *CDKL5* and *RPS6KA3* for intellectual disability, *SAT1* for body freckling, *PDK3* for polyneuropathy.

P10.06

A novel mutation in NEFL gene associated with early onset severe Charcot-Marie-Tooth disease in Karachay populations

R. A. Zinchenko^{1,2}, E. L. Dadali^{1,2}, A. K. Makaov³, A. V. Polyakov¹, M. V. Bulach¹, E. K. Ginter¹;

Moscow, Russian Federation, ³Municipal Budgetary Health Care setting, Chabez, Russian

Federation.

Introduction: Charcot-Marie-Tooth (CMT) - is genetically and clinically heterogeneous group of the peripheral nervous system diseases. On average, in the world their prevalence is 10.0 per 100,000 persons, ranging from 0.1 to 41.0 per 100,000 persons.

Materials and Methods: During expeditions into Ust-Dzhegutinsky district of Karachai-Cherkess 10 patients from one family with autosomal dominant form CMT were identified. We developed and used the panel for TargetSeq containing 400 genes mutations in which are found by NGS of neurogenetic diseases patients. The analysis was performed on Illumina NextSeq 500 by paired-end reads (2x151 bp) with an average coverage of at least 70-100x

paired-end.

Results: Using NGS scanning, we identified heterozygous substitution c.65C>A (p.Pro22His) in exon 1 of the gene NEFL. This nucleotide substitution has not been previously reported in literature and mutations databases (HGMD, IPNMDDB). Then we searched the mutation in other patients, using the method of Sanger sequencing. The mutation c.65C>A was detected in all affected family members in the heterozygous state. The debut of the disease between 13 to 18 years with the appearance of weakness peroneal muscle groups. The speed of the pulse (SPI) on the median nerve in patients was from 33.5 to 42.3 m/s.

Conclusion: This is the first report of missense mutations c.65C>A (p.Pro22His) gene NEFL, associated with a group of intermediate types CMT. This types CMT was found in Karachai family. The prevalence in the region amounts 1:3300 Karachai.

This work was partially funded by RFBR grants 15-04-01859.

P10.08

Prevalence and spectrum of SH3TC2 mutations in Norway

K. A. Arntzen¹, H. Høyer², M. Ingebrigtsen³, Ø. L. Busk², Ø. L. Holla², K. Tveten², H. T. Hilmarsen², K. Ørstavik⁴, C. Tallaksen^{4,5}, M. Nebuchennykh¹, C. Jonsrud⁶, G. J. Braathen², T. Fagerheim³;

¹Department of Neurology, University Hospital of North Norway, Tromsø, Norway,

²Section of Medical Genetics, Telemark Hospital, Skien, Norway, ³Department of

Medical Genetics, University Hospital of North Norway, Tromsø, Norway, ⁴Department of Neurology, Oslo University Hospital, Oslo, Norway, ⁵Institute of Clinical Medicine, University of Oslo, Oslo, Norway.

Charcot-Marie-Tooth disease type 4C (CMT4C) is a demyelinating recessive form of CMT, caused by mutations in the SH3TC2 gene. CMT4C has so far been regarded as a relatively uncommon type of CMT and the literature describes mostly single cases and families. The aim of this study was to investigate the prevalence and spectrum of SH3TC2 mutations in the Norwegian CMT population, and to characterize the clinical manifestations of this patient group.

This project is a co-operation between the two centers in Norway diagnosing CMT4C. All patients diagnosed with homozygous or compound heterozygous mutations in the SH3TC2 gene were invited to participate in the study. The study is based on genetic analysis, information from clinical health records and patient questionnaires.

In total 35 patients from 30 families were diagnosed with homozygous or compound heterozygous mutations in SH3TC2. Most common was the NM_024577.3: c.2860C>T p.(Arg954*) mutation, present in 21 patients as homozygous, and in 13 patients as heterozygous in combination with another SH3TC2 mutations. The additional mutations included among others seven mutations not previously reported in the literature. To date 20 patients have been included in the clinical study. Mean age of onset was four years, affection of arms, scoliosis and reduced hearing were reported by 95, 80 and 50% of the patients respectively.

Mutations in SH3TC2 are one of the five most frequent causes of CMT in the Norwegian CMT population. All patients except one, carried one or two c.2860C>T mutations, a variant which likely has high carrier frequency in Norway.

P10.09

DM2-linked myopathy caused by uninterrupted short (CCTG)₅₀₋₇₀ repeat expansion in CNBP

T. Suominen¹, L. Bachinski², O. Raheem¹, H. Haapasalo³, W. Kress⁴, R. Krahe^{2,5}, B. Udd^{1,6};

¹University of Tampere, Neuromuscular Research Unit, Tampere, Finland, ²Department of Genetics, University of Texas MD Anderson Cancer Center, Houston, TX, United States,

³Department of Pathology, Fimlab Laboratories, Tampere University Hospital, Tampere, Finland, ⁴Institute of Human Genetics, University of Wuerzburg, Biozentrum,

Am Hubland, Wuerzburg, Germany, ⁵Graduate Programs in Human and Molecular Genetics and Genes and Development, University of Texas at Houston Graduate School of Biomedical Sciences, Houston, TX, United States, ⁶Department of Neurology, Tampere University Hospital, Tampere, Finland.

Background and aims: Myotonic dystrophy type 2 (DM2) is one of the most common adult-onset muscular dystrophies in Europe. It is a dominantly inherited multisystemic disease caused by a repeat expansion in intron 1 of CNBP gene. The disease-causing repeat expansions consist of 75-11,000 (CCTG) repeats. In this study, we characterize a new type of DM2-linked mild myopathy in several patients without myotonia associated with very short (CCTG)₅₀₋₇₀ repeat expansions.

Methods: All ten individuals carrying a short (CCTG) repeat expansion have been analyzed by repeat-primed PCR and haplotype analysis. Additionally five patients have been clinically evaluated and muscle biopsy analyzed. For one of the patient, an index patient of a larger family, the mutation has been

studied further by Southern blot, sequencing, allele specific expression, *in situ* hybridization, Western blot and analysis of fetal splice isoforms of DM2 effector proteins.

Results: Clinical features are mild, including myalgic pain, muscle weakness and stiffness. Muscle biopsy showed DM2-like changes. PCR-based methods and Southern blot indicated a repeat expansion of (CCTG)₅₀₋₇₀. In contrast to DM2, ribonuclear foci were not detected, splicing of DM2 effector proteins was normal and CNBP protein level was normal.

Discussion and conclusions: Finding of (CCTG)₅₀₋₇₀ repeats containing mutations in mildly symptomatic patients suggests that even shorter than previously reported expansions may cause a disease, although with a different phenotype. The molecular findings indicate a unique pathomechanism and the term 'myotonic dystrophy' cannot be applied to this new type of disease.

P10.10

Multi-gene panel analysis in the primary diagnosis of limb-girdle muscular dystrophy

V. Mayer¹, S. Bulst¹, A. Nissen¹, S. Kleinle¹, K. Becker¹, M. C. Walter², A. Benet-Pagès¹, A. Abicht^{1,2};

¹Medizinisch Genetisches Zentrum MGZ, Munich, Germany, ²Friedrich-Baur-Institute, Ludwig-Maximilians-University, Munich, Germany.

Introduction: Limb-girdle muscular dystrophies are characterized by great clinical and genetic heterogeneity. Mutations in a number of genes lead to overlapping phenotypes that cannot always be differentiated clinically or through muscle biopsy. Molecular genetic testing is therefore becoming increasingly important to the initial diagnosis of potential dystrophinopathies with significant clinical and familial consequences.

Materials and Methods: Our cohort comprised more than 80 patients with a suspected differential diagnosis of dystrophinopathy and negative test results for DMD gene dosage analysis by MLPA and DMD gene point mutation analysis by next generation sequencing (NGS). As over 700 neurogenetic/neuromuscular genes were captured during the course of technical analysis by NGS, we were able to perform a second-tier expanded data analysis of a gene panel including more than 140 genes known to be responsible for congenital muscular dystrophies or myopathies.

Results: More than 30% of patients tested were found to have a disease-causing mutation in another gene. In other patients sequence variants of unknown clinical significance were detected; the potential clinical relevance of these variants cannot be assessed with certainty without further testing. Conclusion: Multi-gene panels utilizing NGS technologies enable sensitive, cost-efficient, and simultaneous analysis of multiple disease-relevant genes. However, despite the broad analysis, it is not possible to identify pathogenic mutations in all patients. There is also a risk that the analysis of a large number of genes independent of the clinical phenotype may identify variants that can be assessed only in combination with refined clinical or muscle biopsy data and/or segregation analysis.

P10.11

Deletion and duplication patterns of dystrophin gene in Turkish Duchenne/Becker muscular dystrophy patients

F. Guclu-Geyik¹, N. Coban¹, B. Tüysüz², P. Serdaroglu³, Y. Parman⁴, F. Deymeer⁴, N. Erginel-Unaltuna¹;

¹Istanbul University, Institute for Experimental Medicine, Department of Genetics, ISTANBUL, Turkey, ²Istanbul University Cerrahpaşa Faculty of Medicine, Department of Pediatric Genetics, ISTANBUL, Turkey, ³Istanbul University, Istanbul Faculty of Medicine, Department of Neurology, ISTANBUL, Turkey, ⁴Istanbul University, Istanbul Medical Faculty, Department of Neurology, ISTANBUL, Turkey.

Background: Duchenne and Becker muscular dystrophies (DMD/BMD) are X-linked recessive inherited neuromuscular diseases that result from heterogeneous mutations in the dystrophin (DMD) gene. Our aim was to investigate DMD gene deletion/duplication frequencies and patterns in Turkish DMD/BMD patients and carriers.

Methods: Our study comprised of 217 male patients clinically diagnosed or suspected with DMD/BMD and 125 female cases. DMD gene deletion/duplications were detected by Multiplex ligation-dependent probe amplification (MLPA) method.

Results: DMD gene mutations were identified in 44.7% of male probands, of which 36.4% (mean age of diagnosis: 9.48, range; from 0 to 32 age) and 8.3% (mean age of diagnosis 11.78, range; from 2 to 35 age) were deletions and duplications, respectively.

There were 45 deletions, 11 of which were single exon deletions. Duplication pattern however, were found in 17 male patient. Deletions of exons 45-47 (n=6) and 45-50 (n=5) were the most common identified patterns. The range of the duplications in our group was mainly between exons 2-27 and single exon duplications were mostly located in the central region (51-53)

of DMD gene. In the females however, the carrier status was determined to be 27.2%. Interestingly, the DMD mutation was inherited from the mother in 63%, 37% were sporadic cases.

Conclusion: This is the first well-established deletion/duplication database in Turkey. MLPA is a sensitive and useful technology which allows detection of DMD deletions/duplications in affected males and carrier mothers, also offers appropriate genetic counseling in Turkey.

P10.13 MLPA analysis and clinical profile of DMD patients in Turkish population

M. Y. Alp¹, A. Yesilyurt¹, F. A. Pinarli², G. Haliloglu², B. Konuskan², H. Topaloglu²;
¹Dışkapı Yıldırım Beyazıt Research and Training Hospital Genetic Diagnostic Center, Ankara, Turkey, ²Hacettepe University, Faculty of Medicine, Division of Pediatric Neurology, Ankara, Turkey.

Duchenne muscular dystrophy (DMD) is the most common muscular disease in children, and one of the most frequent genetic disorder. It has an incidence of 1:3,500 live born males with a prevalence of 6 in 100000 males. DMD is inherited in X-linked recessive manner caused by mutations in dystrophin gene (DMD) which is the largest human gene encoding dystrophin protein. DMD gene located at Xp21, contains 79 exons, spanning 2.4 Mb of a genomic sequence. New therapeutic strategies e.g exon skipping made genetic diagnosis crucial for patients. In Genetic Diagnostic Center of Dışkapı Yıldırım Beyazıt Training and Research Hospital, 238 clinically diagnosed male DMD patients were examined by MLPA for detecting deletion or duplication in DMD gene. 154 patients (64.7%) had abnormal MLPA results, 140 deletion (58.8%), 14 duplication (5.9%), 84 patients (35.3%) were normal. Most affected exons were exon 50, 46, and 47, respectively. 66.2 percent of MLPA mutations were disrupted readingframe which were candidate of exon skipping. DMD patients were also characterized as follows; mean current age was 8,8 years, mean age at diagnosis was 4.7 years, mean CK levels at diagnosis was 11193 U/L. At diagnosis, 30.5% of patients had asymptomatic CK elevation, 69.5% of patients were symptomatic. 11.8 percent of patients had wheelchair dependency. 29.6 percent of patients had family history, 57 percent of patients had carrier mother. Statistical analysis revealed that positive family history was significantly associated with normal MLPA results, and wheelchair dependency was significantly associated with presence of exonic deletion and duplication.

Background/Objectives: Duchenne muscular dystrophy (Duchenne/DMD) is a severe form of muscular dystrophy caused by mutations in the DMD gene. Molecular testing is essential for an early and accurate diagnosis. Two working groups of international molecular testing experts, organized by BioMarin, met to evaluate the current state of Duchenne/DMD diagnostic

molecular testing and results reporting.

Methods: Twenty-seven Duchenne/DMD experts, including molecular/clinical geneticists, research scientists, and genetic counselors, met in July and November, 2015 to discuss Duchenne/DMD molecular diagnosis and reporting. Representatives from 20 diagnostic laboratories also completed a comprehensive survey.

Results: Laboratories detect large deletions and duplications (~80% of pathogenic DMD mutations) by one or more methods: multiplex ligation-dependent probe amplification (MLPA, 90% of laboratories surveyed), array comparative genomic hybridization (aCGH, 40%), and next generation sequencing (NGS, 50%). Few laboratories still use multiplex PCR (mPCR). All these methods, except mPCR, are sufficient to detect deletions/duplications in DMD; sequence-level mutation detection requires use of Sanger sequencing or NGS. For molecular therapy-eligible Duchenne/DMD, precise molecular analysis, accurate result interpretation, and clear reporting are essential to inform healthcare professionals.

Discussion: The experts recommend an updated molecular diagnostic algorithm with tiered testing options to guide the accurate detection of all DMD mutations and determination of molecular therapy eligibility. MLPA-based single exon deletion/duplication results must be confirmed by an alternative method. If a deletion/duplication is not detected, sequencing is recommended. The experts recommend revising best practices for DMD molecular testing, interpretation, and results reporting due to new developments in molecular diagnostics and therapies in development.

P10.16 Genetic and clinical heterogeneity of dystroglycanopathies: challenging for next-generation sequencing?

J. Oliveira^{1,2}, S. Janssens³, A. Gonçalves^{1,2}, E. Vieira^{1,2}, M. E. Oliveira^{1,2}, T. Moreno⁴, L. Negrão⁵, I. Fineza⁶, M. Sousa^{7,8}, R. Santos^{1,2,9};

Introduction: Dystroglycanopathies, a group of diseases defined by hypoglycosylation of alpha-dystroglycan, are classified into three major subtypes: severe congenital muscular dystrophy (MD) with brain and eye anomalies (type A), congenital MD with mental retardation (type B) and limb-girdle MD (type C). Eighteen different genes have been linked to dystroglycanopathies, the majority coding for proteins involved in O-mannosylglycan biosynthesis. Recently, defects in the synthesis of dolichol phosphate mannose, initially associated with congenital disorders of glycosylation, was shown to cause dystroglycanopathy.

Materials and Methods: Twenty-one patients with suspected dystroglycanopathy – ranging from severe congenital forms to milder adult-onset MD – were genetically characterized by Sanger sequencing, using a stepwise approach or homozygosity mapping. MLPA and/or cDNA analysis was performed in four cases.

Results: Eleven distinct pathogenic variants were identified in four genes: *FKRP* (5 missense and one base-pair duplication, 16 patients), *POMGNT1* (2 variants affecting splicing and 1 missense, 3 patients), *POMT2* (1 missense variant, 1 patient) and *FKTN* (1 multi-exonic duplication, 1 patient). These comprise four unpublished variants: two missense (p.Tyr407Asp and p.Asp360His both in *FKRP*), one frameshift (*FKRP*:c.1234dupC) and one apparently silent substitution causing exon skipping (*POMGNT1*:c.534G>A/r.421_534del).

Conclusions: The expanding clinical and genetic heterogeneity of dystroglycanopathies could justify the application of comprehensive next-generation sequencing (NGS) applications such as whole-exome sequencing. Interestingly, we found four patients with pathogenic alleles that could be problematic for NGS automated analysis pipeline. Thus, it is essential to employ robust analytical algorithms for data analysis and approaches focusing on RNA to successfully characterize these patients.

P10.17

Multi-factor dimensionality reduction: detection gene-gene interactions in DMD studies

V. C. Sacara;

Institute of Mother and Child, Chisinau, Moldova, Republic of.

Epistasis is increasingly assumed to play a crucial role in the architecture of genetics disease. We try to modeling epistasis between 5 genes: dystrophin, MTHFR, MTR, MTRR, eNOS in case of the wheelchair dependency- up to 9or12 years.

A retrospective long-term study was carried out in 148 corticosteroids-free DMD patients. Gene-gene interactions were analyzed using entropy-based MDR 3.02.

The analysis of the hierarchical structure of all components, the best model in case of 9wch consists of four interconnected clusters. The first cluster is presented independent of the dystrophin deletion from other genes. The second cluster also integrates with MTRR gene locus independently interconnected clusters combine the two genes clusters: cycle folate (MTHFR677,MTHFR1298) and MTR-eNOS (both strong synergy), having the effect of interaction between each other- moderate synergy. In group of 12wch, we have identified two separate clusters. The first independent cluster has united the groups of related loci MTHFR1298 and eNOS expressed duplicate the effects of interactions. The second cluster has established a strong synergy between MTHFR677 locus, the dystrophin deletion and MTR, in which the activity of dystrophin is depended from MTR. In the circular graph was found that the effect of MTHFR677 at 12wch decreasing (0.16%), compared with the effect in 9wch(1.78%), also noted the impact of the MTR (0.48) diminishes as compared with the effect of this locus at 9wch(1.08%). But in the 12wch has increased the impact of MTHFR1298locus(1.96%) and information gain of pair «MTHFR1298-eNOS»-1.64%. This method can extend the biological reach of pathway-based results

P10.18

Intergenerational instability in Huntington's disease: insights from mice models

J. L. Neto^{1,2}, J. Lee¹, T. Gillis¹, J. R. Guide¹, B. Lager³, I. Alonso^{2,4}, V. C. Wheeler¹, R. Mouro-Pinto¹;

¹Center for Human Genetic Research - Massachusetts General Hospital, Boston, MA, United States, ²UnIGENE, IBMC - Instituto de Biologia Molecular e Celular and i3S - Instituto de Investigação e Inovação em Saúde, Porto, Portugal, ³CHDI Foundation Inc, Princeton, NJ, United States, ⁴Instituto de Ciências Biomédicas Abel Salazar (ICBAS), Universidade do Porto, Porto, Portugal.

Intergenerational CAG repeat instability is a distinctive feature of Huntington's disease (HD), associated with genetic anticipation. Intergenerational repeat changes are present in patients and mouse models of the disorder. In this work two large breeding datasets of HD knock-in mouse models, globally encompassing more than 18,000 repeat transmissions, led us to confirm and gain new insight into factors influencing intergenerational instability.

The first dataset includes information from 16,000 transmissions across five lines (*Htt*^{Q80}, *Htt*^{Q92}, *Htt*^{Q111}, *Htt*^{Q140}, *Htt*^{Q175}) and allowed us to determine effects of 1) parent-of-origin; 2) sex of offspring and 3) parental CAG repeat length on the frequency and magnitude of unstable transmissions. Parent of origin, but not the sex of the offspring contributed to intergenerational instability. We also determined that paternal CAG size affects the frequency of expansions and stable transmissions, while not significantly altering the rate of contractions, even though the magnitude of both contractions and expansions are affected by CAG length. Importantly, the sizeable dataset revealed the presence of large repeat length changes as seen in patients and not previously appreciated in mouse models.

The second dataset is comprised of about 2,000 transmissions from knock-in mice belonging to six different background strains (129, CD1, FVB, DBA, B6N, B6J), providing insight into effects of genetic background on the frequency of unstable transmissions independent from parental CAG size effects. These results provide novel opportunities to search for CAG instability modifiers through the comparison of genetic variation between different strains.

P10.19

A new early-onset myopathy associated with deficiency in kyphoscoliosis peptidase (KY)

C. Hedberg-Oldfors¹, N. Darin¹, M. Olsson Engman², A. Oldfors¹;

¹University of Gothenburg, Gothenburg, Sweden, ²Blekinge Hospital, Karlskrona, Sweden.

We describe a new congenital myopathy due to a homozygous loss-of-func-

tion mutation in the kyphoscoliosis peptidase gene (*KY*). We investigated a 7.5-year-old girl with walking difficulties from two years of age presented with generalized muscle weakness; mild contractures in the shoulders, hips, and feet; cavus feet; and lordosis but no scoliosis. She had previously been operated with Achilles tendon elongation. Whole-body MRI showed atrophy and fatty infiltration in the calf muscles. Biopsy of the vastus lateralis muscle showed variability in fiber size, with some internalized nuclei and numerous very small fibers with variable expression of developmental myosin heavy chain isoforms. Some small fibers showed abnormal sarcomeres with thickened Z-discs and abortive nemaline rods. Whole-exome sequencing revealed a homozygous one-base deletion (c.1071delG, p.T358fs*3) in *KY*, predicted to result in a truncated protein. Analysis of an RNA panel revealed that *KY* is predominantly expressed in skeletal muscle in humans. A recessive mutation in the murine ortholog *Ky* was previously described in a spontaneously generated mouse mutant with kyphoscoliosis, which developed postnatally and was caused by dystrophy of postural muscles. We describe the first human case of disease associated with *KY* inactivation. As in the mouse model, the affected child showed myopathy and muscle weakness—but in contrast, no kyphoscoliosis.

P10.20

ANOS mutations identified in the Polish LGMD patients by whole exome sequencing

J. P. Fichna¹, A. Macias², M. Suszek², A. Maruszak¹, M. J. Rędowicz³, A. M. Kamińska², C. Żekanowski¹;

¹Department of Neurodegenerative Disorders, Mossakowski Medical Research Centre, Warsaw, Poland, ²Department of Neurology, Medical University of Warsaw, Warsaw, Poland, ³Department of Biochemistry, Nencki Institute of Experimental Biology, Warsaw, Poland.

The anoctamin-5 belongs to a family of proteins involved in a variety of cellular functions including chloride ion transport. The precise function of the anoctamin-5 protein remains largely unknown, however expression pattern suggests its important role in the musculoskeletal system. Recessive *ANOS* gene mutations cause limb-girdle muscular dystrophy (LGMD) and Miyoshi myopathy (MMD3). Here, we describe *ANOS* mutations found in LGMD patients in Poland.

The study group comprised probands representing 82 families with a clinical diagnosis of LGMD. To find causative mutations and comprehensively analyse genetic background of the disease we have determined exomic sequence using Whole Exome Sequencing (WES) method.

We have identified eight different *ANOS* mutations, two of them novel, in seven patients. Two patients presented compound heterozygosity and carried mutations that could be considered pathogenic. In three cases known single known *ANOS* mutations accompany pathogenic variants in *DYSF* and *CAV3*, and might only have phenotype modifying effect. In one case another single, although novel and putatively pathogenic *ANOS* mutation, was identified and further investigation of genetic etiology is needed.

Our study reveals that *ANOS* mutations in the Polish population have lower prevalence compared to the Northern Europe, where it is the second most common cause of LGMD. Additional mutations found apart from the most likely causative ones might also influence the phenotype. WES can be applied as a single genetic test to quickly characterize the comprehensive spectrum of genetic variation.

The research was supported by the NCN 2013/09/B/NZ4/03258 grant, KNOW-MMRC project (JPF) and PL-Grid infrastructure (JPF, bioinformatics).

P10.21

A novel mutation in the desmin gene (DES) cause an autosomal recessive form of limb-girdle muscular dystrophy type 2R without clear-cut desminopathy pathology

B. Balci-Hayta¹, N. Cetin¹, H. Gundesli¹, P. Korkusuz², N. Purali³, B. Talim⁴, E. Tan⁵, D. Selcen⁶, S. Erdem-Ozdamar⁵, P. Dincer¹;

¹Hacettepe University Faculty of Medicine, Department of Medical Biology, Ankara, Turkey, ²Hacettepe University Faculty of Medicine, Department of Histology and Embryology, Ankara, Turkey, ³Hacettepe University Faculty of Medicine, Department of Biophysics, Ankara, Turkey, ⁴Hacettepe University Faculty of Medicine, Department of Pediatrics, Pathology Unit, Ankara, Turkey, ⁵Hacettepe University Faculty of Medicine, Department of Neurology and Neuromuscular Diseases Research Laboratory, Ankara, Turkey, ⁶Mayo Clinic, Department of Neurology and Neuromuscular Disease Research Laboratory, Rochester, NY, United States.

Introduction: The autosomal recessive forms of limb girdle muscular dystrophies (LGMD2) are a group of rare genetic disorders that are characterized by progressive muscle weakness of the shoulder and pelvic girdle muscles and include at least 23 different genetic entities.

Materials and Results: Genome-wide homozygosity mapping was perfor-

med in a consanguineous LGMD2 family with two affected individuals and the LGMD2 phenotype was mapped to chromosome 2q35-q36.3. DNA sequence analysis of the candidate gene DES revealed a homozygous splice site mutation c.1289-2A>G in the affected family members. IF staining and WB analysis showed that the expression and the cytoskeletal network formation of mutant desmin were preserved in skeletal muscle fibres. Interestingly, the affected individuals do not have the classical features of desminopathy, neither cardiomyopathy nor the typical histological changes such as disruption of myofibrillar organization, aggregation of intracellular proteins, dislocation/aggregation of membranous organelles. This novel mutation results in addition of 16 amino acids within the tail domain of desmin, which has been suggested to interact with lamin B protein. We also detected a specific disruption of desmin-lamin B interaction in the skeletal muscle of the patient by confocal laser scanning microscopy.

Conclusions: DES mutations should be considered as a cause of LGMD2 without features of myofibrillar myopathy and the inability of mutant desmin to interact with lamin B may trigger disease development. This study was supported by TÜBİTAK, TURKEY (grant numbers: 108S124 and SBAG-1774). First three authors contributed equally to this study.

The first case of a genetically proven Maple syrup urine disease in Bulgaria

I. Yordanova¹, H. Kadam², T. Todorov¹, R. Tincheva², A. Todorova¹;
¹Genetic Medico-Diagnostic Laboratory Genica, Sofia, Bulgaria, ²University Pediatric Hospital, Medical University Sofia, Sofia, Bulgaria.

Maple syrup urine disease (MSUD) is a rare autosomal recessive disorder of branched-chain amino acid (BCAA) metabolism caused by dysfunction of the multi-enzyme branched-chain alpha-ketoacid dehydrogenase (BCKDH) complex. BCKDH catalyzes the oxidative decarboxylation of branched-chain alpha-ketoacids produced by transamination of the BCAAs leucine, isoleucine, valine. Classic MSUD is the most common phenotype, represented in about 75% of patients, typically manifested as severe neurological impairment during the neonatal period. Affected infants typically show lethargy, weight loss, metabolic derangements and progressive neurologic signs, like alternating hypotonia and hypertonia. MSUD can be caused by mutations in at least 3 genes: BCKDHA on chromosome 19q13, BCKDHB on chromosome 6q14, and DBT on chromosome 1p21. Mutations in BCKDHA gene were associated with approximately 37% of MSUD cases previously described in the literature. Direct sequencing of the BCKDHA gene was performed in order to screen for germline mutations a dizygotic twin pair with MSUD. The parents are first cousins of Iranian origin. The genetic testing showed one already reported c.452C>T, p.Thr151Met homozygous mutation in only one of the twins. Surprisingly, the second one was negative for this mutation. Both parents were heterozygous carriers. The second child is also MSUD affected as reported by the clinicians. There is a need for further review of clinical data and genetic analysis of the rest two genes to clarify the genetic cause for MSUD in the second twin. We hypothesize the presence of a second genetic change associated with the same clinical picture of MSUD in a single consanguineous family.

P10.23

Analysis of 37 / 65 muscle genes in 300 patients with neuromuscular diseases

N. Pluta, G. Emmert, W. Kress, C. R. Müller, S. Rost;
 Department of Human Genetics, Würzburg, Germany.

Introduction: Neuromuscular diseases (NMDs) are clinically and genetically highly heterogeneous with more than 300 associated genes known to date making conventional molecular diagnosis challenging and expensive. Hence, we designed a targeted gene panel consisting of 37 (version 1) and 65 (version 2) genes associated with the most common types of muscular dystrophies and myopathies.

Methods: A total of 300 patients was analysed using the software GenesearchNGS (PhenoSystems) after target enrichment of the selected muscle genes and next generation sequencing on a MiSeq desktop sequencer (Illumina). About 99% of all coding exons were covered >20x, the overall average coverage was >500x.

Results: After removing recurrent sequencing artefacts and common variants (MAF>2%), we detected more than 4000 variants (~1400 different ones) in the 300 patients analyzed, which we classified from benign to pathogenic (class 1-5). Among these were 35% missense, 29% intronic (9-20 bp flanking sequence), 24% synonymous, 7% potential/essential splice, 4% small deletions/insertions and less than 1% nonsense variants. About 70% of the detected variants were classified as benign (~2200) or likely benign

(~720), approx. 20% as uncertain (~820) and 3-4% as likely pathogenic or pathogenic each (~150 each).

Conclusions: At least one likely pathogenic or pathogenic variant was identified in 180 of the 300 patients suffering from different myopathies (detection rate: 60%). Furthermore, in almost all 300 patients analyzed by our muscle gene panel at least one variant of uncertain significance (class 3) was detected which could be regarded as potentially associated with the myopathy.

P10.24

Novel recessive mutations in MYH2 presenting with congenital ophthalmoplegia and bulbar palsy

M. Bertoli¹, M. McEntagart², T. Kerr³, V. Straub¹;

¹The John Walton Muscular Dystrophy Research Centre, MRC Centre for Neuromuscular Diseases at Newcastle, Newcastle upon Tyne, United Kingdom, ²Medical Genetics, St George's University Hospitals, NHS Foundation Trust, London, United Kingdom, ³Department of Paediatric Neurology, St Georges University Hospitals NHS Foundation Trust, London, United Kingdom.

Hereditary myosin myopathies are a group of clinically heterogeneous muscle diseases, caused by mutations in the skeletal muscle myosin heavy chain (MyHC) genes. Mutations in the MYH2 gene (Myosin heavy chain IIa) have been associated both with an autosomal dominant and a recessive form of proximal myopathy with ophthalmoplegia (MYPOP).

We describe two sisters, aged 5 1/2 and 3 years, who presented at birth with partial external ophthalmoplegia and inability to swallow, requiring gastrostomy feeding. The older sister walked by 2 years of age and often complains about leg pain. She had a normal brain MRI and an EMG showed evidence of a bulbar palsy. The younger sister walked before she was 1 year of age. They both show mild proximal weakness. They can walk independently up to 5 minutes and then need to be carried. They fall frequently and have difficulty climbing stairs. Both sisters share the same compound heterozygous novel mutations in the MYH2 gene (p.S294L and p.Q291H), which were identified through exome sequencing via the Complementary Analysis Project on congenital myopathies within the Deciphering Developmental Disorders (DDD) project.

Bulbar involvement has been described in autosomal dominant MYH2 myopathies in a patient presenting in his teens with proximal weakness who consecutively developed ophthalmoplegia and swallowing difficulties, and in a baby presenting with generalised hypotonia and swallowing difficulties at birth. Here we describe the first case of an MYH2-related myopathy due to compound heterozygous missense mutations, presenting at birth with bulbar palsy as the predominant feature rather than weakness.

P10.25

A novel MYH2 mutation in family members presenting with congenital myopathy, ophthalmoplegia and facial weakness

T. Willis¹, C. Hedberg-Oldfors², Z. Alhaswani¹, R. Kulshrestha¹, C. Sewry¹, A. Oldfors²;

¹Robert Jones and Agnes Hunt Hospital, Oswestry, United Kingdom, ²University of Gothenburg, Gothenburg, Sweden.

Myosin heavy chain (MyHC) is a major structural component of the striated muscle contractile apparatus. There are several striated muscle MyHC isoforms encoded by different genes. In adult human limb skeletal muscle, there are three major MyHC isoforms: MyHC I (slow/beta-cardiac MyHC, MYH7), is expressed in slow, type 1 muscle fibers; MyHC IIa (MYH2) is expressed in fast, type 2A muscle fibers and MyHC IIx (MYH1) is expressed in fast, type 2B muscle fibers. Some fibers express both MyHC IIa and IIx. The different muscle fiber types differ in their physiological properties.

Hereditary myosin myopathies have emerged as an important group of diseases with variable clinical and morphological expression depending on the mutated isoform and type and location of the mutation. Myosin myopathy with external ophthalmoplegia is associated with mutations in MYH2 and is inherited in both dominant as well as in recessive manner.

We present a family with myopathy with early onset proximal muscle weakness, facial muscle involvement and ophthalmoplegia, affecting a woman, her sister and two of her children. The clinical features and inheritance raised the suspicion of mitochondrial myopathy with maternal or autosomal dominant inheritance. Muscle biopsy demonstrated lack of type 2A muscle fibers and genetic work up demonstrated that the disease was caused by a novel recessive MYH2 mutation: c.1009-1G>A resulting in skipping of exon 12, which is predicted to result in a frame shift and introducing at premature stop codon at position 347 (p.Ser337LeufsX11).

P10.26

CLCN1 variants identified in a large North American cohort of myotonia congenita patients: novel variants and pedigrees with atypical segregation patterns

J. C. Tarleton;

Fullerton Genetics Lab, Mission Health System, Asheville, NC, United States.

Myotonia congenita (MC) is characterized by impaired muscle relaxation after contraction presenting as mild to severe muscle stiffness when initiating movement. Cramping and transitory weakness may occur in some patients. Stiffness is relieved by repetitive contractions of the muscle, the "warm-up" phenomenon. Mutations in CLCN1, encoding the muscle-specific chloride channel, CLC1, disrupt channel forming homodimers by a variety of mechanisms resulting in MC. Over 200 variants are recorded in HGMD. The recessive form (Becker disease, OMIM 255700) is usually associated with more severe symptoms than the dominant form (Thomsen disease, OMIM 160800). However, numerous examples are known of CLCN1 variants that segregate as dominant in some families yet as recessive in others. Wide phenotypic variation occurs even among individuals with the same mutation suggesting reduced penetrance and genetic modifier effects are common. Reported here is the compilation of over 10 years of CLCN1 sequence analysis on nearly 500 probands and follow up studies of North American MC families. Thirty five previously unreported variants were identified. During segregation analysis of some MC families we found carriers of variants previously classified as recessive had mild myotonia suggesting semi-dominant and reduced penetrance inheritance. Discussed here are two specific examples, one from a family segregating a presumed loss-of-function splice variant and the second from a missense variant. Both have long been classified as recessive. These studies suggest that haplotype insufficiency may sometimes occur in heterozygotes carrying loss-of-function variants and some heretofore recessive missense variants have mild dominant-negative effects.

P10.27

Mutation screening of two presumable Myotonia congenita type Becker endemic regions in Bulgaria

S. Tincheva^{1,2}, B. Georgieva¹, A. Todorova^{1,2}, T. Todorov², I. Litvinenko³, V. Mitev¹; ¹Medical University Sofia, Sofia, Bulgaria, ²Genetic Medico-Diagnostic Laboratory Genica, Sofia, Bulgaria, ³Department of Neurology, University Pediatric Hospital, Medical University, Sofia, Bulgaria.

Myotonia congenita type Becker is an autosomal recessive nondystrophic skeletal muscle disorder, caused by mutations in the CLCN1 gene, encoding skeletal muscle chloride channel-1. The disease is characterized by muscle stiffness and an inability of the muscle to relax after voluntary contraction. It affects primarily the lower limb muscles and later progress to the arms, neck, and facial muscles.

Here we report the results from mutation screening of two presumable endemic regions for CLCN1 mutations in Bulgaria. Previous studies of our group discovered a large family from Bulgarian origin populating a village located in the northwest part of the country. The pedigree showed a number of Myotonia congenita type Becker affected individuals both in vertical and horizontal direction, all of them carrying a homozygous missense substitution p.Tyr524Cys. Endogamous marriages are very unusual for the Bulgarian population, supposing a high carrier frequency in this subpopulation. Screening of 154 residents of the corresponding region showed a significant carrier frequency for the p.Tyr524Cys mutation of about 0.65% (1/154). The second interesting region in the context of Myotonia congenita type Becker is the southwest part of the country, where we found a large family from Bulgarian Turkish origin. The disease causing missense mutation p.Val273Met was again present in homozygous state. Surprisingly, the genetic testing of newborns from southwest Bulgaria showed an even higher carrier status of about 2.6% (3/116), disproving our initial hypothesis of endogamous marriages (traditionally common in this subpopulation) being the cause for the disease in these patients.

P10.28

Becker myotonia: novel mutations in patients born to consanguineous parents

I. Sahin, H. B. Erdem, S. Tasdemir, A. Tatar;

Ataturk University Department of Medical Genetics, Erzurum, Turkey.

Introduction: Myotonia congenita (MC) is an inherited muscle disease characterized by impaired muscle relaxation after contraction, resulting in muscle stiffness, present from childhood. All striated muscle groups may be involved. MC is due to Cl⁻ channel mutations that reduce the stabilizing Cl⁻ conductance and is caused by mutations in the CLCN1 gene. CLCN1 is located on chromosome 7q35 and encompasses 35 kb in genomic DNA with

23 exons. The disease can be inherited either as an autosomal dominant (Thomsen's myotonia, MIM 160800) or an autosomal recessive (Becker's myotonia, recessive generalized myotonia, RGM, MIM 255700) trait. Materials and Methods: We describe three patients from two different healthy consanguineous Turkish family with muscle stiffness and easy fatigability. EMG showed myotonic discharges in all the patients and CK levels were slightly increased in patient 1 and 2 and elevated in patient 3. Genetic investigation has been performed.

Results: Mutation analyses showed a homozygous p.Leu159Cysfs*11 (c.475delC) mutation in patient 1 and a homozygous p.Y150* (c.450C>A) mutation in patient 2 and 3 in the CLCN1 gene. These mutations have never been reported before and in silico analyses showed the mutations as disease causing.

Conclusion: The two new CLCN1 variants can be added to the growing database of MC-associated mutations. Our data expand the spectrum of CLCN1 mutations and provide insights for genotype-phenotype correlations of myotonia congenita.

Detailed clinical features of subjects with novel CLCN1 mutations.			
	Patient 1	Patient 2	Patient 3

Nemaline myopathy may be caused by a variety of large copy number variations in NEB detectable with the NM-CGH array

K. Kiiski¹, V. Lehtokari¹, L. Sagath¹, C. Wallgren-Pettersson¹, K. Pelin^{1,2};

¹The Folkhälsan Institute of Genetics and The Department of Medical and Clinical Genetics, Medicum, University of Helsinki, Helsinki, Finland, ²Department of Biosciences, Division of Genetics, University of Helsinki, Helsinki, Finland.

Our custom designed NM-CGH microarray detects copy number variants (CNVs) in the currently known ten nemaline myopathy-causing (NM) genes and one unpublished gene. NM constitutes a heterogeneous group of disorders among the congenital myopathies. Variants in the nebulin gene (*NEB*) are the most frequent cause for NM. *NEB* consists of 249kb of genomic sequence including 183 exons. Using the NM-CGH array, 315 samples from 230 families have been analysed to date, and a pathogenic CNV has been identified altogether in 14% of the studied NM families. These include 15 different large disease-causing aberrations in *NEB* in 31 different families. 12 aberrations were identified in only one family each, one aberration in two families, one in three families and one recurrent aberration in 36 families. The size of the aberrations vary greatly, covering from only a part of one *NEB* exon (72 bp) to more than half of the gene (133 kb). The recurrent CNV consisting of the 32kb *NEB* triplicate region (TRI), where eight exons are normally repeated three times, was shown to contain a CNV in 16% of the NM families and in 6% of the families the *NEB* TRI CNV was interpreted to be pathogenic. Furthermore, one pathogenic CNV (17-21kb) was also identified in another NM gene, *TPM3*. We are currently updating the NM-CGH microarray to include a larger variety of myopathy causing genes to allow for analysis for the patients with NM-related clinical phenotypes. The NM-CGH microarray method is available for mutation analysis in our laboratory.

A mutation in EPT1 causes neurodevelopmental delay and spastic paraplegia: a first report of impaired Kennedy pathway

A. H. Alkhatayb¹, F. A. Alsalmi¹, F. Almurshedi¹, A. AlFutaisi¹, M. Y. Ahmed², B. A. Chioza², P. Fernandez-Murray³, A. Cazenave-Gassiot⁴, M. R. Wenk⁴, M. A. Patton⁵, D. L. Silver⁵, E. Baple⁶, C. R. McMaster³, S. Alzuhaibi¹, A. H. Crosby⁶;

¹Sultan Qaboos University, Muscat, Oman, ²University of Exeter, Exeter, United Kingdom, ³Dalhousie University, Halifax, NS, Canada, ⁴National University of Singapore, Singapore, ⁵Duke-NUS, Singapore, ⁶University of Exeter, Exeter, United Kingdom.

Many subtypes of hereditary spastic paraplegia (HSP), a highly heteroge-

neous group of neurodegenerative motor neuron disorders, has been associated with mutations in genes involved in lipid metabolism. Here, we report a new form of autosomal recessive complex HSP associated with mutation in the ethanolaminephosphotransferase 1 (EPT1) gene, responsible for the final step in Kennedy pathway forming phosphatidylethanolamine (PE) from CDP-ethanolamine. PE is a glycerophospholipid that, together with phosphatidylcholine (PC), constitutes more than half of the total phospholipids in eukaryotic cell membranes. We determined that the mutation defined dramatically reduces the enzymatic activity of EPT1, thereby hindering the final step in PE synthesis. Additionally, due to CNS inaccessibility we undertook quantification of PE levels and species in patient and control blood samples as an indication of liver PE biosynthesis. Although this revealed alteration to levels of specific PE fatty acyl species in patients, overall PE levels were broadly unaffected indicating that in blood EPT1 inactivity may be compensated for in part via alternate biochemical pathways. These studies define the first human disorder arising due defective CDP-ethanolamine pathway biosynthesis and provide new insight into the role of Kennedy pathway components in human neurological function.

This study is supported by funding from the MRC (G1002279, G1001931), Newlife, The Research Council, Oman (ORG/HSS/09/002), Genome Canada, Genome Atlantic, the Nova Scotia Research Innovation Trust, the Nova Scotia Department of Health and Wellness to CRM, and the Singapore Ministry of Health's National Medical Research Council (CBRG/069/2014).

P10.32

A genotype-first approach to defining a neuromuscular disease

A. Rodriguez¹, M. Miramar¹, S. Izquierdo¹, M. Alcaine¹, A. Lasierra¹, E. Barrio², J. Gonzalez¹, J. Capablo¹, E. Mayayo¹;

¹H.U.Miguel Servet, Zaragoza, Spain, ²Universidad de Zaragoza, Zaragoza, Spain.

Introduction: Medical genetics typically entails the detailed characterization of a patient's phenotypes followed by genotyping to discover the responsible gene or mutation. The genetic study of polygenic or similar clinical manifestations diseases, such as neuromuscular, has historically been difficult, meeting with limited success. This difficulty are progressing to a point where a reverse strategy may be fruitful in assigning the pathogenic effects of many different genes and in determining whether particular genotypes manifest as clinically recognizable phenotypes. The aim of this work is to demonstrate the diagnostic throughput of a genetic study by massive exome sequencing in order to identify variants associated with congenital myasthenia disorders of glycosylation channelopathies and neuromuscular diseases. **Material and Methods:** A 41 years old male patient from neurology comes to our section of clinical genetics with distal myopathy and clinical diagnosis of dysferlinopathy. He's never run and jump well. He notices decreased muscle mass in both twins and difficulty walking fast and misalignment of both feet. He suffers from spasms in lower extremities to small efforts. After written consent, peripheral blood sample were sent to study dysferlin gene. No mutation was found. New sample were sent to an external laboratory (Nim-Genetics) and massive exome sequencing were done (199 genes)

Results: Homozygous pathogenic variant c.7447A>G (p.Lys2483Glu) in the COL6A3 gene were identified. It's Bethlem myopathy associated. Both parents are carriers.

Conclusions: With sequencing becoming increasingly cheaper as well as the preferred frontline diagnostic test, genetics becomes the first step to give the clinical diagnosis of neuromuscular diseases.

P10.33

Clinical spectrum of mitochondrial diseases associated with POLG1, POLG2 and C10orf2 mutations

A. Paramasivam¹, A. K. Meena², M. S. Uppin², K. Thangaraj¹;

¹CSIR-Centre for Cellular and Molecular Biology, Hyderabad, India, ²Department of Neurology, Nizam's Institute of Medical Sciences, Hyderabad, India.

Introduction: Mitochondrial diseases are a heterogeneous group of disorders caused by genetic defects in mitochondrial DNA or in nuclear genes. Mutations in nuclear genes POLG1, POLG2 and C10orf2 required to replicate the mitochondrial genome are reported to affect mtDNA stability such as accumulation of point mutations, multiple deletions and depletion of mtDNA, and cause progressive mitochondrial disorder.

Materials and Methods: we sequenced the exons and intron-exon boundaries of the POLG1, POLG2 and C10orf2 genes from >500 unrelated patients with a heterogeneous array of clinical presentations (Myopathy, CPEO, Ataxia, Progressive myoclonus epilepsy, LHON, Neuropathy and ataxia, Leigh syndrome, Leukodystrophy-ataxia-neuropathy etc.) and 2400 population samples from various parts of India were also used to determine the carrier frequencies of common pathogenic mutations in POLG1 (p.A467T, G848S,

W748S).

Results: We identified several novel and reported non-synonymous pathogenic mutations in the POLG1, POLG2 and C10orf2. We also identified several synonymous variants and variants in non coding regions. Pathogenicity of novel mutations were assessed based upon (a) absence in 100 normal controls, (b) the mutation causes substitution in conserved amino acid residues of the proteins, (c) location in protein regions of structural/functional importance, (d) co-segregation of the mutations with the disease phenotype and (e) mtDNA multiple deletions and/or depletion. Carrier frequency of common POLG1 mutations is 0.08% for A467T, 0.20% for W748 and 0.00% for G848S in India.

Conclusion: Identification of POLG1, POLG2 and C10orf2 mutations is very important for diagnosis, proper medical management and appropriate genetic counseling.

P10.34

Neutral Lipid Storage Disease with Myopathy: first report of an Italian patient with novel PNPLA2 mutations causing an in frame skipping of exon 5

S. Missaglia¹, M. Mora², L. Morandi², D. Cassandrini³, F. M. Santorelli³, L. Maggi², D. Taviani¹;

¹Catholic University of the Sacred Heart, Milan, Italy, ²Fondazione IRCCS Istituto Neurologico „Carlo Besta“, Milan, Italy, ³IRCCS Stella Maris, Pisa, Italy.

Neutral Lipid Storage Disease with Myopathy (NLSDM), is a rare autosomal recessive disorder characterized by excessive lipid accumulation into cytoplasmic lipid droplets present in many tissues, including skin, bone marrow, heart, liver and muscles. Clinically, NLSDM patients present with skeletal muscle myopathy and sometimes with severe dilated cardiomyopathy, hepatomegaly and insulin resistance. NLSDM is caused by a defect in the PNPLA2 gene, which encodes the adipose triglyceride lipase (ATGL), an enzyme that hydrolyses fatty acids from triacylglycerol. Here we report the clinical and genetic findings of an Italian patient carrying two novel PNPLA2 mutations (c.696+4A>G and c.553_565delGTCCCCCTTCTCG). The patient presented at the age of 39 years with right upper limb abduction weakness progressing slowly over the years with asymmetric involvement of proximal muscle in upper and lower limbs. At the age of 53 mild left ventricular diastolic dysfunction was detected. This is the first report of a NLSDM patient with a splice site mutation causing an in-frame exon5 PNPLA2 skipping. Molecular analysis revealed that only one type of PNPLA2 transcript, lacking exon 5, was present in patient's cells. Such aberrant mRNA should cause the production of a ATGL protein able to bind lipid droplets but lacking part of catalytic domain. This is a very interesting case displaying severe PNPLA2 mutations with a clinical presentation ranging from slight cardiac impairment to full expression of a severe asymmetric myopathy. This work was supported by Telethon grant (GGP14066). The authors acknowledge EuroBioBank and the Telethon Network of Genetic Biobanks (GTB12001F), for providing biological samples.

Mutation detection in a patient with muscular dystrophy using a next generation sequencing panel

H. A. van Duyvenvoorde¹, R. F. M. de Co², L. Vijfhuizen¹, W. S. Frankhuizen¹, I. B. Ginjaar¹, S. H. B. Bollen¹, N. van der Stoep¹;

¹Leiden University Medical Center, Department of Clinical Genetics, Leiden, Netherlands, ²Erasmus Medical Center, Department of Child Neurology, Rotterdam, Netherlands.

Introduction:

Limb-girdle muscular dystrophy is a clinically and genetically heterogeneous group of muscular dystrophies. Identification of the specific gene defect can be challenging. Immunohistochemistry testing of muscle biopsies can be helpful to select the confirmatory genetic test. Alternatively, direct testing a LGMD gene panel can help identify the causal gene. We describe a boy with severe childhood onset of LGMD with increasing and especially distal weakness of the muscles. Initial investigation on a muscle biopsy showed moderate reduction of dystrophin and dysferlin. However, no DMD gene mutation was identified. Additional investigations provided no strong indication for a dysferlinopathy or sarcoglycanopathy. Previously, several other genes were tested but no causal gene was identified. Therefore we applied our NGS approach that evaluates 39 genes known to be responsible for various Limb-Girdle muscular dystrophies and several muscular myopathy related diseases.

Materials en Methods: All coding exons and at least 20 bp of flanking intronic sequences were enriched by using the Agilent SureSelectXT Inherited Disease Panel, followed by sequencing on a Illumina HiSeq2000. Data analysis was performed using a home-made pipeline.

Results: High-quality sequence data was obtained. Variant analysis using a low stringency analysis pipeline revealed a homozygous pathogenic frameshift mutation in exon 6 of the SGCG gene.

Conclusions: Although investigation of a muscle biopsy did not clearly indicate the involvement of sarcoglycans, we identified a homozygous pathogenic SGCG gene mutation, establishing the diagnosis LGMD2C. Indicating that a broad high-quality NGS genepanel can identify the causal mutation, if muscle biopsy investigation is not conclusive.

P10.36

Impact of PMP22 duplication on integrins expression in Charcot-Marie-Tooth (CMT1A) transgenic rat model

M. Jouaud¹, L. Richard¹, B. Funalot², F. G. Sturtz¹, A. Lia¹;

¹Univ. Limoges, Maintenance myélinique et neuropathies périphériques, EA 6309, Limoges, France, ²Univ. Paris-Est Créteil, Limoges, France.

Charcot-Marie-Tooth disease is the most prevalent hereditary peripheral neuropathy (1/2500). The most common form (CMT1A) is caused by duplication on Peripheral Myelin Protein 22 (PMP22), leading to peripheral progressive demyelination, associated with sensibility and mobility loss of upper and lower limbs. The role of PMP22 is currently not well established. To better understand its role, Amici et al. (2006) created a Pmp22 knockout murine model and observed a reduced expression for some integrins. These integrins ($\alpha 6 \beta 4$ & $\alpha 6 \beta 1$) are known to be involved in Schwann cells differentiation and myelination. In addition, a CMT1A-transgenic rat strain, carrying supplementary copies of the Pmp22 gene, was created by Sereda et al. (1996). Our goal was to study in this last model the effect of Pmp22 gene duplication on integrins expression.

At various age (from 1 month to 1 year), we studied, on homozygous, heterozygous and wild-type rats sciatic nerves, PMP22 and integrins expression by quantitative Real-Time-PCR, Western-Blotting, immunohistology and electron-microscopy. Our first results show that some of these integrins are not expressed appropriately. In homozygous and heterozygous rats, we observed mislocation of the PMP22 protein and integrins in the Schwann cells. Interestingly, integrins remain collocated with PMP22 despite its bad location. The gene expression and quantity of protein are also varying in correlation with animal's phenotype and nerve pathology.

These experiments show that the Pmp22 overexpression has a potential role on the Schwann cells differentiation and myelination through interactions with integrins and may explain clinical symptoms of CMT1A patients.

P10.38

Molecular diagnosis approach based on selection of candidate genes by prioritization scripts. A case of two affected siblings presenting multi-minicore and central core disease respectively.

S. Carmona¹, C. Sánchez¹, J. Lezana¹, I. Diez¹, C. Torres¹, M. Ruiz¹, J. López¹, S. Franco², C. Benito², J. López-Siles¹;

¹M.G.C. Genetaq, Málaga, Spain, ²Fetal-Maternal Hospital, Málaga, Spain.

Introduction: Multi-minicore (MmD) and central-core (CCD) diseases are two disorders where RYR1 gene plays a crucial role. Most CCD is associated with mutations in RYR1 whereas MmD is related with pathogenic variants in SEPN1 and RYR1. We report a 5-years-old male patient histologically diagnosed with MmD (patient-1), and his 10-years-old brother diagnosed with CCD (patient-2).

Materials and Methods: TruSight-One sequencing panel (Illumina) was carried out and SEPN1 and RYR1 genes were analysed. The variants were generated by alignment against reference genome (UCSC hg19) with BWA aligner and GATK variant caller. Then, three VCF files containing common variants in patients and unique variants were generated using BedTools, and a custom prioritization script was used to select candidate genes based on different phenotype-genotype association databases (Human Phenotype Ontology, DisGeNet, HGMD).

Results: Two variants of clinical interest in heterozygous state were detected in RYR1 only in patient-1 (c.6721C>T:p.Arg2241Stop and c.2122G>A:p.Asp708Asn).

As symptoms of patients could not be explained by these results, we decided to search potential causal variants in other candidate genes selected. A variant of potential interest was detected in TTN in heterozygous state in both patients (c.59866_59869delAGTG:p.Ser19956LeufsX28). Another variant in TTN canonical splice site in heterozygous state (c.15983-1G>A) was detected in patient-1.

Conclusions: These variants in TTN gene do not clearly explain the phenotype of patient-2, but could justify the clinical features of patient-1. We keep analysing variants in other potentially related genes by exome sequencing using the approach described, as scripts are easily scalable.

P10.39

LGMD2D intrafamilial clinical heterogeneity caused by alternative splicing of SGCA gene

L. Gonzalez-Quereda¹, J. Diaz-Manera², M. Rodriguez², E. Gallardo³, C. Lleixa², P. Piñol-Jurado⁵, V. Straub⁶, A. Topf⁶, P. Gallano¹;

¹Genetics Dept. Hospital de la Santa Creu i Sant Pau, U-705 CIBERER, Barcelona, Spain, ²Neurology Dept. Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, ³Genetics Dept. Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, ⁴Neurology Dept. Hospital de la Santa Creu i Sant Pau, CIBERER, Barcelona, Spain, ⁵neurology Dept. Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, ⁶John Walton Muscular Dystrophy Research Centre, Newcastle, United Kingdom.

BACKGROUND: Mutations in the SGCA gene cause limb girdle muscular dystrophy type 2D (LGMD2D), a recessive form of muscular dystrophy mainly affecting proximal muscles. Most individuals present onset in childhood with a progressive and severe clinical course while others have first symptoms at young/adult age and a mild form of the disease.

METHODS: We report a LGMD2D family with three affected siblings. The index case developed muscle weakness involving paraspinal muscles, showing a dystrophic pattern in the muscle biopsy, considered as an axial myopathy. Her two siblings only had hyperckemia. Exome sequencing was performed as part of Myo-Seq project. Sanger sequencing verified the presence of the variants detected. mRNA isolated from muscle biopsy was analysed and the level of different transcripts quantified.

RESULTS: Exome sequencing revealed an intronic deletion located at c.585-31_585-24 of SGCA in homozygous state. mRNA showed the presence of three different transcripts: 1) The wild type, 2) A transcript with a frameshift deletion of exon 6, and 3) A transcript with a cryptic splicing acceptor leading to a cDNA including 26 extra amino acids coming from intron 6. We confirmed a deficiency of alpha-sarcoglycan in the muscle biopsy using IF and WB. The remaining sarcoglycan complex proteins and dystrophin were all normal.

DISCUSSION: The mild clinical presentation of LGMD2D in this family is attributable to the presence of wild type transcript in spite of having a homozygous mutation. The proportion of each transcript can be the key of the different degrees of severity between family members.

X-linked spastic paraplegia with dysarthria caused by insertional translocation into the Xq26.3 located inverted repeat

* Asan¹, T. Thelle², R. Christensen³, L. Bolund⁴, A. Gunnarsson³, Z. Quan¹, X. Zhang¹, J. Li⁵, P. Qvist⁶, A. Børglum⁶, E. Kamsteeg⁶, J. Hedegaard³, B. Peters⁷, L. Sundé³, M. Nyegaard⁴, U. Jensen²;

¹BGI-Shenzhen, Shenzhen 518083, China, ²Regionshospital Viborg, Viborg, Denmark, ³Aarhus University Hospital, Aarhus N, Denmark, ⁴Aarhus University, Aarhus C, Denmark, ⁵Southeast University, Nanjing, China, ⁶Radboud UMC, Nijmegen, Netherlands, ⁷Complete Genomics, Mountain View, CA, United States.

Background and aim: Spastic paraplegia is a genetically heterogeneous disease that can be caused by alterations in one of many loci. We describe a family with X-linked complicated spastic paraplegia with early onset dysarthria. Mild intellectual disability is described in some patients.

Methods: In order to pinpoint candidate gene, we used a combination of linkage analysis, exome sequencing and whole genome sequencing. Linkage analysis showed linkage to a region within Xq26.3 containing 52 genes. As the exome sequencing did not reveal any pathogenic mutations we used the Complete Genomics platform to sequence the entire genome of one patient and one healthy male control. RNA-seq of PAX blood, fibroblasts, iPSC and neuroprogenitor cells were quantified.

Results: Whole genome sequencing detected an insertional translocation of chromosome 4 material into a palindromic inverted repeat located within Xq26. Such translocation has been described before resulting in both XD hypertrichosis and XR hypertrichosis. XR CMT phenotype has also been described as well as hypoparathyroidism. To pinpoint the disruption in gene expression, we analysed the expression of the entire transcriptome and found that the activity of multiple genes was affected.

Conclusion: It is very likely that such insertions changes the topologically associated domains (TADs) and causes a rewiring of the region. However, our results also illustrate the difficulties in pinpointing a single candidate gene. As we suspect that some of the differentially expressed genes are due to normal variation between case and control we will discuss a strategy to narrow down the number of candidate genes.

P10.41

Novel truncating mutation is attributed to Spastic Paraplegia-64

M. Noruzinia^{1,2}, O. Bashiti¹, M. Ahmadvand³, A. Salehi Chaleshtori¹; ¹Department of Medical Genetics, Faculty of Medical Sciences, Tarbiat Modares University, Tehran, Iran, Islamic Republic of, ²Sarem Cell Research Center (SCRC), Sarem Women's Hospital, Tehran, Iran, Islamic Republic of, ³Department of Hematology and Blood Banking, Faculty of Medical Sciences, Tarbiat Modares University, Tehran, Iran, Islamic Republic of.

Introduction: Neurodegenerative genetic diseases of motor neuron characterized by progressive age-dependent defeat of corticospinal motor tract function celebrated as Hereditary Spastic Paraplegias (HSPs). Main features are axonal degeneration and progressive lower limb spasticity. One of them, Spastic Paraplegia-64 (SPG64; OMIM# 615683) is an autosomal recessive paradigm, established by homozygous or compound heterozygous mutations in the ENTPD1 gene.

Materials and Methods: A seven years old male with chief complaints of severe neurodevelopmental delay referred to SCRC in order to genetic testing. Patient's Blood collected from antecubital veins, genomic DNA extracted and applied to exome capture, library generation and exome sequencing. Then inheritance validation of candidate variants confirmed by the Sanger sequencing in all family members.

Results: A homozygous single base pair deletion in exon 8 of the ENTPD1 gene (chr10:9762261delA) that drives a frameshifting and termination of the protein two amino acids downstream to codon 383 (p.Asn383ThrfsTer2; ENST00000371207) was detected. No other variant that warrants to be reported was detected. This frameshift variation is not reported in both 1000 genomes and ExAC databases.

Conclusion: This mutation led to NMD, frameshifting and production of truncated protein. This mutation truncate the ENTPD1 protein in its extracellular domain partially and its helical and cytoplasmic domains entirely. We concluded that this truncated protein is the most logical causative for explanation of the SPG-64 phenotype in reported patient and this mutation would be applied in PND and PGD in the family. This study was funded by SCRC of Sarem women's hospital.

DYNC1H1 gene methylation correlates with a severity of spinal muscular atrophy

M. A. Maretina^{1,2}, G. Y. Zheleznyakova², V. S. Baranov^{1,2}, A. V. Kiselev¹; ¹D.O. Ott Research Institute of Obstetrics and Gynecology RAMS, Saint-Petersburg, Russian Federation, ²Saint-Petersburg State University, Saint-Petersburg, Russian Federation, ³Karolinska Institute Stockholm, Solna, Sweden.

Introduction: Spinal muscular atrophy (SMA) - inherited neuromuscular disorder caused by homozygous mutations of SMN1 gene. Respective of manifestation and achieved motor milestones SMA is subdivided into four clinical types. The number of SMN2 gene copies determines SMA severity. Involvement of some modifiers in SMA progression including DNA methylation is also suspected. Our recent genome-wide methylation study revealed 40 genes with differentially methylated CpG sites in SMA patients compared to healthy subjects. DYNC1H1, SLC23A2 and CDK2AP1 genes picked up in our previous study and most probably participating in SMA progression were chosen for the present work.

Material and Methods: Analysis of melting profiles was carried out in 78 DNA samples from SMA patients with severe type I (40) and mild types III-IV (38) of disease. High-resolution melting procedure with bisulphite-treated DNA was used. Methylation level was estimated by interpolating polynomials using values of DNA standards with known percentage of methylation.

Results: No differences in methylation of 5'-UTR of SLC23A2 and CDK2AP1 as well as exon 41 of DYNC1H1 were found in the patients with severe and mild SMA. Significantly higher methylation of DYNC1H1 exon 37 was registered in mildly affected SMA patients compared to SMA type I patients.

Conclusion: Exon 37 of DYNC1H1 lies within CpG-rich region and apparently should be methylated for preventing spurious transcription initiations. Mutations in DYNC1H1 were shown to be associated with common neuromuscular diseases, such as ALS and dominant SMA. Feasible involvement of DYNC1H1 into SMA pathogenesis is suggested.

P10.43

Analysis of perineuronal net components in neuronal differentiation defects

N. Eskici¹, S. Erdem-Ozdamar², D. Dayangac-Erden¹; ¹Hacettepe University Faculty of Medicine Department of Medical Biology, Ankara, Turkey, ²Hacettepe University Faculty of Medicine Department of Neurology, Ankara, Turkey.

Introduction: Perineuronal net (PNN) is composed of a specialized extracel-

ular matrix which is found around neuronal cell body and dendrites in the central nervous system. PNN is responsible for synaptic stabilization in neurons and regulation of plasticity. It also has neuroprotective role against excitotoxicity and oxidative stress. One of the major elements of PNN are hyaluronan and proteoglycan link protein (HAPLN1), tenascin-R (TNR) and aggrecan (ACAN) proteins.

Materials/Methods: In order to investigate the effects of HAPLN1, TNR and ACAN during neural differentiation; PC12 cell line which is derived from the neural crest lineage and undergo to a neural phenotype when treated with NGF was used as a differentiation model. mRNA, protein expression levels and distribution of PNN were analyzed before and after differentiation (day 3,5,7). Also neurite length analysis were performed.

Results: Our study demonstrated that HAPLN1 and ACAN expression showed an increase at day 7 and the longest neurite were detected at that time point (p<0,05). On the other hand TNR RNA/protein levels remained unchanged. In addition to our results obtained from PC12 model of neuronal differentiation, we used spinal muscular atrophy (SMA) as a disease model which is caused by neuritogenesis defects. Using transcriptome analysis, we identified that extracellular matrix- synapse organization pathways were affected and PNN components showed a significant decrease in SMA fibroblasts. The results were validated and 2 to 5 fold decrease was detected.

Conclusions: In-vitro disease models and mouse models will also provide information on PNN dysfunction in the pathogenesis of other neurodegenerative diseases. TÜBİTAK:114S914

P10.44

Occurrence of CHCHD10 mutations in Finnish patients with motor neuron disorder

S. Penttilä¹, M. Jokela², A. Saukkonen³, J. Toivanen³, B. Udd^{1,4,5}; ¹Neuromuscular Research Unit, University of Tampere, Tampere, Finland, ²Department of Neurology, Turku University, Turku, Finland, ³Department of Neurology, Central Hospital of Northern Karelia, Joensuu, Finland, ⁴University of Helsinki, Folkhälsan Institute of Genetics and the Department of Medical Genetics, Helsinki, Finland, ⁵Department of Neurology, Vaasa Central Hospital, Vaasa, Finland.

Background and aims: Spinal muscular atrophy Jokela type (SMAJ), OMIM #615048) is a relatively benign form of motor neuron disease. The disease is caused by a dominant mutation c.197G>T p.G66V in CHCHD10 that is a founder mutation in Finland. Other mutations in CHCHD10 have been reported to cause frontotemporal dementia-amyotrophic lateral sclerosis (FTD-ALS) with mitochondrial myopathy and isolated mitochondrial myopathy. Some mutations have been associated with FTD-ALS but their pathogenicity has remained uncertain. We wanted to know if the mutation c.197G>T p.G66V might cause other phenotypes besides SMAJ. Other aims of the study were to find out if there are other mutations of CHCHD10 in Finnish patients and if CHCHD10 mutations are frequent among patients with distinct neurogenic disorders.

Methods: Exon 2 of CHCHD10 that harbors all reported mutations was sequenced in 308 patients. In 103 patients the whole coding region of the gene was sequenced. Of the patients included in the study, 208 patients had a phenotype compatible with SMAJ, 22 patients had a non-specific neurogenic disorder, 14 patients had mitochondrial myopathy, and 64 patients had diagnosis of ALS.

Results: The founder mutation was found in 20 patients. All of them were suspected to have SMAJ. No other possibly pathogenic mutations were found, and no mutations were found in other patient groups.

Discussion and conclusions: Our results suggest that the CHCHD10 mutation c.197G>T p.G66V is a common mutation in Finland with a prevalence around 2/100000. The clinical outcome of c.197G>T p.G66V is very restricted to the SMAJ phenotype.

P10.45

Genetic risk factors associated with Sporadic Inclusion Body Myositis

M. Johari, M. Arumilli, N. Sandholm, H. Lohi, P. Hackman, B. Udd; Folkhälsan Institute of Genetics, Helsinki, Finland.

Sporadic Inclusion Body Myositis (s-IBM) is the most frequent disabling progressive muscle disease of unknown cause in elderly people, onset at 45 years or later, with coexistence of degenerative pathology and inflammatory muscle changes. In Finland, the estimated prevalence is 70/million. Because of the dual pathology, different pathogenic mechanisms are considered; one suggests that multiple post-translationally modified proteins accumulated in the s-IBM aging muscle fibers may be eliciting a T-cell inflammatory reaction. This abnormal proteostasis and muscle fiber injury could be the result of defects in several different susceptibility genes, making s-IBM a complex multifactorial disease. The isolation of Finnish population provides an excel-

lent opportunity to look for possible disease causing associations. By whole exome sequencing (WES) followed by association analysis we have found genetic variants that have an observed considerably higher frequency in 30 Finnish s-IBM patients compared to control population. These variants could individually or in combination be associated with higher susceptibility for the disease. We are currently investigating the effects on these associations with an increased cohort size and wider population. Further, we are going to perform in-silico network and pathway analysis to identify possible connections of the identified candidate genes with regard to molecular mechanisms of muscle homeostasis, autophagy and injury.

Systematic analysis of polymorphic tandem repeats through the development of a NGS method

L. Corrado¹, R. Bordoni², L. M. Genovese³, E. Mangano², F. Geraci³, M. Severgnini², R. D'Aurizio³, C. Locci¹, F. De Marchi⁴, L. Mazzini⁴, A. Brusco⁵, G. Manzini⁶, M. Pellegrini³, G. De Bellis², S. D'Alfonso¹;

¹Dept. of Health Science, University of Eastern Piedmont UPO, Novara, Italy, ²Institute for Biomedical Technologies (ITB), National Research Council (CNR), Segrate (MI), Milan, Italy, ³Institute for Informatics and Telematics (IIT), National Research Council (CNR), Pisa (PI), Pisa, Italy, ⁴Dept. of Neurology, Ospedale Maggiore della Carità, Novara, Italy, ⁵Department of Medical Science, University of Torino, Italy, Torino, Italy, ⁶Institute for Informatics and Telematics (IIT), National Research Council (CNR), Pisa (PI), Department of Science and Technological Innovation University of Piemonte Orientale, UPO, Novara, Italy.

Tandem repeats polymorphisms (TRPs) are extremely common throughout the genome and represent good candidates for missing heritability in different neurodegenerative diseases for whom the expansion of TRP represents the major disease gene.

To date, TRPs analysis is a remarkable challenge using current next generation sequencing (NGS) approach and thus they were never systematically analyzed at genome wide level.

The aim of this study is to implement a pipeline for the TRPs analysis from genome-wide NGS data. To this purpose, we successfully implemented a new procedure to genotype TRPs, which we applied to a NGS target-resequencing panel containing over 10000 TRP loci, including 37 known disease-causing TRPs.

Fifteen DNA patients affected by nine different neurodegenerative diseases and carrying expanded alleles of different lengths/repeat motif have been sequenced and analyzed together with one CEPH sample with about 9900 known TRPs genotyping.

Our approach correctly determines the allele size of 76% of known genotypes at 63 TR loci in the CEPH sample. Similarly, when considering the typing in known disease-related loci we obtained a consistent genotyping in almost all cases (98% of 56 genotypes). Even for very large expansions such those in c9orf72 and DM, which are indeed not measurable, we identified those samples carrying a pathological expanded allele. Accordingly, our NGS approach can be applied to discover new disease loci characterized by tandem repeat expansion. With this aim, we are performing a comprehensive genome-wide research of TRPs in all gene regions in a large cohort of ALS patients with a WGS approach.

P10.47

Targeted next-generation sequencing as a diagnostic tool in neuromuscular disorders

S. Lehtinen¹, S. Penttilä¹, T. Suominen¹, B. Udd^{1,2,3};

¹Neuromuscular Research Center, Tampere University and University Hospital, Tampere, Finland, ²Folkhälsan Institute of Genetics and Department of Medical Genetics, Haartman Institute, University of Helsinki, Helsinki, Finland, ³Department of Neurology, Vasa Central Hospital, Vasa, Finland.

Diagnosing neuromuscular disorders is often very challenging. There is considerable overlap of clinical findings between different disorders. Furthermore, the genes expressed in muscles can be large and one gene can cause different disorders.

The aim of this study was to evaluate the diagnostic power of our new analytic tool, MYOcap gene panel. It is a next-generation sequencing (NGS) assay targeted to all exons of all known and predicted myopathy or muscular dystrophy causing genes.

The acquired sequencing data was filtered so that only the variants meeting our quality requirements, having a population frequency less than 1 %, and coverage of at least 20X remained. 40 patients were included in this evaluation study. The patients presented with the clinical phenotype of muscular dystrophy or myopathy but the genetic background of their disorder had not been resolved despite of thorough investigations.

With MYOcap, we were able to reach a definitive diagnosis in 12,5 % of the

cases, usually meaning known mutations in genes compatible with the phenotype. 7,5 % of the cases were suspected to have either a new phenotype linked to a known disease-causing gene or a completely new phenotype-genotype correlation. In 20 % of the cases we could clearly state that no variations compatible with the patient's phenotype were found. In 60 % of the cases further studies were recommended.

We conclude that MYOcap is an effective tool for assigning a genetic diagnosis in neuromuscular disorders and can also be used to discover new phenotype-genotype correlations.

P10.48

Clinical and genetic characterization of the first reported Spanish family with UBQLN2 mutation

B. Quintáns^{1,2}, A. Ordóñez-Ugalde^{1,3}, E. Goberna⁴, P. Díaz¹, S. Züchner⁵, J. Martínez-Simón⁴, Á. Carracedo^{3,6,2}, M. J. Sobrido^{1,6,2};

¹Instituto de Investigación Sanitaria, Santiago de Compostela, Spain, ²CIBERER, Madrid, Spain, ³USC, Santiago de Compostela, Spain, ⁴Complejo Hospitalario Torrecárdenas, Almería, Spain, ⁵University of Miami, Miami, FL, United States, ⁶Fundación Pública Galega de Medicina Xenómica, Santiago de Compostela, Spain.

Introduction: Mutations in the UBQLN2 gene are the cause of a diversity of neurological syndromes: amyotrophic lateral sclerosis 15 (ALS15) with or without frontotemporal dementia (FTD), and spastic paraplegia (HSP). Spanish patients with UBQLN2 mutations have not been reported so far.

Patients and methods: We studied a large family from Southern Spain in which at least 9 members had a progressive disorder combining upper and, subsequently lower motor neuron manifestations. Clinical data were obtained from 11 individuals in 3 generations. The C9orf72 mutation was analyzed by RP-PCR. Whole exome sequencing (WES) was carried out on the proband. Variants in genes causing HSP, ALS and FTD were prioritized.

Results: The C9orf72 expansion was not detected. We identified a previously reported pathogenic variant in UBQLN2 (NM_013444.3:c.1516C>T;NP_011630.15:p.P506S) segregating with the disease. There was variability in onset age (generally younger in males), initial symptoms (variable combination of upper and lower motor neuron), severity and progression rate (generally more severe in men, although one affected woman died at 42). Symptoms of FTD were frequent as disease advanced. Penetrance was complete in males and incomplete in females (asymptomatic carriers in the sixth and eighth decades).

Conclusions: UBQLN2 must be ruled out in patients with HSP, even in the absence of second motor neuron signs. The WES approach is useful for the diagnosis of clinically heterogeneous disorders. Our data are in agreement with the phenotype previously described in families with this particular mutation. Genetic counseling is challenging in this X-linked dominant, devastating disease. Funding: ISCIII-FIS PS09/01830.

P10.49

Activation of the mitochondrial unfolded protein response (UPRmt) pathway in C2C12 myoblast cell line

E. Aksu¹, B. Talim², P. Dincer¹, B. Balci-Hayta¹;

¹Hacettepe University Faculty of Medicine, Department of Medical Biology, Ankara, Turkey, ²Hacettepe University Faculty of Medicine, Department of Pediatrics, Pathology Unit, Ankara, Turkey.

Introduction: The mitochondrial unfolded protein response (UPRmt) is a mitochondrial stress response pathway that adapts the protein folding capacity of the organelle to the load of unfolded and misfolded proteins in normal physiology and disease states. Although the detailed mechanism is not known, UPRmt mechanism activates transcription of nuclear-encoded mitochondrial chaperones and quality control proteases to promote protein homeostasis within the organelle. Mitochondrial dysfunction, one of the main causes of muscle degeneration, has been recognized as a key pathological hallmark of several major neuromuscular disorders. However, the relationship between mitochondrial dysfunction and UPRmt has not been investigated yet. For this purpose, an in-vitro model of UPRmt was generated as a continuously available infrastructure for high-throughput analysis. Materials and Methods: UPRmt activation in C2C12 cells was performed by treating cells with an appropriate non-toxic conditions of antimycin (100/150µM), a known inhibitor of mETC complex III, in serum-free media at 37°C for 90 minutes.

Results: Antimycin-induced UPRmt activation was reported by the observation of decreased mitochondrial membrane potential and impaired dynamics as detected by Mitotracker Red-CMXRos staining, altered bioenergetic function of mitochondria by MTT assay, high levels of reactive oxygen species measured by DCFDA assay and increased levels of mitochondrial specific chaperone Hsp60 by Western Blot.

Conclusions: The development of an in-vitro model of UPRmt in C2C12

cells will pave the way for identifying the novel genes/proteins involved in UPRmt pathway and novel drug targets by screening libraries of small molecules. This study was supported by TÜBITAK (Project no:114S876).

Targeted Whole Exome Sequencing analysis allows for identification of a new case of myoclonus epilepsy and ataxia due to potassium channel mutation (MEAK)

R. Szymanczak¹, K. Spodar¹, A. Wasowska¹, M. Kania¹, E. Matczynska¹, **M. Jurkowska¹**, A. Lasek-BaP, A. Potulska-Chromik², A. Kostera-Pruszczyk³, A. M. Boguszewska-Chachulska¹;

¹Genomed SA, Warsaw, Poland, ²High School of Science, Medical University of Silesia in Katowice, Department of Neurology, Katowice, Poland, ³Department of Neurology, Medical University of Warsaw, Warsaw, Poland.

Whole Exome Sequencing was performed for a seventeen years old male patient with myoclonic jerks, cerebellar ataxia, slight extrapyramidal signs with epileptiform pattern in EEG.

The patient's intellect was normal, he had neither obvious dysmorphic features nor congenital anomalies. CNS imaging and extensive biochemical examinations revealed no apparent abnormalities.

Previous genetic testing of SCA1,2,3, Friedreich ataxia and for a dynamic mutation in the *CSTB* gene, associated with Unverricht-Lundborg disease, gave normal results.

A whole exome sequencing was performed in our laboratory and targeted exome sequencing data analysis has been carried out to identify pathogenic mutations in almost 400 genes associated with: progressive myoclonus epilepsy, spastic paraplegia, ataxia and extrapyramidal signs, and in the mitochondrial genome.

A newly described, recurrent, pathogenic mutation c.959G>A, p.(Arg320His) was identified in one allele of the *KCNK1* gene, which can be considered, with a high probability, to be the main cause of clinical symptoms observed. The carrier status analysis performed in Patients' parents demonstrated that the mutation occurred *de novo*. No pathogenic mutations or potentially pathogenic variants, which could be responsible for the Patient's clinical picture as a whole, have been identified in the other analysed genes.

The result of the analysis support the diagnosis of progressive myoclonus epilepsy type 7, described in the publication of Muona *et al.* (2015) as myoclonus epilepsy and ataxia due to potassium channel mutation (MEAK).

Recently performed targeted neurological examination seems to confirm the MEAK diagnosis.

P10.51

Clinical, molecular and histopathological findings in a girl with Xq28 duplication resulting in X-linked myotubular myopathy

K. Kosma¹, M. Tzetis¹, A. Mitrakos¹, M. Braoudaki¹, C. Sofocleous¹, A. Xaidara², G. Papadimas³, A. Tsezou⁴, S. Kitsiou-Tzeli¹;

¹Department of Medical Genetics, University of Athens, Athens, Greece, ²First Pediatric Department, University of Athens, Aghia Sophia Children's Hospital, Athens, Greece, ³Department of Neurology, University of Athens, Aeginition, Athens, Greece, ⁴Laboratory of Cytogenetics and Molecular Genetics, University of Thessaly, Larissa, Greece.

X-linked myotubular myopathy (XLMTM) is a rare inherited neuromuscular disorder, clinically characterized by severe hypotonia, respiratory failure and skeletal muscle weakness, typical of congenital myopathies, as well as abundant central nuclei as the most prominent histopathological feature on muscle biopsy, thus being grouped in the genetically heterogeneous group of Centronuclear Myopathies (CNMs). XLMTM is associated with mutations and CNVs in the Xq28 chromosomal region, that contains the *MTM1* gene. Here we report a case of a severely affected girl with XLMTM, caused by a maternally inherited duplication in the Xq28 region, identified by high resolution aCGH analysis, utilizing the 4x180k aCGH+SNP platform from Agilent Technologies. Furthermore, we studied the methylation profile to determine the X-inactivation pattern that led to the disease and conducted histopathological examination on tissue from muscle biopsy that confirmed the diagnosis of XLMTM. A full clinical examination was also performed. DNA microarray analysis of the peripheral blood sample and muscle biopsy of the proband and her mother revealed a 661kb microduplication in the Xq28 region, containing the *MAMLD1*, *MTM1*, *MTMR1* and *CD99L2* genes. The muscle biopsy revealed histopathological changes usually observed in centronuclear myopathies. To our knowledge this is the first report of a girl with XLMTM caused by Xq28 microduplication. This case report adds to the knowledge on centronuclear myopathies underlying the necessity of thorough genetic testing in the investigation of rare genetic syndromes.

P10.52

Impact of two SMN1 polymorphisms to improve SMA carriers diagnosis

L. Afías^{1,2}, S. Bernal², E. Martínez³, F. March³, A. Venceslá⁴, M. Baiget¹, E. Tizzano⁵;
¹U705-CIBERER, Barcelona, Spain, ²Genetics Department. Hospital Santa Creu i Sant Pau, Barcelona, Spain, ³Genetics Department. Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, ⁴IRBB-Sant Pau, Barcelona, Spain, ⁵Department of Clinical and Molecular Genetics, Hospital Vall d'Hebron, Barcelona, Spain.

Introduction: Spinal muscular atrophy (SMA) is an autosomal recessive motor neuron disease caused by deletions/mutations in the *SMN1* gene. Classical SMA carriers (1/0) with one of their *SMN1* copies mutated show a frequency around 1/40 in our population. SMA carriers with two copies of the *SMN1* gene in cis have been described. These 2/0 SMA carriers are undistinguishable from non carrier individuals (1/1) by quantitative studies. In the Ashkenazi population, two polymorphisms have been associated with two *SMN1* copies in the same chromosome: g.27134G>T in intron 7 and g.27706_27707delAT in exon 8. Furthermore, these alleles are more frequent in Africans in which the presence of chromosomes with two *SMN1* copies is higher. Material: We analyzed these markers in 368 Spanish individuals including SMA patients with *SMN2-SMN1* hybrid genes, 1/0 carriers, controls and individuals with more than one *SMN1* copy in cis. Methods: Sanger sequencing from the exon 7 to 8 of the *SMN1* gene. Results: Both SNP's are more frequently detected in chromosomes with two *SMN1* copies in cis in comparison with chromosomes carrying one copy. The g.27706_27707delAT was more frequent in *SMN2-SMN1* hybrids than in wild type *SMN1* genes (16.7 versus 1.3%, p<0.05). Conclusion: The impact of these polymorphisms depends on the population studied. In our Spanish population, they are less valuable to predict putative 2/0 carriers and their absence does not exclude the existence of two *SMN1* in cis. The high frequency of g.27706_27707delAT in hybrids genes suggest that chromosomal rearrangements are prone to occur in presence of this polymorphism.

P11 Multiple Malformation/anomalies syndromes

Tissue-specific mosaicism of partial 13q monosomy identified in fibroblasts of the patient with mild intellectual disability, dysmorphic features and skin lesions

K. Ziemkiewicz, M. Smyk, K. Jakubów-Durska, A. Kutkowska-Kaźmierczak, B. A. Nowakowska;
Dep of Medical Genetics, Institute of Mother and Child, Warsaw, Poland.

Introduction: The severity of symptoms in 13q monosomy may vary greatly, depending upon the size and location of the deletion and degree of mosaicism. Large deletions are generally associated with growth delay, mostly severe or moderate mental retardation, defects of the hands and feet, ocular abnormalities, and other major malformations. We describe a girl diagnosed at the age of 2 years 10 months with psychomotor and speech delay, clinodactyly of the 5th finger, big hands and feet and very light iris. At the age of 5 karyotype was performed due to clinical features: linear and whirled hypochromic skin lesions, abnormal iris pigmentation and hair texture. At the age of 6 years patient presented mild intellectual disability and subtle dysmorphic features.

Materials and Methods: aCGH analysis was performed using CytoSure ISCA, OGT and chromosome lymphocytes and fibroblasts analysis by G-banding techniques.

Results: In the aCGH analysis no abnormality was found. GTG banding of metaphases from skin fibroblasts showed the 13q deletion in 38 % of cells. The karyotype was: mos 46,XX,del(13)(q12.1)[16]/46,XX[26]. In chromosome analysis of 600 blood lymphocytes metaphases only one abnormal cell with deletion 13q was detected.

Conclusions: Patients with tissue-specific mosaicism may develop much less severe phenotype despite large size of 13q deletion. Karyotyping of skin, to detect mosaicism is warranted in all patients presenting with hypo/hyperpigmentary changes and/or eyes and hair abnormalities regardless of normal peripheral blood aCGH result.

This work was granted from Ministry of Science and Higher Education (3942/E-215/S/2014 to BAN).

P11.002

Three cases of unusual chromosomal rearrangements involving the chromosome 22q11.2 region

V. Cejnova¹, V. Harmas¹, L. Liskova¹, M. Tothova², P. Hedvicakova³, A. Klimova¹, M. Soukupova¹, J. Lastuvkova¹;

¹Regional Health Corporation, Masaryk Hospital in Usti nad Labem, Department of Medical Genetics, Usti nad Labem, Czech Republic, ²GENVIA, Prague, Czech Republic, ³Department of Biology and Medical Genetics, 2nd Faculty of Medicine, Charles University in Prague and Motol University Hospital, Prague, Czech Republic.

Chromosome 22q11.21 contains a cluster of low-copy repeats (LCRs), referred to as LCR22A-H, that mediate meiotic non-allelic homologous recombination, resulting in either deletion or duplication of various intervals in the region. The deletion of the DiGeorge/velocardiofacial syndrome interval LCR22A-D is the most common recurrent microdeletion in humans, with an estimated incidence of 1: 4,000 births. Although both deletion and duplication events should occur in equal proportions, microduplications of the 22q11.2 region are about half as frequent as microdeletions. Probably, microduplications are underdiagnosed by karyotype analysis and FISH.

We present clinical, cytogenetic and molecular analysis of three cases involving the 22q11.2 region. In the first case, we report prenatal diagnosis of a 2.6 Mb deletion in the 22q11.2 region and a 1.7 Mb duplication in the 16p13.11 region by array CGH in a fetus with congenital heart defect. 16p13.11 microduplication syndrome is a recently described syndrome associated with variable clinical features including behavioral abnormalities, developmental delay, congenital heart defects and skeletal anomalies. In the second case, array CGH showed a 156 kb interstitial microdeletion of 22q11.21 in a pregnant women with complex congenital heart disease. The microdeletion affected ten genes, including CRKL, which is considered a candidate critical gene for the 'central' deletions in 22q11.2. In the third case, we detected prenatally a 22q11.2 microduplication of seven probes (HIRA, CLDN5, KIAA1652, KLHL22, PCQAP, SNAP29 and LZTR1) using MLPA. All findings were confirmed by FISH and we also investigated parents in order to determine the parental origin of chromosomal rearrangements.

Cytogenomic delineation of Brazilian patients with 22q11.2 deletion syndrome associated autoimmune heterogeneous phenotype

C. Milani¹, F. A. R. Madia¹, T. V. M. M. Costa¹, J. G. Damasceno¹, E. A. Zanardo¹, A. T. Dias¹, M. M. Montenegro¹, G. M. Novo-Filho¹, F. B. Piazzoni¹, A. M. Nascimento¹, M. Rocha², D. C. Soares³, M. S. Grassi³, A. F. L. Carvalho⁴, D. Bertola³, M. I. Melaragno⁵, C. A. Kim³, M. M. S. Carneiro-Sampaio³, L. D. Kulikowski^{1,2,3};

¹Faculdade de Medicina da USP, Sao Paulo, Brazil, ²Centro de Reprodução Humana e Genética, Faculdade de Medicina do ABC, Santo Andre, Brazil, ³Unidade de Genética, Departamento de Pediatria, Instituto da Criança, Sao Paulo, Brazil, ⁴Departamento de Biologia Geral, Laboratório de Genética Humana e Mutagenese, Universidade Federal da Bahia, Salvador, Brazil, ⁵Departamento de Morfologia e Genética da Escola Paulista de Medicina, UNIFESP, Sao Paulo, Brazil.

The 22q11.2 Deletion Syndrome phenotype is very heterogeneous with variable expression of the different features including the immunodeficiency. The clinical evidence suggests that the immunodeficiency can be seen in most of the patients with this alteration and the immunological phenotype may vary widely between the patients and the deletion size does not appear to be responsible for this variation. Thus new insights into pathophysiology are important for a better assessment and targeting treatment for the patients.

Cytogenomic alterations in 22q region were investigated using MLPA and SNP-array (HumanCytoSNP-12 BeadChip and CytoSNP-850K BeadChip) to map the presence of Copy Number Variations (CNVs) and Loss of Heterozygosity (LOH) in 31 Brazilian patients with a spectrum of 22q11.2 phenotypic manifestations.

We identified different sizes of genomic alterations in the 22q region. In a cohort of 31 patients (32% males and 68% females) we found 14 deletions and 14 duplications, and 7 patients with loss of heterozygosity including genes associated with lupus erythematosus, polyarthritis, psoriasis, rheumatoid arthritis, sepsis, bronchitis and pneumonia. Hypoparathyroidism, cardiac abnormalities as well as developmental delay and psychiatric disorders were the other features related to some pathogenic CNV showed in these patients.

Cytogenomic investigation permitted a better chromosome breakpoint definition and the identification of deletion and duplication syndromes in 22q region enabling a biological interpretation of the immunologic abnormalities.

Partial trisomy 22q12.1 and monosomy 13q12.1 in a child due to maternal t(13;22)(q12.1;q12.1)

S. Altner¹, N. Kutlay¹, T. Tos², T. Tuncali¹;

¹Department of Medical Genetics, School of Medicine, Ankara University, Ankara, Turkey, ²Department of Medical Genetics, Dr. Sami Ulus Maternity and Child Health Hospital, Ankara, Turkey.

Introduction: 22q11.2 microduplication is a well-defined syndrome and its phenotype is variable from mild intellectual disability to severe congenital malformations. Recently, deletion of proximal arm of the 13q is also reported in the literature. Here we report a family with different derivative chromosomes over a 4.5 year-old female patient referred to our department for suspected chromosome breakage syndromes with partial trisomy 22q12.1 and monosomy 13q12.1 originated from maternal t(13;22)(q12.1;q12.1). Material and Methods: Conventional cytogenetics and FISH analyses were performed in all family members using standart methodology. Chromosomal breakage (DEB) test was performed in index case. Karyotypes were then reported according to the ISCN 2013.

Results: Karyotypes of the mother, the index case (DEB test: result) and the male sibling were determined as follows: 46,XX,t(13;22)

(q12~13;q11~12), 46,XX,der(22)t(13;22)(q12~13;q11~12)

(DEB test: negative) 46,XY,der(13)t(13;22)(q12~13;q11~12).

Conclusion: Index case had the findings of both the partial trisomy of 22q12.1 and the monosomy of 13q12.1 in which severe skeletal malformations, hirsutismus and eventration of diaphragma were due to the latter chromosomal aberration. We suggest a possible role of haploinsufficiency of a gene, FGF9, located at 13q11-12 for the causality.

Chromosomal Microarray (CMA) is a first-tier test in the diagnostic work-out assessment of multiple congenital abnormalities/intellectual disability (MCA/ID) syndromes, detecting pathogenic copy number variations in 15-20% of patients. CMA has allowed the characterization of an increasing number of syndromes, named after their underlying chromosomal unbalance. Even if microdeletions caused by allelic non-homogeneous recombination of repeated duplicons in flanking regions generally have a relatively homogeneous size, their clinical phenotype can show variable expressivity, making the prognosis evaluation difficult. It is even more challenging, for clinical geneticists, to evaluate the prognosis of patients carrying "unique" non-recurrent deletions: the information available in the literature is often very poor, mostly concerning only partially overlapping microdeletions. 2p14p15 microdeletions can be considered as a typical example of the latter group of chromosomal abnormalities. Only three patients have been reported to date, showing ID and dysmorphisms. We report the clinical and molecular cytogenetic characterization of four further ID/MCA patients from France and Spain carrying 2p14p15 microdeletions. The present study and a review of the literature showed that 3/7 patients had sensorineural hearing loss. No deafness-causing gene has been reported so far in 2p14. Here we discuss the possible role of the *ACTR2* and *SPRED2* genes in the observed hearing loss. Significant ophthalmological involvement was noted, including glaucoma and rod degeneration. One patient developed a progressive cardiomyopathy, suggesting that a cardiac follow-up should be systematically warranted, even in the absence of congenital heart disease.

In conclusion, our study contributes significantly to delineate the phenotypic spectrum of 2p14p15 microdeletions.

P11.006

Mild intellectual disability, congenital heart defect and skeletal abnormalities in three patients with 4q13.3 microdeletion

E. Preikšaitienė, Ž. Maldžienė, B. Aleksūnienė, V. Kučinskis;

Dept. Human and Medical Genetics, Faculty of Medicine, Vilnius University, Vilnius, Lithuania.

Many patients have genomic alterations that are described in only few individuals and evaluation of clinical significance of these chromosomal alterations is very challenging. Nevertheless detection of novel pathogenic copy number variants and delineation of novel genomic disorders is an important part of genomic studies.

We report on three affected individuals in a family, a mother and her two daughters, 9 and 15 years of age, with mild intellectual disability, minor facial anomalies, congenital heart defect, short stature, broad chest, and scoliosis. The mother and her older daughter additionally had microcephaly and delayed puberty.

Submicroscopic chromosomal alterations were screened by whole-genome genotyping analysis using the HumanCytoSNP-12v2.1 BeadChips (Illumina Inc., San Diego, CA, USA) and revealed 4q13.3 microdeletion, 1.5 Mb in size. FISH analysis using RP11-373J21 probe overlapping part of ADAMTS3 gene confirmed the deletion in all three affected individuals. This novel chromosomal alteration involves GC, NPFFR2, ADAMTS3, COX18 and ANKRD17 genes. ADAMTS3 gene is highly expressed in specific regions of the developing mouse brain and in connective tissues such as bone and tendon.

This clinical report provides clinical and molecular characterization of previously unreported 4q13.3 microdeletion. ADAMTS3 gene might be a candidate gene for intellectual disability and other clinical features, including short stature. Detailed clinical examination of additional patients with a similar microdeletion is needed for further delineation of this clinically recognizable syndrome.

The work was funded by the Lithuanian-Swiss cooperation programme to reduce economic and social disparities within the enlarged European Union under project agreement No.CH-3-ŠMM-01/04, UNIGENE project.

P11.007

Distal 4q partial trisomy vs. distal 10q monosomy - report of a family with a t(4;10)(q31.3;q24)

G. A. Motei, D. Ozunu, V. Plaiasu;

Mother and Child Care Institute „Prof. Dr. Alfred Rusescu“, Bucharest, Romania.

Distal trisomy 4q and distal monosomy of 10q are rare, complex syndromes of intellectual disability, developmental and behavioral problems and distinctive facial features. The severity of the condition and the signs and symptoms depend on the size and location of the duplication and/or deletion and which genes are involved. Although some cases occur sporadically, most are inherited from a parent with a balanced translocation. Individual cases of trisomy 4q31.3 and deletions of 10q24 are rare and have been previously reported in the literature, with variable clinical manifestations.

We report the case of a boy with partial trisomy for the distal part of the long arm of chromosome 4 (4q31.3-->qter) and a concomitant monosomy 10(10q24-->qter). The patient presented with hydrocephaly, craniofacial dysmorphism, cryptorchidism and axial hypotonia. The chromosomal abnormalities resulted from a paternal balanced translocation involving chromosomes 4 and 10. The inheritance and identity of the translocation was ascertained by extensive familial cytogenetic and FISH studies.

To our knowledge, this report is the first to describe a translocation that resulted in the combination of monosomy 10q24 and trisomy 4q31.3 coexisting in the same individual.

Acknowledgments: This work was supported by Objective 3.3 of Romanian Ministry of Health Program VI and by PN-II-PT-PCCA-2013-4-133 grant

P11.008

Mosaic de novo tetrasomy of 5q35 in a newborn with typical features of 5q35 duplication syndrome and heart defect

K. Kuuse¹, P. Tammur¹, P. Ilisson¹, T. Ilus¹, M. Jürgenson¹, O. Žilina^{1,2}, K. Muru¹;

¹Tartu University Hospital, United Laboratories, Department of Genetics, Tartu, Estonia,

²Department of Biotechnology, Institute of Molecular and Cell Biology, University of Tartu, Tartu, Estonia.

Recently described 5q35 microduplication reciprocal to the common Sotos syndrome deletion (~2 Mb) is associated with microcephaly, short stature, developmental delay and delayed bone maturation. The clinical picture is largely opposite to that of Sotos syndrome (macrocephaly, overgrowth and advanced bone age). The dosage effect of NSD1 (5q35) is suggested to be the cause of the main clinical problems.

We report a dysmorphic newborn with IUGR, microcephaly, short stature,

and prenatally diagnosed congenital heart defect (ASD, VSD, left ventricle hypoplasia). First routine karyotype analysis (GTG-banding) revealed a normal male karyotype. Chromosomal microarray analysis (CMA, HumanCytoSNP-12 BeadChip, Illumina Inc.) revealed a ~8.3 Mb duplication of 5q35.1-qter. To localize the extra copy, FISH analysis was done with Kreatech hTERT/NSD1 and 5p/5q subtelomeric probes. Surprisingly, two additional signals of NSD1 and 5qter were seen, located on a small additional marker chromosome, which was present in ~10% of metaphases (all of them were of bad band quality and so escaped in first analysis), and in 50% of interphase nuclei.

The mosaic tetrasomy due to the presence of der(5q) marker-chromosome in ~50% of cells results in a typical duplication picture seen in CMA as well as in clinical features typical for 5q35 duplication. More severe clinical picture compared to common 5q35 duplication can be explained by encompassing NK2 (cardiac development) and MSX2 (limb and bone development) genes.

Introduction

Williams-Beuren (WBS) and 7q11.23 microduplication (7DUP) syndromes are two neurodevelopmental disorders caused by reciprocal rearrangements at 7q11.23, either deletions (WBS) or duplications (7DUP). These recurrent rearrangements are generated by non-allelic homologous recombination (NAHR) between flanking segmental duplications (SDs).

Methods

By dosage analyses of site-specific nucleotides or cis-morphisms, single and multiple-copy microsatellites in trios, we have investigated the extension and parental origin of the rearrangements in 720 WBS and 99 7DUP patients and evaluated the presence of susceptibility factors in transmitting parents. By haplotype cloning and RT-PCR, we have characterized the junction fragments at sequence level in a subset.

Results

Deletion events were all de novo, while duplications were mostly de novo (88%) and also inherited (12%). The type and size of the rearrangement was similarly distributed in del/dup cases: 1.55Mb (86%/89%), 1.83Mb (12%/7.5%) and atypical (2%/3.5%). No differences were observed in the parental origin. Disrupted alleles were mediated by inter-chromosomal NAHR in 7q11.23 paracentric inversion carriers in 20%/30% (del/dup) of cases. Rearranged chromosomes resulted in different copy number of the NCF1 gene, and the generation of chimeric GTF2IRD2 transcripts in a subset of probands. We further defined a 1.4Kb hotspot for intrachromosomal NAHR of paternal origin within intron 19 of GTF2I and characterized two additional hotspots for reciprocal inversion-mediated events at intron 2 of GTF2IRD2.

Conclusions

Rearrangements causing WBS and 7DUP are the result of reciprocal NAHR events between SDs at 7q11.23. A few hotspots for positional preference of recombination can be identified within SDs.

9p13.3 Interstitial deletion - a new syndrome?

S. I. Ferreira¹, I. M. Carreira^{1,2,3}, M. Pinto⁴, L. Ramos⁴, J. B. Melo^{1,2,3};

¹Laboratório de Citogenética e Genómica, Faculdade de Medicina da Universidade de Coimbra, Coimbra, Portugal, ²CIMAGO – Centro de Investigação em Meio Ambiente, Genética e Oncobiologia, Coimbra, Portugal, ³CNC-IBILI, Universidade de Coimbra, Coimbra, Portugal, ⁴Medical Genetics Unit, Hospital Pediátrico, Centro Hospitalar e Universitário de Coimbra, Coimbra, Coimbra, Portugal.

The 9p deletion syndrome is a clinically characterized syndrome, presenting as a cytogenetically heterogeneous condition with variable deletion sizes. In contrast, 9p interstitial deletions have only been described in five patients. Two patients were characterized by conventional cytogenetics and have larger deletions involving bands 9p12p13, and the other three were

characterized by array-Comparative Genomic Hybridization and have only band 9p13 deleted.

We report a 12 year old male presenting with developmental delay, attention deficit hyperactivity disorder, social personality, short stature, hands tremor, bruxism and facial dysmorphisms that was studied by Agilent 180K oligonucleotide array-CGH. Array-CGH revealed a 2.8Mb de novo interstitial deletion at chromosome 9p21.1p13.3(33,100,287-35,911,318 bp)[hg19], overlapping the previously described patients.

The reported patient presents the smallest 9p13 interstitial deletion as it only includes sub-band 9p13.3, besides 100Kb from band 9p21.1, while the previous described patients have larger deletions including band 9p13. The patients share a 2.1Mb commonly deleted region that includes 65 genes, 34 described in OMIM and 11 in Morbid Map. One of those genes is NPR2, with heterozygous mutations associated with short stature without a distinct clinical phenotype, suggesting that haploinsufficiency of the gene contributes to short stature, a feature reported in the four patients characterized by array-CGH.

These patients share a particular association of clinical features such as developmental delay, attention deficit hyperactivity disorder, social personality, short stature, hands tremor, bruxism and facial dysmorphisms that suggest that 9p13.3 deletion might be a new syndrome.

P11.011

Balanced X-autosome translocation suggests association between AMMECR1 and growth, bone and heart alterations

M. Moyses-Oliveira^{1,2}, R. J. Fish³, G. Giannuzzi², V. A. Meloni¹, C. O. Gigeck¹, J. M. Cerutti¹, A. Di Battista¹, T. Liehr⁴, N. Kozyakova⁴, G. Carnevali¹, M. Neerman-Arbez³, M. I. Melaragno¹, A. Reymond²;

¹Genetics Division, Department of Morphology and Genetics, Universidade Federal de São Paulo, São Paulo, Brazil, ²Center for Integrative Genomics, University of Lausanne, Lausanne, Switzerland, ³Department of Genetic Medicine and Development, University of Geneva Medical School, Geneva, Switzerland, ⁴Institute of Human Genetics, Jena University Hospital, Friedrich Schiller University, Jena, Germany.

Female balanced X-autosome translocations are usually associated with absence of functional copies of the gene mapping at the breakpoint through disruption of the derivative-chromosome copy and inactivation of the normal X-chromosome. We report on a nine year-old girl with karyotype 46,X,t(X;9)(q23;q12)dn, disproportionate short stature (<1st centile), septal atrial defect, scoliosis, bone dysplasia, and normal cognition. Array-CGH and breakpoint sequencing confirmed the full complement of genetic material, whereas replication banding showed preferential inactivation of the normal X-chromosome. The autosomal breakpoint affects a heterochromatic region while the X-chromosomal breakpoint was mapped between the AMMECR1 and RGAG1 genes. Whereas expression of the latter was unmodified, RT-qPCR indicated absence of AMMECR1 expression in the blood and lymphoblastoid cells of the patient. The encoded AMMECR1 protein, which is evolutionary conserved in prokaryotes and eukaryotes including bacteria, archaea, yeast and mammals, localizes to the nucleus in HeLa cells, and contains nucleic acid-binding RAGNYA domains. We show that AMMECR1 is co-expressed with genes implicated in cell cycle and translation regulation; five of which were previously associated with growth and bone alteration syndromes. Our knockdown of the zebrafish orthologous gene resulted in animals with shorter tails, thin and curved bodies, dorsally-kinked tail-ends, poorly defined somites, pericardial edema and hydrocephaly phenotypes reminiscent of our patient's features. Our results suggest that AMMECR1 is potentially involved in cell cycle control and linked to a new syndrome with growth, bone and heart alterations.

First familial case of Angelman syndrome in Bulgaria

B. Karashova¹, D. Avdjieva-Tzavella², T. Todorov¹, A. Todorova^{4,5}, H. Kathom⁶, S. Tsaneva⁷, I. Litvinenko⁸, R. Tincheva¹;

¹University Pediatric hospital Sofia; ²Mediacaal university Sofia, Sofia, Bulgaria, ³University Pediatric Hospital; ⁴Mediacaal university, Sofia, Bulgaria, ⁵Genetic Medico-Diagnostic Laboratory "Genica", Sofia, Bulgaria, ⁶Genetic Medico-Diagnostic Laboratory "Genica", Sofia, Bulgaria, ⁷Department of Medical Chemistry and Biochemistry, Medical University, Sofia, Bulgaria, ⁸Department of Clinical Genetics, University Pediatric Hospital, Medical University, Sofia, Bulgaria, ⁹Genetic Medico-Diagnostic Laboratory "Genica, Sofia, Bulgaria, ¹⁰Department of Child Neurology, University Pediatric Hospital, Medical University, Sofia, Bulgaria.

Introduction: Angelman syndrome (AS) is a neurodevelopmental disorder caused by genetic defects leading to loss of expression of the maternal copy of the chromosome 15q11-13 imprinted region. Most cases are sporadic, being caused by de novo deletion of maternal chromosome 15q11-13 or by paternal uniparental disomy. Familial cases can occur, due to mutations in the UBE3A gene or in the imprinting center.

Materials and Methods: We describe two sibs with mental retardation, absence of speech, and typical facial dysmorphism. The family members were screened by MS-MLPA probemix ME028-B2 Prader-Willi/Angelman for copy number variations and assessment of methylation profile. Both children MS-MLPA profiles were compared with their parents and 3 normal controls.

Results: The test for methylation revealed missing SNRPN methylation specific fragments in the patients profile in comparison to their parents and normal controls, which is compatible with paternal non-methylated fragments and deleted or wrong methylated maternal fragments. The copy number test did not show deletion of the SNRPN specific fragments, but two other fragments, corresponding to AS-SRO region (part of the PWS-AS imprinting center) were deleted. The deletion was detected in both affected children and it was inherited from the asymptomatic mother.

Conclusion: The missing SNRPN methylation specific fragments correspond to wrong methylation (demethylation) on the maternal allele due to deletion of the PWS-AS imprinting center. This mistake in the methylation profile in both affected children affects maternal copy, while in the asymptomatic mother most probably the deletion affects the paternal copy, hence non-pathogenic.

P11.013

A de novo Ser to Thr change of a conserved phosphorylation site in aquaporin-4 was found in a man with ID, short stature, deafness and progressive spastic gait disturbance

S. Berland, G. Houge, III;

Haukeland University Hospital, Bergen, Norway.

Aquaporin-4, encoded by AQP4, is the predominant water channel in the brain with importance for the blood-brain barrier, water and electrolyte balance, and edema formation and clearance.

In an adult with mild/moderate ID, sensorineural hearing loss, ataxia, tremor and progressive spasticity, a de novo missense variant was found in AQP4 (NM_001650.4) c.332G>C, p.(Ser111Thr). Pregnancy and birth had been normal, but shortly thereafter he developed heart failure associated with a cardiomyopathy that later resolved. Neonatal EEG and CT indicated brain ischemic injury, but that also resolved. He had delayed motor and speech development but normal social skills and behavior. A recent cerebral MRI showed large ventricles and atrophic changes in the lentiform nucleus. He is short (L 8 cm < 2.5 p) with a large head (HC 60 cm) and mild facial dysmorphism. Even though no other similar cases have been found, his clinical picture is judged to be compatible with an aquaporin dysfunction.

The S111T change affects a highly conserved phosphorylation site in a short cytoplasmic loop between transmembrane domain 2 and 3 of AQP4, found necessary for channel activation but not regulation of water permeability. Possibly, the change from a serine to a threonine phosphorylation site affects phosphorylation dynamics in a way that disturbs channel fine-regulation upon e.g. local changes in osmolality. This remains to be proven.

P11.014

Clinical relevance of the BP1-BP2 microdeletion of the chromosome 15 in a patient with epilepsy and developmental delay

A. Szabó^{1,2}, M. Czako^{1,2}, K. Hadzsiev^{1,2}, A. Lócsei-Fekete^{1,2}, B. Duga^{1,2}, K. Komlósi^{1,2}, E. Póstyén^{1,2}, T. Szabó^{1,2}, B. Melegh^{1,2};

¹Department of Medical Genetics, Pécs, Hungary, ²Szentagotai Research Centre, Pécs, Hungary.

In the 15q11.2-q13 region five recurrent breakpoints (BP1 to BP5) have been observed. The most common rearrangements are the type I (BP1-BP3) and II (BP2-BP3) deletions associated with well known phenotype (Prader-Willi and Angelman syndromes). Clinical manifestations of type I and II deletions include speech and motor developmental delay, behavioral and characteristic dysmorphic features, however, BP4-BP5 microdeletions comprising CHRNA7 lead to intellectual disability accompanied by epilepsy. Furthermore, in a couple of cases with less severe symptoms, BP1-BP2 (15q11.2) deletions have been published. We investigated a boy having developmental delay, epilepsy and muscle hypotonia using Agilent Human Genome Unrestricted G3 ISCA v2 Sureprint 8x60K oligo-array. Array-CGH revealed a 0.4 Mb deletion of the 15q11.2 BP1-BP2 region which contains only four highly conserved genes, TUBGCP5, NIPA1, NIPA2 and CYFIP1. The association of the concerned genes with the phenotype of our patient and of a few known cases has been suggested earlier. Based on our results we can confirm that haploinsufficiency of the TUBGCP5, NIPA1, NIPA2 and CYFIP1 genes could lead to epilepsy, developmental delay, generalized hypotonia and dysmorphic features. Despite the small number of the affected genes, it is very difficult to set up a correct clinical diagnosis in patients with BP1-

BP2 deletions due to the non-specificity of the symptoms, which emphasize the application of the array-CGH in cases with similar phenotype. This research was supported by Hungarian Scientific Research Fund: 103983.

P11.015

Severe arterial tortuosity syndrome due to a rare SLC2A10 gene mutation

M. Kocova¹, K. Kuzevska-Maneva¹, R. Kacarska¹, V. Anastasovska¹, E. Sukarova-Angelovska¹, M. Ritelli², M. Colombi²;

¹Pediatric Clinic, Skopje, Macedonia, The Former Yugoslav Republic of, ²Department of Molecular and Translational Medicine, School of Medicine, University of Brescia, Brescia, Italy.

Arterial tortuosity syndrome (ATS) is a very rare autosomal recessive disorder mainly characterized by tortuosity and elongation of the arteries and by dyspnea, cyanosis, dysmorphic features, joint hypermobility and skeletal anomalies. Infancy and childhood are the most critical for life-threatening events, such as acute respiratory symptoms, due mostly to complications of stenosis of the pulmonary arteries. Vascular changes might cause aneurysms or artery dissections later in life. The causal gene *SLC2A10* encodes the facilitative glucose transporter 10 and nearly 100 patients and 23 mutations are known.

We report a 10-year-old Macedonian girl who was referred due to easy fatigue and visible vascular pulsations on the neck. She had recurrent dyspnea and moderate cyanosis with effort, but no heart defect was diagnosed in early childhood. She was a slender girl with joint hypermobility, narrow face, high-arched palate and crowded teeth. Enlarged, elongated, and extremely tortuous large and medium size blood vessels were detected on ultrasonography and magnetic resonance angiography. *SLC2A10* molecular analysis revealed homozygous c.254T>C(p.Leu85Pro) mutation in the patient. Her parents were unrelated heterozygous carriers. Interestingly, the same mutation was previously found in two Macedonian brothers with a severe clinical presentation. Detailed family history evaluation revealed that the present patient is a second cousin of these two brothers, with parents being first cousins. However, no consanguinity with the partners was reported.

In conclusion, we describe a patient/family with a mutation causing severe ATS. Molecular analysis is important for genetic counseling and to define targeted clinical follow-up and timely cardiovascular surgery when needed.

P11.016

A recurrent translocation t(1;12)(q43;q21.1) drawn from a systematic survey of balanced translocations in Finns

T. M. Luukkonen^{1,2}, M. Pöyhönen^{3,4}, M. M. Mehrjouy⁵, A. Palotie^{1,6}, A. Anttonen⁷, T. Varilo^{2,3};

¹Institute for Molecular Medicine Finland FIMM, Helsinki, Finland, ²Dept. of Health, National Institute for Health and Welfare, Helsinki, Finland, ³Clinical Genetics, University of Helsinki and Helsinki University Hospital, Helsinki, Finland, ⁴Dept. of Medical Genetics, University of Helsinki, Helsinki, Finland, ⁵Wilhelm Johannsen Centre for Functional Genome Research, Department of Cellular and Molecular Medicine, University of Copenhagen, Copenhagen, Denmark, ⁶Broad Institute of Harvard and MIT, Cambridge, MA, United States, ⁷Laboratory of Genetics, HUSLAB, Helsinki, Finland.

Reciprocal translocations are the most frequent human chromosomal aberrations. At least 6-9% of de novo balanced translocations are associated with abnormal clinical phenotypes. As an outcome of the Systematic Survey of Balanced Chromosomal Rearrangements in Finns, we identified two unrelated families with balanced t(1;12)(q43;q21.1).

In collaboration with the 'International Breakpoint Mapping Consortium IBMC', the breakpoint regions were narrowed down to ~1.3 kb and ~1.25 kb intervals, respectively, using mate-pair sequencing. Sanger sequencing in one family mapped the exact breakpoints to 239,567,377-239,567,379 on chromosome 1 and 73,989,462-73,989,463 on chromosome 12. Analysis of the flanking sequences revealed a breakpoint intersecting Alu element on chromosome 1, and another Alu element in close vicinity of the breakpoint on chromosome 12.

In the first family, carriers (n=6) manifest first with learning problems and later with neurological symptoms (chronic headache, balance problems, tremor, fatigue), episodic ataxia type III, and cerebral infarctions without identified predisposing factor. The carriers in the second family (n=4) demonstrate a variable phenotype including tetralogy of Fallot, transient ischaemic attack, valvular regurgitation, arrhythmia, migraine or hypertension. In both families the translocation seems to co-segregate with the abnormal phenotype. No protein coding genes are affected by the breakpoints, however, we identified *CHRM3* (cholinergic receptor, muscarinic) on chr1, and *KCNK2* (voltage gated potassium channel) and *ATXN7L3B* (ataxin 7-like 3B) on chr12 closest to the translocation breakpoints.

This study demonstrates how a recurrent translocation t(1;12)(q43;q21.1) can result in different phenotypes involving both vascular and neurological manifestations.

Case report: A novel mutation in Bardet-Biedl syndrome 8

M. Mirjalili^{1,2}, F. Harrazi¹, S. Seyedhassani¹;

¹Dr.Seyedhassani medical genetic center, Yazd, Iran, Islamic Republic of, ²Department of Biology, Faculty of Sciences, Yazd University, Yazd, Iran, Islamic Republic of.

Introduction: Bardet-Biedl syndrome (BBS) is an autosomal recessive multi-systemic human genetic disorder characterized by six major defects including obesity, mental retardation, renal anomalies, polydactyly, retinal degeneration and hypogenitalism. In several cases of BBS, few other features such as metabolic defects, cardiovascular anomalies, speech deficits, hearing loss, hypertension, hepatic defects and high incidence of diabetes mellitus have been reported. The BBS displays extensive genetic heterogeneity. To date, 19 genes have been defined as related to BBS.

In this study, we analyzed 18 BBS-related genes in a patient by NGS technique.

Materials and methods: Panel-based next generation sequencing as a reliable technique to detect mutations in 18 BBS-associated genes was used.

Results: NGS detected one novel mutation c.936delA in coding exon 11 of *TTC8* gene that related to BBS type 8. Bioinformatic analysis (CADD score:22.6) confirmed that this mutation is pathogenic in nature. This deletion creates a frame shift that leads to early termination of aminoacid coding, which is expected to affect the function of protein.

Conclusions: We found a novel mutation in *TTC8* gene that related to BBS type 8. This finding can be useful in genetic counseling and Prenatal diagnosis during next pregnancy.

P11.018

Homozygous truncating CEP19 mutation causing novel Bardet-Biedl syndrome

E. Yildiz¹, S. Mumtaz², M. Afzal², S. Malik², A. Tolun¹;

¹Bogaziçi University, Istanbul, Turkey, ²Quaid-i-Azam University, Islamabad, Pakistan.

Introduction: Bardet-Biedl syndrome (BBS) is a rare, pleiotropic ciliopathy with highly variable phenotype. Primary features are retinal dystrophy, obesity, post-axial polydactyly, urino-genital abnormalities and intellectual disabilities. We investigated a consanguineous BBS Pakistani family afflicted with a primary presentation of polydactyly and obesity and accompanying intellectual disability, diabetes and behavioral problems.

Materials and Methods: The disease locus was identified by linkage mapping using SNP genotype data of 14 family members. Whole exome sequencing for two affected subjects revealed rare/novel variants. Results: At the disease locus, an approximately 4.5-Mb region at 3q29 yielding a multipoint LOD score of 3.69, homozygous nonsense *CEP19* c.194_195insA (p.Tyr65*) mutation was identified, for which all the affected individuals plus an unaffected sibling were homozygous. Some affected members of the study family also carry the rare *CCDC28B* variant reported as a modifier of BBS phenotype.

Conclusion: *CEP19* is a novel gene for BBS, with reduced penetrance. It encodes a coiled coil domain containing ciliary protein that localizes to the primary cilia as do some other BBS proteins. The protein sequence is totally conserved between human and chimpanzee. The gene is expressed in several organs. It has been associated with obesity with azospermia in a family. Although the low frequency of the *CCDC28B* variant indicates that the presence of the variant is not circumstantial, the variant did not correlate with phenotype severity. Absence of any renal disturbance in the family can be attributed to the absence of expression of the gene in kidney.

A new case of monozygotic male twins discordant for Beckwith-Wiedemann syndrome caused by KvDMR1 hypomethylation

M. J. Sánchez-Soler¹, M. C. Martínez-Romero², V. López-González², M. J. Ballesta-Martínez¹, J. Susmozas-Sánchez³, S. E. Boonen⁴, A. B. Skytte⁴, G. Glóver², E. Guillén-Navarro⁵;

¹Medical Genetic Sección, H. Clinic University V. Arrixaca, IMIB-Arrixaca, El Palmar, Spain, ²Centro de Bioquímica y Genética Clínica, H. Clínico Universitario V. Arrixaca, IMIB-Arrixaca, El Palmar, Spain, ³Servicio de Neonatología, H. Clínico Universitario V. Arrixaca, El Palmar, Spain, ⁴Department of Clinical Genetics Aarhus University Hospital, Aarhus, Denmark, ⁵Consejería de Sanidad, Murcia, Spain.

In most cases monozygotic twins (MT) are concordant for genetic diseases,

but more than 15 cases of MT discordant for Beckwith-Wiedemann syndrome (BWS) have been described. Incidence of MT among BWS patients is higher than among general population (2.5-8% vs 0.3-0.4%), but it is unclear whether the imprinting defect may trigger the twinning process, or it is the other way around.

We report a case of male MT BWS discordant, naturally conceived without any significant family history. Mother presented gestational diabetes controlled by diet, and in 24 weeks ultrasound, severe hydrocephaly and polyhydramnios was detected in the 2nd twin. Delivery was at 26+6 weeks, and both were admitted to NICU. 1st twin (BWS) weighed 1000g (61th percentile). He developed bronchopulmonary dysplasia (BDP) and apnea as consequence of macroglossia, without other complications. He had capillary malformation on the forehead, coarse features, inguinal hernia, but neither hemihypertrophy nor psychomotor delay. Methylation study performed in blood and buccal swab showed KvDMR1 hypomethylation. 2nd twin weighed 1050g. He underwent surgery in the first month because of hydrocephaly consequence of aqueduct stenosis. He also developed BPD, and mild psychomotor limitations secondary to central nervous system infection following the operation. Methylation study was normal in both samples. This is the first case in which KvDMR1 hypomethylation discordance has been detected in blood sample, suggesting that the imprinting defect occurred after the twinning process, maybe due to an inadequate maintenance of methylation state. Specific environmental factors or ART use were not documented, so other predisposing factors should be implicated.

P11.020

Unraveling unusual presentations of classical syndromes by exome sequencing: the case of primary microcephaly

A. Verloes¹, S. Passemard², M. Schiff³, Y. VIAL², C. Dupont², M. Ouachée⁴, J. Viala⁵, E. Cuadro⁶, R. Kom⁶, S. Drunat⁶;

¹Clinical Genetic Dept, PARIS, France, ²Clinical Genetic Dept, Robert DEBRE Hospital, PARIS, France, ³Child Neurology Dept, Robert DEBRE hospital, PARIS, France, ⁴Clinical Hematology Dept, Robert DEBRE Hospital, PARIS, France, ⁵Child Gastroenterology Dept, Robert DEBRE Hospital, PARIS, France, ⁶Dept of Pediatrics, Cayenne Hospital, Cayenne (French Guiana), France.

We illustrate situations where exome sequencing allowed „salvage“ of diagnoses missed because the typical clinical picture is absent. The first case is a 10 years girl, from Guadeloupe island, with IUGR, congenital microcephaly, gastrostomy, and late onset susceptibility to infections. She had multiple CAL spots, but no skin photosensitivity. Biallelic BLM mutations were found by exome, and the diagnosis of Bloom syndrome, was confirmed by SCE study. We missed it because the facial pseudo-lupic rash was lacking, and disorality was of unusual severity. The second patient, a 4 years girl, had severe congenital microcephaly, progressive spasticity, profound ID, and no Ichthyosis. Her EEG showed a disorganized pattern, but no epileptic discharges. She never presented seizures. Her similarly affected elder brother, died at 4 months of gastroenteritis. Seizures were not reported. In both, MRI showed small brain without malformation. Conventional blood screenings (including AA chromatography) showed no abnormalities. CSF was not investigated in the absence of epilepsy. By exome, we found biallelic mutations in PHGDH, coding the first enzyme in the serine synthesis pathway. Very low serine level in CSF confirmed the diagnosis. Microcephaly, deep delay and spasticity are typical of serine synthesis defects, but the very early appearance of refractory epilepsy is considered as constant. We illustrate how „simple“ diagnosis can be missed when missing key sign misplaces diagnostic thinkings. We also illustrate the danger of restricting access to targeted diagnostic DNA panels. The generalization of diagnostic exomes will certainly lead to expand the clinical spectrum of known Mendelian entities.

P11.021

PLS3-related bone disorder in brothers with syndromic features

E. Nishi^{1,2}, T. Koshi^{1,2}, K. Masuda³, Y. Katoh³, K. Shirahige^{3,4}, K. Izumi^{1,2};

¹Division of Medical Genetics, Nagano children's hospital, Azunimo city, Japan, ²Department of Medical Genetics, Shinshu University School of Medicine, Matsumoto, Japan, ³Research Center for Epigenetic Disease, Institute for Molecular and Cellular Biosciences, The University of Tokyo, Tokyo, Japan, ⁴CREST, Japan Science and Technology Agency, Kawaguchi, Austria.

Plastin 3 (PLS3) is a protein involved in the formation of filamentous actin bundles. Recently, a total of 21 individuals from 8 families have been reported with PLS3-related familial osteoporosis/osteoporotic fractures (van Dijk et al., 2013; Fahiminiya et al., 2014; Laine et al., 2015). We report on an additional family with a novel PLS3 variant, identified through genetic screening for syndromic developmental delay.

The proband is a 12-year-old boy manifesting facial characteristics (hypertelorism, upslanted palpebral fissures, broad nasal tip, blue sclerae), mild

developmental delay, hearing impairment, inguinal/umbilical hernia, joint laxity, and recurrent fractures associated with decreased bone mineral density. His younger brother had similar manifestations. SNP array analysis detected no pathogenic copy number variations. Exome sequencing revealed a novel missense variant in PLS3 in both of the brothers, which was detected in their mother. The variant, altering highly conserved amino acid and localized at the CH2 actin binding domain 1 of PLS3 protein, was presumed to be pathogenic through disrupting the interaction between PLS3 and actin. Previously reported patients with PLS3 mutations, loss-of-function type in most, had osteoporosis with/without osteoporotic fractures, and only two were described to have non-skeletal features (epilepsy, spastic cerebral palsy). Manifestations shared by the present brothers implicate a wider phenotypic spectrum of PLS3 abnormalities, though non-skeletal features in both of them might have been caused by other genetic factors.

P11.022

A case report of 6p25p22 duplication associated with BOFs clinical features

P. Rendeiro¹, T. Lourenço², R. Lemos¹, C. Ventura¹, S. M. Pereira¹, J. Pinto-Basto¹, J. Sá¹, P. Tavares¹;

¹CGC Genetics, Porto, Portugal, ²CGC Genetics, Lisboa, Portugal.

Branchio Oculo Facial syndrome (BOFs_MIM:113620) is a rare autosomal dominant disorder caused by haploinsufficiency of the transcription factor AP-2 alpha gene (TFAP2A). TFAP2A is known to activate gene transcription crucial to embryo development, in particular, embryogenesis of the eye, ear, face, body wall, limbs and neural tube. Three major clinical indications may assist a clinical diagnostic of BOFs: branchial cleft sinus defects, ocular anomalies, and characteristic facial anomalies, such as cleft or pseudo cleft lip and palate. Nevertheless, this disorder has been characterized with variable expression between patients. The genetic makeup of individuals with BOF syndrome always compromises TFAP2A function and normally is presented in the form of a microdeletion, a complex deletion/de novo insertion or point mutation(s) within TFAP2A. We report a 2yo boy with classic clinical features of BOF syndrome and an interstitial duplication on 6p25.2p22.3. To the best of our knowledge, so far no patient with BOF syndrome has been reported to carry a duplication on 6p25.2p22.3.

Array CGH was performed on an Affymetrix platform, Cytoscan 750K. Data analysis was performed on ChAS Software, Affymetrix (reference NCBI_hg19). Karyotype was performed on peripheral blood following standard protocols.

Patient's examination demonstrated clinical manifestations typical of BOF syndrome, including branchial, ocular and facial anomalies, such as right cervical branchial cyst, blepharophimosis and dysmorphic features. Array CGH revealed a 13.9Mb duplication at 6p25.2p22.3 (Chr6:4,066,234-18,025,300), resulting in a complete duplication of TFAP2A and 75 other genes. Karyotype analysis allowed definition of the type of structural rearrangement present in the patient [46,XY,dup(6)(p25.2p22.3)].

P11.023

Cat eye syndrome often without cat eye?

G. Cardoso¹, R. Costache², L. Oprea¹, O. Mantescu¹, M. Malageanu¹, S. Grigore¹, D. Craiu³, V. Radoi^{1,2};

¹Syneo Central Laboratory, Bucharest, Romania, ²Genetics Division, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania, ³Pediatrics Neurology Division, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania.

Cat eye syndrome is a rare condition involving a partial trisomy or tetrasomy of part of chromosome 22, clinically characterized by highly variable congenital malformations. The syndrome name is derived from a particular appearance of the vertical colobomas (“cat eye”) in the eyes of several patients. We present here a case of a patient diagnosed with cat eye syndrome, without “cat eye”.

A two-year-girl was ascertained through non-specific developmental delay, hypotonia, major anomalies (including anal atresia, spontaneously resolving ASD, possible Pierre Robin sequence characterized by

microretrognathia and bifid uvula), plus minor craniofacial dysmorphism - including pre-auricular tags. It inspired an interesting and captivating differential diagnosis to the genetics team, considering disorders not limited to: a possible cat eye syndrome, duplication 22q11.2 syndrome, Emmanuël syndrome, or rather a variant of unbalanced translocation involving a chromosome 22 and another cytogenetic partner.

Classical cytogenetics analysis revealed an acrocentric derived supernumerary marker chromosome (GTG banding), satellited at one end (Ag NOR banding), and made up of a lot - but not exclusively - heterochro-

matic material (CBG banding). Spectral karyotyping identified its origin in chromosome 22 and chromosomal microarray showed a 3 MB partial tetrasomy 22q11.1-22q11.21 encompassing the cat eye critical region. The above mentioned chromosomal conditions originating in 22q abnormalities have an overlapping spectrum and sometimes they are a difficult call for the geneticist; further cytogenetic investigations are protean in such cases. Cat eye syndrome without cat eye (coloboma) may be more frequent than we have thought.

P11.024

CDC42 as a new human disease gene associated with thrombocytopenia and intellectual disability

K. Kosaki¹, T. Takenouchi¹, T. Uehara¹, S. Ida², R. Kosaki³, N. Okamoto⁴;
¹Center for Medical Genetics, Keio University School of Medicine, Tokyo, Japan, ²Department of Gastroenterology and Endocrinology, Osaka Medical Center and Research Institute for Maternal and Child Health, Osaka, Japan, ³Division of Medical Genetics, National Center for Child Health and Development, Tokyo, Japan, ⁴Department of Medical Genetics, Osaka Medical Center and Research Institute for Maternal and Child Health, Osaka, Japan.

CDC42 encodes critical regulator for the cell cycle and actin cytoskeleton formation. More than 5000 articles have been published concerning Cdc42 in various organisms. The conditional homozygous knockout of Cdc42 in mice results in macro-thrombocytopenia and structural abnormality in the central nervous system. However, no human disorder associated with CDC42 mutations has been described until our identification of two patients with de novo CDC42 (p.Tyr64Cys) mutation [MIM 616737: Takenouchi-Kosaki syndrome]. The two patients shared macro-thrombocytopenia, developmental delay, lymphedema of the lower extremities, and contracture of the fingers as common features. Characteristic facial features included arched eyebrows, mild ptosis, eversion of the lateral portion of the lower eyelid, exotropia, midfacial hypoplasia, short philtrum, thin upper lip, and malocclusion. The present observation of the two unrelated patients with a strikingly similar phenotype and the same CDC42 mutation establishes that CDC42 is a new human disease gene and that a mutation in CDC42 causes a recognizable syndromic form of thrombocytopenia. Differential diagnosis of isolated thrombocytopenia and intellectual disability include Jacobsen syndrome (11q23 deletion), Braddock-Carey syndrome (21q22), and Takenouchi-Kosaki syndrome. Takenouchi-Kosaki syndrome caused by CDC42 mutation is clinically recognizable in that the size of the platelets is large and lymphedema is a unique feature. Lymphedema could be ascribed to the CDC42 mutation, since Cdc42 directly interacts with Rac1, the defect of which leads to lymphedema in mice.

P11.025

Molecular characterization of the first Spanish case of Hypotrichosis with juvenile macular dystrophy (HJMD)

F. Blanco-Kelly, L. Rodriguez da Silva-Jacy, I. Sanchez-Navarro, R. Riveiro-Alvarez, M. Lopez Martinez, M. Corton, C. Ayuso;
 Servicio de Genética, ISS-Fundación Jiménez Díaz, Madrid, Spain.

Introduction: The CDH3 gene on 16q2 is responsible for two ultrarare autosomal recessive disorders characterized by hypotrichosis and progressive macular dystrophy: Hypotrichosis with Juvenile Macular Dystrophy (HJMD) and Ectodermal Dysplasia, Ectrodactyly and Macular Dystrophy (EEM). **Patients and methods:** A Spanish male born in 1998 from non-consanguineous healthy parents sent to the Genetic Department from University Hospital Fundación Jiménez Díaz, with a suspected diagnosis of decalvating spinulosis follicular keratosis (probable Siemens Syndrome) and inverse retinitis pigmentosa. Neither limb nor dental abnormalities were observed. Sanger sequencing of coding exons of ABCA4 and CDH3 were performed. In addition, MLPA analysis using a commercial kit was used to study ABCA4 exonic deletions or duplications. **Results:** First, differential diagnosis of isolated juvenile macular dystrophy was performed. Only a heterozygous missense p.Val2050Leu variant in ABCA4 was found after a comprehensive analysis of coding regions and gene rearrangements. A second allele was not found. Further CDH3 sequencing allowed to detect compound heterozygous variants: a novel maternal missense change p.Val205Met, predicted as probably pathogenic by in silico analysis and a previously reported paternal frameshift c.830del p.Gly277Alafs*20. Clinical revision allowed reclassified this patient as HJMD. **Conclusions:** This is the first report of a Spanish patient with HJMD and the first report of a patient carrying mutations in the CDH3 gene in Spain. A new mutation has been described in CDH3. This work reflects the importance of both the joint assessment of clinical signs and the evaluation of the pedigree for a correct genetic study approach and diagnostic.

P11.026

The face of the developmental disorders of chromatin remodeling

S. Douzjou^{1,2}, S. Banka^{2,1};
¹Manchester Centre for Genomic Medicine, Central Manchester University Hospitals NHS Foundation Trust, Manchester Academic Health Science Centre, Manchester, United Kingdom, ²Institute of Human Development, University of Manchester, Manchester, United Kingdom.

Developments in technology led to increased understanding of the genetic basis of the Chromatin Disorders, a group of developmental disorders caused by disruption of chromatin remodelling (DDCRs). We used Facial Dysmorphology Analysis technology (FDNA®) to objectively evaluate the craniofacial dysmorphic features of DDCRs. We propose that a condition should be recognizable by gestalt if it fulfills the following criteria: (i) the 'syndromic face' is significantly different from the average, general population face (denoted as 'severity'); (ii) the syndromic face is significantly different from typical faces of other syndromes (denoted as 'distinctiveness'); (iii) the variability between faces of patients with the same syndromic diagnosis is minimal.

As variability is difficult to assess without knowing the full spectrum of the conditions, we focused our analysis on the severity and distinctiveness of DDCRs by using published, 2D facial photographs of patients with 20 distinct, molecularly confirmed DDCRs to create a common 'facial photo crop' for DDCRs. This was proven to be distinct to the 'average, normal face'. To evaluate the severity and distinctiveness of the DDCR faces, we compared each of the 20 syndromes' facial photo crops (n=5) to 1) other syndromes in the DDCR group (19 syndromes); 2) other dysmorphic syndromes not in the DDCR group (100 other syndromes); 3) normal (1000 photographs). Methods included the mean area under the curve (AUC) to compare between samples and ROC curve plotting the true positive rate as function of false positive rates. We report the results of this analysis and discuss its implications.

Background: Most approaches are insensitive to the full mutational spectrum of chromosome rearrangements associated with human developmental abnormalities. Therefore, our aim is to introduce next-generation sequencing (NGS) into clinical cytogenetics, creating a sequence-based Next-Gen Cytogenetics to catalyze a dramatic advancement in clinical diagnostics. **Methods:** Twenty families with chromosome rearrangement-associated diseases, including two prenatal (PN) cases, have been enrolled. Fourteen of these were also analyzed by NGS using large-insert paired-end libraries. **Results:** The majority of these cases were confirmed to be balanced reciprocal rearrangements, whereas 4 were complex chromosomal rearrangements including 1 of chromothripsis. Thus far, over 50 breakpoints were identified disrupting protein coding genes, lncRNAs, or intergenic regions, thus revealing candidate genes or genomic loci. These cases are further assessed for pathogenicity from positional effects on genes located within topological domains (TADs) containing the breakpoints using DECIPHER predictions of haploinsufficiency. In one PN case, the 16q24 breakpoint disrupts ANKRD11, etiologic in the autosomal dominant KBG syndrome (OMIM #148050), predicting an abnormal phenotype. The chromothripsis case, submitted as 46,XY,t(7;14)(q22;q32.1),inv(15)(q21.2q26.1), proved by NGS to carry two further deletions, at 3p12 (5.3 Mb) and 15q14 (488 kb), as well as an insertion of 644.4 kb from 15q14 into 3p14. The inv(15) is in fact a complex rearrangement of 15q with eight breakpoints. **Conclusions:** We demonstrate that NGS-based chromosomal rearrangement characterization leads to major improvements in identification of chromosomal aberrations and in prediction of clinical outcomes of postnatally and prenatally detected genomic rearrangements, and to contributions to human genome annotation.

CLAPO Syndrome: An update on phenotype and molecular approaches

R. Martín Arenas¹, V. Martínez-Glez², P. Lapunzina², E. Vallespín², V. Fernández-Montaño², Á. Del Pozo², J. Silla-Castro², K. Ibanez², J. López-Gutierrez², L. Rodríguez-Laguna²;

¹INGEMM-IdiPAZ, Madrid, Spain, ²INGEMM-IdiPAZ-CIBERER, Madrid, Spain, ³Hospital Universitario La Paz, Madrid, Spain.

Introduction: CLAPO syndrome (OMIM:613089) is a vascular/overgrowth disorder characterized by Capillary malformation (CM) of the lower lip, Lymphatic malformation (LM) of the face and neck, Asymmetry, and Partial Overgrowth. Six cases have been reported so far. Inheritance pattern is still unknown, but somatic mosaicism is suspected.

Methods and Results: We performed a retrospectively review of CLAPO patients diagnosed in our hospital (10 cases) between 2008 and 2015, the largest cohort to date. The hallmark clinical feature is the CM of the lower lip, expressed congenitally in all patients; all other features can be present at birth or develop at a later stage in life. Eight patients showed LMs involving oral mucosa and neck. LM seems to be more frequent in the oral cavity, specifically in tongue, and it is commonly complicated with severe haemorrhagic events. Five patients showed asymmetric overgrowth at birth, and only one presented generalized overgrowth. As a preliminary molecular approach we performed NGS experiments (100x) in paired blood/tissue samples, using a custom panel covering about 300 vascular/overgrowth related genes, including *PIK3CA*, *PTEN*, etc. No germinal/somatic mutations were detected. **Conclusion:** Here, we present an expansion of the phenotype of CLAPO syndrome, in which we more clearly define some of the originally described clinical manifestations. We have also discarded, at medium reading depths, the presence of somatic mosaic mutations in genes known to cause clinically related syndromes. Our future approach includes increasing reading depth in candidate genes, for better detection of low mosaics, and to perform whole exome NGS.

Buenos Aires, Argentina, ⁴Departments of Oral Biology and Pediatric Dentistry and Center for Craniofacial and Dental Genetics, School of Dental Medicine, University of Pittsburgh, Pittsburgh, PA, United States, ⁵Medical and Molecular Genetics Institute (INGEMM), IdiPAZ, La Paz Hospital and CIBER of Rare diseases (CIBERER), Madrid, Spain.

Background: A high prevalence of cleft lip with or without palate (CL±P) was detected in Patagonia (Argentina) and Amerindian ancestry appointed as a risk factor. In this presumably more homogenous population, we searched for de novo copy number variation (CNV) in CL±P subjects.

Method: 30 families with isolated CL±P (31 affected and 113 total individuals) were genotyped on the Affymetrix Genome-Wide SNP 6.0 array. CNVs identification was performed on Genotyping Console and CHAS (Affymetrix). From all identified CNVs from affected subjects, we filtered out those with lesser chances of pathogenicity according to the following criteria, considering a minimum of 60% overlap: (1) mean-maker-distance higher than 5kbp; (2) CNVs also present in healthy relatives; (3) common CNV from DGV and (4) within 1mbp from telomeres and centromeres.

Results: We detected 28 de novo CNVs larger than 200kbp, 6 of which overlapped genes previously associated with CL±P. Five were deletions (no homogenous loss) and 23 duplications. Five segments were detected in 3 subjects and 7 were detected in 2 subjects, indicating recurring de novo duplications in unrelated individuals.

Conclusion: Results corroborates the role of the following genes to the aetiology of CL±P: *GLI2*, *PKP1*, *MXK*, *PVRL1*, *CDH1* and *TYMS*. 22 genomic segments not previously associated with CL±P were also identified, contributing to a more general framework of the CNV role in CL±P, evidencing the complex aetiology of the condition and the need for biological evidence of all CNVs appointed here and in the literature.

Non-syndromic cleft lip with or without cleft palate (nsCL/P) is one of the most common congenital malformations and has a multifactorial etiology. To date, a number of common risk variants have been identified for nsCL/P, explaining about 24% of the genetic heritability. It has been suggested that some of the remaining genetic liability might be explained by rare de novo mutations, which is supported by the frequent observation of sporadic nsCL/P cases and a higher nsCL/P recurrence risk in offspring compared to parents.

We performed whole exome sequencing (WES) in 50 sporadic nsCL/P cases of Central European ancestry and their unaffected parents. Exome capture was performed using SureSelect^{XT} Human All Exon V5 and libraries were sequenced using 1x125bp paired-end sequencing. Raw data were processed using the default BWA/GATK v.3.4 pipeline including VQSR and the genotype refinement workflow. Annotation of the possible de novo events was done using ANNOVAR.

We identified 158 high-confidence de novo variants of which 59 were either missense or nonsense variants which did not map to regions of segmental duplications. Validations were performed on all variants with a quality-by-depth ≥ 4, excluding variants with bad WES reads in the region of interest. So far, we confirmed all 27 residual variants, including their de novo status.

Our preliminary results show the presence of de novo mutations in nsCL/P patients. We are currently performing further confirmation and follow-up studies investigating the causality of the true de novo variants. These results will be presented at the conference.

Our preliminary results show the presence of de novo mutations in nsCL/P patients. We are currently performing further confirmation and follow-up studies investigating the causality of the true de novo variants. These results will be presented at the conference.

¹Institute of Human Genetics, University of Bonn, Bonn, Germany, ²Department of Genomics, Life & Brain Center, University of Bonn, Bonn, Germany, ³Department of Orthodontics, University of Bonn, Bonn, Germany, ⁴Department of Neonatology and Pediatric Intensive Care, Children's Hospital, University of Bonn, Bonn, Germany, ⁵Medical Genetics and Mitochondrial Research Group, Latvian Biomedical Research and study Centre, Riga, Latvia, ⁶Institute of Child Health; University College London, London, United Kingdom, ⁷Institute of Human Genetics, Ulm University, Ulm, Germany, ⁸Orthodontic Department, College of Dentistry, Thamar University, Thamar, Yemen, ⁹Institute of Medical Biometry, Informatics and Epidemiology, University of Bonn, Bonn, Germany.

The most frequent subtypes of orofacial clefts are nonsyndromic cleft lip with or without cleft palate (nsCL/P) and nonsyndromic cleft palate only (nsCPO), both considered multifactorial. A common syndromic form of clefting is Van der Woude syndrome (VWS) where patients have CL/P or CPO, often but not always associated with lower lip pits. Recently, ~5% of VWS patients were identified with mutations in the grainy head-like 3 (GRHL3) gene. To investigate GRHL3 in nonsyndromic clefting, we evaluated 672 European patients with apparently nonsyndromic clefts (576 nsCL/P, 96 nsCPO) sequencing the GRHL3 coding region. We identified four novel truncating GRHL3 mutations in nine patients from four families, two of them de novo. All individuals harboring mutations had exclusively nsCPO. Most interestingly, in nsCPO patients we identified a higher minor allele frequency for rs41268753 (0.099), compared to controls (0.049; P=1.24x10⁻²). This association was replicated in nsCPO/control cohorts from Latvia, Yemen and the UK (Pcombined 2.63x10⁻⁵; ORallelic 2.5 (95% CI 1.6-3.7)), and reached genome-wide significance in combination with imputed data from a GWAS in nsCPO triads (P=2.73x10⁻⁹). Notably, this variant is not associated with nsCL/P (P=0.45). Rs41268753 encodes the highly conserved p.Thr454Met (GERP = 5.2) which numerous in silico prediction programs denote as dele-

terious, has a CADD score of 29.6 and increases protein binding capacity in silico. Thus, our targeted sequencing approach has identified the first common genetic risk factor for nsCPO, and the first gene with rare mutations and a common risk variant for nsCPO in the coding region.

Copy Number Variations (CNVs) in patients with multiple malformations and intellectual disability

R. Staneva¹, S. Hadjidekova¹, M. Pancheva¹, D. Avdjieva-Tzavella², B. Rukova¹, Z. Hammoudeh¹, O. Antonova¹, V. Damyanova¹, M. Mihaylova¹, R. Tincheva², D. Toncheva¹;
¹Department of Medical Genetics, Medical University of Sofia, Sofia, Bulgaria,
²Department of Clinical genetics - University Pediatric Hospital, Medical University of Sofia, Sofia, Bulgaria.

Introduction: In recent years array CGH analysis seems to have been established as an invaluable tool for diagnostics in the field of dysmorphology and intellectual disability. The data gathered the last decade allowed to further refine the interpretation of results and helped to discriminate pathogenic from normal variants.

Materials and Methods: 81 patients with multiple malformations, intellectual disability and normal karyotype were included in the study. Peripheral blood sample was collected from every participant after signed written informed consent. Array CGH analysis was performed on Agilent ISCA 4x44k v2.0 oligo-arrays by manufacturer's protocol. Arrays were scanned on Agilent G2505A scanner. Data was analyzed by Bluefuse Multi software v4.2. Variants were further classified based on size, frequency, type, gene content and function into four groups - benign, probably benign, VUS and pathogenic.

Results: 281 CNVs were identified. Average number of CNVs per patient is 3,5. Pathogenic CNVs (n=13) were found in 13,6% (n=11) of our patients. Among pathogenic CNVs deletions were 69,2% (n=9), while duplication represented 30,8% (n=4). Pathogenic CNVs sized greater than 1mb represent 76,9% (n=10). 30,8% (n=4) of pathogenic variations were considered irrelevant to the phenotype. Benign CNVs (n=118) and probably benign CNVs (n=110) were respectively identified in 69,1% (n=56) and in 72,8% (n=59) of the patients in our cohort. VUS (n=39) were identified in 35,8% (n=29) of patients.

Conclusion: Our study enriched the available data on the copy number variations in Bulgarian population and helped to reclassify some of the VUS as probably benign.

P11.033
Severe Cockayne syndrome or COFS? (Or both?)

J. Behunova, F. Laccone;
 Institute of Medical Genetics, Medical University of Vienna, Vienna, Austria.

Background/Aim: The authors report on a case of severe form of Cockayne syndrome (CS) with a mutation in ERCC6-gene, that had been described before by COFS (cerebro-oculo-facio-skeletal) syndrome, and discuss a delineation between these two entities.

CaseReport: A boy was born in term with a low-normal birth size (2500/48/32) and without cataract or arthrogyriposis. Postnatally proceeded severe feeding difficulties (PEG), severe growth retardation (-5,5 SD) and microcephaly (-6,6 SD). In his age of 3,5 y he could not sit and stand alone and showed no speech. His face was not typical „old-looking“, but showed some dysmorphism and extreme dental caries. The trunk was hypotonic, extremities hypertonic, with mild contractures of elbows and knees. Other findings presented cryptorchism, general brain atrophy (MRI), no photosensitivity and no retinopathy. DNA: Homozygote mutation in the ERCC6-gene (c.2047C>T, p.Arg683*)

Discussion: A patient with the same mutation published as a COFS syndrome showed low-normal birth size, congenital arthrogyriposis and cataracts with sunken eyes, postnatally severe feeding difficulties, seizures, severe developmental and growth delay with microcephaly (-5 SD) and notable photosensitivity. On the other hand, a few patients with other mutations in ERCC6-gene had been referred as severe CS or CS/COFS, because their congenital symptoms (IUGR, microcephaly, cataract, arthrogyriposis) and absent neurological development fulfilled also the definition of COFS.

Conclusion: Severe Cockayne syndrome and COFS share highly overlapping features and the same molecular-biochemical characteristics, thus it might be helpful to overcome the historical separation and to recognize them as one entity.

P11.034
Further evidence of the c.314G>A (p.Arg105Gln) mutation in the SMARCE1 gene as a rare cause of Coffin-Siris syndrome

M. Sánchez Soler¹, I. Valenzuela², L. Fernández², E. Vallespín³, T. Vendrell², M. Ballesta-Martínez¹, V. López-González¹, V. Fernández-Montaño³, F. Nieto³, K. Ibañez⁴, J. Silla-Castro⁴, A. del Pozo⁴, F. Santos-Simarro⁵;

¹Sección de Genética Médica, Servicio de Pediatría, Hospital Clínico Universitario Virgen de la Arrixaca, Murcia, Spain, ²Genética Clínica, Área de Genética Clínica i Molecular, Hospital Universitari Vall d'Hebron, Barcelona, Spain, ³Genómica Estructural y Funcional, INGEMM, Hospital Universitario La Paz, Madrid, Spain, ⁴Bioinformatics section, INGEMM, Hospital Universitario La Paz, Madrid, Spain, ⁵Genética Clínica, INGEMM, Hospital Universitario La Paz, Madrid, Spain.

Introduction: Mutations in several components of the BAF complex have been identified in Coffin-Siris syndrome (CSS), a rare congenital malformation syndrome characterized by developmental delay, coarse facial features and hair and digital abnormalities. Most patients harbour mutations in *ARID1B* gene (60-70%) but at least mutations in another 5 genes of the complex have been detected. To date, *SMARCE1* mutations account for only 2% of the cases, with just two variants reported: c.218A>G (p.Tyr73Ser) in two patients and c.314G>A (p.Arg105Gln) in one patient and his affected mother (the latter of uncertain pathogenicity).

Material and methods: A cohort of 18 unrelated patients with features suggestive of CSS has been screened using a custom next generation sequencing panel (BAF_v1.1 Roche NimbleGen) including the genes of the BAF complex as well as other interacting genes.

Results: We present two additional patients in whom the variant p.Arg105Gln in *SMARCE1* has been detected, confirmed to be *de novo* in one case, while results of parental testing in the second will be presented in due course. Clinical details of the patients as well as comparison to previously reported patients will be presented.

Conclusions: Despite lack of functional studies, our results support the pathogenicity of this variant and provide further insight into the clinical manifestations of these patients. The p.Arg105Gln mutation in *SMARCE1* seems to be a rare recurrent mutation responsible of CSS and should be included in the molecular screening of these patients.

Clinical features and mutation spectrum of Coffin-Siris syndrome in Malaysia: A case series

W. P. Ong¹, M. A. M. Haniffa¹, G. S. Ch'ng¹, Y. Tsurusaki², N. Miyake², N. Matsumoto², W. T. Keng¹;

¹Department of Genetics, Hospital Kuala Lumpur, Kuala Lumpur, Malaysia, ²Department of Human Genetics, Yokohama City University Graduate School of Medicine, Yokohama, Japan.

Introduction: Coffin-Siris syndrome (CSS) is a rare disorder characterised by intellectual disability, distinctive facies, hypoplastic/aplastic 5th fingernails and/or toenails and growth retardation. Pathogenic variants in *ARID1A*, *ARID1B*, *SMARCA4*, *SMARCB1*, *SMARCE1* of the SWI/SNF complex are known to cause CSS.

Method: Between January 2013 and July 2015, 17 patients with clinical diagnosis of CSS underwent whole exome sequencing (WES) in search of the SWI/SNF complex genes.

Results: We report 12 individuals (5 males, 7 females) with molecular confirmation. All had developmental delay, dysmorphism with coarse facies, thick lower lips, hirsutism and hypoplastic nails. Five patients had microcephaly; 8 had failure to thrive; 9 had short stature; 2 had secundum ASD. Cases with non-typical features would also be highlighted. WES identified heterozygous mutations in *ARID1B* in 10 probands, and in *SMARCB1* in 1 patient. Interestingly, a boy with features more in-keeping with CSS had a mutation in *SMARCA2*, the gene associated with Nicolaides-Baraitser syndrome, highlighting the many similarities of these two syndromes. All were novel mutations. Seven were *de novo*, one child was adopted, four others have yet to be determined. The *ARID1B* mutations included 4 frameshift insertions, 3 frameshift deletions, 2 nonsense mutations and 1 splice site mutation. The *SMARCB1* and *SMARCA2* mutations were missense mutations. The child with *SMARCB1* seemed the worst affected with severe growth retardation and cognitive impairment.

Conclusions: Mutations in *ARID1B* are the predominant cause for CSS in Malaysia. Due to overlapping phenotypes with Nicolaides-Baraitser syndrome and chromosomal abnormalities, molecular confirmation directs accurate genetic counselling and expands the phenotypic spectrum.

P11.037

Additional Clinical Findings in two sisters with LAMM syndrome

M. Basdemirci¹, A. G. Zamani¹, S. Sener², M. Tassoker², H. Cetmil², A. Zamani², M. S. Yildirim³;

¹Department of Genetics, Meram Medical Faculty, Necmettin Erbakan University, KONYA, Turkey, ²Department of Radiology, Faculty of Dentistry, Necmettin Erbakan University, KONYA, Turkey, ³Department of Chest Disease, Meram Medical Faculty, Necmettin Erbakan University, KONYA, Turkey.

Microtia and Microdontia (LAMM) syndrome is a rare condition, although its prevalence is unknown. Approximately a dozen affected families have been identified. It is characterized by bilateral sensorineural congenital deafness with labyrinthine aplasia, microtia and microdontia. Minor dysmorphic signs such as long face, micrognathia, anteverted ears and skin tags on the upper part of the auricle can be observed in the patients. It is an autosomal recessive condition and associated with homozygous or compound heterozygous mutations in the FGF3 gene.

A 29-year-old woman was admitted with microdontia, oligodontia and sensorineural hearing loss signs to the genetics department. Bilateral microtia with skin tag on the upper part of the left auricle as well as anteverted ears were observed in physical examination. Keratoconus was observed in ophthalmologic examination MRI of her inner ear showed bilateral complete labyrinthine aplasia. A CT of the chest revealed a dilated azygos vein. Her sister also had the same symptoms. Parents were first degree cousins. Pedigree analysis showed autosomal recessive trait. Both the patient and her sister were diagnosed with LAMM syndrome.

In this report, we describe two sisters with autosomal recessive LAMM syndrome characterized by three major findings: complete labyrinthine aplasia, microtia and microdontia. Additional clinical findings, dental abnormalities, follow-up, management and mutation types of FGF3 gene will be discussed in detail.

P11.038

Identification of Congenital Diaphragmatic Hernia genes by Whole Exome Sequencing

M. Kammoun¹, P. Brady¹, H. Van Esch¹, J. Deprest², K. Devriendt¹, J. R. Vermeesch¹;

¹Department of Human Genetics KU Leuven, Leuven, Belgium, ²Department of Obstetrics and Gynecology, University Hospitals Leuven, Leuven, Belgium.

The genetics of Congenital Diaphragmatic Hernia (CDH) is poorly understood. We hypothesize that Whole Exome Sequencing (WES) application will advance our understanding of genes involved in CDH pathogenesis.

We performed WES on 13 patients from 9 different families. Dominant and recessive models were taken into account for variants calling in all cases. We identified pathogenic variants in known CDH causal genes: ZFPM2, KMT2D and PORCN. In addition, we observed probably pathogenic variants in 3 genes thus far not yet known to cause CDH, including PIGN in a fetus with complex bilateral CDH.

Similarly to the previous reports, ZFPM2 mutations are the most incriminated in CDH and are also observed with a reduced penetrance and a variable expressivity in our families. This gene is a GATA4 activity modulator and is subsequently important for diaphragm and heart development. PORCN gene lesions cause of X-linked Focal Dermal Hypoplasia that was previously considered to be embryonic lethal in male. Interestingly, we are the first to report PORCN variant in non-mosaic males. Defective PORCN, leads to an impairment of WNT trafficking through the cell which affects the downstream genes dependent on this pathway. PIGN is involved in Glycosylphosphatidylinositol anchor biosynthesis. Prior to our report, PIGN mutations were described in association with multiple malformations but seldom with CDH which we suggest to result from a more severe loss of function. As for the new candidate genes, they are known to cause X-linked Intellectual disability and the confirmation of their implication in diaphragm development is ongoing.

P11.039

Cytogenetic study in children with congenital heart defects and multiple congenital anomalies: ten years of experience

A. Boglis¹, F. Tripoti¹, C. Banescu^{1,2};

¹University of Medicine and Pharmacy of Tirgu Mures, Tirgu Mures, Romania, ²Genetic Department of Emergency Clinical County Hospital Tirgu Mures, Tirgu Mures, Romania.

Introduction: Chromosomal abnormalities often are detected among children with congenital heart defects (CHDs) when associate multiple congenital anomalies (MCA), with an estimated prevalence of 6-13 cases of CHDs per 1000 live births. The aim of this study was to determine the presence of chromosomal abnormalities detected by conventional cytogenetic analysis among children with CHDs and MCA.

Material and Methods: We report a retrospective study of 160 children with CHDs and MCA who were referred to the Genetic Department of Emergency Clinical County Hospital Tirgu Mures, Romania, between 2006 and 2015. All patients were clinically evaluated for the presence of dysmorphic features and congenital anomalies. Karyotype analysis was performed in all patients from fresh peripheral blood.

Results: Among the 160 children identified with CHDs, 55.6% females, with age ranging from 1 day to 15 years, 65 had a normal karyotype. Chromosomal abnormalities were observed in 95 patients (59.4%), 84 (88.4%) were numerical (70 patients with +21, 5 with +13, 3 with +18, 2 with 45,X, 1 with 47,YYY, and 3 polysomy X) and 11 (11.6%) structural [2 with der(21;22) and der(15;21), 3 with del(5p), del(13q), del(X)(q11), 2 with i(18q), i(18p), inv(9), r(4)]. The most frequent type of CHD associated with chromosomal abnormality were ventricular and secundum atrial septal defects.

Conclusions: Our findings showed that conventional cytogenetic analysis is still useful in understanding the etiology of CHDs and multiple congenital anomalies. Furthermore, molecular cytogenetic techniques is needed for an accurate diagnosis, when karyotype is normal.

P11.040

Array CGH studies in postnatal diagnosis of 45 cases with multiple congenital malformations including gastrointestinal tract defects

E. Obersztyń¹, A. Kutkowska-Każmierczak¹, B. Wisniewiecka-Kowalnik¹, M. Bartnik¹, M. Smyk¹, M. Kędzior¹, J. Castaneda¹, N. Beznikow¹, P. Wlasienko¹, R. Śmigieł², K. Żak¹, E. Sawicka¹, B. Nowakowska¹;

¹National Institute of Mother and Child, Warsaw, Poland, ²Medical University Wrocław, Wrocław, Poland.

Introduction: Gastrointestinal tract malformations represent 5 -10% of congenital defects among newborns. Esophageal atresia (EA), tracheoesophageal fistula (TEF) and anal atresia are the most common, comprising 89% of cases. Chromosomal aberrations have been reported in 6 -10% patients with GI defects whereas the etiology of most cases remains unknown. Array CGH is currently offered as a rapid method for identification of genomic changes with potential role in the etiology of birth defects. Our study's aim was to evaluate the prevalence of pathogenic chromosomal aberrations in neonates with multiple congenital anomalies (preferentially gastrointestinal tract malformations) with or without dysmorphic features.

Patients and methods: 45 patients were qualified for aCGH studies according to clinical inclusion criteria in the years 2013-2015. The investigation was carried out using the oligoarray set (CytoSure ISCA 60k v2 OGT, UK). Parental origin studies using FISH / aCGH were also performed.

Results: We present a summary of our results including detailed clinical data, type, localization and size of aberrant changes as well as their parental origin. Copy number changes were identified in 8/45 (18%) patients. There were 4 deletions (10q22.3q23.1mat; 6q22.3q23.3mat; 15q11.2mat; 17q11.2mat), 3 duplications (10p15.3p11.21(de novo); 2p23.1 (?); 15q24mat) and one case of supernumerary der(22), as a result of maternally inherited translocation (11;22). To our knowledge, anorectal atresia has not been previously reported in 10q22.3 deletion syndrome. Genotype-phenotype considerations are presented.

Conclusion: Our results confirm the utility of aCGH as a first - tier test in multiple congenital malformations.

Supported by Polish Ministry of Science and High Education: 3942/E-215/S/2015

A missense mutation in the NIPBL gene isoform A cause a mild and atypical familiar case of Cornelia de Lange Syndrome

B. Puisac^{1,2}, L. Ström³, C. Baquero-Montoya^{4,1}, T. Visnes⁵, M. Gil-Rodríguez¹, M. Hernández-Marcos^{1,2}, E. Teresa-Rodrigo^{1,2}, P. Gómez-Puertas⁵, Q. Pan-Hammarström³, I. Bueno^{6,2}, F. J. Ramos^{1,6,2}, J. Pié^{1,2};

¹University of Zaragoza, Zaragoza, Spain, ²CIBERER, Zaragoza, Spain, ³Karolinska Institute, Stockholm, Sweden, ⁴Hospital Pablo Tobón Uribe, Medellín, Colombia, ⁵Center of Molecular Biology „Severo Ochoa”, Madrid, Spain, ⁶University Hospital „Lozano Blesa”, Zaragoza, Spain.

Cornelia de Lange syndrome (CdLS) is a congenital developmental disorder characterized by facial dysmorphism, growth retardation, limb malformations and intellectual disability. Approximately 60% of patients have pathological variants in the NIPBL gene and many show the CdLS classical phenotype. We report on two brothers with atypical mild CdLS phenotype who have a missense mutation in NIPBL [c.8387A>G; p.(Tyr2796Cys)]. Both patients have brachycephaly, synophrys, long lashes, mild intellectual disability and an unusual broad bulbous nose. Interestingly, this last feature is described in CdLS patients with mutations in the HDAC8 gene. The mutation identified in our patients is located at the last exon (E47) of the NIPBL gene and it

only affects to its isoform A. In order to better understand the genotype-phenotype correlation, we performed “in vitro” studies with the brothers’ fibroblasts that revealed a sensitivity to radiation similar than controls and much lower than other CdLS patients with mutations in NIPBL. Moreover, pyrosequencing studies of different tissues of both cases ruled out the presence of somatic mosaicism. Overall, these results suggest that the position of the variant at the end of the NIPBL gene, that alters only the isoform A of the protein, is likely the cause of the atypical mild phenotype of the two brothers. This work has been funded by ISCIII-FIS (Ref. P112/01318) and Gobierno Aragón (Ref. B20).

P11.042

Defining Cornelia de Lange syndrome type 4 phenotype: A young boy with RAD21 mutation

P. Marin Reina¹, M. Roselló Piera², C. Orellana², F. Martínez², P. Ortega³, A. Pérez Aytés¹;
¹Neonatal Research Unit. Hospital UyP La Fe, Valencia, Spain, ²Genetics Department. Hospital UyP La Fe, Valencia, Spain, ³Pediatric Nephrology Unit. Hospital UyP La Fe, Valencia, Spain.

Introduction: Mutations in RAD21 have been associated to a mild phenotype of Cornelia de Lange Syndrome (CdLS-4). We present a patient with a complex malformative pattern and a novel mutation in RAD21.

Patient description: The patient was referred to the genetics clinic at the age of 2 years. He was born at 41 weeks to a 31 year old G2P2 mother and a 31 year old father. Birth weight: 3.620kg. After birth, hypospadias, preauricular tags and dysplastic kidneys were diagnosed. On the physical examination, his weight was at 82th centile (13,5kg), height at 6th centile (83cm) and OFD<1th centile (43cm, -3,79SD). He had bilateral clinodactyly of 5th finger; absence of distal interphalangeal crease in 3th-4th fingers, limitation to elbows extension (radial luxation), ocular refractive defect and mild speech delay. Follow-up: Perthes disease. Chronic renal failure (Renal transplant at 4½ year old). He attends normal school with special support for speech (IQ: 75).

A study of next generation sequencing genetics with a custom panel of 1274 genes associated to neurodevelopmental disorders showed that our patient had a mutation in exon 2 of RAD21 gene (c.68G>A (p.Trp23Ter)) resulting in a premature stop codon. This mutation is absent in both parents.

Discussion: Very few patients with CdLS-4 have been reported. Comparing our patient with the previously reported, long philtrum, thick and arched eyebrows, short middle 5th finger phalanges, radial head anomalies and mild developmental deficit emerge as the more common features. More patients are needed to an accurate delimitation of CdLS-4 phenotype.

P11.043

Multiple systems anomalies syndrome caused by a complex rearrangement resulting in a 7 Mb deletion at 11q24 with two adjacent duplications in 11q23.3-q24.1 and 11q24.3-q25 - a case of Jacobsen syndrome?

R. M. Zechi-Ceide¹, N. M. Kokitsu-Nakata¹, L. P. Maximino², M. B. Rafacho³, A. C. V. Krepischki⁴, C. Rosenberg⁴, A. Richieri-Costa¹;

¹Department of Clinical Genetics, Hospital for Rehabilitation of Craniofacial Anomalies, University of São Paulo (HRCA-USP), Bauru, Brazil, ²Department of Speech Language and Hearing – Bauru Dental School, University of São Paulo, Bauru, Brazil, ³Post-Graduation Program in Rehabilitation Sciences, Hospital for Rehabilitation of Craniofacial Anomalies, University of São Paulo (HRCA-USP), Bauru, Brazil, ⁴Department of Genetics and Evolutionary Biology, Biosciences Institute, University of São Paulo, São Paulo, Brazil.

Orofacial cleft is the most common craniofacial anomaly, which can occur isolated or part of the clinical spectrum of hundreds of highly heterogeneous syndromes. In many instances to establish the accurate diagnosis is a great challenge, mainly in countries where the access to molecular tests is restricted. Here, we reported a 9 years old Brazilian girl with short stature, macrocephaly, coarse facies, deep set eyes, midface hypoplasia, prominent jaw, cleft palate, delayed of eruption of teeth, short neck, sensorineural hearing loss, recurrent pneumonia, eczema, progressive alopecia, multiples spots, motor delay, speech delay, severe language impairment, learning difficulties and intellectual disability. Karyotype and cranial MRI were normal. Hematological tests showed anisocytosis and microcytosis. Array-CGH detected a complex rearrangement at 11q24, with a deletion of 7 Mb in 11q24.1-24.4 flanked by two duplications: a 3,9 Mb duplication in 11q23.3-q24.1, and a duplication of a 5,7 Mb segment in 11q24.3-q25. The deleted segment contains 40 genes, including the genes BSX, NRGN, ETS-1, FLI-1 and ARHGAP32, responsible for most significant morbidity problems in Jacobsen syndrome. There is an important overlap between the clinical signs of our patient and the Jacobsen syndrome; despite this, the whole of the clinical manifestations

in our patient is unique, suggesting a hitherto not unreported new syndromic picture. We considered that genes mapped within the duplicated regions (~60 genes) probable are contributing to phenotype, encompassing genes already related to cleft palate and ectodermal dysplasia. The accurate diagnosis in this patient has led to specific investigations, resulting a more effective management.

P11.044

Reverse phenotyping of a patient with CRIPT gene mutation and further delineation of the associated phenotype

B. Demeer¹, A. Dadban², P. Vabres³, A. Varenterghem⁴, J. Thevenon⁵, D. Bremond-Gignac⁶, J. Rivière⁵, C. Thauvin-Robinet⁷, L. Olivier-Faivre⁷;

¹genetics department/EA4666, Amiens, France, ²dermatology department, Amiens, France, ³dermatology department, Dijon, France, ⁴Pediatric gastroenterology department, Amiens, France, ⁵molecular genetics department, Dijon, France, ⁶Ophthalmology department, Amiens, France, ⁷genetics department, Dijon, France.

We report on a 3 ½ year old boy, with prenatal onset growth deficiency (height : -4SD), microcephaly (OFC :-3.5 SD), transient neonatal pancytopenia, facial dysmorphism, feeding difficulties, developmental and speech delay, global hyperlaxity, significant sleep disturbance, and genital, ocular and extremities anomalies. He also presented with generalized pigmentation anomalies, and signs of ectodermal dysplasia. When last seen for follow-up at 5 years old, he had developed epilepsy. Array CGH (Agilent 60k), cytogenetic diagnosis of chromosomal breakage syndrome and metabolic screening were negative. Whole exome sequencing performed found a homozygous frame-shift mutation of the CRIPT gene, recently described as a novel primordial dwarfism gene (Shaheen et al, 2014). The mutation (c.132delA), described as “probably pathogenic”, was confirmed by sanger sequencing. Both healthy consanguineous parents were proved to be carrier in the heterozygous state.

Few available clinical data of the 2 described patients shows very similar clinical appearance with strikingly facial dysmorphism, growth deficiency, microcephaly, psychomotor delay, and ocular and extremities anomalies. Mottled hypopigmentation is noted in the older patient described.

This description is an example of “reverse phenotyping”. The first description of the CRIPT gene by Shaha et al, helped us to reach a diagnosis in our patient. Nevertheless considering this new case the term of “primordial dwarfism” seem to be too restrictive. For instance, cutaneous signs are specific in our patient. Reports of additional patients will help to further delineate the associated phenotype of this unique syndrome.

P11.045

Another case of de novo microdeletion 6q13-q15

I. Micule¹, L. Kornejeva¹, I. Inashkina², B. Lace²;

¹Childrens’ Clinical University Hospital, Riga, Latvia, ²Biomedical Research and Study Center, Riga, Latvia.

Microdeletion of 6q13-q15 is rare, less than 30 patients have been reported in the literature. Patients suffer from intellectual disability and a distinctive pattern of major and minor anomalies. Here we report a patient with this microdeletion with aim to further delineate this microdeletion syndrome.

The patient is a 6 months old Caucasian boy, born to healthy unrelated parents after IVF pregnancy. Diagnostic amniocentesis was done in 16th gw with subsequent FISH analysis for the most common aneuploidies due to the biochemical trisomy screening abnormalities. The results were normal and the pregnancy continued. US revealed agenesis of corpus callosum in the 21st gw and megacystis and dystopic right kidney in the 34th gw. Cesarean section was performed in the 37th gw, because of progressive oligohydramnios and breach presentation.

At birth the child was edematous and hypotonic, he had respiratory distress and tendency to hypoglycemia. Kidney hypoplasia and hydronephrosis were secondary to the posterior urinary valve. Brain MRI confirmed complete agenesis of corpus callosum and gyrus cinguli, colpocephaly, smaller cerebellar hemispheres and inferior vermis. He had umbilical and inguinal hernias, bilateral cryptorchidism. Presenting minor anomalies were up-slanted palpebral fissures, low-set ears, long philtrum, micrognathia, narrow high palate, and wide halluces.

aCGH (CGHTM- 4x180K) was performed and revealed a de novo microdeletion arr6q13q15(7,470,262,0-8,899,132,7)x1.

At 6 months the boy has psychomotor retardation, generalized hypotonia, strabismus, and nystagmus. He developed renal failure during episode of infection and peritoneal dialysis was initiated, which was interrupted when his renal function improved on clinical recovery.

P11.046

A partial deletion(Xp)/duplication(Xq) case due to maternal pericentric inversion(X) confirmed by microarray

O. Boz¹, B. Sarikepe¹, E. Ceylan¹, G. Gonen¹, E. Tepeli¹, N. Semerci¹, F. Duzcan¹, O. Kirbiyik², B. Ozyilmaz², G. Bagci¹;

¹Pamukkale University, Department of Medical Genetics, Denizli, Turkey, ²Tepecik Training and Research Hospital, Department of Medical Genetics, Izmir, Turkey.

Carrying a parental pericentric inversion can cause deleted/duplicated offsprings. According the literature, del(Xp)/dup(Xq) is a rare chromosomal aberration in males due to maternal pericentric inv(X).

A seven days old male patient was referred us because of dysmorphic features. He was born at 35 weeks gestation age by C/S because of oligohydramnios. Physical examination findings were narrow biparietal diameter, broad nasal root and nasal bridge, depressed nasal tip, short columella, long, flat philtrum, thin upper lip and retromicrognathia. The patient's karyotype was 46,XY. We performed subtelomeric FISH analysis because of non-syndromic dysmorphic features. Two signals for Xqter were detected on each tip of X chromosome, but no signal was detected for Xpter. His microarray analysis revealed that there were 3.7Mb deletion on Xp22.33p22.31 which contains 9 OMIM genes, 2.5Mb deletion on Xp22.33 pseudoautosomal region which contains 23 OMIM genes, 2 Mb duplication on Xq28 which contains 52 OMIM genes and 270Kb duplication on Xq28 pseudoautosomal region which contains 3 OMIM genes. Chromosomal analysis from both parents were performed for possible pericentric inversion of X chromosome and another chromosomal aberrations. Paternal karyotype was normal, but his mother had pericentric inversion of X chromosome which was confirmed by subtelomeric FISH analysis. His brother also had pericentric inversion(X). We present this case in order to contribute to the literature. It is important to provide genetic counseling that pericentric inversion carrier parents have risk of deleted/duplicated offsprings and affected children.

Patient With 22q11.2 Microdeletion and Atypical Clinical Features

V. Šliužas^{1,2}, Ž. Maldžienė^{1,2}, B. Burnyte^{1,2}, V. Kučinskas^{1,2}, A. Utkus^{1,2};

¹Department of Human and Medical Genetics, Faculty of Medicine, Vilnius, Lithuania, ²Centre for Medical Genetics, Vilnius University Hospital Santariskiu Klinikos, Vilnius, Lithuania.

We report on a girl with prominent expressive language impairment, microcephaly, dental, ocular, anorectal anomalies and dysmorphic features. Array-CGH analysis has revealed microdeletion of chromosome 22 spanning ~2.5 Mb at 22q11.21q11.22 (20,098,507-22,556,733 hg19). FISH analysis has confirmed de novo microdeletion origin. Huge variety of different size deletions in this particular site as well as high density of the genes in chromosome 22 forms variety of phenotypes for the DiGeorge, VCFs and related syndromes. Clinical features of our patient distinguish from DiGeorge syndrome, because deletion does not include HIRA and TBX1 genes. Moreover, the deletion detected in our patient genetically and phenotypically distinguishes from previously reported central 22q11.2 deletions. Renal and urogenital anomalies that are common in patients with central 22q11.2 deletion have not been observed in our patient. Additionally, our patient has dental anomalies including hypodontia, abnormal shape and enamel hypoplasia of the central incisor which have not been reported in patients with similar deletions. The distal breakpoint of the deletion coincide with common central 22q11.2 microdeletion breakpoint while the proximal breakpoint of the deletion is atypical and is located more proximally than in previously reported patients with central 22q11.2 microdeletion. Our case confirms the statement that deletions of 22q11.2 region do not represent a single clinical entity but vary depending on the specific mediating low copy repeats and the intervening gene content and emphasizes array-CGH method as the most powerful diagnostic tool.

P11.048

A new case of distal 22q11.2 microdeletion of region LCR22 E-F

J. M. Carbonell-Perez¹, M. E. Sanchez-Gutierrez¹, J. Saenz-Hurtado¹, E. Galan-Gomez², P. Mendez-Perez²;

¹Hospital Infanta Cristina, Badajoz, Spain, ²Hospital Materno Infantil, Badajoz, Spain.

Introduction: There are different 22q11.2 distal microdeletions, depending on the mediating LCRs (D to H). They vary in size and position but in literature they have been considered as a single clinical entity. Recently, a classification has been proposed based on size and gene content that proposes three different entities. They share some clinical features: Developmental delay, intellectual disability and mild dysmorphic features. One of them is a

small deletion of about 700 Kb (LCRs E to F). This small deletion is usually a de novo event, is rare (only five patients reported in literature) and shows a milder phenotype without growth restriction or cardiovascular defects.

Materials and methods: The patient was a 10-year-old boy who was attended in Clinical Genetics Unit because of mild intellectual disability. Both parents were phenotypically normal (mother with hypothyroidism) and he was born after 40 weeks of uneventful pregnancy. He had normal developmental milestones but learning difficulties at school. An array-CGH analysis was performed using a 60K platform (Perkin Elmer). FISH with LSI BCR probe was used in patient and parents.

Results and conclusions: Patient had a deletion of about 700 kb in distal 22q11.2 region (LCRs E to F) that was inherited from an apparently normal father. This deletion is rare and usually a de novo event. We report the second patient with an inherited deletion of this region. Our patient supports that this deletion is characterized by a mild phenotype and can be inherited from an apparently normal parent.

A case with atypical cutaneous finding expand the phenotype of the 22q11.2 distal deletion syndrome

S. Ahn, J. Kim, S. Shin, S. Lee, J. Choi;

Yonsei University College of Medicine, Seoul, Korea, Republic of

Introduction:Interstitial deletions of chromosome 22q11.2, including DiGeorge and velocardiofacial syndrome, are the most common microdeletions. Recently, rare 22q11.2 distal deletion syndrome with distinct genomic and clinical features from DiGeorge/velocardiofacial syndrome has been delineated. The 22q11.2 distal deletion syndrome is characterized by developmental delay, pre- and postnatal growth restriction, facial dysmorphism, and mild skeletal anomalies. We report a patient with phenotype compatible with the 22q11.2 distal deletion syndrome and with novel phenotype, cutaneous hemangioma.

Materials and Methods:A 3-year-11-month old male was referred for genetic evaluation for moderate mental retardation and developmental delay. He had short stature, microcephaly, small forehead, high palate, tongue tie, clinodactyly, left cryptorchidism, and large strawberry hemangioma on his trunk. G-banding karyotype using peripheral blood was normal. For screening of common microdeletion syndromes, multiple ligation-dependent probe amplification (MLPA) using P245 microdeletion syndrome probemix was performed.

Results:MLPA showed heterozygous deletion only for one probe site in PPIL2 gene at 22q11.21, which located distal to common deleted region of DiGeorge syndrome. For confirmatory analysis of screening result, subsequent MLPA using P250 DiGeorge probemix showed heterozygous deletion for two additional probe sites located in TOP3B and HIC2 genes. The deletion involved low-copy repeats (LCR) 22-D region, distinct from recurrent deletion of DiGeorge/velocardiofacial syndrome, and contained 51 genes.

Conclusions:We have identified a rare 22q11.2 distal deletion syndrome case with previously unreported cutaneous feature. Our finding can expand our knowledge of the clinical spectrum of the 22q11.2 distal deletion syndrome. MLPA is an easy and sensitive analytical method to diagnose these small-sized microdeletion syndromes.

P11.050

DNMT3A p.Arg882His somatic mutation recurrently observed in adult acute myeloid leukemia can cause Tatton-Brown-Rahman syndrome when present in germline

R. Kosaki¹, H. Terashima², M. Kubota³, K. Kosaki⁴;

¹Division of Medical Genetics, National Center for Child Health and Development Hospital, Setagaya, Tokyo, Japan, ²Division of Neurology, National Center for Child Health and Development Hospital, Setagaya, Tokyo, Japan, ³Division of Neurology, National Center for Child Health and Development Hospital, Setagaya, Tokyo, Japan, ⁴Center for Medical Genetics, Keio University School of Medicine, Tokyo, Japan.

DNA methylation plays critical role for both embryonic development and tumorigenesis and is mediated through various DNA methyltransferases. Germline mutations in the de novo DNA methyltransferase DNMT3A cause peculiar form of overgrowth syndrome, Tatton-Brown-Rahman syndrome (TBRS). Somatic mutations in DNMT3A are causally associated with acute myeloid leukemia (AML) and p.Arg882His represents the hotspot. Mutation spectrum in TBRS and AML never overlapped to date. Furthermore, no patients with TBRS have reported to have developed AML. We report a livebirth and survival of an infant with the TBRS phenotype who had the germline de novo DNMT3A mutation at the AML somatic mutation hotspot p.Arg882His. The female patient had a birth weight of 3926 g (+2.2SD) and length of 54 cm (+2.7SD). Characteristic features included hypotonia,

round face, narrow palpebral fissures, ventricular septal defect, umbilical hernia, sacral cyst, Chiari type I anomaly, and intellectual disability. At age 6 years, she had overgrowth with a weight of 29.2 kg (+3.2 SD) and a length of 125.8 cm (+3.1SD) and head circumference of 55cm (+2.8SD). Identification of the same variant (DNMT3A p.Arg 882 His) as both germline mutation associated with TBRS and somatic mutation associated with AML directly links mechanistic basis of the two diseases for the first time. We conclude that mutations responsible for TBRS and those for AML are likely to exert the same mode of action: decreased methyltransferase activity and reduced DNA binding activity. From a clinical standpoint, our observation indicates surveillance for hematologic abnormalities is needed among patients with TBRS.

P11.051

A novel mutation of TBC1D24 identified in a Turkish family with DOORS syndrome

E. Atli, H. Gurkan, S. Demir Ulusal, Y. Karal, E. I. Atli, H. Tozkir;
Trakya University, Edirne, Turkey.

Introduction: Deafness, onchodystrophy, osteodystrophy and mental retardation (DOOR or DOORS) syndrome (OMIM 220500) is a rare autosomal recessive disorder of unknown cause. Small or absent nails and hypoplastic terminal phalanges are seen in most individuals. The syndrome is also associated with seizure disorder. Approximately 50 affected individuals have been described in the medical literature. Half of the patients with all clinical features have mutations in TBC1D24.

Materials and Methods: A 18-month-old girl case born to a G3P2A1 female at term with NSVD as 2200 gr. Her parents were second degree consanguineous. Microcephaly, short neck, broad forehead, pointed chin, hypertelorism, high narrow palate, preauricular tag, flat nasal bridge, open nose wings, absent fingernails were determined in physical examination. Optometry, EEG and cranial MR results were normal in our patient. The patient had hearing loss, mental retardation and tonic-clonic seizures for 7 times.

Results: Cytogenetic analysis revealed 46,XX,inv(9)(p11q13) karyotype. We performed sanger sequencing for TBC1D24 (OMIM 613577) gene with deep intronic in-house designed primers. We identified a homozygous single base alteration c.1415 G>A (p.G428R) in TBC1D24 gene. This mutation was found in the proband's parents.

Conclusions: To our knowledge, the c.1415 G>A mutation has not been reported previously. The c.1415G>A was considered to be damaging by SIFT software, probably damaging (score 1.000) by Polyphen, and disease-causing by Mutation Tester and the CADD scaled c-score was 34. Therefore, our finding is considered as the first case report of this mutation.

P11.052

6,6 Mb de novo 22q11.1-q11.22 duplication in a patient with anomalous pulmonary venous drainage, intestinal malrotation and pre B acute lymphoblastic leukemia

L. - Cimbalištie, B. Aleksuniene^{1,2}, V. Dirse³, I. Tamulienė⁴;

¹Department of Human and Medical Genetics, Vilnius, Lithuania, ²Centre for Medical Genetics at Vilnius University Hospital Santariškių Klinikos, Vilnius, Lithuania, ³Hematology, Oncology and Transfusion Medicine Center at Vilnius University Hospital Santariškių Klinikos, Vilnius, Lithuania, ⁴Centre for Pediatric Hematology/Oncology, Childrens Hospital, Affiliate of Vilnius University Hospital Santariškių Klinikos, Vilnius, Lithuania.

The 22q11.2 duplication syndrome is an extremely variable disorder ranging from normal to cognitive deficits, dysmorphic facial features, congenital defects and overlaps with some features of DiGeorge/ Velocardiofacial syndromes.

We present a patient with dysmorphic features, congenital defects who was diagnosed with pre-B acute lymphoblastic leukemia (pre-B-ALL). The proband is the first child of non-consanguineous parents was born with birth weight 3900 g, height 59 cm. Anamnestically he had the surgeries of anomalous pulmonary venous drainage and the intestinal malrotation. At the age of 4, pre-B ALL and secondary hyperparathyroidism were diagnosed. The following dysmorphic facial features were noted: mild ptosis, broad flat nose, down slanting palpebral fissures, opened mouth. His psychomotor development was normal.

Chromosome analysis revealed a mosaic karyotype 47, XY,+mar[85]/46,XY[15]. To further determination the chromosomal origin of the marker chromosome whole-genome SNP array was carried out and identified a de novo 6.6 Mb gain at chromosome region 22q11.1-q11.22. The additional genome-wide analysis of patient bone marrow confirmed germline 22q11.1-q11.22 duplication, and revealed other somatic aberrations - 9.8 Mb in size deletion and hyperdiploidy with trisomies of 6, 11, 14,

17, 18 chromosomes. The mosaic duplication encompasses a region containing over 90 genes including the TBX1 gene, which overexpression might be responsible for the patient's phenotype. SEPT5, GP1BB, DGCR2, CLTCL1, CDC45L genes, which are responsible for the cell cycle division, cells proliferation and could be leukemia-related. We do hypothesize, that this duplication may influence the clonal events in the bone marrow and increase the predisposition to pre-B-ALL.

P11.053

Duplication, partial duplication and triplication of 9p in children and their impact on phenotype (4 cases)

K. Adamová¹, V. Curtisová¹, P. Čapková¹, M. Holzerová², M. Jarošová², A. Šantavá¹, J. Srovnal³;

¹Department of Medical Genetics, University Hospital and Palacky University, Olomouc, Czech Republic, ²Hemato-Oncology Clinic, University Hospital and Palacky University, Olomouc, Czech Republic, ³Institute of Molecular and Translational Medicine, University Hospital and Palacky University, Olomouc, Czech Republic.

We present four cases of aberrations of the short arm of chromosome 9 detected postnatally in children and the impact on their phenotype.

We describe two cases of full trisomy 9p, one case of partial trisomy 9p and one case of tetrasomy 9p. In two patients isochromosome i(9p) and isodicentric chromosome idic(9q) were present. Only one aberration arose as a consequence of balanced chromosomal translocation in mother all other cases were the novo. Patients were examined by G-banding, FISH and CGH or array CGH.

Trisomy 9p is a rare chromosomal syndrome (Rethoré sy) originally reported in the medical literature in 1970 and first proposed as a distinct syndrome in 1975. It is one of the most frequent autosomal rearrangements compatible with long survival rate. It arises either as a consequence of balanced CHA in parents or the novo and is associated with mental retardation and characteristic facial dysmorphism. There is some discrepancy in the literature regarding the consistency of clinical features present with relation to the size of the duplicated segment.

Tetrasomy 9 is a very rare chromosomal disorder first described in 1973 (Ghymsers et al). Isochromosome or isodicentric chromosome is present in most cases. Phenotype features of tetrasomy 9p are variable among affected individuals including varying degrees of growth retardation, abnormal facial features, and mental retardation. Death in the neonatal period is common.

P11.054

Interstitial deletion and duplication of 15q25.2-q25.3

C. B. Mueller-Hofstede, N. Lichey, U. E. Siebers-Renelt, P. Wieacker, A. Röpke;
Institut für Humangenetik, Muenster, Germany.

We report on a girl with a complex chromosomal rearrangement in the region of 15q25.2-q25.3 detected by array CGH analysis. Clinically, the girl presented at the age of 23 months because of global developmental delay and failure to thrive. Birth-weight, length and head circumference were in the normal range. After birth, difficulties of feeding and hypotonia were observed. Hereafter she developed moderate psychomotoric retardation. At presentation she showed short stature, microcephaly, dystrophy and unspecific craniofacial dysmorphism.

Chromosomal analysis generated inconspicuous results. Array CGH analysis uncovered a complex rearrangement with an interstitial 1,6 Mb deletion in 15q25.2 adjacent to a 607,9 kb duplication in 15q25.2-q25.3. The imbalances were confirmed by qPCR in the child and excluded in both parents. FISH analysis using two BAC clones revealed a small paracentric inversion (inv(15)(q25.2q25.3)) in the mother.

Isolated deletions in 15q25.2 have already been described in individuals with intellectual disability. Inverted duplications associated with terminal deletions resulting in the loss of the subtelomeric region are reported for different chromosomes (Zuffardi et al. 2009). To the best of our knowledge an interstitial inverted duplication with deletion has been described only once in 1p36.1 (Milosevic et al. 2014). In contrast to our patient there was no predisposing chromosomal abnormality in both parents.

We report on a rare case of interstitial inverted duplication with deletion of 15q25.2-q25.3 resulting from a maternal paracentric inversion. This underlines the necessity of an additional cytogenetic workup of the parents including FISH analysis for the detection of predisposing structural rearrangements.

P11.055

The 3rd W522X mutation in EIF2AK3 gene from Turkey: a new patient with Wolcott-Rallison syndrome

A. Unal, T. Bahsi, A. Bakır, E. Percin;
Gazi University, Medical Genetics Department, Ankara, Turkey.

Introduction: Wolcott-Rallison syndrome (WRS), also known as multiple

epiphyseal dysplasia with early-onset diabetes mellitus is a rare autosomal recessive multisystemic disorder. Its characteristic clinical features are permanent neonatal or early infancy insulin-dependent diabetes and later onset skeletal dysplasia. Other frequent clinical manifestations are hepatic and renal dysfunction, mental retardation, cardiac abnormalities, exocrine pancreatic dysfunction, primary hypothyroidism and neutropenia. Although WRS is a rare disease, it is the most common cause of permanent neonatal diabetes mellitus (PNDM) in consanguineous families. The exact frequency of this rare syndrome is unknown because patients may die before showing the characteristic features of the syndrome.

Case: This report presents a case of WRS in an 8-year-old girl with neonatal diabetes and short stature whose elder brother died of diabetes mellitus at 2-months-old age before having a molecular diagnosis.

Results: We found a homozygous W522X mutation in *EIF2AK3* gene in our patient which was only found in another two unrelated Turkish families.

Discussion: W522X mutation in *EIF2AK3* gene seems to be confined to Turkey and may be a common mutation in WRS patients from this country. In this paper, we compare the clinical features of the patients having W522X mutation with other patients reported to date. Except the characteristic features as diabetes mellitus and epiphyseal dysplasia, all the WRS patients show extensive phenotypic variability that correlates poorly to genotype which suggests that there is no correlation between any specific mutation and the clinical manifestation.

P11.056

Paternal uniparental disomy as an etiologic cause of Ellis van Creveld syndrome

M. C. D'Asdia¹, V. G. Naretto², B. Torres¹, G. Botta³, A. Sciarrone⁴, A. Onori¹, I. Torrente^{1,5}, B. Marino⁶, L. Bernardini³, A. De Luca¹;

¹CSS-Mendel Institute, Rome, Italy, ²S.C. Genetica Medica - U. A.O. - U. Città della Salute e della Scienza, Torino, Italy, ³Servizio di Anatomia Patologica. Presidio Ospedaliero O.I.R.M. - Sant'Anna A.O. - U. Città della Salute e della Scienza, Torino, Italy, ⁴Centro di Ecografia e Diagnosi prenatale. A.O.-U. Città della Salute e della Scienza, Torino, Italy, ⁵Department of Experimental Medicine, Sapienza University, Rome, Italy, ⁶Department of Pediatrics, Sapienza University, Rome, Italy.

Ellis-van Creveld (EVC; OMIM 225500) syndrome is an autosomal recessive disorder characterized by a disproportionate limb dwarfism, chondroectodermal dysplasia, congenital heart disease, postaxial polydactyly, and dysplastic fingernails and teeth, resulting from loss-of-function mutations in *EVC* or *EVC2* genes. We report a fetus presenting with micromelia, narrow thorax with short ribs, and polydactyly of hands on ultrasound scan at 21 weeks' gestation. The pregnancy was terminated at this stage and autopsy revealed brachydactyly, postaxial polydactyly of both hands, short ribs, abnormally short long bones, and dysplastic iliac wings. Fetal tissue was collected fresh in order to perform molecular assays. Sequence analysis of the 21 coding exons of *EVC* gene revealed that the fetus was homozygous for a frameshift mutation, NM_153717.2:c.1388del;p.(Thr463Serfs*37). DNA from parental blood samples was analyzed to confirm the carrier status of the parents. Analysis of the samples showed that the mutation identified in the fetus was not present in the mother. The simplest explanation for this would have been a maternally inherited deletion. SNP-array testing was performed to determine the gene copy number and analyze the haplotype in the 4p16.2 region in which *EVC* gene is located. The results showed no deletion, but the haplotype revealed the uniparental isodisomy of chromosome 4. Characterization of the homozygous nature of the mutation through parental genotyping and SNP-array analysis allowed us to confirm that uniparental isodisomy of the paternal chromosome 4 carrying the mutated *EVC* gene played an etiologic role in the disease.

P11.057

Mutations in *DYNC2L1* cause Ellis-van Creveld phenotype

M. Niceta¹, M. C. Digilio², K. Margiotti³, M. L. Dentici⁴, F. R. Lepr⁵, F. Pantaleoni¹, S. Barresi¹, A. Palma¹, P. Bencivenga¹, A. De Luca¹, A. Novelli⁶, E. Bertini⁵, B. Dallapiccola⁶, M. Tartaglia¹;

¹Genetics and Rare Diseases Research Division, Bambino Gesù Children's Hospital, IRCCS, Rome, Italy, ²Medical Genetic Unit, Bambino Gesù Children's Hospital, IRCCS, Rome, Italy, ³Laboratory of Medical Genetics, Bambino Gesù Children's Hospital, IRCCS, Rome, Italy, ⁴IRCCS-Casa Sollievo della Sofferenza, Mendel Institute, Rome, Italy, ⁵Department of Neurosciences, Unit of Molecular Medicine, Bambino Gesù Children's Hospital, IRCCS, Rome, Italy, ⁶Scientific Directorate, Bambino Gesù Children's Hospital, IRCCS, Rome, Italy.

DYNC2L1 encodes a component of the dynein-2 complex of intraflagellar transport (IFT), which is crucial for proper ciliogenesis. Biallelic, probably inactivating, mutations in *DYNC2L1* have previously been reported to cause a broad phenotypic spectrum, including Jeune syndrome and diverse phenotypes within the spectrum of "short-rib thoracic" dysplasias. We previously described two sisters exhibiting features fitting Ellis-van Creveld syndrome but also presenting with hydrometrocolpos and partial atrioven-

tricular canal defect. Here, we performed whole exome sequencing in one of the two sisters, and identified compound heterozygosity for inactivating mutations in the *DYNC2L1* gene. Sanger analyses confirmed these variants in both affected sisters and in a third member of the family, who displayed an overlapping phenotype. Our finding indicates that inactivating *DYNC2L1* mutations can underlie Ellis-van Creveld phenotype.

P11.058

Alternations in genes expression microarray in esophageal atresia tissues - the role of cytokine-cytokine receptor interaction and Rho cell motility signaling pathways

A. Jakubiak, P. Leszczynski, P. Skiba, M. M. Sasiadek, R. Smigiel; Medical University, Wroclaw, Poland.

Esophageal atresia (EA) with or without tracheoesophageal fistula belongs to common congenital anomalies. EA may occur as isolated (IEA) or syndromic (SEA). EA etiology is complex and still unexplained. It is suggested that multifactorial mechanism combined with epigenetic factors play role in EA etiology.

The material for study was RNA extracted from esophageal tissue acquired from newborns with esophageal atresia. The control group was RNA extracted from esophageal tissues taken from aborted fetuses and stillborn neonates without congenital defects. In first step the gene expression profiling in IEA and SEA vs control was done. The expression analysis was performed by microarray methods (Agilent SurePrint G3 Human GE). After the functional analysis of signaling pathways (by KEGG database and DAVID) two pathways were chosen - cytokine-cytokine receptor interaction and Rho cell motility signaling pathway and nine genes (*CCL2*, *LIF*, *TNF*, *TNFRSF6B*, *LIMK1*, *ARHGEF1*, *ARHGEF11*, *TLN1*, *VCL*) were analyzed by real-time PCR (The LightCycler® 480 System, Roche). Microarray examination was performed on 26 tissues, real-time PCR was done in group of 20 tissues (10 of IEA and 10 of SEA). Statistical analysis after Real-time PCR was done by Rest2009 Software, Qiagen GmbH.

In microarray we identified about 4800 up and down regulated probes between IEA and controls and about 5000 up and down regulated probes between SEA and controls. About 2300 probes occurred both in IEA and SEA groups. Analysis after real-time PCR showed down-regulation for *ARHGEF1* gene in IEA vs. control and for *LIF* gene in SEA vs. control.

P11.059

Trio-based whole exome sequencing reveals de novo causative mutations in esophageal atresia

R. Zhang;

Institute of Human Genetics, University of Bonn, Bonn, Germany.

Esophageal atresia with or without tracheoesophageal fistula (EA/TEF) occur approximately 1 in 3500 live births representing the most common malformations of the upper digestive tract comprising five anatomical subtypes classified on the basis of the location and the type of anastomosis that exists between the trachea and the esophagus. The etiology is yet poorly understood.

Here we performed whole exome sequencing in 34 case-parent-trios with EA/TEF to identify disease causing de novo events. WES was performed using a 100bp paired-end read protocol as per the manufacturer's recommendations on an Illumina HiSeq2000 sequencer. Data analysis was done by bwa-aln, gatk, samtools and the de novo probability tool DeNovoGear using the VARBANK pipeline (CCG, Cologne).

Using standard filter criteria our preliminary analysis identified 28 apparent de novo variants in 17 unrelated patients. Of these we confirmed 26 de novo variants with Sanger sequencing. Of these CHD7 has been previously associated with syndromic EA/TEF phenotypes. Currently we evaluate the remaining variants for their possible involvement in the development if EA/TEF in large EA/TEF patient cohorts.

P11.060

Utilization of whole exome sequencing for undiagnosed diseases in Hong Kong

C. Mak, H. Chung, Y. Chu;

Department of Paediatrics, The University of Hong Kong, Hong Kong, Hong Kong.

Introduction: In the past few years, undiagnosed diseases programs worldwide have had increasing success in finding the etiology of pediatric diseases. However, in Hong Kong, whole exome sequencing (WES) is not funded by the government and there is yet to be a large collaborated effort to utilize this technology. We piloted the use of WES in pediatric patients sup-

ported by research funding and collaboration with overseas centers. **Materials and Methods:** 70 pediatric patients with undiagnosed diseases were recruited through the genetic clinic, and singleton DNA samples were sent for WES in collaboration with an overseas laboratory. After initial analysis of the variant based on the phenotype, segregation analysis for candidate pathogenic variants was performed locally. **Results:** Using a singleton WES strategy followed by targeted parental Sanger sequencing, pathogenic variants were found in over 30% (n=21) of the patients, including conditions recently identified with mutations identified in causative genes e.g. ASXL3, DDX3X, PIGO, PURA etc. We shall present some illustrative patients and address the challenges of implementing this technology in our local healthcare system. **Conclusions:** With limited resources, we piloted the application of WES for undiagnosed pediatric diseases in Hong Kong. Importantly our strategy of singleton WES followed by targeted parental Sanger sequencing has made it less costly compared to trio-based WES and yet achieving a diagnostic rate comparable to those reported overseas. **Acknowledgement of grant support:** This work was supported by grants from the S K Yee Medical Foundation and The Society for the Relief of Disabled Children.

Retinitis pigmentosa in combination with hearing loss can be a feature of different Mendelian disorders. We describe a novel syndrome caused by biallelic mutations in the "exosome component 2" (EXOSC2) gene. Three individuals from two unrelated German families presented with a previously undescribed disorder encompassing childhood myopia, early onset retinitis pigmentosa, progressive sensorineural hearing loss, hypothyroidism, short stature, brachydactyly, recognizable facial gestalt, premature aging, and mild intellectual disability. Whole exome sequencing revealed homozygous and compound heterozygous mutations in EXOSC2 in all three patients who shared a large 6.7 Mb rare haplotype on chromosome 9 encompassing EXOSC2.

EXOSC2 encodes the "ribosomal RNA-processing protein 4" (RRP4) - one of the core components of the RNA exosome. The RNA exosome is a multi-protein complex that plays key roles in RNA processing and degradation. One of the discovered amino acid substitutions p.Gly30 by Valin located within the N-terminal domain of EXOSC2 would change the inter-atomic distance between the mutated EXOSC2 residue and neighboring amino acids of EXOSC4 and, therefore, destabilize EXOSC2-EXOSC4 interaction. A similar mechanism was proposed for the recurrent mutation p.Gly31Ala in the NT domain of EXOSC3. Intriguingly, the EXOSC2-associated phenotype shows only minimal overlap with the previously reported diseases associated with mutations in the RNA exosome core component genes EXOSC3 and EXOSC8. Taken together, we report on a novel condition that is caused by altered RNA exosome function and expands the spectrum of clinical consequences of impaired RNA metabolism.

P11.062

Any direct role of FANCA in mitochondria?

R. Bottega¹, S. Ravera², M. Faleschini¹, R. Bortul¹, E. Cappell³, C. Dufour³, M. Zweyer¹, A. Savoia¹;

¹Department of Medical Sciences, University of Trieste, Trieste, Italy, Trieste, Italy, ²Biochemistry Lab., Department of Pharmacy, University of Genova, Genova, Italy, Genova, Italy, ³Clinical and Experimental Hematology Unit, G. Gaslini Children's Hospital, Genoa, Italy, Genova, Italy.

Fanconi anemia (FA) is a genetic disorder characterized by chromosomal instability, congenital abnormalities, pancytopenia, and predisposition to cancer. Though they play a role in DNA repair processes, the FA proteins are likely to have other functions. Indeed, FA cells show defective mitochondria associated with increased levels of reactive oxygen species and apoptosis.

In order to provide insights into the role of FANCA, one of the FA proteins, we investigated its localization and found that it resides not only in the nucleus and the cytoplasm but also in mitochondria. We also analysed its expression in cells derived from patients. Unexpectedly, proteins affected by amino acid substitutions are stably expressed in the cytoplasm, suggesting that they could be hypomorphic, exerting some role in the mitochondria. Consistent with this hypothesis, the mitochondrial phenotype is less severe in cells carrying one or two missense alleles than in those completely lacking FANCA (null cells).

The energetic and respiratory metabolism of mitochondria was restored or partially restored when null FANCA cells were transfected with wild type or missense mutant forms of FANCA, respectively, further strengthening the hypothesis of a role of FANCA in mitochondria.

The potential role of the FA proteins in mitochondria has long been neglected despite evidence for defects of this organelle in FA cells. Finding that FANCA localizes in the mitochondrion leads the way into investigations that could explain the increased redox status and apoptosis observed in FA.

P11.063

Screening of Fanconi Anemia associated genes reveals BRIP1 mutation frequency may be higher than expected in patients from Turkey

G. Bagirova, G. Toksoy, S. Avci, Z. Uyguner, U. Altinoglu, S. Basaran, H. Kayserili; Department of Medical Genetics, Istanbul Medical Faculty, Istanbul University, Istanbul, Turkey.

Introduction: FA is recessively inherited chromosomal instability syndrome characterized by bone marrow failure, congenital malformations and cancer predisposition. Pathogenic variants of FANCA are attributed to 60-70%, while BRIP1 is associated in approximately 2% of the FA patients.

Material and method: Targeted gene panel is design to cover all the coding exons of 17 FA genes plus flanking exon-intron regions up to 10 bp. Genetic analysis is performed on Ion Torrent PGM platform, and detected mutations and/or alterations considered to be pathogenic are verified by Sanger and screened in family for segregation with inheritance pattern.

Results: 6 out of 14 alleles found to carry mutations. Two different homozygous mutations (c.894-2A>G and c.4261-2A>C) in FANCA and one compound heterozygous [(c.205+5G>T)+(c.761_764delAGCA)] mutations in BRIP1 gene are identified, accounting to three DEB positive patients.

Conclusions: 72 different mutations of BRIP1 gene are known and out of 14 are involved in germ line bi-allelic FA. c.761_764delAGCA identified in our study is novel and attained to be the second deletion that is reported in the context of FA, striking the DEAD-2 domain of the encoding protein that is different than the former (c.2255_2256delAA), damaging the HELIC domain.

The results of the limited number of individuals tested in this study, reveals that the DEB positivity assures the definitive diagnosis and if the DEB test is ignored, mutation detection rate is calculated to be 42%, when presently known FA genes are analyzed, in which that the 28% holds for FANCA and the 14% holds for BRIP1 associated mutations.

P11.064

A de novo 13q31.1q.31.2 deletion spanning MIR17HG associated with Feingold syndrome type 2 and keratoconus

F. Sirchia^{1,2}, E. di Gregorio¹, B. Pasini^{1,2}, E. Grosso¹, A. Brusco^{1,2}, D. Carli^{1,2}, G. Gai¹, V. Naretto¹, A. Zonta¹, G. Restagno¹;

¹Città della Salute e della Scienza University Hospital, Medical Genetics Unit, Torino, Italy, ²University of Torino, Department of Medical Sciences, Turin, Italy.

We report on a 58-year old woman with microcephaly, mild dysmorphic features, bilateral keratoconus, digital abnormalities, short stature and mild cognitive delay. The phenotype was suggestive for Feingold syndrome type 2, an autosomal dominant disorder characterized by a variable combination of microcephaly, digital abnormalities, short stature and mild-to-moderate intellectual disability. MIR17HG is the gene known to cause the disease (FGLDS2, MIM614326).

Karyotype analysis showed a deletion on chromosome 13q, further defined by Array-CGH to span a 17.3-Mb region on 13q31.1q31.2, including the MIR17HG gene. The deletion was proved to be de novo by real-time qPCR. Feingold type 2 is a very rare Mendelian syndrome, described in few patients worldwide. Our proband shows a never reported association between FGLS2 and keratoconus. We noted that the 17.3-Mb deletion on chromosome 13q partially overlap with the keratoconus 7 locus, identified by linkage analysis on Ecuadorian families (MIM614629). Thus we suspect that haploinsufficiency of a gene nearby MIR17HG, defined by the overlapping segment between our deletion and the linkage region is causing keratoconus. Nine genes are included in this segment. Among these, the best candidates are MBLN2 and IPO5. MBLN2 encodes a muscleblind protein responsible for terminal differentiation of muscle and photoreceptor tissues. IPO5 encodes a protein nuclear transport and it is expressed in human cornea. In conclusion, we describe a possible contiguous gene syndrome phenotypically characterized by Feingold syndrome type 2 and keratoconus, due to a large deletion on 13q overlapping MIR17HG and a still to be identified gene for keratoconus.

P11.065

A novel synonymous mutation in FGFR1 causes Hartsfield syndrome

C. Courage^{1,2}, J. Neidhardt³, F. Dallèves², J. Lemke⁴;

¹Folkhälsan Institute of Genetics, Helsinki, Finland, ²Division of Human Genetics, University Children's Hospital, Inselspital, Bern, Switzerland, ³Institute of Human Genetics, University of Oldenburg, Oldenburg, Germany, ⁴Institute of Human Genetics, University of Leipzig, Leipzig, Germany.

Hartsfield syndrome is a rare clinical entity characterized by the triad of holoprosencephaly, ectrodactyly and cleft lip/palate. In addition to these symptoms patients with Hartsfield syndrome can show developmental delay of variable severity, isolated hypogonadotropic hypogonadism (IHH), central diabetes insipidus, vertebral anomalies, eye anomalies and cardiac malformations. Mutations in FGFR1 have been described to cause a wide phenotypic spectrum such as Hartsfield syndrome, hypogonadotropic hypogonadism with or without anosmia, Jackson-Weiss syndrome, osteoglyphonic dysplasia, Pfeiffer syndrome and trigonocephaly type 1.

Here we describe a novel synonymous mutation in FGFR1 identified by exome sequencing in two siblings born to non-consanguineous healthy Swiss parents. The male patient presented with lobular holoprosencephaly with a single maxillary incisor, ectro-/syndactyly on both feet, syndactyly on both hands, craniosynostosis of the sagittal suture, delayed puberty and developmental delay. His younger sister was diagnosed with diabetes insipidus, in addition to syndactyly of the right foot and an aortic isthmus stenosis. A cranial MRI showed agenesis of corpus callosum and colpocephaly. The novel synonymous missense mutation c.1029G>A (p.Ala343Ala) FGFR1 detected in both affected siblings, was excluded in DNA extracted from leukocytes of the parents and their healthy sister. Therefore, we assume a gonadal mosaicism or somatic mosaicism including germ cells of this mutation. In one of the FGFR1 isoforms this guanine to adenine substitution is located in a specific splice acceptor region, which we currently are functionally validating in vitro.

Fraser syndrome (FS) is a rare autosomal recessive malformation disorder described for the first time in 1962. Major criteria are cryptophthalmos, syndactyly, respiratory and urinary tract anomalies. Mutations have been identified

within 3 genes, FRAS1, FREM2 and GRIP1, all involved in mesenchymal-epidermal adhesion during embryonic development. This descriptive study analyzed the prenatal ultrasound and fetal phenotype in 35 cases of FS. Termination of the pregnancy was performed in 24 cases, intra-uterine death was diagnosed in 8 cases, between 16 and 36 weeks of pregnancy, and 3 cases died after birth. All cases presented dysmorphic features with nose and ear dysplasia. Complete or abortive cryptophthalmia and renal anomaly (agenesis, hypoplasia or dysplasia) were present in 34/35 cases, syndactyly in 33/35, bronchopulmonary anomalies in 30/34, genital anomalies in 30/35, and sexual phenotype was frequently difficult to establish. Multiple anomalies were observed in the digestive tract: low set umbilicus (23/34), anal atresia/stenosis (16/33), intestinal malrotation (10/33) and omphalocele (6/35). Ultrasound results were available in 24 cases. Reported anomalies were oligoamnios (18), ascites (8), renal anomalies (19), bronchopulmonary anomalies (11), ophthalmologic anomalies (4), ear dysplasia (2) and syndactyly (2). The fetal and postnatal phenotype of FS is very specific, while ultrasound diagnosis is complicated by the presence of oligoamnios. This study shows that cardinal FS diagnosis criteria are rarely found on prenatal ultrasound. Evidence for low set umbilicus, micropthalmia, and genital anomalies should lead to consider the diagnosis of FS.

P11.067

Frontonasal dysplasia in two girls with EFN1 gene duplications

I. V. Kanivets^{1,2,3}, V. G. Solonichenko³, S. N. Stavtseva⁴, F. A. Kononov^{1,2}, D. V. Pyankov^{1,2}, S. A. Korostelev^{1,2};

¹Genomed Ltd, Moscow, Russian Federation, ²FSBI „Research Centre for Medical Genetics“, Moscow, Russian Federation, ³Filatov Children's clinical hospital, Moscow, Russian Federation, ⁴Z.I. Kruglaya Regional Children's Clinical Hospital, Orel, Russian Federation.

Frontonasal dysplasia occurs in patients with various genomic abnormalities, including chromosomal rearrangements, point mutations and copy number variations (CNVs) affecting single genes. We examined two girls, aged 1 year and 5 months, with developmental delay, frontonasal dysplasia, and other congenital anomalies. In addition to frontonasal dysplasia, the 1-year old girl had hypotonia, deformed low-set ears, hemangioma of upper lip. In the 5-months old girl, additional phenotypic features included plagiocephaly, camptodactyly and umbilical hernia. Chromosomal microarray analysis (CMA) using SNP array (Affymetrix Cytoscan 750k) was performed as a first-line test according to ACMG recommendations. Both girls appeared to have a copy number gain of EFN1 gene: a 1-year old girl had 3 copies (molecular karyotype: arr Xq13.1(67,923,907-68,158,871)x3, size 235 kb), and a 5-months old girl had 4 copies (molecular karyotype: arr Xq13.1(67,863,904-68,457,240)x4, size 693 kb). According to the OMIM database, point mutations and deletions (but no duplications so far) in EFN1 gene were described in X-linked dominant Craniofrontonasal syndrome (304110) with prevalence in female patients.

The use of CMA allows identification of genes having clinically significant dosage effect associated not only with copy number losses, but with gains as well. This may lead to a revision in the testing strategy for patients with distinctive facial features.

Introduction: Frontoal nasal dysplasias (FND) are facial malformations characterized by hypertelorism, median facial cleft and nasal tip anomalies. Their rarity and the lack of molecular basis in most entities explain clinical

and genetic heterogeneity. Mutations in ALX genes family are responsible for autosomal recessive (ALX1, ALX3, ALX4) or dominant (ALX4) FND. Cranio-fronto-nasal syndrome (CFNS), acromelic FND and Teebi syndromes are caused by mutations in respectively EFNB1, ZSWIM6 and SPECC1L. Molecular basis of oculo-auriculo-fronto-nasal (OAFNS), oculo-cerebro-cutaneous (OCCS) and Pai syndromes are not known.

Material and methods: We report a series of 35 patients referred to sequence ALX genes. Sanger sequencing of ALX1, ALX3 and ALX4 was performed in 14 individuals and identified one ALX3 heterozygous mutation in one patient. Based on the phenotype, we identified 24 FND, 2 CFNS, 5 OAFNS, 2 OCCS, and 2 Teebi syndromes. Sanger sequencing of EFNB1 was performed in both individuals presenting with CFNS. Trio exome sequencing was performed in seven patients.

Results: We identified de novo EFNB1 mutations in the two CFNS patients, as well as new mutations in known genes (YWHAE, OTX2 and SPECC1L) in patients respectively labeled as FND, OCCS and Teebi syndrome, and a de novo variant in a candidate gene in a fetus with FND. Replication cohorts are being sequenced.

Conclusion: This series and these results highlight the input of exome sequencing in the identification of molecular basis in syndromes with FND, leading to a better clinical description of these rare entities and allowing to broaden the phenotypic spectrum of known syndromes.

P11.069

Genetic and genomic analysis in patients affected by Gorham-Stout disease and general lymphatic anomalies

L. Rodríguez Laguna¹, M. Crespo¹, V. Fernandez-Montaño¹, R. Martín-Arenas¹, E. Vallespín¹, A. del Pozo¹, K. Ibañez¹, J. Silla-Castro¹, G. Herranz², G. Oliva-Molina¹, R. Mena¹, M. Gomez¹, I. Rueda-Arenas¹, J. Nevado¹, P. Lapunzina², J. López-Gutiérrez³, V. Martínez-Glez²;

¹INGEMM-idiPAZ, Madrid, Spain, ²INGEMM-idiPAZ-CIBERER, Madrid, Spain,

³Department of Pediatric Surgery, Hospital Universitario La Paz, Madrid, Spain.

Introduction: Gorham-Stout disease (GSD) and general lymphatic anomalies (GLA) are potentially fatal conditions with significant mortality rates, characterized by lymphatic malformations (LMs) and different patterns of osteolysis. The genetic causes are still unknown, but somatic mosaicism is suspected.

Methods and Results: Our database includes 78 GSD and 52 GLA patients. All experiments included paired blood/tissue samples. Genomic dose experiments (Illumina SNP BeadChips) did not detect common UPD/CNV regions (germinal or somatic). Mutational screening using NGS experiments (Exome and TruSight One, Illumina), was performed in 18 patients. In-house bioinformatics tools were developed to call somatic variants. A list of 578 candidate genes was obtained —48 were somatic—. No *PIK3CA* mutations —known to be associated to cystic LMs— were detected, but variations in other four PI3K associated genes were found. As a second step we designed a custom NGS panel with a 1.000X vertical coverage, including the 578 candidate genes as well as *PIK3CA* associated genes and other vascular/lymphatic genes. We present here a preliminary candidate gene list.

Conclusion: Use of NGS —at large reading depths— and specific bioinformatic algorithms for detecting somatic variations in paired blood/tissue samples, is the appropriate methodology for gene discovery in entities caused by mutations in somatic mosaicism form. We have obtained a candidate gene list, including four PI3K associated genes, taking us closer to the cause of GSD/GLA. Our future approach includes the isolation of lymphatic endothelial cell from LMs in GSD/GLA patients as a necessary tool for further genetic and functional analysis.

P11.070

The eighth patient with Gorlin-Chaudhry-Moss Syndrome

S. Lanciotti¹, C. Coco², F. Brancati³;

¹Section of Genetics, Department of Biomedicine and Prevention, Tor Vergata University, Rome, Italy, ²Altamedica maternal-fetal Medical Centre, Rome, Italy, ³Section of Genetics,

Department of Medical, Oral and Biotechnological Sciences, Gabriele D'Annunzio University, Chieti, Italy.

Gorlin-Chaudhry-Moss Syndrome (GCMS; OMIM%233500), firstly described in 1960 in two sisters, is a neglected condition reported in the medical literature in only seven females. GCMS associates craniosynostosis (coronal), ectodermal dysplasia features including hair (diffuse hypertrichosis, synophrys, coarse hair) and teeth (abnormally shaped, hypodontia, microdontia) abnormalities, microphthalmia, conductive deafness, minor congenital heart defects and hypoplastic labia majora. All patients show normal intelligence. Although craniofacial manifestations are characteristic partial overlap with Saethre-Chotzen syndrome exist. We report the eighth case of GCMS diagnosed at the age of 14 years. She was the second child of healthy

unrelated parents born post-term after uneventful pregnancy. At 10 weeks, she was hospitalized for marked craniofacial dysmorphism, cleft palate, bilateral microphthalmia with cataract, interventricular and interatrial septal defects with patent ductus arteriosus. Growth was delayed. Cranial CT scan confirmed craniosynostosis involving the coronal sutures. At clinical examination diagnosis was suggested based on craniofacial characteristics including brachycephaly with midface hypoplasia, low frontal hairline, synophrys, microphthalmia, posteriorly angulated ears, bifid nasal tip, prominent columella, dental abnormalities, arched narrow palate with bifid uvula, generalized hypertrichosis and short stature. Left cutaneous syndactyly of toes 2-3 was evident. We requested an audiogram revealing left sided conductive hearing loss. GCMS is exceedingly rare with core features consisting in craniosynostosis, ocular and ectodermal derivatives defects. Autosomal recessive inheritance was suggested since the disease recurred in two pairs of sisters. So far, no gene associated to this syndrome exists thus radically limiting diagnosis and reproductive options in affected individuals and their families.

P11.071

Growth retardation, delayed bone age and mild developmental delay in a patient with microduplication at 2p25.1- case study

K. Wojciechowska¹, A. Poluha¹, B. Wiśniewicka², B. Nowakowska², J. Kowalczyk¹;

¹Childrens University Hospital, Lublin, Poland, ²Institute of Mother and Child, Warsaw, Poland.

More than 20 patients have been reported in the literature with duplication of the short arm of chromosome 2. The affected patients had both different sizes of the duplications and they also have different clinical features. Recurrent phenotypic features include growth retardation, delayed bone age and mild developmental delay. We report a 12- year-old female patient with 180 kbp duplication at 2p25.1 which she inherited from her mother. Our patient is noted to have severe growth retardation, delayed bone age and mild developmental delay. Also her mother has relatively low height.

Investigation with whole-genome oligonucleotide microarray CGH analysis which was performed using clinical 60K microarrays from Oxford Gene Technology (CytoSure ISCA v2) revealed duplication spanning of approximately 180 kbp and between breakpoints rs9,955,335 and rs10,136,171 at 2p25.1.

This duplicated region contains GRHL1, KLF11, CYS1 genes as well as a part of the TAF1B gene.

Litreature review revealed that GRHL1 gene plays an important role in epithelial development and epidermal differentiation. KLF11 is involved in the regulation of cell growth and differentiation and it is a glucose- inducible regulator of the insulin gene.TAF1B is a component of RNA polymerase I core factor complex.

Our patient is the first reported patient with a duplication of above- mentioned genes and her clinical features conform the symptoms which are present in most of the reported patients with different duplications at the short arm of chromosome 2.

P11.072

Novel missense FGFR1 mutation in a patient with Hartsfield syndrome

M. Piotrowicz¹, A. Sowińska-Seidler², A. Jamsheer², L. Jakubowski¹;

¹Department of Genetics, Polish Mother's Memorial Hospital Research Institute, Lodz,

Poland, ²Department of Medical Genetics, Poznan University of Medical Sciences, Poznan, Poland.

Hartsfield syndrome is a rare genetic disorder characterized by the association of holoprosencephaly (HPE) and ectrodactyly, with or without cleft lip/palate, and variable additional abnormalities. Dominant or recessive FGFR1 loss of function mutations have been recently shown to give rise to Hartsfield syndrome.

In this paper, we report a sporadic case of a male subject with Hartsfield syndrome who presented with ectrodactyly, semilobar HPE, bilateral cleft lip and palate, bilateral vesicoureteral reflux, cryptorchidism, mental retardation, and facial dysmorphism composed of flat facial profile, dysplastic ears, and thin vermilion border. No causative abnormalities were found at the cytogenetic level, including karyotype and 1.4 M array CGH. Upon molecular screening of FGFR1 gene by means of Sanger sequencing, we detected a novel heterozygous missense c.1868A>G (p.Asp623Gly) variant, which was subsequently confirmed to occur as a de novo mutational event. The variant was predicted to be damaging to the protein function by the common bioinformatic algorithms used for pathogenicity assessment (MutationTaster2, SIFT, Polyphen2). Additionally, the variant was not annotated in ExAC, EVS or dbSNP databases, however a substitution within the same amino acid position (p.Asp623Tyr) was already described in another case of Hartsfield syndrome.

Our paper provides a detailed clinical presentation of newly identified male individual affected with Hartsfield syndrome and expands the mutational spectrum associated with this extremely rare genetic condition. Funding: This work was supported by a grant from the National Centre for Research and Development (LIDER/008/431/L-4/12/NCBR/2013) to Aleksander Jamsheer.

P11.073

Case report: A novel *CCBE1* gene mutation for Hennekam lymphangiectasia syndrome

F. Harrazi¹, M. Yavari^{1,2}, S. Seyedhassani¹;

¹Dr.Seyedhassani medical genetic center, Yazd, Iran, Islamic Republic of; ²Department of Biology, Faculty of Sciences, Yazd University, Yazd, Iran, Islamic Republic of.

Introduction: Hennekam lymphangiectasia syndrome is a rare autosomal recessive condition. Onset is usually in childhood. The syndrome presents with lymphedema, intestinal lymphangiectasia, intellectual deficit and facial dysmorphism. The diagnosis of Hennekam is suspected on the basis of clinical phenotypic features. Phenotypic abnormalities relate to impaired pre-natal and postnatal lymphatic flow resulting from mutations in the collagen and calcium-binding EGF-domain 1 (*CCBE1*) during lymphangiogenesis. In this study, we analyzed the DNA sequences of *CCBE1* gene in a patient aged 3 years old with Hennekam syndrome.

Materials and methods: The entire coding regions of the *CCBE1* gene were analyzed for mutations by PCR-based direct DNA sequencing.

Results: One novel homozygous mutation IVS7(+12) A>G at position 640 on *CCBE1* gene has been detected. The heterozygosity of the parents for this IVS7 was confirmed by direct sequence analysis. Bioinformatic analysis confirmed our studies.

Conclusions: This mutation occurs in the deep intronic positions. Activation of an intronic cryptic acceptor site and creation of an intronic ESE site could be created by the mutation. Complementary assessment such as functional study should be considered for suggestion of prenatal diagnosis.

P11.074

A Turkish girl with Hennekam Syndrome

A. I. Gurler, T. Bahsi, D. Karaer, K. Karaer;

Dr Ersin Arslan Training and Research Hospital medical genetic, gaziantep, Turkey.

Hennekam syndrome is an autosomal recessive syndrome, characterized by generalized lymphatic dysplasia (ie. lymphedema and lymphangiectasia), variable intellectual disability and characteristic dysmorphic features. Recent studies reported patients with Hennekam Syndrome having mutations in *CCBE1* gene.

A 7 years-old girl was referred to our center because of mild intellectual disability and dysmorphic features. She was borned to healthy 2nd degree cousins relative parents. The child had chylous acid, lymphatic congestion and dysmorphic features (bilaterally epicanthus, hypertelorism, flat nasal bridge, full cheeks, flat malar region, long philtrum). A mutation analysis of *CCBE1* gene was requested. The results revealed a previously published sequence variant a missense c.520C>T (p.Cys174Arg) in a homozygous state. The patient we describe here has a lymphatic dysplasia with mild intellectual disability and dysmorphism caused by mutation in *CCBE1*, highlighting the phenotypic variability that can be seen with abnormalities in this gene.

P11.075

Microdeletions/duplications in patients with holoprosencephaly phenotype

L. A. Ribeiro-Bicudo¹, N. A. Bergamo¹, B. S. Maranhão¹, J. T. Arruda¹, V. M. Torres¹, J. Marino¹, B. F. Gamba², A. R. Costa³;

¹Federal University of Goiás, Goiânia, Brazil, ²Sao Paulo State University, Botucatu, Brazil, ³Sao Paulo University, Bauru, Brazil.

Holoprosencephaly (HPE) is a malformation sequence in which the cerebral hemispheres fail to separate into distinct left and right halves, resulting in midline structural anomalies of the central nervous system and face. Numerous different heterozygous mutations have been identified in HPE patients, including missense, nonsense, deletion, and frameshift mutations located throughout the gene. In addition, in a recent study of over 200 patients with isolated HPE, 22% were found to have copy number variations (CNVs). However, the majority of etiologies of isolated HPE have yet to be determined.

In the present work, the MLPA technique was performed in 52 individuals within the HPE spectrum who presented negative mutational screening test for the major HPE genes, and anomalies were found in seven cases. These

aberrations included five deletions and two duplication in genes related to HPE. Three individuals had deletions involving *SHH* on 7q, one individual had a duplication involving *SHH* on 7q, one individual had a deletion on 18p involving the *TGIF1* gene, and another individual had a duplication on 13q involving the *ZIC2* gene. Our results also showed that microdeletions/duplications in the major HPE genes *SHH*, *TGIF*, and *ZIC2* are causative for the frank HPE phenotype, being the *SHH* the major one (9.5% in *SHH*, 1,9% in *TGIF*, and 1,9% in *ZIC2*). As HPE patients are surviving longer, we believe that an effort to search for CNVs is a valuable tool for genetic counseling when analyses for mutations in the known HPE genes are negative.

Grants: Fapeg

P11.076

TBX3 and TBX5 duplication: a family with an atypical overlapping Holt-Oram/Ulnar-Mammary syndrome phenotype

M. Holder-Espinasse¹, E. Thomas¹, A. Davies², N. Timoney³, A. Frigiola⁴, M. Logan⁵;

¹Clinical Genetics Department, Guy's Hospital, London, United Kingdom, ²Genetics laboratories, Guy's Hospital, London, United Kingdom, ³Plastic Surgery Department, St Thomas Hospital, London, United Kingdom, ⁴Cardiology Department, St Thomas Hospital, London, United Kingdom, ⁵Randall Division of Cell and Molecular Biophysics, King's College London, Guy's Campus, London, United Kingdom.

Holt-Oram syndrome (HOS) is a rare autosomal dominant heart-hand syndrome due to mutations in the *TBX5* transcription factor. A wide spectrum of *TBX5* mutations has been previously reported, mostly resulting in null allele and haploinsufficiency, but some mutations also affect the nuclear localisation of the *TBX5* protein or its interaction with co-factors and downstream targets. *TBX5* duplications have been previously reported in association with atypical HOS phenotypes. Ulnar-Mammary syndrome (UMS) is also a rare autosomal dominant condition due to mutations in the *TBX3* gene. Clinical variability is the rule for both HOS and UMS and incomplete penetrance has often been reported. Contiguous chromosome 12q24 deletions comprising both *TBX5* and *TBX3* genes have been identified but to our knowledge, mirror duplications have never been described.

We report on a large family with at least 10 affected individuals presenting with a 399kb duplication at 12q24.21 identified on array-CGH and comprising *TBX5* and *TBX3* genes, over 3 generations. Patients are presenting with variable limb anomalies involving both the radial and the ulnar rays and interesting cardiac findings such as hypertrabeculation of the left ventricular cavity, possibly in keeping with left ventricular non compaction, tachycardia, persistent arterial duct or aortic stenosis... Additional findings such as accessory nipples were also noted. Fluorescent in situ hybridisation is currently pending to confirm the breakpoints of the 12q24.21 duplication and the underlying mechanism. We will also attempt to look at allele-specific expression and to sequence around the breakpoints to explain the molecular contribution to the clinical findings.

Chitayat Syndrome: hyperphalangism, facial anomalies, hallux valgus, and bronchomalacia results from a recurrent c.266A>G (p.Tyr89Cys) variant in the *ERF* gene

M. Balasubramanian¹, J. A. Bernstein², H. Lord³, S. Levesque⁴, F. Thuriot⁴, A. Wenger², G. Sillon⁵, H. Guturu⁶, D. L. Sureka⁷, G. Bejerano^{2,6,7}, D. Chitayat⁸;

¹Sheffield Clinical Genetics Service, Sheffield, United Kingdom, ²Stanford Children's Health, Lucile Packard Children's Hospital, Stanford University School of Medicine, Stanford, CA, United States, ³Oxford Medical Genetics Laboratories, Oxford University Hospitals NHS Foundation Trust, The Churchill Hospital, Oxford, United Kingdom, ⁴Department of Pediatrics, Centre Hospitalier Universitaire de Sherbrooke, Sherbrooke, QC, Canada, ⁵Department of Medical Genetics, McGill University Health Center, Montreal, QC, Canada, ⁶Department of Computer Science, Stanford University, Stanford, CA, United States, ⁷Department of Developmental Biology, Stanford University, Stanford, CA, United States, ⁸The Prenatal Diagnosis and Medical Genetics Program, Department of Obstetrics and Gynecology, Mount Sinai Hospital; Division of Clinical Genetics and Metabolism, Department of Pediatrics, The Hospital for Sick Children; University of Toronto, Toronto, ON, Canada.

Background: In 1993, Chitayat et al., reported a newborn with hyperphalangism, facial anomalies, and diffuse bronchomalacia. We have identified 2 more families with similar findings. Characteristic features include bilateral accessory phalanx resulting in shortened index fingers; hallux valgus; facial features including prominent eyes, hypertelorism, depressed nasal bridge and upturned nose; respiratory compromise due to bronchomalacia necessitating ventilatory support; pectus excavatum.

Methods: Trio-based exome sequencing was performed in 3 unrelated families. Putative de novo variants were identified from exome data using DeNovoGear software and validated using Sanger sequencing.

Results: The same variant c.266A>G p.(Tyr89Cys) Refseq NM_006494.2 in *ERF*: de novo (Patient 1&2) and inherited from affected father (Patient 3),

was identified. The p.Tyr89Cys is an aromatic polar neutral to polar neutral amino acid change, highly conserved across species and lies within the functionally important ets-domain of the protein. This variant has never been reported (1000 genomes, dbSNP build 144, EVS or EXAC). The recurrent c.266A>G p.(Tyr89Cys) ERF missense variant causes Chitayat syndrome. Discussion: ERF has been shown to suppress ets-induced transformation and be regulated by phosphorylation throughout the cell cycle via ras/MAPK signalling pathway. ERF variants have been associated with complex craniosynostosis. In contrast, none of the patients with the c.266A>G p.(Tyr89Cys) variant have craniosynostosis. Conclusions: We report the molecular aetiology of Chitayat syndrome consistent with the classical triad of hyperphalangism, characteristic face and respiratory abnormalities. We discuss potential mechanisms for this distinctive phenotype associated with p.Tyr89Cys substitution in ERF and explore why this variant does not present with craniosynostosis.

Infantile encephalopathies are a group of clinically and biologically heterogeneous disorders for which the genetic basis remains largely unknown. Here, we report a previously unrecognized syndromic neonatal encephalopathy characterized by profound developmental disability, severe hypotonia, seizures, diminished respiratory drive requiring mechanical ventilation, brain atrophy, corpus callosum dysgenesis, cerebellar vermiform hypoplasia, and facial dysmorphism. Biallelic inactivating mutations in TBCK (TBC1 domain-containing kinase) were independently identified by Whole- Exome Sequencing (WES) as the cause of this condition in four unrelated families. Matching these families was facilitated by sharing phenotypic profiles and WES data in a recently released web-based tool (Geno2MP) that links phenotypic information to rare variants in families with Mendelian traits. TBCK is a putative GTPase-activating protein (GAP) for small GTPases of the Rab family and has been shown to control cell growth and proliferation, actin cytoskeleton dynamics, and mTOR signaling. Two of the three mutations are predicted to truncate the protein (c.376C>T [p.Arg126*] and c.1363A>T [p.Lys455*]), and loss of the major TBCK isoform was confirmed in primary fibroblasts from one affected individual. The third mutation, p.Arg511His, alters a conserved residue within the TBC1 domain. Structural analysis implicates Arg511 as a required residue for Rab-GAP function, and in silico homology modeling predicts impaired GAP function in the corresponding mutant. These results suggest loss of Rab-GAP activity is the underlying mechanism of disease. In contrast to other disorders caused by dysregulated mTOR signaling associated with focal or global brain overgrowth, impaired TBCK function results in progressive loss of brain volume.

Exome sequencing of rare diseases in founder populations and identification of novel disease associated genes

C. Gonzaga-Jauregui¹, E. Puffenberger², C. Van Hout¹, K. Brigatti², A. King¹, K. Praveen¹, M. Kuebler², J. G. Reid¹, J. D. Overton¹, S. Mellis¹, A. Shuldiner¹, F. Dewey¹, K. Strauss²;

¹Regeneron Genetics Center, Regeneron Pharmaceuticals Inc., Tarrytown, NY, United

States, ²Clinic for Special Children, Strasburg, PA, United States.

Introduction: Founder populations derive from a small number of initial individuals and are often culturally or geographically isolated from gene

inflow from cosmopolitan populations. As a consequence, founder populations maintain a relatively homogeneous genetic background that is amenable for genetic studies and novel gene discovery.

Materials and Methods: We have performed exome sequencing in families within two founder populations of Amish and Mennonite ancestry seen for genetic evaluation at the Clinic for Special Children in Strasburg, PA, USA. We sequenced the exomes of the proband, parents, and all available affected and unaffected siblings. We performed pedigree-based variant analyses and segregation in order to identify candidate disease genes.

Results: As expected for founder populations, we identified known and novel recessive disease genes, including a case of two recessive disorders segregating together in this population. In addition, we have also identified several novel genes responsible for previously unreported rare disorders and novel variants in recently reported intellectual disability and developmental delay genes such as ARID1B, SETBP1, PURA, SYNGAP1, among others.

Conclusions: We demonstrate the utility of genomic sequencing in individuals with genetic disorders and their family members to reach a fast and accurate molecular diagnosis and identify novel disease genes in the context of a relatively homogeneous genetic background provided by founder populations such as the Amish and Mennonites. The spectrum of variation observed ranges from autosomal recessive homozygous variants specific to these populations to sporadic de novo variants, often occurring in genes known to be related to intellectual disability.

P11.080

Intragenic CASK deletion found in mosaicism in a female patient

J. Sá, R. Lemos, C. Ventura, S. M. Pereira, J. Pinto-Basto, P. Tavares, P. Rendeiro; CGC Genetics, Porto, Portugal.

CASK gene encodes for calcium/calmodulin-dependent serine protein kinase, essential for normal brain development. Disruption of CASK gene is associated with Mental Retardation and Microcephaly with Pontine and Cerebellar Hypoplasia (MICPCH, MIM 300749), where patients present a remarkably consistent phenotype, including severe intellectual disability/developmental delay, severe postnatal microcephaly and a distinctive facial phenotype.

We report a 2-year-old female infant with a 109 Kbp intragenic deletion in CASK gene found in mosaicism, within approximately 25% of the cells. To the best of our knowledge, this is the first case to report mosaicism in a female carrier of intragenic CASK deletion.

Array CGH was performed on an Affymetrix platform, Cytoscan 750K. Data analysis was performed on CHAS Software, Affymetrix (reference NCBI_hg19). MLPA was performed on peripheral blood following standard protocols.

Patient's clinical report included postnatal microcephaly and reasonable psychomotor development, but slow in the motor area. Neurological examination results were normal. Array CGH revealed a genomic profile with a 109 Kbp deletion at Xp11.4(41,480,031-41,589,514), involving CASK, GPR34 and GPR826 genes. MLPA analysis confirmed a CASK intragenic deletion encompassing exons 4 to 12. Additionally, MLPA also detected a mosaic state of the deletion, in about 25% of the cells, which was not possible to identify on aCGH. Parents were later studied with normal outcome and, therefore, the variant was established as de novo. These results, with high probability, explain the subtle phenotype of moderately slow motor development found in the infant.

P11.081

An infant with a ring chromosome 11 and 11q24 deletion

O. Altıok Clark¹, B. Nur², B. Karaman³, A. Toyul¹, E. Mihci², S. Berker Karauzum⁴;

Turkey, ⁴Akdeniz University School of Medicine Department of Medical Biology and Genetics, Antalya, Turkey.

Ring chromosomes (RCs) are uncommon findings with a frequency of less than 1:30,000, occurring mostly sporadically. Ring formation is caused when both arms of a chromosome break and reunion, leading to the loss of distal segments. Phenotypic abnormalities observed in patients with ring chromosomes may correlate with the deleted regions. Ring chromosome 11 is has only been described in 20 cases in the literature. All of these cases have growth failure and some degree of intellectual disability, in addition to other abnormalities. Herein, we report a 5 month-old infant with 46,XY, r(11)(p15.5;q24?) [47] /46,XY, dic r(11)(p15.5;q24?) [3] karyotype. FISH analysis with subtelomeric probes for 11p and 11q revealed a terminal deletion on 11q. Additionally, array comparative genomic hybridization refined the

deletion to a 8.8Mb region at 11q24.2q25 (126,120,523-134,924,542), with 42 RefSeq genes including disease causing genes such as TIRAP, KIRREL3, ETS1, FL11, KCN1, KCN5, BARX2, ST14, NTM, OPCML, JAM3, ACAD8, B3GAT1. The phenotype is significant for thrombocytopenia, which disappeared spontaneously at 6 months, hypospadias, atrial septal defect, and mild motor retardation which has some overlapping features with Jacobsen syndrome that is associated with 11q23 deletion.

To the best of our knowledge, there have only been 21 cases, including our own, of constitutional RC11 described. Herein we discuss the genes that involved with the deletion and phenotypic features associated with Jacobsen Syndrome.

P11.082

Investigating potential non-Mendelian inheritance patterns in ciliopathies: the case of Joubert Syndrome

I. G. Phelps¹, M. Grout¹, J. Dempsey¹, C. Isabella¹, D. O'Day¹, I. Glass¹, B. O'Roak², J. Shendure¹, C. Center for Mendelian Genomics³, D. Doherty¹, R. Bachmann-Gagescu⁴;

¹University of Washington-Dept of Pediatrics, Seattle, WA, United States, ²OHSU-Molecular & Medical Genetics, Portland, OR, United States, ³University of Washington, Seattle, WA, United States, ⁴University of Zurich- Medical Genetics, Zürich, Switzerland.

Introduction: Non-mendelian inheritance, "triallelism" and digenicity/oligogenicity (=heterozygous variants in ≥2 different JS genes), as well as genetic modifiers, have been reported in various ciliopathies. We investigated their possible occurrence in Joubert syndrome (JS), a ciliopathy characterized by a distinctive hindbrain malformation, and typically caused by biallelic mutations in one of >25 genes.

Methods: We sequenced 25 JS genes in 386 individuals with JS and 175 controls using targeted capture and next-generation sequencing.

Results: Two rare deleterious variants (RDVs) in one JS gene were identified in 248/386 individuals (64%) ("recessively solved patients"). We found no indication of triallelism, since 0/69 unaffected siblings carried the same two RDVs as their affected relative. We identified 24/138 unsolved patients with RDVs in ≥2 JS genes as candidates for oligogenicity, while 14/175 controls carried RDVs in ≥2 JS genes. RDV types and patterns differed between unsolved patients and controls. Finally, we investigated whether additional heterozygous RDVs in JS genes, present in 108/248 (43%) solved patients, acted as genetic modifiers. Pair-wise comparisons between samples sharing identical causal RDVs identified no correlation between number of RDVs and disease severity.

Conclusion: Our data offer little support for triallelism or oligogenicity as clinically-relevant alternative inheritance mechanisms in JS, and the number of additional RDVs in "solved patients" does not correlate with phenotypic severity. In patients with possible oligogenic inheritance, future work will focus on identifying 2nd RDVs in genes with single RDVs and functional work to assess effects of candidate oligogenic and modifier variants.

Grant support: NIH-R01NS064077 and SNSF-PZ00P3_142404/1.

P11.083

Might the inheritance pattern of a syndrome mislead the clinician? Two different syndromes in a patient

E. Isik¹, T. Atik¹, S. E. Keskin², S. Gokben², H. Onay³, O. Cogulu¹, F. Ozkinay¹;

¹Ege University Faculty of Medicine, Department of Pediatrics, Subdivision of Pediatric Genetics, Izmir, Turkey, ²Ege University Faculty of Medicine, Department of Pediatrics, Subdivision of Pediatric Neurology, Izmir, Turkey, Izmir, Turkey, ³Ege University Faculty of Medicine, Department of Medical Genetics, Izmir, Turkey, Izmir, Turkey.

Introduction: Joubert syndrome (JS) and Cowden syndrome (CS) are two different single gene disorders. JS, a rare autosomal recessive ciliopathy syndrome, is characterised by hypotonia, ataxia, developmental delay and oculomotor apraxia. Nineteen genes responsible for the JS have been identified. CS, an autosomal dominant syndrome, is characterised by macrocephaly, subcutaneous lipomas and susceptibility to cancer development. *PTEN* gene mutations are responsible for the CS. In this study, we present a patient who shows clinical features of both JS and CS, and carries mutations in both *AHI1* gene and *PTEN* genes.

Case Report: A five year-old-boy was referred to pediatric genetics subdivision cause of intellectual disability and epilepsy. He was born to consanguineous parents. On physical examination, his weight and height were below the 3rd percentile and where as his head circumference at the 97th percentile. He had generalised hypotonia, macrocephaly and subcutaneous lipomas. On cranial MRI, cerebellar vermis hypoplasia and molar tooth sign were detected. The diagnosis of JS was established and molecular analysis revealed a homozygous c.2742_2744delTCT (p.Leu915del) mutation on the *AHI1* gene, on of the JS genes.

Because macrocephaly and subcutaneous lipomas were unusual for JS, an additional genetic disease, CS, was considered in the patient. Sanger sequencing of *PTEN* revealed a heterozygous novel c.381_385delGGAAA

(p.K128TfsX50) mutation which was inherited from his mother.

Conclusion: In the literature, coincidence of these two syndromes have not been previously reported. This case is presented to emphasize blended phenotypes could be resulted from several concomitant single-gene disorders in the same patient.

P11.084

Kabuki syndrome: a Spanish case series

V. Seidel¹, S. García-Miñaur², E. Vallespín², V. Martínez-Glez², G. Gordo², A. Naughton³, G. Malone³, P. Lapunzina², F. Santos-Simarro²;

¹Clinical Genetics/ Pediatrics, Hospital MI Gregorio Marañón, Madrid, Spain, ²INGEMM-CIBERER, Hospital Universitario La Paz, Madrid, Spain, ³Manchester Centre for Genomic Medicine, Manchester, United Kingdom.

Introduction: Kabuki syndrome is a clinically heterogeneous multiple congenital malformation syndrome with distinctive facial features and developmental delay. Two histone methyltransferase genes have been identified as causes, *KMT2D* and *KDM6A*.

Material and methods: We present 20 cases diagnosed with Kabuki syndrome, seen at two large hospitals in Madrid, Spain.

Results: Age at diagnosis ranged from 5 months to 16 years. 17 cases had a molecular confirmation (16 *KMT2D* and 1 *KDM6A* mutation, all de novo), 2 will be presented in due course and one was negative for both genes. Of the 16 *KMT2D* mutations 11 were truncating. Molecular details will be provided. The combination of congenital anomalies, developmental delay and characteristic facial features was variable but the distinctive eyebrows and long palpebral fissures reminiscent of the Kabuki make-up of Japanese theatre were present in all. Additional features found in our series, rarely or not previously described as part of the syndrome, were trigonocephaly in one case, unilateral corneal opacity and iris coloboma in another, and autoimmune cholangitis in the girl with *KDM6A* mutation. One patient died at 10 years from complications of her heart anomalies. Interestingly, one case with a milder phenotype and not so characteristic facial dysmorphism was found to be a mosaic for a *KMT2D* frameshift mutation c.1275delA (p.Gln425Hisfs*10) in 30-40% of blood.

Conclusions: This is the first series of cases with Kabuki syndrome in Spain. Additional cranial, ophthalmological and hepatic features are shown. A case with mosaicism for Kabuki syndrome is presented.

P11.085

Under the mask of Kabuki-like syndromes: a pilot Czech study

J. Paderova, J. Drabova, A. Holubova, M. Vickova, M. Havlovicova, R. Pourova, M. Malikova, A. Puchmajerova, V. Caganova, A. Krepelova, M. Macek sr., M. Macek jr.; Department of Biology and Medical Genetics, Charles University Prague - 2nd Faculty of Medicine and University Hospital Motol, Prague, Czech Republic.

Introduction: Kabuki (make up) syndrome (KABUK; OMIM 148920) is mainly due to autosomal de novo pathogenic variants. Distinctive facial features and the degree of intellectual disability are broad making its clinical diagnosis difficult even for experienced clinical geneticists, in particular in Kabuki-like phenotypes.

Material and Methods: A representative cohort of Czech KABUK / Kabuki-like patients was examined (2013-2015) by Sanger DNA sequencing, MLPA, array CGH, followed by next-generation sequencing-based (NGS) gene panel assays (TruSight One, Illumina). Correlation of molecular genetic- and cytogenetic test outcomes was compared to the reliability of clinical diagnosis. In addition, 3D digital phenotyping of facial gestalt was carried to further characterise these patients.

Results: In 24 KABUK / Kabuki-like cases pathogenic variants in *KMT2D* were detected in 9 patients. Array CGH revealed likely pathogenic CNVs on chromosomes X and 15, respectively, in 2 patients. NGS detected likely pathogenic variants in genes associated with intellectual disability (*HUWE1*, *GRIN1*), including genes coding for mandibulo-facial dysostosis (*EFTUD2*, *EDNRA*). Nonetheless, in 5 cases their underlying genetic etiology has not been elucidated, while in the remainder familial consent for further testing is pending.

Conclusion: Array CGH and broad NGS-based gene panels have a high diagnostic yield in KABUK/Kabuki-like phenotypes. Genomic testing may foster elucidation of otherwise ambiguous clinical diagnoses. 3D facial gestalt phenotyping proved to be a useful tool for further stratification of such patients and eventual prioritisation of detected variants.

Supported by: 00064203, CZ.2.16/3.1.00/24022OPPK, LD14073 and NF-CZ11-PDP-3-003-2014.

P11.086

KAT6A syndrome: expanding the phenotypic spectrum

P. R. Blackburn, N. J. Boczek, M. A. Cousin, G. J. Beek, E. W. Klee, D. Babovic-Vuksanovic; Mayo Clinic, Rochester, MN, United States.

Introduction: KAT6A syndrome or autosomal dominant mental retardation 32 (MRD32, OMIM#616268) is a novel disorder caused by mutations in the K(lysine) acetyltransferase 6A (KAT6A) gene, characterized by microcephaly, developmental delay, hypotonia, and intellectual disability. So far, only ten children have been reported. We describe a male patient with the c.3385C>T variant who shares many of the same clinical features as well as arthrogryposis multiplex congenita (AMC), previously undescribed in KAT6A syndrome.

Materials and Methods: The patient was born with bilateral cryptorchidism, inguinal hernia, hypotonia and craniofacial dysmorphism. The echocardiogram revealed an atrial septal defect (ASD) and patent ductus arteriosus (PDA). He had contractures of the hands, feet, hips, knees, and elbows. The karyotype and aCGH were normal. Molecular testing for myotonic dystrophy, Prader-Willi syndrome, Rubinstein-Taybi, and Freeman-Sheldon syndrome was negative. Whole exome sequencing revealed a de novo variant in KAT6A.

Results: This is the 4th reported case of KAT6A syndrome with the c.3385C>T (p.R1129*) truncating variant. Given the frequency of this mutation and the fact that it falls within a CpG dinucleotide suggests that it may be prone to spontaneous deamination and likely represents a hotspot mutation in this disorder.

Conclusions: Here we present a new case of KAT6A syndrome in a patient with AMC, thus expanding the clinical spectrum of this newly described disorder. Heterozygous truncating mutations in the related KAT6B gene cause genitopatellar syndrome (OMIM#606170) characterized by congenital contractures of the lower extremities and undeveloped patellae, suggesting that KAT6A and KAT6B may have overlapping roles in development.

P11.087

Diagnosing a rare case of KAT6B related disorder using targeted massively parallel sequencing

T. Szemes^{1,2,3}, J. Radvánszky^{4,2}, D. Ďurovčíková⁵, M. Hikkelová⁶, M. Hýblová^{2,2}; ¹Comenius University Science Park, Bratislava, Slovakia, ²Geneton Ltd., Bratislava, Slovakia, ³Faculty of Natural Sciences, Comenius University, Bratislava, Slovakia, ⁴Institute of Clinical and Translational Research, Biomedical Research Centre, Slovak Academy of Sciences, Bratislava, Slovakia, ⁵Department of Medical Genetics, Slovak Medical University, Bratislava, Slovakia, ⁶Alpha medical Ltd., Bratislava, Slovakia.

Introduction: Say-Barber-Biesecker-Young-Simpson (SBBYS) syndrome and genitopatellar (GTPT) syndrome are clinically similar disorders with certain overlapping symptoms. They are currently considered distinct clinical entities which have been shown to be caused by de novo truncating sequence variants resulting from nonsense and frameshift causing DNA changes in the KAT6B (lysine acetyltransferase 6B) gene.

Materials and methods: Family trio with affected child manifesting serious multiple congenital anomalies with unsettled diagnosis was analyzed using multiple method approach including array-CGH and two commercial gene-panel based MPS assays. Identified genetic variants were evaluated using GeneTalk and HGMD software.

Results: Among several likely benign genomic variants, we were able to identify a de novo truncating c.4592delA (p.Asn1531Thrfs*18) variant in the last KAT6B exon supporting observed phenotypic features overlapping SBBYS syndrome and GTPT syndrome.

Conclusion: We were able to identify a novel genetic variant associated with an overlapping SBBYS syndrome and GTPT syndrome. Our findings also suggest that the clinical distinction between these disorders may be blurred and thus conventional clinical classification can be problematic. Based on our observation we support opinion that disorders associated with KAT6B pathogenic mutations should be referred to as "KAT6B spectrum disorders" or "KAT6B related disorders", rather than their current distinct classification into SBBYS syndrome or GTPT syndrome.

P11.088

An unusual prenatal presentation of Kleeftstra syndrome with congenital diaphragmatic hernia

S. Giangiobbe¹, M. F. Bedeschi¹, F. Ciralli², M. G. Patricelli², C. Cesaretti³, L. Ronzoni², M. Calvello¹, F. Lalatta¹; ¹Clinical Genetic Unit, Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlinico, Milan, Italy, ²Neonatal Intensive Care Unit, Department of Clinical Science and Community Health, Università degli Studi di Milano and Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy, ³Medical Genetic, Molecular Biology and cytogenetics lab., Ospedale San Raffaele, Milan, Italy.

Introduction: Kleeftstra syndrome (KS) is characterized by intellectual disability, hypotonia and distinctive facial features. It can be caused either by a 9q34.3 deletion that includes the EHMT1 gene or by a EHMT1 mutation. Several additional clinical findings have been observed in KS patients. We describe a case of an unusual prenatal presentation of KS with congenital diaphragmatic hernia (CDH), never reported before as part of the KS phenotypic spectrum.

Case description: A 34-year-old woman with unremarkable family and medical history was referred to our department at 21 weeks of gestation of her second pregnancy for genetic counseling. The pregnancy was uneventful until 20 weeks of gestation when morphologic ultrasound detected moderate left CDH, which was then confirmed by a level II scan. CGH analysis on amniocytes revealed a 3,9 Mb de novo deletion on 9q34.2-34.3 that included the EHMT1 gene. A female fetus was delivered vaginally at 35 weeks with a weight of 2100 g and an Apgar score of 9-10. Post-natal echocardiography showed complex cardiac septal and valvular defects. She died a week after from cardiorespiratory failure.

Conclusions: The deletion we detected also encompasses the COL5A1 gene, whose loss likely contributed to the development of CDH. CDH may thus be part of the phenotypic spectrum of KS due to deletions that extend over several genes; penetrance seems incomplete as the two cases previously reported in the literature with similar deletions did not develop CDH. As in our case, CDH presence may have a negative prognostic impact on the syndrome.

P11.089

Kleeftstra syndrome diagnosed in an unusual way

Y. K. Terzi¹, A. Ozcan¹, I. Eroglu², Z. Yilmaz Celik¹; ¹Baskent University Faculty of Medicine Department of Medical Genetics, Ankara, Turkey, ²Baskent University Faculty of Medicine Department of Pediatric Neurology, Ankara, Turkey.

Introduction: Launch of new techniques enabled the diagnosis of genetic disorders more precisely. Every method has its own advantages and disadvantages, thus the diagnostic laboratory uses all methods in an order to make the correct diagnosis. Multiplex Ligation-dependent Probe Amplification (MLPA) analysis is a method used in detection of deletions or duplications of genes. Here we report an 11-year-old boy consulted to our department due to mental retardation and dysmorphic features with a suggested diagnosis of Di George syndrome.

Materials and methods: Peripheral blood lymphocyte cultures were set up as well as DNA isolation and following MLPA analysis.

Results: The boy was the second child of a 41-year-old mother and father. Conventional cytogenetic analysis revealed a normal karyotype. We did not detect deletion of the Di George region during analyses, however we detected a heterozygous deletion of EHMT1 gene which is used as a reference gene in the commercial kit (P250-B2 DiGeorge Lot No: 0614).

Conclusions: MLPA method is a sensitive and handy tool for diagnosis of microdeletion syndromes as well as other conditions that result from genomic imbalances. We diagnosed the patient incidentally while looking for another abnormality. When we re-evaluated the patient after the results, we observed the dysmorphic features were consistent with the diagnosis. Although coincidental findings might be harmful in some circumstances, in this example off-target effect of MLPA help us to make diagnosis.

P11.090

Lacrimo-auriculo-dento-digital syndrome: Description of two families reveals great phenotypic variability

A. Beleza-Meireles, E. Hughes, M. Harrison, D. Josifova; Guy's Hospital, London, United Kingdom.

Lacrimo-auriculo-dento-digital syndrome (LADD) is an autosomal-dominant condition characterised by abnormalities of the lacrimal and salivary glands, teeth and hands. Only about 60 cases have been described in the literature. Mutations in the FGFR2, FGFR3 and FGF10 genes cause LADD syndrome. We report two familial FGF10 related cases and provide literature review.

Case 1 is a 12 year old girl presenting with dry mouth secondary to salivary glands hypoplasia. She also had absent lacrimal ducts, small ears and dental anomalies. Molecular analysis revealed an exon 3 deletion in FGFR10. Her father, who carried the mutation, had blocked tear ducts as a child. His mother and brother have teeth abnormalities. Her cousin through her paternal uncle was independently diagnosed with LADD syndrome.

Case 2 is an 11 year old girl with complete absence of salivary glands, widespread dental decay, obstructed tear ducts, and cognitive and behavioral difficulties on the autistic spectrum. She developed focal seizures secondary to focal cortical dysplasia identified on brain MRI. Her father underwent several surgical procedures to improve the patency of his nasolacrimal ducts in childhood. He was found to have agenesis of the parotid and right submandibular glands, although he was asymptomatic. Both were found to have the p.Arg78Leu mutation in FGFR10.

This report underlines the phenotypical variability that may be present as a result of FGFR10 mutations, ranging from LADD syndrome to aplasia of the lacrimal and salivary glands (ALSG). ALSG and LADD may represent variable presentations of the same clinical spectrum caused by FGF10 mutations.

Introduction: Lacrimo-Auriculo-Dento-Digital syndrome (LADD; MIM# 149730) is extremely rare, with only approximately 60 patients reported to date. It is caused by heterozygous mutations in FGF10, FGFR2, or FGFR3, which result in abnormalities of the eyes, ears, teeth and limbs. Phenotypic expressivity is highly variable and genotype-phenotype correlations are not known. Here, we present the clinical and molecular characterization of a female patient with a novel likely pathogenic variant in FGFR2.

Case Report: The 2-month-old girl was referred to the Medical Genetics consultation due to bilateral agenesis of the thumbs. She had low-set, simple ears and a cup-shaped right ear. Parents reported alacrimia and absence of lacrimal puncta was observed. Lower central incisors were peg-shaped. Clinical diagnosis of LADD syndrome prompted direct sequencing of FGF10, FGFR2 and FGFR3. A novel, de novo heterozygous missense variant was identified in FGFR2 (NM_000141.4): c.1928C>A, p.(Ala643Glu). Ala643 is conserved down to fruitfly and is in the tyrosine kinase domain of the fibroblast growth factor receptor. Bioinformatic prediction tools supported potential pathogenicity of the change. We propose that p.(Ala643Glu) reduces the receptor activity via a dominant-negative effect.

Conclusion: This clinical case expands the spectrum of genetic variants that cause LADD syndrome. The confirmation of the clinical diagnosis enabled precise genetic counselling to the parents. Given a low recurrence risk, in the subsequent pregnancy, they opted to do prenatal diagnosis by ultrasound to exclude major malformations associated with LADD syndrome.

Leri's pleonosteosis associated with a duplication of 8q22.1, a case report from Argentina

S. Menazzi¹, A. P. Solari¹, L. Espeche¹, M. A. Mori², J. Nevado², S. Rozental¹;

¹National Medical Genetics Centre, Buenos Aires, Argentina, ²INGEMM-La Paz University Hospital, Madrid, Spain.

Leri's pleonosteosis is an autosomal dominant congenital rheumatic disease associated with digital anomalies (including contractures and limited motion), facial dysmorphism, chronic pain, short stature, spinal nerve compression and scleroderma-like skin. This entity has been reported in a family with a microduplication of 8q22.1 [Banka et al].

We describe a 36-year-old woman with a duplication of 8q22.1 with facial dysmorphism (short palpebral fissures, hypoplasia of the ala nasi), brachydactyly, growth in 3rd centiles, mild intellectual disability and digital and vertebral anomalies. She did not finish primary school and has a non-specified behavior disorder, and was reluctant to being interviewed or examined. She had 3 healthy siblings with normal phenotype, her parents were non-consanguineous and her mother had similar dysmorphic features. The patient had recently been diagnosed with hypothyroidism, had conductive hearing loss (due to tympanic perforation), a deviated nasal septum and a lumbosacral transitional vertebrae with disc protrusion at L3-L4. Her hands and feet X-ray revealed short and broad phalanges and metacarpals. Karyotype analysis with G-banding and MLPA (SALSA P036 and P070) were

performed, with normal results, and Karyoarray® (Agilent 60K) revealed a 1 Mb duplication of 8q22.1, involving genes GDF6 and SDC2. To the best of our knowledge this is the second case report of the association between Leri's pleonosteosis and duplication of 8q22.1, expanding the clinical spectrum of this disease, and supports the putative genetic basis of this condition. Specialists in these fields (rheumatology and genetics) should be aware of this disease for proper assessment and genetic counseling.

P11.093

A de novo missense mutation in LMNA associated with a segmental progeroid phenotype in a Turkish patient

M. C. Ergoren¹, S. G. Temel^{2,3}, F. Uysal⁴, M. Schotik⁵, J. Altmüller⁶, P. Nürnberg⁶, G. Yigit⁷, B. Wollnik⁸, E. Ciftci⁹;

¹Near East University, Faculty of Medicine, Department of Medical Biology, Nicosia, Cyprus, ²Near East University, Faculty of Medicine, Department of Histology & Embryology, Nicosia, Cyprus, ³Uludag University, Faculty of Medicine, Department of Histology & Embryology, Bursa, Turkey, ⁴Uludag University, Faculty of Medicine, Department of Pediatric Cardiology, Bursa, Turkey, ⁵University of Cologne, Institute for Developmental Biology, Cologne, Germany, ⁶University of Cologne, Cologne Center for Genomics, Cologne, Germany, ⁷University Medical Center Göttingen, Institute of Human Genetics, University, Göttingen, Germany.

Mutations in the LMNA gene encoding lamin A/C are associated with a wide spectrum of phenotypes affecting different tissues and organ systems. The clinical features of these disorders can overlap, however are generally categorized into two groups: dilated cardiomyopathy, neuromuscular disorders; and premature aging, lipodystrophy disorders. The Hutchinson-Gilford progeria syndrome and mandibuloacral dysplasia are segmental progeroid syndromes caused by mutations within LMNA. Dominant LMNA mutations have also been reported in patients with a less well-characterized so called atypical progeroid syndrome.

We report a 15 years old female who initially presented with progeroid features, growth retardation and facial dysmorphism including prominent eyes, full cheeks, marked retrognathia, high arched palate, beaked nose, scleroderma atrophic skin, and sparse thin scalp hair. Additionally, she presented with limitation of extension of both wrists and elbows, and slight scoliosis. Physical examination revealed low weight and short stature and although she has regular menstruation cycles she has poor breast development. Her ECG showed a structurally normal heart, with normal left ventricle diameter and ejection fraction and no sign for dilated cardiomyopathy, but severe tricuspid regurgitation and mild mitral regurgitation. Trio exome sequencing revealed the presence of a de novo heterozygous missense mutation, c.176T>G resulting in a leucine to arginine change at codon 59. Three female patients have been described with a LMNA mutation affecting leucine at position 59; interestingly however, our patient does not show primary ovarian failure and dilated cardiomyopathy as described in the other patients, indicating variable expression of phenotypic presentation.

P11.094

Perinatal presentation of Loey's-Dietz Syndrome due to a novel mutation in TGFRB2. Further delineation of the neonatal phenotype

I. Valenzuela¹, P. Fernandez¹, F. Munel¹, A. Sanchez², G. Giral³, A. Linde⁴, T. Vendrell¹, E. Tizzano¹;

¹Department of Clinical and Molecular Genetics and Rare Disease Unit, Hospital Vall d'Hebron Barcelona, Spain., Barcelona, Spain, ²Department of Neuropediatrics, Hospital Vall d'Hebron, Barcelona, Spain., Barcelona, Spain, ³Department of Neuroradiology, Hospital Vall d'Hebron Barcelona, Spain., Barcelona, Spain, ⁴Department of cardiology, Hospital Vall d'Hebron Barcelona, Spain., Barcelona, Spain, ⁵Department of Neonatology, Hospital Vall d'Hebron Barcelona, Spain., Barcelona, Spain.

Loey's-Dietz syndrome (LDS) is an autosomal dominant connective tissue disorder characterized mainly by cardiovascular, craniofacial and skeletal features.

We report on a patient whose prenatal examination implied the diagnosis of arthrogryposis multiplex congenita and neonatal assessment showed craniofacial and cardiovascular findings that suggested the diagnosis of LDS. The clinical diagnosis was confirmed by detection of a de novo mutation in the TGFRB2 gene c.1381T>C (p.Cys461Arg) previously unreported in databases and predicted to be pathological and deleterious using five in silico predictive programs.

Few prenatal and neonatal cases of LDS have been reported in the literature. Our patient presented aortic root dilatation, arterial tortuosity and musculo-skeletal anomalies. Remarkable craniofacial defects include hypertelorism, blue sclerae, strabismus, bifid uvula and cleft palate. Two interesting findings previously underreported were facial milia and multiple central nervous system cysts mainly in the anterior horns of the lateral ventricles.

We also review the clinical manifestations to delineate a recognizable phe-

notype at this stage. In the published cases with neonatal presentation, aortic root dilatation was the first sign in 30% of patients. In the remaining cases, (70%), muscle and skeletal findings were the initial manifestation. This suggests that when arthrogryposis multiplex congenita is detected in a foetus or in a neonate the differential diagnosis should include the possibility of LDS even though no cardiologic finding at diagnosis. It is important to delineate the clinical manifestations of neonatal LDS to allow a prompt diagnosis and subsequent management to prevent detrimental complications.

P11.095
Delination of a Marker Chromosome by aCGH in a Patient with Undiagnosed Intellectual Disability and Neurodevelopmental Disorder

R. Celik¹, I. Suer², A. Koparr², A. Onul^{1,3}, A. Yüksel⁴, M. Ozen^{3,5,6},
¹Biruni University, Reyhan Genome Center, Istanbul, Turkey, ²Istanbul University, Istanbul Medical Faculty, Department of Internal Medicine, Division of Medical Genetics, Istanbul, Turkey, ³Biruni University, Department of Medical Genetics/Molecular Biology and Genetics, Istanbul, Turkey, ⁴Biruni University, Istanbul, Turkey, ⁵Department of Medical Genetics, Cerrahpasa Medical School, Istanbul University, Istanbul, Turkey, ⁶Department of Pathology and Immunology, Baylor College of Medicine, Houston, TX, United States.

Introduction: Complex small supernumerary marker chromosomes (sSMC) are one of the subgroups of sSMC and consist of more than one chromosome. Identifying the origin of marker chromosome is very important for clinicians to better manage the patients.

Material and Methods: A 32 month-old girl admitted to our center for development disorder and mental/motor disabilities. Conventional cytogenetic technique was used for cytogenetic analysis. aCGH analysis applied by Illumina Human CytoSNP 12 Beadchip.

Results: Patient's clinical features include microcephaly, distinct eye structure, broad nasal root, micrognathia, highly arched palate, and small extremities. Cytogenetic analysis revealed a de novo marker chromosome with an unknown origin. SNP array analysis determined by Illumina Human CytoSNP 12 Beadchip showed two duplications: 12.7 Mb duplication covering 15q11.1-q13.3 and 542 Kb covering 22q11.23-q12.1. According to the Decipher database 15q11.1-q13.3 duplication was reported to be associated with hypotony, deep philtrum, highly arched palate, intellectual disability, hypothalamo-hypophyseal tract abnormalities, seizures and optic atrophy. On the other hand the phenotypic features of 22q11.23-q12.1 were reported as abnormal face and neonatal hypotony.

Conclusion: In conclusion, we were able to determine the source of marker chromosome previously undetermined. We propose a targeted array analysis to uncover marker chromosomes.

P11.096
Additional findings in the Matthew-Wood syndrome

P. Ozyavuz Cubuk¹, L. Ho², B. Reversade², E. F. Percin¹,
¹Gazi University Hospital, Medical Genetics Department, Ankara, Turkey, ²Institute of Medical Biology, Human Embryology Laboratory, A*STAR, Singapore, Singapore, ³Department of Paediatrics, National University of Singapore, Singapore, Singapore.

Introduction: Matthew-Wood syndrome (MWS), also termed microphthalmia, syndromic 9 (MCOPS9, MIM 601186), is an autosomal recessive disorder characterised by ocular, respiratory and cardiac abnormalities. Mutations in retinoic acid 6 gene (STRA6) have been reported in clinically diagnosed patients with MWS. Here we presented a case with MWS, who has characteristic findings of the syndrome as well as dextrocardia and bilateral streak gonads which was not defined previously in this syndrome.

Case: The proband was a stillborn girl baby with normal intrauterine growth. Postmortem examination and autopsy showed that bilateral anophthalmia, bilateral pulmonary agenesis, complete tracheoesophageal fistula, complex cardiac defects, dextrocardia, malrotation of the colon, right cystic renal dysplasia and bilateral streak gonads.

Results: Molecular analysis showed a homozygous exonic missense C>T mutation in STRA6 gene (NM_022369) at coding position 878 (c.878C>T, p.Pro293Leu, rs118203958).

Discussion: It is known that dextrocardia and streak gonads are undefined in patients with MWS to date, but they are a part of PAGOD syndrome which demonstrates significant phenotypic overlap with MWS. The etiology of PAGOD syndrome is unknown but hypothesis that a vitamin A metabolic defect. This situation suggests that these two new findings completely arise as a result of vitamin A deficiency. It should be made the molecular tests in similar cases because of it will not allow to be made differential diagnosis with only clinical diagnosis.

P11.097
A case with Meckel-Gruber syndrome (dysencephalia splanchnocystica) caused by a novel mutation in CEP290 gene.

A. Bakır, V. Topçu, E. S. Çakar,
 Zekai Tahir Burak Education and Research Hospital, Ankara, Turkey.

Meckel-Gruber syndrome (MKS) is a rare pleiotropic autosomal recessive developmental disorder which was first described by Johann Friedrich Meckel in 1822 and G.B. Gruber in 1934. More than 200 cases have been reported worldwide with an incidence ranging from 1:13.250 to 1:140.000. It's characterized with typical manifestations of occipital encephalocele, bilateral polycystic kidneys and post-axial polydactyly. Here, we report a foetus, product of a consanguineous marriage who was demonstrated to have oligohydramnios, encephalocele and multicystic kidney detected by USG in antenatal assessment at the 17th week of gestation. The foetus was diagnosed Meckel-Gruber syndrome (MKS). Parents approved termination of pregnancy due to multiple foetal anomalies. A skin biopsy was taken during postabortal examination. Molecular genetic analysis of fetal DNA using NGS revealed a novel mutation in homozygous condition, c.1915G>T (p.Glu639*), in exon 20 of CEP290. DNA analysis from peripheral lymphocytes of parents showed the same mutation in heterozygous condition.

P11.099
Meier-Gorlin syndrome: GMNN mutations causing autosomal-dominant primordial dwarfism compared to pre-replication complex gene mutations underlying autosomal-recessive primordial dwarfism

E. M. H. F. Bongers¹, S. A. de Munnik¹, J. Schoots¹, L. C. Burrage^{2,3}, S. R. Lalani², W. Charng², J. R. Lupski^{2,3,4}, H. G. Brunner¹, D. Lugtenberg¹, Y. Yang^{2,5},
¹Dept of Human Genetics, Radboud university medical center, Nijmegen, Netherlands, ²Dept of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX, United States, ³Dept of Pediatrics, Texas Children's Hospital, Houston, TX, United States, ⁴Human Genome Sequencing Center, Baylor College of Medicine, Houston, TX, United States, ⁵Exome Laboratory, Baylor Miraca Genetics Laboratories, Houston, TX, United States.

Meier-Gorlin syndrome (MGS) is a genetically heterogeneous microcephalic primordial dwarfism syndrome known to be caused by biallelic loss-of-function mutations in one of five genes encoding proteins involved in DNA replication initiation (ORC1 [origin recognition complex 1]/ORC4/ORC6/ CDT1 and CDC6). Thus far, mutations in these genes with an autosomal-recessive inheritance pattern have been established in about 80% of individuals with primary clinical hallmarks of MGS, including short stature, microtia and small/absent patellae. Recently, we identified *de novo* heterozygous (two truncating and one missense) mutations in *GMNN* by whole-exome sequencing, encoding the DNA replication inhibitor geminin in three individuals fulfilling the clinical diagnostic criteria of MGS. A gain-of-function mechanism was shown to result in autosomal-dominant MGS. The three individuals with *de novo* mutations in *GMNN* demonstrate a more severe growth retardation compared to 38 individuals with pre-replication complex gene mutations, fullness of the peri-orbital region, lumbar hyperlordosis and developmental delay and/or cognitive impairment, a rare finding in autosomal-recessive MGS. Based on the severity of the phenotype, we speculate that *ORC1* and *GMNN* mutations might perturb DNA replication to a greater extent than the other MGS-associated genes, and perhaps *GMNN* mutations have a more profound effect on the replicative burst and cell growth required for brain development, head size expansion, and height. The identification of autosomal-dominant MGS caused by *GMNN* mutations expands the genetic heterogeneity of MGS, helps identifying the molecular etiology in additional individuals, and provides further insights into the relationship between DNA replication, cell growth, and organismal development.

P11.100
Exome sequencing diagnosed a family with two rare recessive diseases

D. Svaneby, M. M. Aagaard, A. B. Bojesen;
 Clinical Genetics Department, Vejle, Denmark.

A non-consanguineous family had four children, two severely affected sons, a healthy son and daughter. The phenotypic characteristics of the affected sons are; severe hypertrophic cardiomyopathy, micro-lissencephaly, seizures, growth retardation, and skin affection. Previous genetic investigation revealed a MYH7B mutation in the first affected son, but no explanation for the brain malformation was found. Despite normal prenatal ultrasound and MRI scans, the second affected son was born. Exome sequencing was then performed to reveal the genetic cause for the micro-lissencephaly. Material and Methods: We performed exome sequencing on the parents and the affected sons. We analyzed data according to inheritance pattern and phenotype defined by HPO terms.

Results: The two affected sons harbor mutations in two genes, both in compound heterozygotic form. Two mutations in MYH7B, a frameshift deletion and a non-sense mutation (chr20:g.33567201C>T and chr20:g.33586952ACAG> -) and two mutations in RTTN, a splice-site and a missense mutation (chr18:g.67813014C>T and chr18:g.67833426T>G). Pathogenic MYH7B mutations have been associated with hypertrophic cardiomyopathy, while expected pathogenic RTTN mutations affecting both alleles have recently been associated with growth retardation and a severe brain phenotype with microcephaly.

Conclusion: We diagnosed two different recessive diseases in two severely affected brothers with a complex phenotype using exome sequencing. In cases with a well-defined phenotype and inheritance but no obvious matching syndrome, two diseases are to be considered. Together, the two recessive diseases can explain the phenotype in this family, highlighting the strength of parents-offspring exome sequencing to diagnose two rare recessive diseases in the same family.

P11.102 Microcephalic osteodysplastic primordial dwarfism type II (MOPDII) with 46,XY complete gonadal dysgenesis: co-occurrence of two rare condition in a single patient

A. Gezdirci¹, T. Akcay², A. Jackson³;

¹Department of Medical Genetics, Kanuni Sultan Suleyman Training and Research Hospital, Istanbul, Turkey, ²Department of Pediatric Endocrinology, Kanuni Sultan Suleyman Training and Research Hospital, Istanbul, Turkey, ³MRC Human Genetics Unit, Institute of Genetics and Molecular Medicine, University of Edinburgh, Edinburgh, United Kingdom.

Background: Microcephalic osteodysplastic primordial dwarfism type II (MOPDII) is a form of microcephalic primordial dwarfism characterized by extreme pre and postnatal growth retardation, severe microcephaly, skeletal dysplasia, abnormal dentition, insulin resistance, and increased risk for cerebrovascular disease. MOPD II is caused by mutations in PCNT, encoding pericentrin, which anchors a wide range of centrosomal proteins and protein complexes during cell division.

46,XY complete gonadal dysgenesis (46,XY CGD) is characterized by a 46,XY karyotype, normal female external genitalia, completely undeveloped (streak) gonads, no sperm production, and presence of normal müllerian structures.

Methods and Results: Here, we report a 12 years old female patient who has severe pre and postnatal growth retardation, severe microcephaly, retrognathia, relatively large nose, high-pitched voice, skin hyperpigmentation, left hip dysplasia, clitoral hypertrophy with diagnosis of MOPDII. Mutational screening of the PCNT gene showed c.3465-1G>A homozygous splice acceptor site mutation. This mutation is highly likely pathogenic variant but which is not described in the literature so far. Interestingly, she has 46,XY karyotype and SRY FISH was found positive. Abdominal MRI revealed hypoplastic uterus and ovaries. We thought that the patient has second genetic etiology for this situation. Whole exome sequencing (WES) is ongoing.

Conclusion: To our best knowledge, this is the first report with combined phenotypes of MOPDII and 46,XY CGD. We present this case because of the coexistence of two rare condition in the same patient.

P11.103 Identification of a heterozygous BUB1B mutation in a family with mosaic variegated aneuploidy syndrome

G. Kayhan, M. A. Ergun, F. E. Percin;

Medical Genetics Department, Gazi University Hospital, Ankara, Turkey.

Introduction: Mosaic variegated aneuploidy syndrome (MVA) 1 is caused by biallelic mutations in the BUB1B gene and characterized by severe microcephaly, developmental delay, increased risk of malignancy and mosaic aneuploidies involving multiple different chromosomes. Also, heterozygous mutations of BUB1B gene cause premature chromatid separation (PCS) trait. Opposite of this classical knowledge, heterozygosity for mutations in the BUB1B gene has been previously identified in 7 unrelated MVA families. Here we present a new MVA family with heterozygous mutation in the BUB1B gene.

Case: The proband was 11-year-old male with severe microcephaly, intellectual disability and Eisenmenger's syndrome. Two siblings with the same findings had died.

Results: Whole exome sequencing identified heterozygous c.C580T (p.R194X) mutation (maternal) in the BUB1B gene. Karyotype analysis showed various aneuploidies in 25% of his cells. The proband, mother and father showed 55%, 35%, 0% PCS cells in the lymphocyte culture, respectively. There was no mutation in the CEP57 gene related with MVA2.

Conclusions: The difference of PCS cells ratio of the proband (55%) and the unaffected mother (35%) shows that there is a relationship between PCS cell ratio and MVA phenotype. PCS cells are generally greater than 50% in MVA patients. Although, authors have focused on that the second allele haplotype 6G3 (26020GT, 1046GA, D15S994) may be associated with the MVA phenotype, G1046A (paternal) polymorphism was determined in the second allele in our proband. So, further studies are needed to clarify the relationship between the BUB1B mutations and PCS/MVA phenotypes.

P11.104 Mosaic 19q12q13.11 deletion associated with mild intellectual disability and congenital malformations

O. S. Kurinnaia^{1,2,3}, S. G. Vorsanova^{1,2,3}, M. A. Zelenova^{2,1,3}, K. S. Vasin^{2,1,3}, I. Y. Iourov^{2,1,4};

¹Research and Clinical Institute for Pediatrics named after YE Veltishev at the Pirogov Russian National Research Medical University, Ministry of Health, Moscow, Russian Federation, ²Mental Health Research Center, Moscow, Russian Federation, ³Moscow State University of Psychology and Education, Moscow, Russian Federation, ⁴Department of Medical Genetics, Russian Medical Academy of Postgraduate Education, Ministry of Health, Moscow, Russian Federation.

Introduction. Since chromosome 19 is one of the most gene-rich in a human genome, most of the rearrangements are severely deleterious or incompatible with life. For instance, chromosome 19q13.11 microdeletion syndrome is generally associated with intellectual disability, speech disturbances, pre- and post-natal growth retardation, microcephaly, ectodermal dysplasia, and male genital malformations. Here, we describe a similar mosaic case.

Materials and Methods. Cytogenetic and molecular karyotyping with bioinformatic analysis were used to address the case of an 8-year-old boy with mild intellectual disability, ADHD, epilepsy, congenital malformations (i.e. pectus excavatum, hydrocele and inguinal hernia, flatfoot, sinus node dysfunction) and facial dysmorphisms (low-set dysplastic auricles, almond-shaped eyes with downslanting palpebral fissures).

Results. A mosaic 19q12q13.11 deletion (29,373,242-34,341,260) was detected in about 70% of the cells (encompassing almost 5 Mb and 20 OMIM genes). Using bioinformatic analysis, we were able to define candidate genes for the index case: *UQCRCF1* (involved in metabolic pathways and neurodegenerative diseases pathways), *CCNE1* (involved in cell cycle, p53 signaling and PI3K-Akt signaling pathways) and *KCTD15* (a negative regulator of AP2-alpha regulating neural crest formation during early development).

Conclusions. Despite the deletion at the 19q13.11 deletion syndrome region, neither the critical region nor most of the described cases have matched the deletion described. Additionally, since there have been no descriptions on similar mosaic deletions, we concluded that this is the first case of mosaic 19q12q13.11 deletion that lead to an atypical neuropsychiatric phenotype. Supported by the Russian Science Foundation (grant: 14-15-00411).

P11.105 45,X/47,XX,+18 mosaicism in a young girl: clinical presentation and different distribution of cell lines in peripheral blood lymphocytes and skin fibroblasts

P. Battaglia¹, A. Capucci¹, I. Loddo¹, A. Tanzariello¹, L. Serra², M. Lanari², O. Calabrese¹;

¹UOC Genetica Medica - AUSL Imola, Imola, Italy, ²UOC Pediatria - AUSL Imola, Imola, Italy.

The female proband, the third child of healthy, unrelated parents, was born at term after an uneventful pregnancy, except mild IUGR during the last month. Birth weight was 2530g, length 45cm (<3°P). Psychomotor development was normal, with mild language delay (first words at 3 years). Menarche occurred at 11 years and 5 months, characterized by menorrhagia. She was referred for clinical and cytogenetic evaluation at the age of 14 because of short stature and anemia.

On clinical examination, height was 135,5 m (<<3°P), weight 50,5kg (50-75°P), occipitofrontal circumference 53cm (50°P).

She presented round face, short neck, thin upper lip, short philtrum, narrow palate, short hands, several nevi on face and trunk, left fourth metatarsal shortening, scoliosis and mild myopia.

Cytogenetic investigation performed on peripheral blood lymphocytes showed the presence of a mosaicism 45,X/47,XX,+18 characterized by two cell lines (85% trisomy 18 and 15% monosomy X), confirmed by FISH analysis. The distribution of cell lines was found to be reversed in skin fibroblasts, where FISH analysis with pericentromeric specific probes showed the presence of three cell lines: monosomy X and trisomy 18 cell lines in 78,3% and 19,6% respectively, and a female normal cell lines in 2,1%.

Constitutional mosaicism for two distinct chromosome aneuploidies is a rare cytogenetic abnormality. Clinical manifestations depend on the distribution of the aneuploid cell lines in different tissues. In our proband, the

prevalence of monosomy X cell lines and the presence of a normal cell line in skin fibroblasts, better correlates with the mild clinical picture.

P11.106

Case report: Tandem duplication in ZEB2 in a patient with suspected Mowat-Wilson syndrome

K. Wittkowski, A. Munzig, M. Ziegler, S. Chahrokh-Zadeh, D. Wahl, I. Rost; Center for Human Genetics and Laboratory Diagnostics (AHC), 82152 Martinsried, Germany.

Mowat-Wilson syndrome is a multiple congenital anomaly syndrome mainly characterized by typical dysmorphic features, severe intellectual disability, microcephaly and Hirschsprung disease. In addition, organic anomalies and seizures are common. Mutations of the ZEB2 gene were identified as disease-causing and haploinsufficiency of ZEB2 has been reported to cause Mowat-Wilson syndrome. The ZEB2 gene encodes a transcription factor which is involved in the development of the neural crest and derived structures.

We report on a 3-year old boy, born to healthy parents, presenting with a complex valvular heart defect, short stature, microcephaly, craniofacial dysmorphism, absent speech and delayed motor development. Initial genetic investigations of Angelman-syndrome (methylation assay, deletion-/UPD-testing, sequencing of UBE3A gene) and Pitt-Hopkins syndrome (sequencing and MLPA analysis of TCF4 gene) revealed negative results.

We performed molecular genetic diagnostics of the ZEB2 gene consisting of Sanger sequencing and MLPA (multiplex ligation-dependent probe amplification) analysis. By MLPA analysis we identified a heterozygous duplication of exon 9. Quantitative PCR confirmed this single exon duplication. Analysis of both parents revealed that the deletion had occurred de novo in the patient. By sequencing an RT-PCR fragment we could demonstrate on RNA level that both copies of exon 9 are arranged in tandem. This duplication results in a translational frame shift and a premature translational termination signal. It has not yet been described in literature and databases. As the tandem duplication of exon 9 of ZEB2 probably leads to loss of function of one allele it is likely to cause the clinical appearance of the patient.

P11.107

PIG-o-pathies, a new cause of mental retardation, hypotonia, seizures and congenital anomalies

E. Zonneveld-Huijssoon, P. M. van Hasselt, A. Bloem, L. de Vries, M. van Haelst, K. Lichtenbelt; UMC Utrecht, Utrecht, Netherlands.

Introduction: Whole exome sequencing reveals increasing numbers of new disease genes. Genes of the GPI-bioanchor synthesis-pathway are being reported as new causes for a number of syndromes. At this moment, at least 10 genes of this pathway are reported in OMIM with a known phenotype.

Methods: We recently diagnosed three patients with a PIG-o-pathy (PIGA, PIGV and PIGN) and applied an immunological assay for the expression of GPI-coupled proteins, which allows for functional testing of variants of unknown significance in GPI-bioanchor genes. Additionally, we made an overview of all clinical features that have thus far been reported in the literature in PIG-o-pathy patients and categorized them based on occurrence and pivotalness for the diagnosis.

Results: The expression of GPI-coupled proteins was reduced in our patient with two PIGN variants of unknown significance. Moreover, this patient showed persistent restricted diffusion in structures in the mesencephalon and diencephalon on brain MRI till 15 months of age. We here show that common features like severe developmental delay, hypotonia, seizures and more distinguishing pivotal features like elevated alkaline phosphatase, vesicourethral reflux, hypoplastic nails and anorectal anomalies are associated with PIG-o-pathies.

Conclusion: An immunological assay can be useful in the interpretation of variants of unknown significance in genes of the GPI-bioanchor synthesis pathway. Moreover, as the common features in PIG-o-pathies are aspecific, the more pivotal features reported here may further help in establishing the diagnosis. Whether the observed brain MRI changes are specific for PIG-o-pathies remains to be elucidated.

P11.108

Nucleotide excision repair diseases : from Nobel prize 2015 to the unravelling of uncommon and incomplete patient phenotypes

N. Calmels¹, M. Spitz², G. Greff³, N. Kempf⁴, S. Samimi¹, C. Obringer³, J. Tarabeux¹, M. Miguet¹, L. Mary¹, D. Bessis⁴, J. Gardeazabal⁵, B. Gener⁶, I. Llano-Rivas⁶, A. Mazur⁷, B. Keren^{8,9}, C. Depienne^{8,9}, J. Muller^{1,3}, J. Mandel¹, V. Laugel^{2,3};

¹Laboratoire de Diagnostic Genetique, Hopitaux Universitaires de Strasbourg, Institut de Genetique Medicale d'Alsace, Strasbourg, France, ²Service de Pediatrie, Hopitaux Universitaires de Strasbourg, Strasbourg, France, ³Laboratoire de Genetique Medicale-INSERM U1112, Institut de Genetique Medicale d'Alsace, Faculte de medecine de Strasbourg, Strasbourg, France, ⁴Departement de Dermatologie, Hopital Saint-Eloi, Montpellier, France, ⁵Servicio de Dermatologia, Cruces University Hospital, BioCruces Health Research Institute, Bizkaia, Spain, ⁶Servicio de Genetica, Cruces University Hospital, BioCruces Health Research Institute, Bizkaia, Spain, ⁷Department of Pediatrics, Pediatric Endocrinology and Diabetes, Faculty of Medicine, University of, Rzeszow, Rzeszow, Poland, ⁸AP-HP, Hôpital de la Pitié-Salpêtrière, Département de Génétique, Paris, France, ⁹Sorbonne Universités, UPMC Univ Paris 06, Inserm, CNRS, UMR 75, U 1127, UMR 7225, ICM, Paris, France.

Compromised nucleotide excision repair (NER) activity (deciphered by Aziz Sancar, 2015 Nobel laureate) causes various autosomal recessive diseases including the cancer-prone disorder xeroderma pigmentosum (XP) and the severe multisystem condition, Cockayne syndrome (CS). Clinical recognition and molecular characterization of these defects remain challenging, due to overlapping symptoms and genetic heterogeneity. Our goal was to develop a single mutation-screening strategy for these diseases.

We set up a NGS assay based on the enrichment of 16 NER-related genes by multiplex amplification coupled with sequencing on PGM(Ion Torrent). We prospectively analyzed the samples from an international cohort of 40 patients referred for suspected NER-related disorder and we compared the corresponding phenotypes to our personal cohort of 126 NER patients previously characterized by classical sequencing.

We identified causative mutations in 43% of cases, including patients with very mild, incomplete or combined phenotypes and uncommon genotypes (Table1). Four unrelated XP patients from the Basque country revealed a common splicing mutation in POLH demonstrating a new founder effect. We also identified two patients linked to the very rarely implicated genes ERCC3(XPB) and ERCC5(XPG).

Targeted NGS is efficient for the molecular diagnosis of NER-related disorders. It is particularly useful for phenotypes with combined features or unusually mild symptoms. Molecular characterization allowed appropriate clinical follow-up of the patients, and helped refining the clinical spectrum of NER diseases. Granted from Agence de Biomedecine.

HGNC gene name (legacy name)	Number of patients	Final diagnosis	New mutations discovered in this study	Distinctive characteristic
ERCC8(CSA)	5	Cockayne syndrome	6	2 patients with unusual mild clinical presentation
ERCC6(CSB)	4	Cockayne syndrome	2	
POLH	4	Xeroderma pigmentosum	2	Founder effect in Northern Spain Refining the clinical follow-up
ERCC2(XPD)	2	Xeroderma pigmentosum		
ERCC3(XPB)	1	UV-sensitive syndrome	1	Mild clinical presentation. Only 9 patients described worldwide
ERCC5(XPG)	1	XP/CS complex	1, the first splicing mutation	Only 20 patients described worldwide.

Diagnostics of neurofibromatosis - atypical cases

J. Štika¹, V. Hořínová²; ¹synlab genetics s.r.o., Prague, Czech Republic, ²Hospital Jihlava, Jihlava, Czech Republic.

Introduction: The occurrence of cafe-au-lait spots (CALs) in the skin is associated with a number of severe clinical syndromes. Among them, the most common is neurofibromatosis type 1 (NF), caused by mutations in the NF1 gene.

Materials and Methods: Two unrelated children, female and male, with multiple CALs but without further clinical signs of NF were examined. The same clinical phenotype was also found in other members of the two families. In these individuals, a mutation analysis of the NF1 gene based on amplicon next generation sequencing (GS-Junior, Roche) with primers amplifying all exons and exon-intron boundaries was performed. Ligated adaptors were used for library preparation.

Results: Two different mutations were found in the two families. In the female proband's family, a previously reported mutation, c.2970_2972delAAT was identified. Similarly to our case, it was reported in connection with atypical NF with CALs with no other signs of clinical disease. In the second family, a new mutation, c.3103delAinsTTTC, segregating with CALs was identified. Conclusion: Two different NF1 mutations were found in two families with atypical NF manifested by multiple CALs not accompanied by other appa-

rent signs of clinical disease. One of them was identified as a new mutation. The result show that patients with multiple CALS with apparently no other signs of NF should be examined for *NF1* mutations.

P11.110

NF1 microduplication in two identical twins: description of the phenotype and comparison with previous described cases

O. Garcia Campos¹, P. Garcia Murillo², A. Verdú Pérez¹, C. Catali²;

¹Neuropediatric service, Hospital Virgen de la Salud, Toledo, Spain, ²Genetic department, Hospital Virgen de la Salud, Toledo, Spain.

Introduction: NF1 deletions are a well-known cause of Neurofibromatosis type 1, due mostly to non-allelic homologous recombination between low-copy repeats on the flanking regions. Despite this mechanism, very few cases of NF1 duplication have been described.

Materials and Methods: Two identical twins came to the attention of the neuropediatric service for developmental and speech delay and minor dysmorphic traits. Additional clinical and instrumental studies were performed. Genetic round-up included standard karyotype and CGH-array. Review of the literature was performed and we attempted comparison of the phenotype of the present cases with similar ones.

Results: Array-CGH detected a small 17q11.2 duplication involving the entire NF1 gene in one twin. MLPA study confirmed the presence of the duplication in her sister. Systematic review of published cases allowed oriented exploration in search of previously described features. We detected partial discordance of the phenotype, i.e. normal enamel and presence of some café-au-lait spots which has not been described before.

Conclusions: Phenotypes associated to NF1 duplication are highly variable and only few unspecific features like global developmental delay are shared by patients. Differences are probably due to small differences in additional microduplicated genes, while other features could be age-related. Extensive follow-up is warranted and, although clinically distinct from its reciprocal NF1 syndrome, careful evaluation of neurocutaneous symptoms is suggested.

P11.111

Molecular screening of NFIX in patients with Sotos-like overgrowth (Malan syndrome): 4 new mutations affecting the DNA-binding domain

I. Dapía, J. Tenorio, G. Gordo, P. Arias, T. Consortium, P. Lapunzina; Medical and Molecular Genetics Institute (INGEMM), Madrid, Spain.

Introduction: The Nuclear-Factor I-X (NFIX) is a member of the nuclear factors-I (NFI) family proteins, involved in gene expression regulation. De novo heterozygous variants in NFIX may cause two different syndromes: Marshall-Smith syndrome (MSS; MIM #602535) or a less severe Sotos-like phenotype, recently proposed to be referred as Malan syndrome (MIM #614753). The overgrowth phenotype (Malan syndrome) has recently been associated to NFIX haploinsufficiency due to point mutations clustered around exon 2 (which encodes the DNA-binding domain) or due to whole gene deletions. Frameshift and splice-site variants around exons 6-8 are thought to be causing a more severe phenotype as they may escape nonsense-mediated RNA decay. To date 25 mutations have been described in association to the MSS phenotype. Only 20 have been reported in relation to the overgrowth phenotype so far.

Methods: We performed molecular analysis of the NFIX gene by conventional sequencing in a group of patients with overgrowth features but unclear clinical diagnosis. The effect of the mutations was predicted "in silico" by different bioinformatics tools.

Results: 5 heterozygous mutations in the NFIX DNA-binding domain were identified, 4 of them not previously reported. The patients showed some Sotos-like clinical features but no NSD1 abnormalities. All patients presented a significant delay in speech.

Conclusions: Genetic testing of NFIX should be considered in patients with Sotos-like features but no NSD1 alterations. To date the number of patients suffering from NFIX-related diseases is scant, thus further studies will be necessary in order to establish a specific clinical phenotype.

P11.112

Clinical exome sequencing: Improving genetic diagnosis of complex diseases

A. Arteche¹, L. Rausell¹, M. Galvez², M. Bermejo¹, M. Lazaro¹, M. Molero¹, A. Gomez¹, L. Cabrera¹, P. Marin-García¹, C. Ruiz¹, J. Garcia-Planells¹, M. Garcia-Hoyos¹;

¹Instituto de Medicina Genómica (IMEGEN), Paterna, Spain, ²Genellpharma, Bogota, Colombia.

The human exome represents 1-2% of the entire human genome and is estimated to contain 85% of the mutations causing Mendelian diseases. Next generation sequencing (NGS) offers rapid sequencing of the whole-exome compared to traditional molecular testing. This undoubtedly, contributes to significant advances in the study of etiology, origins, and causes of complex genetic diseases. NGS gives us the possibility not only to make previously unthinkable genetic diagnosis but also to reduce costs without affecting accuracy.

In this study, we present the genetic characterization of a patient with heterogeneous clinic using whole-exome sequencing (WES).

Our patient is a 12 years-old girl (46, XX), phenotypically characterized by precocious aging since her childhood, hyperelasticity, cutis laxa, and increased susceptibility to fractures. WES was carried out using the TruSight One kit (Illumina) that targets the coding regions of >4,800 genes associated with known clinical phenotypes (12Mb of the genome).

All variants, detected at >20X depth and with >30% of heterozygosity, were annotated and classified according ACMG guidelines, and were prioritized considering our patient's phenotype.

The exome analysis revealed a non-previously reported nonsense change in homozygosity (c.190C>T; p.Gln64*) in the gene GORAB (MIM*607983). This GORAB gene had been previously associated with Geroderma Osteodysplasticum (MIM#231070), an autosomal recessive disease that perfectly matches the phenotype of our patient.

The targeted exome sequencing that analyses all known clinically relevant genes, is a useful tool for the genetic diagnosis in patients with heterogeneous phenotype in whom no clear genetic causes were suspected.

P11.113

Genetic variants near the GREM1 locus are associated with a clinical subtype of nonsyndromic cleft lip and palate

Nonsyndromic clefts are a common birth defect of multifactorial etiology. The most common type is cleft lip, which occurs with or without cleft palate (nsCLP and nsCLO, respectively). The genetic architecture of both types is not yet fully understood.

Here we performed a meta-analysis on genetic and clinical data from three large cohorts and identified strong association between a region on chromosome 15q13 and nsCLP (P=8.13×10⁻¹⁴ for rs1258763; relative risk (RR): 1.46, 95% confidence interval (CI): 1.32-1.61) but not nsCLO (P=0.27). The 5 kb region of strongest association maps intergenically between Gremlin-1 (GREM1) and Formin-1 (FMN1) genes. GREM1 is an antagonist in the BMP4 pathway which has been implicated in facial genesis. Based on analyses of the murine Grem1 expression pattern during embryonic craniofacial development, we further subdivided the nsCLP patient cohort and observed a more than two-fold increase in risk for patients displaying clefts of both the lip and soft palate but with an intact hard palate (RR: 3.76, 95% CI: 1.47-9.61, Pdiff<0.05). Notably, in four of six multiplex-families with rare mutations in GREM1, the rare allele also co-segregated with the clinical subtype. In silico annotation such as chromatin interaction analyses further support GREM1 as plausible candidate gene at 15q13.

This study identified a non-coding region at 15q13 as the second, genome-

wide significant locus for nsCLP, after 13q31. Moreover, the data suggest a genetic contribution to a rare clinical nsCLP entity which specifically involves clefts of the lip and the soft palate which develop at different embryological time points.

Noonan syndrome (NS) is a multisystem disorder caused by mutations in genes encoding elements of RAS/MAPK pathway. The aim of our study was the identification of the molecular defect underlying NS phenotype in Polish patients. The classic Sanger sequencing and next generation sequencing techniques were applied to analyze only selected genes or exome /clinical exome, respectively.

The mutations in *PTPN11*, *SOS1*, *RAF1* and *RIT1* genes were identified in 115, 23, 16 and 7 patients, respectively. Among the identified mutations, several unpublished before were found including: familial variant in *SOS1* - p.Thr734Pro and *de novo* variants in *RAF1*: p.Gly169Arg and p.Gly361Ala. Also two new variants in *RIT1* were found: p.Gly31Arg and p.Lys23Glu in residues affecting protein structure or interaction with GTP/GDP, respectively. Further Sanger sequencing of selected genes revealed the presence of mutation in *KRAS* and *NRAS* genes in 3 and 2 patients, respectively. A novel *de novo* variant p.Glu153Lys in *NRAS* gene was identified.

Till now, the exome/clinical exome sequencing performed for 54 patients allowed to identify molecular cause of the disease in 20 (37%) patients, including variants in genes related to RAS/MAPK pathway (eg. p.Arg366Ter variant in *RASA2*), to other dysmorphic clinical entities like Kabuki syndrome (eg. *de novo* c.4032_4034+1del variant in *KDM6A*) or novel NS candidate genes (eg. familial variant p.Ser247Asn in *LZTR1*). The application of sequencing techniques allows to identify novel potentially pathogenic variants that should be tested with functional (including in silico) studies and/or co-segregation analysis.

Supported from NCN research projects no. 2011/01/D/NZ5/01347 and 2013/09/B/NZ2/03164.

P11.115

Resolving molecular basis of novel phenotype: recessive, dominant and *de novo* disorders segregating in a consanguineous family

P. Le Quesne Stabej¹, H. Williams¹, C. James¹, L. Ocaña¹, M. Tekman², H. C. Stanescu², R. Kleta², Division of Medicine, UCL, D. Morrigh³, A. Calder⁴, M. Bitner-Glindzicz¹;

¹Genetics and Genomic Medicine, UCL Institute of Child Health, London, United Kingdom, ²Division of Medicine, UCL, London, United Kingdom, ³NE Thames Regional Genetics Laboratory Service, London, United Kingdom, ⁴Radiology Department, Great Ormond Street Hospital NHS Foundation Trust, London, United Kingdom.

We report a consanguineous family with four offspring. The mother has non-syndromic hearing loss (NSHL), 1st child has NSHL and craniometadiaphyseal dysplasia (CMDD) - wormian bone type, 2nd child has NSHL only, 3rd child suffers from significant developmental delay with microcephaly in addition to NSHL and 4th child has CMDD - wormian bone type only. We performed whole exome sequencing (WES), linkage analysis and array Comparative Genomic Hybridisation (CGH) on all family members. There is a strong history of hearing loss on the mother's side of family. She is married to her 1st cousin with normal hearing. Whole exome sequencing (WES) identified a deafness-causing splice variant in an autosomal recessive deafness gene *PDZD7* which resides in a linkage region (LOD score 3.6). In the two children diagnosed with a very rare skeletal phenotype (CMDD - wormian bone type), WES unexpectedly disclosed a heterozygous *COL1A1* variant shared between the two affected sibs as the cause of skeletal phenotype. The variant has been previously described to cause two skeletal phenotypes different to the phenotype in this family and was inherited from the apparently

unaffected mosaic father in an autosomal dominant fashion. This is the first report of molecular diagnosis made for CMDD - wormian bone type. Array-CGH detected a *de novo* unbalanced translocation as the cause of microcephaly with severe developmental delay in the 3rd child. WES analyses, linkage and array-CGH enabled accurate molecular diagnosis of three distinctive phenotypes segregating as a dominant, recessive or occurring *de novo* in one consanguineous family.

P11.116

Oculo-auriculo-vertebral spectrum: High-Throughput Analysis

E. Rubinato¹, D. Vozzi¹, I. Gandin¹, A. Morgan¹, A. D'Eustachio², M. La Bianca², V. Pecile², P. Gasparini¹, F. Faletta²;

¹Department of Medical, Surgical and Health Sciences, University of Trieste, Trieste, Italy, ²Institute for Maternal and Child Health IRCCS, Burlo Garofolo, Trieste, Italy.

Oculo-auriculo-vertebral spectrum (OAVS) is a developmental disorder affecting structures derived from the first and second branchial arches during blastogenesis. The phenotype is clinically heterogeneous and it is typically characterised by craniofacial anomalies (ear malformations, hemifacial microsomia, mandible anomalies, orofacial cleft), hearing loss, ocular defects (epibulbar dermoids, microphthalmia) and vertebral defects. There is also a high rate of associated anomalies in other organs/systems such as heart defects, renal and central nervous system malformations. Both genetic and environmental factors are thought to contribute to the OAV spectrum, however, the mechanism and etiology are still poorly understood. Linkage and array analysis have detected several candidate loci for this genetically heterogeneous condition (including deletions, duplications, unbalanced translocations, partial trisomies of chromosomes 7, 8, 9, 10p, 22), but no recurrent chromosomal abnormalities have been identified so far.

The aim of our study is to identify candidate genes potentially involved in the pathogenesis of this condition. To achieve our goal we selected five unrelated patients presenting with the classical OAVS phenotype and without pathogenic Copy Number Variations (CNVs) detected by High-Density SNP-array (HumanOmniExpress BeadChip, Illumina, CA). Then, Whole Exome Sequencing analysis (Ion Proton™-LifeTechnologies) was carried out in all patients. CNV analysis was carried out by CoNIFER (<http://conifer.sourceforge.net>) with a confidence value ≥1.5. Preliminary data shows no possibly pathogenic variants in genes shared by at least three out of five patients. Further analysis are currently undergoing. Updated data will be presented and discussed.

P11.117

Two novel MID1 mutations and the variable expression of developmental delay in X-linked Opitz G/BBB syndrome

N. Maia^{1,2}, M. Nabais Sá^{2,3}, N. Tkachenko³, G. Soares³, I. Marques^{1,2}, A. M. Fortuna^{3,2}, R. Santos^{1,2,4}, A. P. M. de Brouwer⁵, P. Jorge^{1,2};

¹Unidade de Genética Molecular, Centro de Genética Médica Jacinto de Magalhães (CGMJM), Centro Hospitalar do Porto, Porto, Portugal, ²Unidade Multidisciplinar de Investigação Biomédica (UMIB), Instituto de Ciências Biomédicas Abel Salazar (ICBAS), Universidade do Porto, Porto, Portugal, ³Unidade de Genética Médica, Centro de Genética Médica Jacinto de Magalhães (CGMJM), Centro Hospitalar do Porto, Porto, Portugal, ⁴UCIBIO/REQUIMTE, Departamento de Ciências Biológicas, Faculdade de Farmácia, Universidade do Porto, Porto, Portugal, ⁵Department of Human Genetics, Donders Institute for Brain, Cognition and Behaviour, Radboud University Nijmegen, Nijmegen, Netherlands.

X-linked Opitz G/BBB syndrome (XLOS) is a midline multiple congenital condition characterized by facial dysmorphisms such as telecanthus/hypertelorism, broad nasal bridge and cleft lip/palate. Other features are variably present, including heart and anal defects, hypospadias, brain malformations and intellectual disability and/or developmental delay (ID/DD). Extensive inter and intra-familial phenotypic variability was previously described particularly regarding the presence of ID/DD in XLOS patients, even when caused by the same *MID1* mutation. *MID1* has E3 ubiquitin ligase activity that specifically targets protein phosphatase 2A for degradation. Controlling protein phosphatase 2A is essential for proper hippocampus development. To date over 90 different *MID1* mutations have been described and associated with the presence of ID/DD in XLOS patients.

We analyzed the coding sequence of the *MID1* gene in eight male patients, pertaining to six unrelated families, with a clinical suspicion of XLOS. Two novel variants, c.1656del and a *de novo* c.1215_1228dup, were identified in four patients from two families. Interestingly, the patient with the *de novo* mutation did not present ID/DD, showing a global developmental quotient of 110.

A descriptive statistical analysis of the specific clinical features of our two index patients and of those described in the literature with genotypic data (n=103), revealed no correlation between ID/DD penetrance and type of

mutation or affected MID1 protein domain (missense mutations, in the latter). This could indicate absence of an effective phenotype-genotype correlation concerning ID/DD or alternatively insufficient data due to poorly described cognitive deficits in these patients (i.e. full IQ assessment is often missing).

P11.118

OFD1 in males: Congenital heart defects are included its phenotypic spectrum

A. Bouman¹, M. Alders¹, L. van Leeuwen², N. Thuijs³, M. van Maarle¹;
¹AMC, Department of Clinical Genetics, Amsterdam, Netherlands, ²AMC, Department of Obstetrics and Gynaecology, Amsterdam, Netherlands, ³AMC, Department of Pathology, Amsterdam, Netherlands.

Oral-facial-digital syndrome type 1 (OFD1) is an X-linked dominant disorder caused by mutations in the *OFD1* gene. This condition is characterized by facial anomalies and abnormalities of oral tissues, digits, brain and kidneys. Almost all affected patients are female, as OFD1 is lethal in males mostly in the first or second trimester of pregnancy.

Although OFD1 is a disorder of the primary cilia, congenital heart defects are not frequently reported in both males and females with OFD1. Only a few cases were published this far, describing male OFD1 patients with a congenital heart defect.

Here, we present a case of an affected male fetus with a pathogenic hemizygous *de novo* mutation in *OFD1* (c.2101C>T; p.(Gln701*)). Ultrasound examination demonstrated severe hydrocephalus, hypoplastic cerebellum and hypoplastic left ventricle of the heart. The pregnancy was terminated at 16 weeks of gestation. Post-mortem examination of the fetus confirmed previous findings and also demonstrated polydactyly of both hands and one foot.

By presenting this case of a male fetus with confirmed OFD1 and a congenital heart defect, we would like to create awareness that congenital heart defects are included in the phenotypic spectrum of OFD1. This is especially of importance when prenatally multiple malformations are seen and the suspicion of OFD1 is raised, also when the family is unsuspected for OFD1. A clinical summary of this case and previous male OFD1 cases with a congenital heart defect will be demonstrated.

P11.119

LRP5-linked Osteoporosis-Pseudoglioma syndrome mimicking isolated microphthalmia

S. Guntekin Ergun¹, M. A. Ergun¹, G. Gumus Akay², N. A. Akarsu³, F. E. Percin⁴;
¹Gazi University Faculty of Medicine Department of Medical Genetics, Ankara, Turkey, ²Ankara University, Brain Research Centre, Ankara, Turkey, ³Hacettepe University Faculty of Medicine, Department of Medical Genetics, Gene Mapping Laboratory, Ankara, Turkey, ⁴Gazi University Faculty of Medicine, Department of Medical Genetics, Ankara, Turkey.

Introduction: Osteoporosis-Pseudoglioma syndrome (OPGG; MIM 259770) is a rare autosomal recessive disorder manifesting juvenile-onset osteoporosis and blindness. Affected individuals often have multiple bone fractures, particularly in spinal bones. Vision problems affect the retina and named as pseudoglioma since the conditions resemble an eye tumor known as retinal glioma. Mild intellectual disability, hypotonia, abnormal flexible joints or seizures are frequently associated with the disorder. It is caused by biallelic mutations in the *LRP5*. Here we reported a four generation consanguineous family in which three members, ranging between 19 and 28 years, were affected by bilateral isolated microphthalmia.

Materials and Methods: Homozygosity mapping and exome sequencing have been performed to clarify the genetic etiology of the bilateral isolated microphthalmia in this family.

Results: The exome sequencing revealed a homozygous splice-site mutation in *LRP5* (c.2827+1G>A) in the index patient.

Conclusions: Although no osteoporosis or bone fracture history in any of the affected members, dual-energy X-ray absorptiometry revealed osteoporosis in the spine in two examined affected members. Two sisters with compound heterozygous mutations in *LRP5*: c.889dupA and c.2827+1G>A associated with bilateral retinal detachment, microphthalmic eye, retro-lental masses and reduced bone density have recently been reported. Thus, microphthalmia and reduced bone density observed in our family considered to be a component of OPGG syndrome. Taken together our study showed that isolated microphthalmia can be the prominent symptom in a subset of OPGG families and, even no associated findings observed, bone mineral density measurement is essential for appropriate genetic counselling in such cases.

P11.120

Analysis of overgrowth disorders through custom NGS panel of 183 genes (OGLYVAS)

J. Tenorio, G. Gordo, I. Dapía, P. Arias, E. Vallespín, K. Ibañez, J. Silla, Á. Del Pozo, T. Consortium, P. Lapunzina;
 INGEMM, Madrid, Spain.

Introduction: Overgrowth syndromes (OGS) comprise a group of conditions in which growth parameters are above of the mean and are usually accompanied by other clinical manifestations. In some cases, there is high overlapping between different OGS, making essential the molecular diagnosis. Material and Methods: We have designed a custom panel of NGS in which we included: i) genes responsible for any OGS, ii) genes related to the pathways that leads to any disorder that resemble an OGS and iii) genes within a loci implicated in any overgrowth disorders described in the literature. Thus, 183 genes have been included. Eighteen patients, divided into those with clear phenotype but unconfirmed diagnosis (n=3) and those with non-syndromic overgrowth and intellectual disability (n=14) were tested. One sample with known mutation and phenotype has been included as an internal control.

Results: After variants filtering, fourteen mutations have been found in eleven unrelated patients, five of which are causative genes for well-known overgrowth syndromes. Otherwise, nine variants have been found in seven genes which are within a deletion or duplication syndrome with overgrowth and/or genes that act in several growth pathways but without a clear relation between their mutations and phenotype abnormalities.

Conclusions: Custom NGS panel of genes of overgrowth disorders is an extremely cost-effective tool to diagnose those cases in which there is high clinical overlapping between different syndromes and also gives the possibility to find mutation in genes from growth pathways that could explain the phenotype in undiagnosed cases of non-syndromic overgrowth.

Grants: FIS15/1481

P11.121

OVOL2 variants in a syndrome with cleft lip, colonic atresia and other congenital abnormalities

P. J. G. Zwijnenburg, J. M. Weiss, H. J. Meijers-Heijboer, Q. Waisfisz;
 VU university medical center, Amsterdam, Netherlands.

Ultrasound screening at 20+2 weeks showed a bilateral cleft lip in the fetus of a non-consanguineous couple. At 30+5 weeks, a boy was born with normal weight, height and OFC. He suffered from respiratory insufficiency, bilateral cleft lip-palate, a Peters anomaly, right sided aortic arch, severe tracheomalacia and atresia of the transverse colon. Karyotyping, SNP array and analysis of *B3GALT1*, *CHD7* and *ASXL1* was normal. He remained respiratory insufficient and died after 6 weeks.

Shortly after whole exome sequencing (WES) was initiated, mother was pregnant. At 17+1 weeks an ultrasound showed a bilateral cleft lip without other abnormalities and the pregnancy was terminated. A female fetus was born with a bilateral cleft lip-palate. Autopsy showed malrotation and a short ascending colon, cysts in the intestinal wall, uterus bicornis and hemivertebra.

WES analysis revealed compound heterozygous variants in *OVOL2*, c.447C>A p.(Cys149*) and c.538del p.(Cys180Alafs*15) in both sibs. p.(Cys149*) is a nonsense variant in the second last exon, most likely resulting in nonsense mediated mRNA decay. p.(Cys180Alafs*15) causes a premature stopcodon in the last exon and therefore predicted not to result in nonsense mediated decay. To our knowledge, this is the first report on nonsense variants in *OVOL2* in humans. *OVOL2* is considered to play an important role in early embryonic development; *Ovol2*-deficient mice display severe defects including underdeveloped branchial arches, abnormal gut morphology and aberrant vascularization.

Therefore, we consider the nonsense variants in *OVOL2* likely to be causative for this syndrome of bilateral cleft lip-palate, colonic atresia and other congenital malformations.

P11.122

Diagnosis of Pallister Killian syndrome by aCGH analysis

Z. Yilmaz Celik¹, Y. K. Terzi¹, I. Erof², F. I. Sahin¹;
¹Baskent University Faculty of Medicine Department of Medical Genetics, Ankara, Turkey, ²Baskent University Faculty of Medicine Department of Pediatric Neurology, Ankara, Turkey.

Introduction: Array comparative genomic hybridization (aCGH) is a high resolution cytogenetic tool for detection of segmental genomic copy number variations (CNVs). Large numbers of genetic syndromes associated with loss or gain of human genome have been diagnosed by this method. Here we report a one year old girl consulted due to dysmorphic face and hypotonia. Although, conventional cytogenetics revealed a normal karyotype, we iden-

tified a 12p11.1p13.33 copy number gain by aCGH.

Materials and methods: Peripheral blood lymphocytes were used for DNA isolation. aCGH analysis was carried on by Roche NimbleGen 630K array ISCA Plus Cytogenetics array and was analyzed by Nexus 7.5 software. The LSI TEL/AML1 ES Dual Color translocation probe was used for detection of tetrasomy 12p mosaicism.

Results: The girl was the second child of nonconsanguineous parents. She had dysmorphic features including frontal bossing, round face, sparse scalp hair, low-set abnormal ears, wide nasal bridge, short nose, long filtrum, thin upper lip, everted/thick lower lip, short neck. We detected copy number gain on short arm of the chromosome 12 encompassing about 34.5 Mb by aCGH. This data was also approved by FISH. However, FISH analysis revealed that the patient carried 10% mosaic i(12p) in lymphocyte cultures.

Conclusions: As a result the patient was diagnosed as Pallister-Killian syndrome. Peripheral blood lymphocytes were utilized for FISH to confirm diagnosis, so we did not perform invasive skin biopsy. This finding approved the previous reports suggesting that aCGH analysis may be enough to make diagnosis Pallister-Killian syndrome without any invasive applications.

P11.123

Postnatal diagnosis of Pallister-Killian Syndrome after non-invasive prenatal testing

We report on a newborn girl, the second child of healthy parents, born after an uneventful pregnancy. In order to avoid the risk of invasive prenatal diagnostics, a non-invasive prenatal test was performed, excluding trisomies 13, 18 and 21. Furthermore, high-resolution ultrasound at 20-22. week's gestation showed normal results. The parents felt save and were looking forward to give birth to a healthy child. Immediately after birth an increased muscle tone, as well as an anteriorly positioned anus, a duplication of the right great toe and dysmorphic facial features were evident. Audiometry showed moderate hearing disturbance, ultrasound of the heart revealed an atrial septal defect. The sorrowful parents were convinced by the genetic counselor, that further genetic investigations were indicated and agreed to Array-CGH analysis. A mosaic tetrasomy 12p - causative for Pallister-Killian Syndrome - was detected. All symptoms of the child could be assigned to this diagnosis. Further involvement of eyes, skin and lungs could be excluded. The diagnosis of this severe and rare chromosomal disorder was explained to the parents, and their question, whether there had been a diagnostic failure during pregnancy was appeased. Meanwhile the parents feel content with their 6 months old girl and accept her slow but continuous development as well as the decisions they had taken during pregnancy, having undergone various steps of trauma processing and supervision.

P11.124

Deletion of PDKCC gene in a patient with mexoaxial and preaxial polydactyly, complex cardiac defect and facial features of Pallister Hall syndrome

R. D. Clark;

Loma Linda University Medical Center, Loma Linda, CA, United States.

Deletion of the *PDKCC* gene (MIM 614150) at 2p21 has no known phenotypic consequence in humans. However, the mouse homolog of *PDKCC*, *Vlk*, is a hedgehog target that interacts with *Gli3* to regulate chondrocyte differentiation. A patient with suspected Pallister-Hall syndrome had a deletion at 2p21 that included only the *PDKCC* gene suggesting that haploinsufficiency for this gene may mimic a mutation in *GLI3*. The mother was a 33 year old obese G8P4034 with bicornuate uterus and diet controlled gestation diabetes mellitus A1 (HgA1c 5.5) from 30 weeks gestation. The patient was prenatally diagnosed with transitional AV canal, right ventricular hypoplasia, cleft mitral valve with regurgitation and pulmonary valve hypoplasia. Amniocentesis revealed a normal karyotype and microarray. Birth weight was 3476 grams, head circumference was 36.5 cm (98thile). After delivery other anomalies were: macrocephaly, central polydactyly of the left hand, preaxial polydactyly of the hallices, hypoplastic nails, facial dysmorphism, absent gag reflex, increased tone of the upper extremities. Pallister Hall syndrome was suspected clinically but the *GLI3* gene analysis was normal. MRI of the brain showed mildly enlarged ventricles and sulci with irregular gyri. The prenatal microarray report was amended after delivery, identifying a 94 kb deletion at 2p21 of the *PKDCC* gene. Parental microarrays are pending. This is the first report of an abnormal phenotype in a human associated with a deletion of *PKDCC* and it suggests that this gene functions in the same pathway as *GLI3*.

P11.126

Hallmark features of CLAPO syndrome in two patients with PROS phenotype and confirmed PIK3CA somatic mosaic mutations

V. Martínez-Glez¹, G. Gordo¹, L. Rodríguez-Laguna¹, G. Herranz¹, S. García-Minaur¹, F. Santos-Simarro¹, J. López-Gutiérrez², P. Lapunzina¹;

¹INGEMM-CIBERER-IdiPaz-Hospital Universitario La Paz, Madrid, Spain, ²Vascular Anomalies Center, Plastic Surgery, Hospital Universitario La Paz, Madrid, Spain.

PROS (*PIK3CA*-Related Overgrowth Spectrum) comprises a group of segmental overgrowth syndromes caused by somatic mutations in the *PIK3CA* gene, including previously considered separate syndromes such as Megalencephaly-Capillary malformation (MCAP) and CLOVES (Congenital Lipomatous Overgrowth, Vascular malformations, Epidermal nevi, And Skeletal/Spinal abnormalities). However, as somatic mosaicism makes clinical expression variable in severity and location, the complete phenotypic spectrum in PROS is still to be elucidated. On the other hand, CLAPO syndrome (Capillary malformation of the lower lip, Lymphatic malformation of the face and neck, Asymmetry and Partial/generalized Overgrowth), is another rare disease in this group of the overgrowth syndromes, with a highly similar phenotype to PROS, but of unknown cause, although somatic mosaicism is also suspected. Here we describe two patients with multiple clinical and radiological features associated to PROS and confirmed *PIK3CA* mosaic mutations. These patients also show two manifestations not described as part of the PROS spectrum and considered to be the hallmarks of CLAPO syndrome —Capillary malformation of the lower lip and Lymphatic malformation of the face and neck—. Therefore, we report a phenotypic overlap between these two entities and suggest a possible pathogenic association, which should be further explored in patients with CLAPO.

P11.127

In vitro studies with an AKT inhibitor, ARQ092, provide evidence for a new and more effective therapeutic option in PIK3CA Related Overgrowth Spectrum (PROS) patients

D. Locante¹, V. Grossi¹, S. Di Tommaso¹, C. Ranieri¹, R. Bagnulo¹, A. Peserico¹, G. Forte², P. Sanese¹, A. Giglio³, Y. Yu⁴, G. Abbadesse², C. Simone^{1,2}, N. Resta¹;

Introduction: In PROS, *PIK3CA* germline and postzygotic mutations constitutively activate the PI3K/AKT/mTOR pathway causing congenital segmental overgrowth, while are absent in surrounding healthy tissues. mTOR inhibitors are empirically tested in these patients. We aim to assess the effects on PROS patient-derived cells of pathway blockage upstream of mTOR by the potent and selective allosteric AKT inhibitor ARQ 092, an experimental drug with activity and long-term tolerability in many cancer patients, being also tested in Proteus patients.

Materials and methods: We performed targeted deep sequencing of pathway genes in six PROS patient-derived cells to identify causative mutations and immunoblots to assess the phosphorylation status of AKT and its downstream targets (pS6, pPRAS40, pFOXO3a, pBAD, pGSK3 α - β). Anti-proliferative effect of ARQ 092 and PI3K/AKT/mTOR inhibitors (wortmannin, LY294002, syrolimus) was evaluated, with or without serum, in PROS cells from six patients.

Results: ARQ 092 potently inhibited Akt signaling and exerted a strong anti-proliferative effect by inducing cell death more efficiently than comparators, with 50% of surviving cells after 60 hours of treatment with 5 μ M dose.

Conclusions: Our data show that PROS cells are 'addicted' to AKT and PROS treatment benefits more of AKT than mTOR inhibition. Clinical development of ARQ 092 in PROS patients is warranted.

P11.128

PROS spectrum: Two different germline and somatic mutations in PIK3CA in a patient with segmental overgrowth, hemimegalencephaly and vascular malformations

F. López Grondona¹, P. Abenia Auson², P. Fernández Álvarez¹, I. Valenzuela Palafoll¹, M. del Campo Casanelles¹, V. García Pato¹, A. Cueto González², T. Vendrell Bayona¹, M. Borregan Prats¹, L. Martínez Ribot¹, E. Tizzano Ferrari¹;

¹Vall d'Hebron Hospital, Barcelona, Spain, ²Hospital Universitario Miguel Servet, Zaragoza, Spain.

In 2015 the acronym PROS (*PIK3CA* - Related Overgrowth Spectrum) was defined to encompass syndromes characterized by overgrowth, megalencephaly, vascular and skin malformations related with somatic mutations in the gene phosphatidylinositol-3-kinase (*PIK3CA*). We present a patient with

a germinal mutation present in blood, skin, and buccal mucosa and a second somatic mutation present only in overgrowth affected tissues.

A 4-year-old boy with congenital asymmetric macrocephaly, segmental overgrowth and vascular malformations of skin was initially diagnosed as Proteus syndrome (PS). Studies in PTEN and AKT1 were negative and was referred to our Center.

He showed right hemimegalencephaly, polymicrogyria and schizencephaly, right hemifacial overgrowth, vascular malformations, segmental overgrowth in lower extremities and upper limb hypotrophy. Suspicion of related PROS was made and PIK3CA mutations were investigated in blood samples, skin biopsy from two areas of hypertrophy and buccal mucosa.

Results: We amplified exons 8-10 and 21 of PIK3CA (NG_012113.2, NM_006218.2) as hot spot of mutations.

The patient was heterozygous for the germline mutation c.1634A>C, (p.Glu545Ala) + c.1658_1659 delGTinsC (p. Ser553Thrfs*7) in all the analyzed tissues. This complex allele was previously describes as pathological and associated with Cowden and Cowden-like Syndromes. DNA obtained from the hypertrophic areas revealed a somatic mutation c.3139C>T (p.His1047Tyr) previously described in Megalencephaly-capillary malformation (MCAP) patients.

PIK3CA mutations have been described as somatic in mostly PROS cases, except for a few patients with megalencephaly-capillary malformation and germinal mutations. This is the first report of two PIK3CA mutations supporting the double hit hypothesis on the genesis of these phenotypes.

P11.129

Hypomyelinating leukodystrophy-8 and cerebellar hypoplasia with endosteal sclerosis are allelic disorders caused by mutations in POLR3B

M. García-Murias^{1,2}, **M. Sobrido**^{1,2,3}, **A. Schlüter**^{2,4}, **A. Pujol**^{2,4}, **C. Castro-Fernández**^{1,5}, **F. Barros**^{1,2,3}, **P. Blanco-Arias**^{1,2,3}, **P. Cacheiro**^{1,5}, **S. Beltrán**^{6,7}, **M. Gut**^{6,7}, **S. Laurie**^{6,7}, **A. Carracedo**^{2,3,5}, **J. Eiris-Puñal**⁸, **B. Quintáns**^{1,2};

¹Instituto de Investigación Sanitaria, Santiago de Compostela, Spain, ²CIBERER, Madrid, Spain, ³Fundación Pública Galega de Medicina Xenómica, Santiago de Compostela, Spain, ⁴Laboratory of Neurometabolic Diseases, ICREA, IDIBELL, Barcelona, Spain, ⁵USC, Santiago de Compostela, Spain, ⁶CNAG-CRG, Centre for Genomic Regulation, Barcelona Institute for Science and Technology, Barcelona, Spain, ⁷Universita Pompeo Fabra, Barcelona, Spain, ⁸Complejo Hospitalario Universitario, Santiago de Compostela, Spain.

BACKGROUND: cerebellar hypoplasia with endosteal sclerosis (OMIM 213002) is a disease of unknown cause with a few cases published in the scientific literature. Hypomyelinating leukodystrophy-8 (HLD8) with hypodontia and hypogonadotropic hypogonadism (also known as 4H syndrome) is caused by mutations in POLR3B. **AIM:** To describe two patients from the same family with cerebellar hypoplasia and mutations in POLR3B. **CASE REPORT:** A 22 years-old male was diagnosed at the age of 5 with cerebellar hypoplasia and endosteal sclerosis. He had microcephaly, short stature, myopia, dental dysplasia, hypogonadism, scoliosis, ataxia, intention tremor and psychomotor retardation. His 5-years old cousin had myopia, astigmatism, psychomotor retardation, microcephaly, hypodontia, and ataxia. Her brain MRI showed cerebellar hypoplasia and hypomyelination. Endosteal sclerosis was not present in the girl. Whole exome sequencing was carried out in both patients and the unaffected parents of one of them. The patients were compound heterozygous for two likely pathogenic variants in POLR3B: NM_018082.5:c.[1568T>A]+[2974G>A]; NP_060552.4:p.[V523E]+[G992S]. The p.V523E variant has been described in several patients, while the p.G992S variant was not reported previously. All the heterozygous carriers in the family were asymptomatic. **CONCLUSIONS:** Mutations in POLR3B cause cerebellar hypoplasia with endosteal sclerosis. We show that this disease is part of the phenotypic spectrum of the 4H syndrome. This study adds another example to consolidate the cost-effectiveness of whole exome sequencing for the diagnosis of rare diseases, especially when several affected individuals can be analyzed. Introduction: GNAS heterozygous inactivating mutations cause PPHP/POH

or PHP1A depending on the parental allelic origin of the mutation (paternal or maternal, respectively). POH is characterized by progressive ossifications of dermal, skeletal muscle and deep connective tissues during childhood, whilst PHP1A is characterized by resistance to PTH in association with features of Albright Hereditary Osteodystrophy (AHO).

Patients and Methods: First family, 28 years old woman presented with cutaneous calcifications from early childhood followed by deep tissue tumors. Her daughter was neonatally diagnosed with congenital hypothyroidism, but as she grew features of AHO and PTH resistance were noted. In the second family, a 30 years old female presented with cutaneous calcification from infancy which than progressed into deep tissues. Her 3.5 years old son was diagnosed with congenital hypothyroidism, PTH resistance, AHO phenotype and he presented epilepsy with calcification of the basal ganglia. GNAS gene was sequenced in both families.

Results: Molecular analysis of GNAS gene revealed a novel missense mutation (p.Gln19*) in exon 1, in the girl and mother of the first family. In the second family, a novel heterozygous missense mutation was identified in exon 6 of GNAS gene, p.Arg160Pro n the boy and her mother, confirming correlation with the disease.

Conclusions: These results further expand the spectrum of GNAS mutations associated with POH/PHP1A and underline the importance of identifying such genetic alterations to supplement clinical evaluation and genetic counseling.

Cerebral Neoplasms in Proteus syndrome: case report

M. R. Pizzino¹, **I. Loddo**², **M. Crapanzano**¹, **C. Pidone**¹, **M. C. Cutrupi**¹, **S. Briuglia**¹;

¹Dipartimento di Paediatric Science Messina, Messina, Italy, ²University of Messina, Messina, Italy.

Introduction: Proteus syndrome (PS) is extremely rare disease with malformations and overgrowth of different tissues. Prognosis is severe with premature death. It is caused by mosaic mutation of (PI3K)-AKT signaling pathway. Features are asymmetrical overgrowth of limbs, hyperostosis, cerebriform connective nevi, skeletal deformities, benign and malignant tumors, capillary vascular malformations and deep venous thrombosis.

Case report: We report a 15 years girl with a severe expression of PS. She had serious deformities of skull, thorax, arms, hands, feet, macrodactyly, scoliosis, various deep vein thrombosis, ovaries cystadenoma and bullous pulmonary disease. Then she showed progressive respiratory failure, behavior changes, depression, headaches, fatigues. Brain MNR showed severe hyperostosis and two lesions like meningioma, with significant compression on the midbrain, brain parenchyma and cerebral edema, hydrocephalus. The severe progression of lesions determined respiratory failure and patient death.

Conclusion: CNS malformations and meningioma have been previously reported in patients with PS. Because of brain tumor late diagnosis and severe complications, therapy has been extremely difficult and patient died. The PS prognosis varies depending on the severity of complications. Patients should be examined regularly and annual physical examination and radiography is also recommended. An appropriate follow up are most important, but extreme rarity of PS makes very difficult the multidisciplinary approach. **References:**

Instituto de Salud Carlos III (ISCIII), Madrid, Spain, ³qGenomics Laboratory, Barcelona, Spain, ⁴Consejería de Sanidad, Murcia, Spain.

Introduction: Autosomal recessive inheritance accounts for 25% of intellectual disability (ID). Diagnosis can be challenging as clinical presentation is frequently undifferentiated. Whole exome sequencing (WES) is a powerful tool for gene discovery.

Clinical report: We report on two male siblings affected by syndromic ID, born to consanguineous parents of Roma origin, with a previous healthy daughter.

The patients are 15 and 5 years old. The eldest displays moderate ID, no expressive language, hand flapping, hearing loss, ventricular septal defect, vesicoureteral reflux, and a limp due to Perthes disease. The youngest presents with psychomotor delay, epilepsy and growth retardation. Their dysmorphic features include broad nasal bridge, wide mouth with a bow-shaped upper lip, large ears, sacral dimples and deep creases on palms and soles.

Results: WES revealed a homozygous stop variant c.T741A;p.Y247X in the PCDHB10 gene, validated by Sanger. This novel variant was not observed in the variant databases and segregated as expected within the family.

Discussion: We have identified a possible new syndrome characterized by ID, dysmorphic features and palmoplantar lipomatosis, caused by a novel stop homozygous mutation in a gene not previously reported as causal. Although further analysis is necessary, almost all protocadherin family genes are widely expressed in the brain and play important roles in its development and function, what could support its pathogenicity. Due to the association of ID and deep creases, Pierpont, Coffin-Siris and Wiedemann-Steiner syndromes should be regarded as differential diagnoses. Our report emphasizes the clinical utility of WES in patients with undiagnosed ID.

³Commissariat à l'énergie atomique et aux énergies alternatives, CEA Saclay, Gif-sur-Yvette, France, ⁴University of Versailles - St Quentin en Yvelines (UVSQ), Division

of Medical Genetics, Montigny, France, ⁵INSERM, U970, Paris centre de Recherche

Cardiovasculaire-PARCC, Paris, France.

Introduction: Pseudoxanthoma elasticum (PXE) is a rare, autosomal recessive disorder, characterized by ectopic mineralization and fragmentation of elastic fibers of connective tissues, leading to skin, eye and cardiovascular system symptoms. PXE is caused by loss of function mutations in ABCC6, coding a membrane transporter of unknown function.

Methods: A comprehensive molecular analysis of 306 French PXE probands diagnosed using the Phenodex score, was performed (including Sanger sequencing of all exons, Long-range PCR focusing the recurrent multiexonic deletion, and MLPA). Topography of the mutations was analysed, and genotype-phenotype correlation analysis was performed in patients with 2 mutations: group H (haploinsufficient, 2 predicted loss-of-function variants), group M (predicted residual conservation of the transporter function, 2 missense mutations) and group HM (one of each type of variants).

Results: Molecular analysis led to the identification of 142 distinct mutations with 66 novel mutations and a detection rate of 88%. Significant results were found: (1) Mutations distribution was specific to some regions and residues of the transporter (p=0,005), (2) a more severe ocular and vascular phenotype exists in patients in groups H and HM than in group M (p=0,05), (3) renal lithiasis and strokes, which are not included in the Phenodex score, were found respectively in 11 and 10% of cases.

Conclusion: This is the largest cohort ever published and characterized, and we propose a revised Phenodex classification, as well as personalized care and prevention based on the patients' molecular status, enhancing vascular follow-up in patients with complete haplo-insufficiency of the gene.

P11.134

Noonan Syndrome and RAS-MAPK pathway: a road map over the last 45 years in a tertiary hospital

A. M. Cueto-González, T. Vendrell-Bayona, S. Boronat, M. Clemente, F. López-Gronadona, M. Borregan-Prats, L. Martínez-Ribot, E. Tizzano-Ferrari;
Hospital Vall d'Hebron, Barcelona, Spain.

Germline mutations in genes of the RAS/MAPK pathway induced the activation of a cascade of events causing proliferation, differentiation, survival and cell death. Clinical consequences in patients including: short stature, congenital heart defects, facial dysmorphism, developmental delay and ectodermal anomalies among the most significant that are known as RASopathies. We compiled all patients diagnosed with RASopathies during the last 45 years in our Clinical Genetics Department to characterize their phenotype-genotype correlation.

In total we have diagnosed 144 patients with clinical features compatible with RASopathies. In 55 of them we found the causative molecular defect. In 37 patients mutations in PTPN11 were found (4 familial, and a Leopard phe-

notype in one case); 9 patients showed SOS1 mutations (2 familial); 3 had mutations in BRAF (all sporadic cases with phenotype cardio-facio-cutaneous); 1 in the NRAS; 2 in RAF1 (both sporadic); 1 in RIT1 (sporadic) and 1 in SHOC2 (sporadic). CGH array revealed one partial duplication in RAF1 (0,07Mb). A comprehensive phenotype-genotype correlation was performed. Noonan Syndrome is the most frequent diagnosed syndrome with characteristic features that make clinical diagnosis very accurate. However, many of that features overlap with clinical findings described in the other genes in the RAS/MAPK pathway making specific diagnosis more difficult.

P11.135

Spectrum of pathogenic variants and clinical characterisation of a representative cohort of Czech patients with RASopathies

Introduction: RASopathies represent a group of clinically and molecularly intersecting disorders comprising the Noonan syndrome (NS), NS with multiple lentigines (NSML), Noonan-like syndrome with loose anagen hair (NS/LAH), CBL-mutation associated syndrome, cardio-facio-cutaneous syndrome (CFCS), Costello syndrome (CS), neurofibromatosis type 1 (NF1) and Legius syndrome (LS). These clinical entities are due to pathogenic variants in RAS/MAPK signalling pathway genes. Overlap of phenotypic features makes clinical diagnosis challenging, while molecular genetic analysis fosters etiological diagnosis.

Materials and Methods: Targeted analysis of *PTPN11*, *SOS1*, *RAF1*, *RIT1*, *BRAF*, *KRAS*, *MAP2K1*, *MAP2K2*, *HRAS*, *SHOC2*, *CBL*, *RRAS*, *SPRED1* and *NF1* by Sanger -and/or HaloPlex enrichment assay (Agilent Technologies, USA) followed by next generation sequencing (MiSeq platform; Illumina, USA) in a representative group of 162 unrelated Czech cases with clinically diagnosed NS or related disorders, excluding NF1 and LS, was performed.

Results: Altogether, pathogenic variants were found in 69 (42.6%) of all cases and NS confirmed in 59 patients. Four patients were diagnosed with NSML, in 3 cases pathogenic variants indicating CFCS were detected and *HRAS* variants associated with CS were revealed in 2 instances. One patient was diagnosed with NS/LAH. All detected substitutions were missense, one variant in RIT1 is novel.

Conclusion: Molecular, as well as clinical findings, generally correspond to previous studies. Our data facilitate genotype-phenotype correlations and aid clinical diagnosis in this heterogeneous group of disorders.

A family case of Mitchell-Riley syndrome/Martinez-Frias syndrome

M. Sanchez-Gutierrez¹, J. M. Carbonell-Perez¹, J. Saenz-Hurtado¹, E. Galan-Gomez², R. Hernandez-Rastrollo²;

¹Hospital Infanta Cristina, Badajoz, Spain, ²Hospital Materno Infantil, Badajoz, Spain.

Introduction: Mitchell-Riley syndrome/Martinez-Frias syndrome (mrs/mfs) is a rare, autosomal recessive disorder with multisystem involvement and poor prognosis. The Martinez-Frias syndrome is characterized by pancreatic hypoplasia, intestinal atresia, and gallbladder aplasia or hypoplasia, with or without tracheoesophageal fistula. When the patient also presents neonatal diabetes, it is called Mitchell/Riley syndrome.

Materials and methods: We report a family case of Mitchell-Riley syndrome/Martinez-Frias syndrome with a genetic mutation in RFX6. The patient is a healthy pregnant woman in her 26 weeks gestation (G3P2). Her first daughter, born of non-consanguineous gypsy parents, had a pancreatic hypoplasia, intestinal atresia and neonatal diabetes. She died at 17 months. This child was diagnosed of mrs/mfs and showed a homozygous missense mutation on exon 4, c.541C>T, p.R181W. The patient and her couple are heterozygous. Second daughter is heterozygous and showed at birth intestinal atresia that was surgically corrected. In last pregnancy, the fetus showed polyhydramnios and "double bubble" suggestive of duodenal atresia. The fetus showed the homozygous missense mutation, c.541C>T, and the pregnancy was terminated. The sister of the patient died at 15 month age, with neonatal dia-

betes and intestinal atresia. Her couple suffers diabetes type I and intestinal atresia. He has some relatives with intestinal atresia.
Conclusions: Further study of patients with RFX6 mutations should clarify its role in pancreatic, intestinal and enteroendocrine cellular development. Furthermore, it should be investigated on the role of heterozygous mutation in the development of intestinal atresia and DM type I.

De novo heterozygous mutation in ADGRL2 is associated with microlissencephaly and rhombencephalosynapsis

M. Vezain^{1,2}, M. Lecuyer³, A. Laquerrière^{3,4}, V. Dupé⁵, L. Pasquier⁶, L. Ratié⁵, S. Odent⁶, L. Trestard⁷, T. Frébourg^{1,2,8}, B. Gonzalez², P. Saugier-Verber^{1,8,2};

¹INSERM U1079, IRIB, Normandy University, Rouen, France, ²Normandy Centre for Genomic Medicine and Personalized Medicine, Rouen, France, ³ERI28, IRIB, Normandy University, Rouen, France, ⁴Pathology Laboratory, Rouen University Hospital, Rouen, France, ⁵UMR6290 CNRS IGD, University of Rennes1, Faculty of Medicine, Rennes, France, ⁶Department of Genetics, Rennes University Hospital, Rennes, France, ⁷Department of Genetics, Belvédère Hospital, Mont-Saint-Aignan, France, ⁸Department of Genetics, Rouen University Hospital, Rouen, France.

Rhombencephalosynapsis (RS) is a rare cerebellar malformation defined by vermian agenesis with fusion of the cerebellar hemispheres. In most cases, RS presents as a sporadic condition consistent with *de novo* dominant mutations. In sporadic forms, RS occurs in isolation or in combination with other cerebral and extra-cerebral malformations. The association of microlissencephaly with RS has never been reported so far. Moreover, the molecular bases of non-syndromic forms of RS remain unknown.

Using comparative index case-parents exome sequencing strategy, we identified a heterozygous *de novo* missense variant in the *ADGRL2* gene in a fetus affected with RS, microlissencephaly and growth retardation. *ADGRL2* encodes latrophiline 2, an adhesion G-Protein-Coupled Receptor whose exogenous ligand is α -latrotoxin. *In situ* hybridization showed that *Adgrl2* was strongly expressed in the telencephalon, mesencephalon and rhombencephalon at HH12 for chicken embryo and E9.5 for mouse embryo. By using microfluorimetry experiments to evaluate the intracellular calcium (Ca^{2+}) release in response to α -latrotoxin binding, we showed that Ca^{2+} release was significantly reduced in the fetus amniocytes versus wild-type amniocytes from control fetuses at the same developing stage, as well as in HeLa cells transfected with mutant *ADGRL2* cDNA versus wild-type construct. A cell adhesion assay and a wound healing assay demonstrated that the mutation increased cell adhesion properties and reduced cell motility. HeLa cells overexpressing mutant *ADGRL2* displayed a highly developed cytoplasmic F-actin network.

Given the role of LAT-1, the *C. elegans* latrophilin orthologue, in the anterior-posterior tissue polarity pathway, we hypothesize that RS results from abnormal tissue polarity signaling.

Whole exome sequencing of a patient with intellectual disability and without recognizable phenotype yielded a mutation, c.3779+1G>A, in the intron20 splice donor site of CREBBP. Mutations at different positions within the same intron20 splice donor site, were observed in 3 patients clinically suspected as having Rubinstein-Taybi syndrome (RSTS). All mutations were *de novo* and likely disease causing. To investigate a putative difference in splicing between the patient without RSTS phenotype and the three patients with RSTS phenotype, we analysed the effects of these mutations on splicing of the pre-mRNA of CREBBP. As no RNA of patients was available, we generated a new and improved exon-trap vector, pCDNAGHE, and tested the effect of the various mutations on splicing *in vitro*. All mutations lead to skipping of exon20. In one of the patients with an RSTS phenotype there was also some normal splicing detectable.

In conclusion, we describe a patient with a CREBBP mutation with intellectual disability and a phenotype not resembling RSTS. Three other patients in whom the diagnosis RSTS was clinically suspected, also carry a mutation in the same splice donor site. However, the splicing pattern obtained by exon trapping cannot explain the phenotypic differences and suggests the involvement of modifying genes, altering the expressivity of the disease phenotypes.

P11.139

A satellited 15q chromosome: clinical, cytogenetic and molecular characterization

S. Massara¹, C. Ruggiero¹, L. Espeche¹, V. Cazayous², V. Qualina², L. Furfuro¹, S. Rozental¹, C. Sargiotto¹;

¹Centro Nacional de Genética Médica, Buenos Aires, Argentina, ²Hospital El Cruce, Florencio Varela, Argentina.

Nucleolar organizer regions and satellites are located on the short arms of acrocentric chromosomes. There are several reports of satellited non-acrocentric chromosomes. Sometimes, the ectopic NORs are attached to a terminal chromosome band as a result of balanced or unbalanced rearrangements that, depending on the particular type of rearrangement and the chromosomes involved, will be associated with phenotypic abnormalities or constitute rare familial polymorphisms.

Up to our knowledge, the present report describes the most distal 15q terminal deletion informed to date and the second associated with NOR translocation.

We report on a 21 years old patient with short stature and mild intellectual disability. The patient presented IUGR, hip dysplasia, feeding difficulties. Clinical assessment showed nail hypoplasia, widening halux, cubitus valgus and venous sinus corona radiata. She failed to complete first school.

The GTW (550 bands) banding technique showed a terminal deletion at 15q26.3 and NOR staining confirmed the presence of ectopic stalks. MLPA technique confirmed the subtelomeric deletion and arrayCGH analysis revealed that the anomaly involved a 4.6 Mb deletion. Parental karyotypes were normal.

It is difficult to establish a phenotype / genotype correlation due to the few reported cases of 15q terminal deletion. Pre and postnatal growth retardation seem to be a regular clinical feature and could be related to haploinsufficiency of the IGF1R gene. We emphasize the value of the right combination of cytogenetic and molecular techniques for the characterization of NORs ectopic regions.

P11.140

Somatic mosaic mutation in SETBP1 identified in the mother of a girl with Schinzel-Giedion syndrome

T. Vendrell Bayona¹, P. Fernandez Alvarez², A. Cueto¹, F. Lopez¹, M. Borregan¹, L. Martinez¹, M. Lines³, L. Carrasquill⁴, E. Tizzano¹;

¹Department of Clinical and Molecular Genetics and Rare Diseases Unit, Hospital Vall d'Hebron, Barcelona, Spain, Barcelona, Spain, ²Department of Clinical and Molecular Genetics and Rare Diseases Unit, Hospital Vall d'Hebron, Barcelona, Spain, Barcelona, Spain, ³2- Department of Pediatrics, Neonatology Section, Hospital Vall d'Hebron, Barcelona, Spain, Barcelona, Spain, ⁴Endocrinology and Nutrition Department, Vilanova University Hospital, Barcelona, Spain.

Introduction: Schinzel-Giedion syndrome (SGS) is a severe congenital condition affecting many body systems. Manifestations include distinctive facial features, neurological problems, hydronephrosis, typical skeletal malformations, genital and cardiac anomalies. It is very rare, although the exact prevalence is unknown.

SGS is usually caused by *de novo* mutations in the SETBP1 (18q21.1), probably resulting in a gain-of-function or dominant-negative effect. Children with this condition have a higher risk of developing certain types of tumours including sacrococcygeal germ cell tumours.

We report on a girl with SGS caused by germinal mutations in the SETBP1 gene inherited from his mother who showed a somatic mosaicism.

Material and methods: The girl was diagnosed neonatally by her manifestations: coarse face with midface retraction, bilateral hydronephrosis, and skeletal anomalies. The mother was 34 year old with diabetes and a history of neonatal malignant sacrococcygeal teratoma. SETBP1 was analyzed by Sanger sequencing.

Results: The study revealed a heterozygous transition in SETBP1 resulting in a substitution at a highly conserved residue: c.2605A>C (p. Ser869Arg). The mutation was not found in other patients or in databases variants in the general population.

The mutation study in the mother showed different levels of somatic mosaicism ranging from 37% in blood and buccal cell samples to 6% in urine. **Conclusions:** SETBP1 is constitutionally mutated in developmental disorders and somatically mutated in cancer. We present the first molecularly documented evidence of germline and somatic mosaicism for a STBP1 mutation, identified in the mother of a child with Schinzel-Giedion syndrome.

P11.141

A novel splicing site mutation of PLK4 that is required for centriole biogenesis and genomic stability causes Seckel Syndrome.

T. Dincer¹, G. Budak², C. Semerci³, A. Ölmez⁴, Y. Dodurga⁵, M. Özmert⁶, B. Toraman¹, A. Yıldırım⁷, H. Ergin⁸, A. Alver⁹, N. Akarsu⁸, E. Kalay¹;

¹Department of Medical Biology, Faculty of Medicine, Karadeniz Technical University, Trabzon, Turkey, ²Department of Medical Biology, Institute of Health Science, Karadeniz Technical University, Trabzon, Turkey, ³Department of Medical Genetics, Pamukkale University Medical Faculty, Denizli, Turkey, ⁴Department of Pediatric Neurology, Denizli State Hospital, Denizli, Turkey, ⁵Department of Medical Biology, Pamukkale University Medical Faculty, Denizli, Turkey, ⁶Department of Neonatology, Pamukkale University Medical Faculty, Denizli, Turkey, ⁷Department of Medical Biochemistry, Faculty of Medicine, Karadeniz Technical University, Trabzon, Turkey, ⁸Gene Mapping Laboratory, Department of Medical Genetics, Hacettepe University Medical Faculty, Ankara, Turkey.

Seckel syndrome is a genetically heterogeneous rare autosomal recessive disorder characterized by severe prenatal and postnatal growth retardation, severe microcephaly with mental retardation and a characteristic 'bird-headed' facial appearance. Up to date, eight genes have been associated with Seckel syndrome of which their encoding protein participates in DNA damage response, genomic stability, centriole biogenesis and centrosome function such as mitotic spindle organization and mitotic progression. Using genome-wide SNP array genotyping and homozygosity mapping we mapped Seckel syndrome to chromosomal region 4q26.1-q26.3 in a Turkish family. Direct sequencing of PLK4 (Polo-Like Kinase 4) gene, which encodes a master regulator of the centriole biogenesis, revealed a homozygous splicing acceptor site transition resulting in hypomorphic premature translation termination mutation (p.Asp11Profs14Stop). PLK4-Seckel fibroblasts obtained from patient showed impaired centriole biogenesis and disrupted mitotic morphology. Moreover, G2/M delay and extended cell doubling time were observed. Further evaluation of the PLK4-Seckel cells showed that PLK4 is also essential for genomic stability and DNA damage response that are required for proper development of organism.

P11.142

Detection of low level somatic mosaic mutations in a gene panel for segmental overgrowth.

M. Alders, M. A. Haagmans, O. R. Mook, M. M. A. M. Mannens, H. J. Blik; Department of Clinical Genetics, Academic Medical Center Amsterdam, Amsterdam, Netherlands.

Somatic mutations in genes of the PI3K/AKT/mTOR pathway causing segmental overgrowth may be present in very low percentages. This can hinder the identification of causal mutations. Sanger sequencing, but also standard NGS diagnostic pipelines, are able to identify mosaic mutations with a detection limit of approximately 10%. Targeted analysis of specific sites is most commonly used for a more sensitive detection of mutations. With the growing number of known causal mutations there is a need for a high sensitive mutation scanning method to analyze the complete coding sequences of the genes involved rather than analysis of hotspots. We have developed a NGS based gene panel test for segmental overgrowth (AKT1, AKT3, MTOR, PIK3CA, PIK3R2, PTEN, TSC1 and TSC2), especially for the detection of low level mosaicism. Samples are sequenced with high coverage (average 1500-2000 reads, minimum 500 reads) and an analysis pipeline was developed that is able to detect mosaic mutations as low as 1%.

P11.143

Clinical Evidence of Crossover in the SHOX Gene

E. Göktas, A. G. Zamani, M. S. Yildirim; Department of Medical Genetics, Meram Medical Faculty, Necmettin Erbakan University, KONYA, Turkey.

Mutations of the SHOX gene are common cause of various genetic growth disorders, including isolated short stature, L'eri-Weill syndrome and Langer syndrome. L'eri-Weill syndrome characterized by short stature, mesomelia and Madelung deformity.

We describe 10y old girl with disproportionate short stature and mesomelic shortenings of the limbs. On X-ray examination shortening of the distal portion of the extremities and deformity in distal epiphysis of radius was seen. The patient was diagnosed L'eri-Weill syndrome together with the clinical findings and SHOX FISH analysis planned. The index patient's father, sister and paternal aunt showed disproportionate short stature and mesomelic shortenings of the limbs but her brother was normal stature. Their chromosome analyses were normal but metaphase FISH with a SHOX-specific probe showed a deletion of the SHOX gene on the X chromosome in the female index patient, her sister and her paternal aunt but in the index patient's father FISH showed a SHOX deletion on the Y chromosome.

The deletion was originally located on the father's Y chromosome but transmitted to daughter's X chromosome by crossover during meiosis. The index patient's sister and paternal aunt have SHOX deletion on X chromosome. Interestingly, the index patient's brother FISH analysis was normal. This means that a crossover has occurred between the X and Y chromosomes in the father's spermatogenesis. After crossover, the father transmitted X chromosome with SHOX deletion to both daughters but transferred normal Y chromosome to son.

This family is presented as clinical evidence of crossover in the SHOX gene.

P11.144

Hepatoblastoma in a female with Simpson Golabi Behmel Syndrome: should we monitor females with SGBS as we do for males?

D. Hays¹, E. Amouyal¹, Y. Capri¹, S. Rossignol², C. Baumann¹, A. Verloes¹, L. Perrin¹; ¹Robert Debré Hospital, APHP, Paris, France, ²Trousseau Hospital, APHP, Paris, France.

Simpson Golabi Behmel Syndrome (SGBS) (OMIM 312870) is a X-linked syndrome characterized by pre- and post-natal overgrowth, macrocephaly, characteristic facies, organomegaly, variable congenital malformations, mild/moderate intellectual deficiency and increased tumoral risk. It is caused by point mutations or genomic rearrangements in the glypican 3-gene (GPC3). We report on two girl sibs and their mother with SGBS. The first girl was born without macrosomia. She had a macroglossia that spontaneously regressed. She died from post-surgical complications of a hepatoblastoma at age three. Her sister was born after a pregnancy marked by polyhydramnios. She had macrosomia, macroglossia, nephromegaly and diffuse hepatomegaly. Wiedemann Beckwith syndrome was excluded. A novel c.213_214insC heterozygous missense insertion (p.Q23TfsX46) was identified in exon 1 of GPC3 by Sanger sequencing in the family. X inactivation was not biased. The patient is currently followed on a yearly basis with abdominal ultrasound scan, and screened for tumoral markers and urinary catecholamins. The mother is asymptomatic.

Females with mutation in GPC3 can express SGBS. Dysmorphic features, macrosomia, diaphragmatic hernia, and developmental delay have been reported. Lyonisation has been proposed as the underlying mechanism for variable expression of SGBS in female patients (Yano 2011). SGBS predisposes to embryonal tumors. In males, the risk has been estimated at 8% (Cottreau 2013). Cancers were only reported in two affected females: one low-grade ovarian carcinoma, and one breast cancer. Guidelines for neoplasia screening have been proposed for males. Observation of hepatoblastoma in females with SGBS raises the question of applying the same policies in both sexes.

P11.145

A de novo mutation in the SNAP25 gene in a patient with epileptic encephalopathy, hypotonia and contractures identified by trio-based exome sequencing

H. Gabriel¹, S. Fehr¹, P. Stoebe¹, K. Hoertnagel¹, S. Biskup¹, C. Schell-Apacik²; ¹CeGaT, Tuebingen, Germany, ²Praxis f. Humangenetik, Berlin, Germany.

The Synaptosomal-associated protein-25 (SNAP25) is part of the SNARE protein complex which is involved in the release of neurotransmitters. So far, only two patients with mutations in SNAP25 have been described in the literature by whole exome sequencing: Rohena et al. (2013) identified a de novo SNAP25 mutation in an 15y old patient suffering from hypotonia, MR and epilepsy, and more recently, Shen et al. (2015) describe an 11y old patient who was suffering from MR, joint contractures, weakness and ataxic dysarthria. Exome sequencing revealed a de novo SNAP25 missense mutation. Here we describe a third patient with a de novo SNAP25 mutation. The patient was stiff at birth and had multiple joint contractures. First seizures were observed at the age of 2m. Epileptic encephalopathy was suggested after MRI imaging. He died at the age of 1y. As the result of the complex syndromal phenotype of the patient, trisomy 18 was suggested, however karyotyping and array-CGH testing showed a normal karyotype. Multiple genetic disorders were then suspected. Sequencing of a set of genes involved in these syndromes revealed no causative mutation. Finally, trio-exome sequencing was performed in an attempt to identify a genetic cause. We were able to identify a de novo SNAP25 mutation, p.Ile192Asn, which was predicted "pathogenic" by prediction tools. With this report we support the pathogenicity and demonstrate the clinical variability of SNAP25 gene mutations. Further, to our knowledge, this is the first patient combining the two major symptoms; contractures and epilepsy.

P11.146

Subnuclear re-localization of SOX10 and p54NRB correlates with a unique neurological phenotype associated with SOX10 missense mutations: genotype/phenotype correlations?

S. Marlin¹, A. Kavó², S. Gherbi¹, A. Chaoui², A. Jacquette³, V. Bara¹, R. Touraine⁴, Y. Watanabe², L. Lecerf⁵, M. Holder⁶, R. Mendoza-Londono⁶, V. Pingault², **N. Bondurand⁷**; ¹Centre de Référence des Surdités Génétiques, Département de Génétique, Paris, France, ²INSERM, Creteil, France, ³Service de Génétique, Hôpital Pitié-Salpêtrière, Paris, France, ⁴Service de Génétique, CHU Saint Etienne, Saint Etienne, France, ⁵Guy's et St Thomas's Hospital, London, United Kingdom, ⁶The Hospital for Sick Children and University of Toronto, Toronto, ON, Canada.

SOX10 is a transcription factor with well-known functions in neural crest and oligodendrocyte development. Mutations in SOX10 were first associated with Waardenburg-Hirschsprung disease (WS4; deafness, pigmentation defects and intestinal aganglionosis). However, variable phenotypes that extend beyond the WS4 definition are now reported. The neurological phenotypes associated with some truncating mutations are suggested to be the result of escape from the nonsense-mediated mRNA decay pathway; but no mechanism was suggested for missense mutations, of which approximately 20 have now been reported. Here, we present two sporadic and one familial cases with mutations affecting the proline 175 of SOX10, presenting with WS2 (WS without HSCR) and an unusual peripheral and central progressive neurologic phenotype, including psychiatric diseases. Interestingly, these mutations, as well as one affecting the adjacent amino acid, all lead to specific subnuclear relocalization of the resulting proteins in vitro. Indeed, mentioned mutants co-localize in foci with the Drosophila behavior human splicing (DBHS) protein family members, including p54NRB, known as a paraspeckle marker and new SOX10 partner. Of note, the co-transfection of wild-type and mutant SOX10 constructs led to the sequestration of wild-type protein in observed foci and altered synergistic activity between SOX10 and p54NRB. We propose that such dominant negative effect may contribute to or be at the origin of the unique progressive and severe neurological phenotype observed in affected patients. This new molecular/cellular mechanism could underlie the unique phenotype associated with some SOX10 missense mutations, and possibly other genes involved in related or unrelated pathologies.

P11.147

Multigenerational Family with STAR Syndrome: A Novel FAM58A Variant and an Expansion of the Phenotypic Spectrum

N. J. Boczek¹, T. Kruisselbrink, M. A. Cousin, P. R. Blackburn, E. W. Klee, R. H. Gavrilova, B. C. Lanpher; ¹Mayo Clinic, Rochester, MN, United States.

Introduction: STAR syndrome is a rare X-linked disorder characterized by toe Syndactyly, Telecanthus, Anogenital malformations, and Renal malformations (OMIM: 300707). There are only ten cases described in the literature, all of which have loss-of-function variants in *FAM58A*. Seven of these cases have a de novo variant in *FAM58A*, while there are only two inherited mother-daughter pairs described.

Materials and Methods: The patient was delivered at term and was noted to have ductus arteriosus, bicuspid aortic valve, and bilateral 3-5 toe syndactyly at birth. She is currently 8 years of age and has a history of tethered cord, neurogenic bladder, learning differences, esotropia, and unilateral sensorineural hearing loss. The patient's mother and maternal half-sister have similar clinical histories with congenital heart defects, syndactyly, and anogenital malformations; however there are differences in phenotypic severity. Clinical whole exome sequencing (WES) was completed at Baylor Miraca Genetics to identify the genetic syndrome in this family.

Results: WES revealed a novel variant, c.651G>A (p.W217X), in *FAM58A*, identified in both the patient's mother and half-sister as well. This family represents the 11-13th cases described with STAR syndrome, and represents the third instance of familial inheritance.

Conclusions: To our knowledge, this is the first instance of a nonsense variant in *FAM58A* described in patients with STAR syndrome, and represents the third family with inherited disease. This family highlights that tethered cord and hearing loss should potentially be added to the phenotypic spectrum of STAR syndrome and shows the phenotypic variability of this syndrome amongst family members.

P11.148

A Further Family Of Stromme Syndrome Carrying CENPF Gene Mutation: Confirming The First Stromme Gene Description Study

F. Ozkinay¹, T. Atik¹, E. Isik¹, Z. Gormez², M. Sagiroglu², O. Atana Sahin³, N. Corduk⁴, H. Onay⁵;

¹Ege University, School of Medicine, Department of Pediatrics, Subdivision of Pediatric Genetics, Izmir, Turkey, ²Informatics and Information Security Research Center, TUBITAK-BILGEM, Kocaeli, Turkey, ³Acibadem University, Institute of Health Sciences, Biochemistry and Molecular Biology, Istanbul, Turkey, ⁴Pamukkale University, Department of Pediatric Surgery, Denizli, Turkey, ⁵Ege University, School of Medicine, Department of Medical Genetics, Izmir, Turkey.

Background and Aims: Stromme syndrome is an extremely rare genetic disorder characterized by microcephaly, anterior ocular chamber anomalies and "apple peel" type jejunal atresia. Here we report a Stromme Syndrome family with two affected siblings whose whole exome sequencing (WES) results revealed a homozygous truncating frameshifts mutation in CENPF gene. This family confirms very recent gene identification study reported by Filges et al.

Case: A 3-month-old girl was hospitalized due to prenatally diagnosed microcephaly, microphthalmia and dysmorphological features. Parents had a history of previous child with the same findings and "apple peel" intestinal atresia as an additional finding.

Regarding the clinical features of both affected siblings, the diagnosis of Stromme syndrome was established. WES of these two cases showed the homozygous mutation (c.5912_5913insA)/(p.T1974Nfs*9) in CENPF gene (RefSeq NM_016343.3; MIM#600235) as the most probable defect underlying the syndrome. Both parents were heterozygous for the mutation.

Conclusions: During our confirmation studies with another Stromme case, Filges et al. reported that CENPF gene is responsible for Stromme syndrome. This is the second report that the CENPF mutations cause Stromme syndrome.

P11.149

Unusual phenotypic features in the presentation of rare chromosome 6q subtelomeric microdeletion

H. M. Kathom¹, D. Avdjieva-Tzavella¹, S. Bichev², B. Karashova¹, R. Tincheva¹, A. Savov²; ¹Department of Clinical Genetics, University Pediatrics Hospital, Medical University Sofia, Sofia, Bulgaria, ²National genetics laboratory, Sofia, Bulgaria.

Introduction: Subtelomeric microdeletions are found to be major reason for psychomotor retardation and dysmorphism. Some such as 6q terminal microdeletion are very rare. Patients with this microdeletion present mainly with microcephaly, short neck, broad nose, psychomotor retardation, hypotonia and seizures, and retinal anomalies.

Materials and Methods: We report on a 9 years old girl, with unilateral choanal atresia, eye leucoma, facial dysmorphism, and muscular hypertonia at birth. Since 3 months of age she developed an epilepsy. At 9 years of age she presented with: severe mental retardation, short stature, microcephaly, low weight, low frontal and occipital hair lines, narrow forehead, downslanting palpebral fissures, "beak-like" nose, short, broad and slightly flattened philtrum, maxillary prognathism, high arched palate, low set ears, long neck with retroflexion, deformed chest, thoracolumbar scoliosis, long fingers and toes (arachnodactyly), and increased muscle tone. A screening for most common microdeletions, subtelomeric deletions and duplications, was performed using multiplex ligation-dependent probe amplification. Commercial MLPA kits (MRC-Holland) were used for detecting imbalance at the subtelomere regions of chromosomes; each kit consists of one probe for each subtelomere.

Results: A 6q terminal subtelomeric microdeletion was found, involving the *PSMB1* gene.

Conclusions: In rare subtelomeric deletions is quite hard to establish clear phenotype-genotype correlation, as very small differences in the length of the affected region could change the spectrum of presented features. Our case is specific because of the lack of hypotonia, short neck, broad nose, retinal abnormalities, which are considered so far as major presentations of 6q subtelomeric deletion syndrome.

Objective: We aimed to delineate the neurodevelopmental spectrum associated with SYNGAP1 mutations and to investigate genotype-phenotype correlations.

Methods: We sequenced the exome or screened the exons of SYNGAP1 in a total of 251 patients with neurodevelopmental disorders. Molecular and clinical data from patients with SYNGAP1 mutations from other centers were also collected, focusing on developmental aspects and the associated epilepsy phenotype. A review of SYNGAP1 mutations published in the literature was also performed.

Results: We describe 17 unrelated affected individuals carrying 13 different novel loss-of-function SYNGAP1 mutations. Developmental delay was the first manifestation of SYNGAP1-related encephalopathy; intellectual disability became progressively obvious and was associated with autistic behaviors in eight patients. Hypotonia and unstable gait were frequent associated neurological features. With the exception of one patient who experienced a single seizure, all patients had epilepsy, characterized by falls or head drops due to atonic or myoclonic seizures, (myoclonic) absences, and/or eyelid myoclonia. Triggers of seizures were frequent (n=7). Seizures were pharmaco-resistant in half of the patients. The severity of the epilepsy did not correlate with the presence of autistic features or with the severity of cognitive impairment. Mutations were distributed throughout the gene, but spared spliced 3' and 5' exons. Seizures in patients with mutations in exons 4-5 were more pharmaco-responsive than in patients with mutations in exons 8-15.

Conclusion: SYNGAP1 encephalopathy is characterized by early neurodevelopmental delay typically preceding the onset of a relatively recognizable epilepsy comprising generalized seizures (absences, myoclonic jerks) and frequent triggers.

P11.151

The new syndrome of hypogonadotropic hypogonadism, arrhythmogenic right ventricular dysplasia, facial dysmorphism and absence of corpus callosum is associated with TAX1 binding protein 3 gene variation

M. Arafat¹, **E. Hershkovitz**², **Z. Afawi**³, **N. Loewenthal**⁴, **A. Haim**², **A. Levitas**⁴, **R. Parvari**^{1,5};

¹The Shraga Segal Department of Microbiology, Immunology & Genetics, Faculty of Health Sciences, Ben-Gurion University of the Negev, Beer Sheva, Israel, ²Pediatric Endocrinology & Metabolism Unit, Soroka University Medical Center, Beer Sheva, Israel, ³Sackler Faculty of Medicine, Department of Neurology, Tel-Aviv University, Ramat Aviv, Israel, ⁴Director of Pediatric Cardiac Imaging, Department of Pediatric Cardiology, Soroka University Medical Center and Faculty of Health Sciences, Ben-Gurion University of the Negev, Beer Sheva, Israel, ⁵National Institute of Biotechnology Negev, Beer Sheva, Israel.

Introduction: Hypogonadotropic hypogonadism (HH) is a genetically heterogeneous syndrome characterized by decreased secretion or action of gonadotropin releasing hormone (GnRH), resulting in reduced sex hormone production and various clinical signs of hypogonadism. Arrhythmogenic right ventricular dysplasia/cardiomyopathy (ARVD/C) is a cardiomyopathy disease that may result in arrhythmia, heart failure, and sudden cardiac

death. The aim of this study was to identify and characterize the genetic basis of congenital HH and ARVD/C in a consanguineous Bedouin family of nine members with two affected brothers.

Materials and Methods: Genotyping was done on the parents and two affected children. Exome sequencing was performed on the DNA of one brother. **Results:** The homozygous chromosomal regions contained 39 variations, reported in less than 10% of population variation databases. Following bioinformatics predictions for damaging effect, segregation in the family and analysis of prevalence in the Bedouin population, one candidate remained in the Tax1 (human T-cell leukemia virus type-I) binding protein-3 (TAX1BP3) gene. The variation- Ile33Thr substitutions is predicted to change the structure of PDZ domain that mediates protein-protein interactions and affected the stability.

Conclusions : The new clinical syndrome could be mediated by damaging the interaction of TAX1BP3 with the Potassium Channel KCNJ4 and improper function of the Wnt signaling pathway in which TAX1BP3 was suggested to participate.

P11.152

Temple syndrome with atypical features: a case report

M. Yakoreva^{1,2}, **T. Kahre**^{1,2}, **S. Pajusalu**^{1,3}, **T. Reimand**^{1,2,3}, **K. Õunap**^{1,2};

¹Tartu University Hospital, United Laboratories, Department of Genetics, Tartu, Estonia, ²Department of Pediatrics, Institute of Clinical Medicine, University of Tartu, Tartu, Estonia, ³Department of Biomedicine, Institute of Biomedicine and Translational Medicine, University of Tartu, Tartu, Estonia.

Temple syndrome (TS) is a rare imprinting disorder characterized by pre- and postnatal growth retardation, hypotonia, poor feeding, motor and developmental delay, scoliosis, premature puberty and a variety of dysmorphic features. Maternal uniparental disomy of chromosome 14 is the underlying cause of TS. Isolated methylation defects and paternal deletions of imprinted locus 14q32 could be found in other TS cases.

We present a case of TS in a 4-years-old girl with some atypical features. The patient was born at the 35th weeks of gestation with weight 1832g (-1.5SD) and length 42cm (-2SD). Pregnancy was complicated by IUGR and oligohydramnios. Shortly after the birth AVSD, congestive heart insufficiency and kyphoscoliosis were diagnosed. During the first years of life, the child had feeding difficulties, poor weight gain, hypotonia and severe psychomotor developmental delay. Later, dysmorphic features, body asymmetry, increasing linear pigmentation on the arms and legs, hyperopia, strabismus and cognitive delay were noted. She started to walk independently at 2.5 years of age. Her height now is -5SD, weight and OFC -2.5SD.

UPD7-UPD14 MS-MLPA analysis revealed a complete hypomethylation of MEG3 gene (14q32.2). The same result was obtained using DNA from fibroblasts, urine and buccal swab. Comparative analysis of the SNPs using her mother's CMA results showed maternal heterodisomy of the whole chromosome 14. No mosaicism was detected.

Unlike previously described cases, our patient has more severe clinical presentation of TS with congenital heart defect, vision problems and skin pigmentation changes. This work was supported by the Estonian Research Council grant PUT355.

Temple syndrome among patients with Prader Willi syndrome-like phenotype

A. Lande¹, **M. Kroken**¹, **K. Rabben**², **L. Retterstøl**¹;

¹Dep of Medical Genetics, Oslo University Hospital, Oslo, Norway, ²Frambu Center for Rare Disease, Oslo, Norway.

Introduction: Temple syndrome (TS) and Prader Willi syndrome (PWS) share many features in infancy and childhood. TS is an important, but often neglected, differential diagnosis to PWS. We wanted to estimate the proportion of TS in patients with PWS-like phenotype.

Materials and methods: In all samples submitted for PWS testing during 2014 and 2015, we consecutively conducted analysis also for TS. A total of 150 samples were included. The main indications for testing were hypotonia in infancy or childhood, developmental delays and/or overweight. For TS-testing, we employed a methylation-sensitive MLPA-kit for detection of methylation aberrations in chromosomal region 14q32.

Results: 3 out of 150 patients (2%) with PWS-like phenotype proved to have TS. In comparison, 6 out of 150 patients (4%) got the diagnosis of PWS molecularly confirmed. All three TS patients fit the phenotype previously reported with the following shared features: low birth weight, neonatal hypotonia, feeding difficulties and slight developmental delay. The two oldest patients were overweight, and the oldest patient (9 years old) had learning disabilities. In one of the patients, we confirmed maternal uniparental di-

somy 14 by satellite testing. We will pursue such analysis in the other two patients.

Conclusions: TS is believed to be underdiagnosed, and our results support this view. In concordance with recent papers, we conclude that analysis for TS should be performed whenever genetic testing for PWS is indicated in children.

Analysis of Polymorphisms and Haplotypes of NOS2, PTGS2 and VEGFA Genes in Individuals with Thalidomide Embryopathy

T. W. Kowalski^{1,2}, L. Tovo-Rodrigues^{3,1}, L. R. Fraga¹, M. T. V. Sanseverino^{4,1,2}, M. H. Hutz¹, L. Schuler-Faccini^{1,2,4}, F. S. L. Vianna^{1,2,4},

¹Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil, ²Instituto Nacional de Genética Médica Populacional, Porto Alegre, Brazil, ³Universidade Federal de Pelotas, Pelotas, Brazil, ⁴Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil.

Introduction: Thalidomide embryopathy (TE) affected more than 10,000 babies around the world in the 1960s. Thalidomide was a drug marketed as safe, once its teratogenic properties were unknown at the time. The molecular mechanisms underlying thalidomide's teratogenesis remain not fully comprehended. The hypothesis that teratogenesis occurs due to thalidomide's antiangiogenic properties has been largely investigated in experimental models. However, polymorphisms in genes affected by thalidomide were not evaluated in humans.

Methods: In the present study, ten functional polymorphisms in genes of angiogenesis pathway were accessed in 38 individuals with TE and 136 subjects without congenital anomalies of the Brazilian population. The Single Nucleotide Polymorphisms (SNPs) rs2779249 and rs2297518 of NOS2; rs689465, rs689466 and rs20417 of PTGS2; rs699947, rs1570360, rs2010963 and rs3025039 of VEGFA were genotyped by real-time PCR or Sanger sequencing. Microsatellite (CCTTT)_n of NOS2 was accessed through fragment analysis. Haplotypes were inferred through Phase Bayesian algorithm. Statistical analysis was performed in SPSS v.18.

Results: All polymorphisms were in Hardy-Weinberg Equilibrium. It was not identified a significant difference of allelic, genotypic or haplotypic frequencies when comparing both groups evaluated. Risk haplotypes were compared with pattern of congenital anomalies in TE individuals, and also no significant association was observed.

Conclusion: In this investigation we could not suggest a risk or protective allele for TE in genes NOS2, PTGS2 and VEGFA, although other studies concerning endophenotypes and other candidate genes should also be performed in a larger sample of thalidomide's victims.

Spectrum of TSC1 and TSC2 alterations in Russian patients with tuberous sclerosis

E. N. Suspitsin^{1,2}, G. A. Yanus^{1,2}, M. Y. Dorofeyeva³, T. A. Ledashcheva⁴, E. N. Imyanov^{1,2,5}; ¹St.-Petersburg State Pediatric Medical University, St.-Petersburg, Russian Federation, ²N.N. Petrov Institute of Oncology, St.-Petersburg, Russian Federation, ³Research Institute of Pediatrics and Pediatric Surgery, Moscow, Russian Federation, ⁴City Center for Medical Genetics, St.-Petersburg, Russian Federation, ⁵I.I. Mechnikov North-Western Medical University, St.-Petersburg, Russian Federation.

Background: Tuberous sclerosis (TS) is a genetic disease characterized by development of hamartomas of multiple organs (brain, kidneys, retina, skin, etc.). TS prevalence in Russia approaches to 1:30000, however TSC1/2 mutation distribution has not been subjected yet to systematic studies.

Material and methods: DNA samples of 53 patients with clinical signs of tuberous sclerosis were tested for mutations in TSC1 and TSC2 genes using Sanger sequencing and MLPA. The vast majority of cases (50 of 53) were sporadic, i.e., no clinical signs of TS were detected in the parents.

Results: TSC1/2 mutations were detected in 46/53 patients (87%): 34 (74%) carried mutations in the TSC2 and 12 (26%) in the TSC1; this ratio is in agreement with data obtained in European countries and the USA. It is of note that mutations were detected in 5 of 7 patients with one major and 0-1 additional minor features. All but one alteration were unique; splice-site mutation TSC2 c.138+1G>A was found in 2 unrelated patients. Large rearrangements (exon deletions/duplications) were found in 5/46 (11%) and affected exclusively TSC2; this is substantially higher compared to estimates done in other studies (0.2-6%).

Conclusions: Tuberous sclerosis in Russian patients appears to have some peculiarities: 1) domination of sporadic form of the disease; 2) absence of recurrent mutations; 3) high frequency of large rearrangements.

Some patients with mutations had only one major diagnostic feature; thus, relaxed clinical criteria should be applied for justification of TSC1/2 mutation testing.

Enhancing the genetic understanding of Waardenburg Syndrome type II

S. Issa^{1,2,3}, Y. Watanabe¹, E. Faubert⁴, L. Lecerf¹, N. Bondurand¹, S. Marlin⁵, V. Pingault²; ¹INSERM, U955, IMRB Team 6, Creteil, France, ²INSERM, U1163, Institut Imagine, Paris, France, ³Université Paris Est Creteil, Faculté de Médecine, Creteil, France, ⁴AP-HP, Hôpital H.Mondor - Département de Génétique, Creteil, France, ⁵Centre de Référence des Surdités Génétiques, Département de Génétique, Hôpital Necker, Paris, France.

Waardenburg syndrome (WS) is one of the most common types of autosomal dominant syndromic hearing loss and is characterized by association with pigment disturbances of hair, skin and iris. WS is clinically classified into four subtypes (WS1-4) depending on the presence of additional features. Mutations in 5 major genes of the neural crest pathway are found in this syndrome: MITF, PAX3, SOX10, EDNRB and its ligand EDN3. Nevertheless, a large number of cases still remain unexplained at the molecular level, notably in WS2 (70%). Whole Exome sequencing was performed in order to enhance the understanding of the molecular basis of WS2.

In a sporadic case (sequenced in trio), we were able to identify a missense variation in EDNRB, a gene previously involved in WS4, but with a different mode of transmission. Screening of our WS2 cohort led to the identification of 6 additional cases with mutations in this gene: 4 missense changes, one frameshift and one splice site mutation. Immunofluorescence experiments performed on the mutants and wildtype proteins (as well as previously described mutants and polymorphic missense changes as controls) revealed three mutants localizing in the cytoplasm instead of the membrane in different cell lines. A minigene was constructed for the splice site mutant and the resulting cDNA conserved 4 intronic base pairs, predicting a frameshift with early stop codon. In vitro functional tests are being conducted to analyze the transcriptional and post-translational regulation of key players in the melanocytic pathway upon over expression of each mutant.

P11.158

A clinical description of a rare familial case of Weaver syndrome caused by novel heterozygous EZH2 variant c.2050C>A (p.Arg684Ser)

A. Poluha^{1,2}, K. Wojciechowska², A. Bury³, A. Sobczynska-Tomaszewska⁴, K. Czernska⁴, I. Jaszczuk², M. Holweg⁵, M. Lejman⁵, D. Winnicka⁵, M. Babicz⁵, B. Styka⁵, J. R. Kowalczyk²; ¹Department of Pediatrics, Skaraborg Hospital, Skovde, Sweden, ²Department of Pediatric Hematology, Oncology and Transplantology, Children's University Hospital, Lublin, Poland, ³Department of Pediatric Endocrinology and Diabetology with Endocrine-Metabolic Laboratory, Children's University Hospital, Lublin, Poland, ⁴MedGen Medical Center, Warsaw, Poland, ⁵Genetic Laboratory, Department of Pediatric Hematology, Oncology and Transplantology, Children's University Hospital, Lublin, Poland.

Weaver syndrome is a rare congenital disorder characterized by pre- and postnatal overgrowth, spectrum of developmental delay, advanced bone age and characteristic craniofacial morphology. It is caused by constitutional heterozygous EZH2 pathogenic variants.

The majority of cases thus far reported appear to have been sporadic and there is not much data available regarding long-term follow up of adults with EZH2-related Weaver syndrome or clinical variability in rare familial cases.

Here we present three individuals from a previously unreported family identified to have a novel EZH2 variant. Proband is a 7 years-old boy with developmental delay, moderate intellectual disability, behavioral problems, increased pre- and postnatal length, soft and doughy skin, broad thumbs, hipertrichosis and distinctive craniofacial dysmorphic features: macrocephaly, broad forehead, flat occiput, long philtrum, large ears, widely spaced eyes and horizontal chin crease. His 29 years-old mother and 55 years-old maternal grandmother are both of a tall stature and have similar craniofacial morphology although no evidence of intellectual disability.

Sequence analysis of EZH2 detected in a proband and then confirmed in mother and grandmother a novel, heterozygous variant c.2050C>A (p.Arg684Ser) in the highly conserved SET domain. It is likely to be pathogenic based on the fact that it segregates with the overgrowth phenotype in reported family and that recurrent substitution of the same amino acid residue Arg684 in EZH2 by a different amino acid is well known to be pathogenic.

In summary, we expand the mutational spectrum of EZH2-related overgrowth and point out to clinical variability in rare familial case.

P11.159

Molecular screening of EZH2: analysis of 23 patients with clinical features of Weaver Syndrome

G. Gordo¹, I. Dapía¹, J. Tenorio¹, P. Arias¹, M. del Campo², M. P. Tirado³, M. A. Ramos-Arroyo⁴, F. Santos-Simarro¹, P. Lapunzina¹;

¹Institute of Medical and Molecular Genetics-INGEMM. Hospital Universitario La Paz, Madrid, Spain, ²Servicio de Genética. Hospital Vall D'hebron., Barcelona, Spain, ³Servicio de Neurología pediátrica. Hospital La Paz, Madrid, Spain, ⁴Servicio de genética. Hospital Virgen del camino, Pamplona, Spain.

Introduction: Weaver syndrome (WS) (MIM #277590) is an overgrowth disorder characterized by pre- and postnatal overgrowth, variable learning disability and distinctive craniofacial features. It is also characterized by advanced bone age (usually carpal osseous maturation), camptodactyly and an increased frequency of tumours. The prevalence of WS is still unknown due to the scant number of cases reported up to date. In 2011, mutations in the Enhancer of Zeste Homolog 2 (EZH2) were associated with the development of WS. EZH2 is a histone-methyltransferase that acts as the catalytic agent of the polycomb-repressive complex 2 (PRC2) and it is also involved in the PI3K/mTOR pathway which includes other genes implicated in different overgrowth disorders.

Material and methods: We performed molecular analysis of EZH2 in 23 patients with a clinical diagnosis of WS. Genomic DNA was extracted from peripheral blood, and mutational analysis by conventional sequencing was performed. Variants pathogenicity was evaluated through bioinformatics tools. Results: We found three different missense mutations affecting conserved domains of the protein. Two of them were not previously reported and are located in the SANT domain which is involved in DNA-binding. All three patients showed clinical features compatible with WS. To date, only one of them developed a tumour.

Conclusions: WS is a rare disease with few cases reported in the literature. In this study we described two new variants probably associated to the development of this disease. Additionally, one of the mutations appeared in a patient who developed a neuroblastoma early in the infancy.

Opitz C Syndrome (OTCS, MIM #211750) is a rare and severe pathology of unknown genetic cause and unclear pattern of inheritance. It presents with malformations and developmental delay and clinically overlaps with the more severe Bohring-Opitz Syndrome (BOS, MIM #605039). In BOS, half of the patients bear *de novo* truncating mutations in the *ASXL1* gene.

We studied 14 families with patients diagnosed as OTCS or BOS, from different countries. *ASXL1* was sequenced in all of them and 6 patients (and their parents) were analyzed by whole exome sequencing (WES).

We found an *ASXL1* mutation in one Scottish BOS patient.

In a Spanish OTCS patient we found a *de novo* truncating mutation at the imprinted and maternally silenced *MAGEL2* gene. The mutation was present on the paternal chromosome. Other truncating mutations in this gene have been found associated with the Shaaf-Yang syndrome and with severe arthrogyriposis, suggesting clinical heterogeneity for *MAGEL2*.

In an Italian OTCS patient we found a *de novo* mutation at a *FOXP1* splice site, associated with developmental delay, speech impairment and contractures, all traits present in the patient.

Finally, two Russian OTCS sibs were reevaluated and re-diagnosed as affected with congenital myopathy and two recessive *RYR1* mutations were identified by WES.

Selected variants in the exomes of the other three patients are currently being validated.

Our results suggest that OTCS is a highly genetically heterogeneous pathology.

Next generation sequencing: the prenatal diagnostic test for fetuses with severe ultrasound abnormalities?

M. J. V. Hoffer¹, A. C. J. Gijbbers¹, S. Bollen¹, M. E. Y. Laurence-Bik¹, I. J. H. M. van Minderhout¹, S. Smit¹, I. F. A. C. Fokkema², A. Haeringen¹, M. Koopmans¹, T. P. Potjer¹, K. van der Tuin¹, G. W. E. Santen¹, N. S. den Hollander¹, C. A. Ruivenkamp¹;

¹Dept. of Clinical Genetics, Leiden University Medical Center, Leiden, Netherlands, ²Dept. of Human Genetics, Leiden University Medical Center, Leiden, Netherlands.

At present, the standard prenatal genetic diagnostic screening tool for fetuses with ultrasound abnormalities is microarray analysis. However, recently, in patients with intellectual disability and/or developmental delay (ID/DD), next generation sequencing, proved to be a much better tool, it demonstrated in about 20% of the cases the disease-causing aberration. In our study we investigated whether whole exome sequencing (WES) could also be a promising tool to unravel the underlying defect for fetuses with ultrasound abnormalities.

Nine fetuses with a severe, unexplained ultrasound abnormality and their unaffected parents (trios) were postpartum included in our series of patients for WES. The exome sequences were analysed with a stringent post-sequencing annotation pipeline including an ID/DD gene panel of ~700 genes for filtering of the data. Analysis of the whole exome was only performed when informed consent was available and the gene panel did not reveal a candidate mutation. All remaining variants with a potential clinical consequence were validated by Sanger sequencing. In 33% of the cases we were able to identify the causal genetic variant.

In conclusion, WES demonstrates to be the a good diagnostic tool to unravel the underlying genetic cause in a substantial portion of the fetuses with severe ultrasound abnormalities.

The process of genetic counselling and the genotype-phenotype correlation in a popliteal pterygium syndrome: a case report

N. Capdevila, E. Gabau, R. Ballester, M. Guitart, N. Baena, S. Pina; Parc Taulí Sabadell, University Hospital, Sabadell, Spain.

Introduction: Popliteal pterygium syndrome is a congenital malformation that includes orofacial, musculoskeletal and genitourinary anomalies. It is caused by mutations in the IRF6 gene and characterized by an autosomal dominant inheritance, incomplete penetrance and variable expression. Clinical manifestations may include from lower lip pits or mounds to cleft complete palate with the presence of cutaneous webbing across one or more major joints in the lower extremities.

Presentation case: Pregnant woman in the first trimester of pregnancy comes to genetic counselling consultation, because six months ago she had an abortion after detecting the presence of bilateral cleft lip with cleft palate and low mobility of the lower limbs in the foetus. After fetal autopsy, the diagnostic suspicion is a popliteal pterygium syndrome by the characteristic nail dysplasia. The IRF6 gene sequencing is performed, and Cys84Arg mutation is detected allowing the study of the carrier parents.

Conclusion: The joint assessment of the multidisciplinary team and the correct diagnostic orientation determined by the fetal autopsy has provided an accurate genetic diagnosis. Although the spectrum of mutations of IRF6 gene has an incomplete penetrance and variable expressivity, it has been possible to offer a correct and detailed genetic counselling to the progenitors on the current pregnancy.

Detection of a homozygous 11kb inversion by whole exome sequencing in a patient with Xeroderma pigmentosum

P. Jaset, S. Azzarello-Burri, T. Herget, M. Papic, M. Zweier, D. Niedrist, A. Baumer, A. Rauch;

Institute of Medical Genetics, University of Zurich, Schlieren-Zurich, Switzerland.

Whole exome sequencing (WES) is a powerful tool in detecting point-mutations and small indels but is not commonly used to discover bigger structural rearrangements. With an overall diagnostic yield of about 50% in 262 single/trio cases, we found in approx. 70-80% of our cases a pathologic point substitution. Moreover, in about 11-16% we were detecting small deletions and in 9-14% small insertions. While the biggest pathologic deletion was 28 bps and the biggest pathologic insertion 13bps, structural rearrangements much bigger than those are difficult to detect, but might explain a certain percentage of our unsolved cases. Here we report a 20 year old male with spinocellular carcinoma of the face, lymphnode metastasis and already multiple facial tumorexcisions. The initial Next Generation Sequencing ap-

proach with the Illumina cancer panel was negative for the suspicious genes DDB2, ERCC2, ERCC3, ERCC4, ERCC5, XPA und XPC. The subsequent targeted WES approach on additional genes associated with Xeroderma pigmentosum revealed an 11kb homozygous inversion with 1 breakpoint located within the coding exon 4 of the POLH gene. Mapping of the unmatched nucleotides from the reads resulted in a second intronic breakpoint 11189 bp downstream, between exon 8 and 9 of the POLH gene, predicted to disrupt the whole gene.

To our knowledge we report here for the first time a homozygous inversion detected by whole exome sequencing.

P12.002

The importance of Chromosome Microarray Analysis (CMA) in karyotypically normal children with Acute Lymphoblastic Leukemia (ALL)

A. Mitrakos, A. Kattamis, M. Tzetzis, K. Katsibardi, E. Kanavakis, S. Kitsiou-Tzeli; University of Athens, Athens, Greece.

The significance of genetic profiling in patients with ALL has been underlined by recent discoveries which have led to novel risk stratification subgroups and new treatment approaches, overall increasing Event Free Survival rates. Here we evaluate the efficiency of high resolution aCGH+SNP analysis when compared to conventional karyotype.

We studied bone marrow samples obtained after diagnosis from 8 children (median age 7 years old) with B-cell and B-cell precursor ALL (n=3 and n=5 respectively), that presented with normal or non diagnostic conventional karyotype and are part of a larger cohort. Following DNA isolation we utilized the high-resolution aCGH+SNP 2X400K platform (Agilent Technologies), that covers the entire genome with an average resolution of 7kb for CNVs, and can also identify regions of LOH. The results were compared to conventional cytogenetic techniques and assessed in the light of the clinical outcome for each patient.

Clinically relevant CNVs were detected in 7/8 cases (87.5%). The most common aberrations involved the ETV6 gene (n=5). One case with hyperdiploidy (54 chromosomes) and one case with hypodiploidy (37 chromosomes) were also detected, with the smallest CNV detected being a 28kb deletion involving PAX5 gene. Aberrant genomic regions harbored hematopoiesis (RUNX1), cell-cycle regulation (CDKN2A/2B), as well as oncogenes and tumor suppressor genes. Additionally, regions with LOH were identified, encompassing important genes (IKZF1, RARA).

We conclude that in a plethora of cases conventional cytogenetic techniques may not accurately depict the genetic profile of ALL patients in the clinical setting, increasing the necessity for additional approaches like CMA.

P12.005

Isochromosome der(17)(q10)t(15;17) in acute promyelocytic leukemia resulting in an additional copy of the RARA-PML and loss of the p53: report of two cases

V. Djordjevic, M. Dencic-Fekete, J. Jovanovic; Clinical center of Serbia, Belgrade, Serbia.

Introduction: Isochromosome of the long arm of the derivative chromosome 17, originating from the translocation t(15;17) [ider(17)(q10)t(15;17) or ider(17q)] in acute promyelocytic leukemia (APL), is a very rare chromosome aberration which has been associated with a poor prognosis.

Materials and Methods: We report two APL patients, their clinical and laboratory data associated with ider(17q). Cytogenetic analysis was performed on unstimulated bone marrow cells. Chromosomes were examined with modified Giemsa stain HG-banding technique. Interphase and metaphase fluorescence in situ hybridization (FISH) studies were performed on bone marrow cytogenetic specimens which were previously used for karyotype analysis. Detection of PML-RARA and RARA-PML fusion genes were performed using the DF SureFISH 15q24.1 together with the DF SureFISH 17q21.2 probes. Detection of p53 gene was performed using LSI TP53 (17p13.1) probe. DNA probes were applied following standard procedures outlined by the manufacturer. An RT-PCR assay was performed to detect the PML-RARA fusion gene.

Results: Cytogenetic analysis of bone marrow cells of both patients showed mosaic karyotype with the ider(17q) and reverse transcription polymerase chain reaction (RT-PCR) was positive for long (L) isoform of PML-RARA fusion transcript. FISH analysis confirmed extra copy of RARA-PML fusion gene or ider(17q) and loss of the normal tumor suppressor p53 gene in both of the patients.

Conclusions: Results both of the reported APL cases with ider(17q) indicated that the duplication of der(17) gives a growth advantage to the relevant clone which becomes dominant. Moreover, loss of the normal tumor suppressor gene p53 may also contribute to this growth advantage.

Adenocarcinoma of the gastroesophageal junction by NF1: risk by offspring?

N. Dragicevic¹, A. Gehrig¹, A. Rosenwald², E. Kunstmann¹;

¹Institute of Human Genetics, University of Würzburg, Würzburg, Germany, ²Institute of Pathology, University of Würzburg, Würzburg, Germany.

We report the occurrence and investigation of an adenocarcinoma of the gastroesophageal junction in a 41-year-old woman with previously clinical diagnosed neurofibromatosis type 1 in age of 20 year. A family history was positive, her father and uncle had café-au-lait spots. In the maternal family an aunt and cousin suffering from stomach and breast tumor.

The patient with multiple café-au-lait patches, axillary freckling and dermal neurofibroma, had also a benign tumor of the breast. She presented with loss of appetite, nausea, loss of weight, vomit, iron deficiency and respectly abdominal pain.

A gastroscopy with biopsy leading to the identification of an invasive moderately differentiated adenocarcinoma of the gastroesophageal junction Type of „Barrett- Carcinoma“.

By DNA sequencing in exon 26 of NF1 gene was detected germline deletion c.3457_3460delCTCA. Genetic investigation of CDH1-gene was negative. To assess the relationship of the tumor to the NF1 mutation, DNA was extracted from paraffin-block and not revealed loss of heterozygosity at the NF1 gene. Son of the patient, 6 years old is the holder of the famous mutation in the NF1 gene. At was discussed about risks of morbidity and prevention of adenocarcinoma, as well as other possible mechanisms of tumorigenesis, excluding LOH (1, 2).

BRAF and KRAS mutations in colonic polyps as molecular marker of risk of metachronous advanced neoplasia.

M. Juarez¹, C. Egoavil¹, E. Hernandez-Illan¹, M. Rodriguez-Soler², A. Garcia-Martinez¹, P. Zapater³, C. Guarinos⁴, C. Alenda⁴, L. Castaño-Soler⁵, J. Martinez⁶, F. Ruiz⁷, L. Compañ⁷, J. Aparicio⁶, J. Casellas⁶, O. Murcia⁶, M. Giner-Calabuig¹, A. Castillejo⁸, V. Barberá⁹, J. Soto⁹, R. Jover⁹;

¹Unidad de investigación- Hospital General de Alicante, Alicante, Spain, ²Unidad de Hepatología-Hospital General de Alicante, Alicante, Spain, ³Servicio de Farmacología-Hospital General de Alicante, Alicante, Spain, ⁴Servicio de Patología- Hospital General de Alicante, Alicante, Spain, ⁵Hospital General de Alicante, Alicante, Spain, ⁶Unidad de Gastroenterología- Hospital General de Alicante, Alicante, Spain, ⁷Unidad de gastroenterología- Hospital General de Alicante, Alicante, Spain, ⁸Unidad de Genética Molecular- Hospital General de Elche, Elche, Spain, ⁹Unidad de gastroenterología- Hospital General de Alicante, Elche, Spain.

BACKGROUND AND AIM: Our aim is to study if molecular characteristics of polyps can add information about risk of metachronous advanced neoplasia.

METHODS: We retrospectively included 308 patients diagnosed with colonic polyps (2007-2009) who have at least one surveillance colonoscopy made more than 6 months after the baseline, until 2014. 995 polyps were collected and tested for somatic BRAF(V600E) and KRAS(codons 12, 13) mutations. Patients were classified into 3 subgroups based on mutational profile of their polyps at baseline: 1) non-mutated polyps, 2) at least one BRAF-mutated polyp or 3) at least one KRAS-mutated polyp.

RESULTS: 661 polyps were classified as adenomas (66.4%), being 0.8% BRAF mutation and 11.6% KRAS mutation. 334 (33.6%) polyps were classified as serrated lesions: 281 (84.1%) HPs, 38 (11.4%) SSP, 8 (2.4%) TSA and 7 (2.1%) MP. A 39.4% of serrated polyps showed BRAF mutation, and 20.9% KRAS mutation. 289 patients could be classified in three mutational profiling groups: 14.9% were considered as BRAF mutated, 22.8% as KRAS mutated and 62.3% did not present any mutation in these markers. In univariate analysis, KRAS mutation was associated with development of metachronous advanced polyps (KRAS: 30.3%; BRAF: 16.3%; non-mutated: 15.6%; p = 0.029), more specifically advanced adenomas (KRAS 21.2%; BRAF 9.3%; non-mutated 10.0%; p=0.049). This association is also observed in the multivariate analysis, adjusted by age and sex (OR: 2.267, 95% CI: 1.152-4.461).

CONCLUSION: Our results suggest the presence of KRAS mutation in polyps at baseline is an independent risk factor for the development of metachronous advanced lesions.

P12.008

Risk factors for the presence of pathogenic APC and biallelic MUTYH mutations in patients with multiple adenomas

S. W. ten Broeke¹, S. S. Badhal¹, T. van Wezel², H. Morreau², F. J. Hes¹, H. F. Vasen³, C. M. Tops¹, M. Nielsen¹;

¹Department of Clinical Genetics, Leiden, Netherlands, ²Department of Pathology, Leiden, Netherlands, ³Department of Gastroenterology and Netherlands Foundation for the Detection of Hereditary Tumours, Leiden, Netherlands.

Background. Patients with multiple colorectal adenomas may carry germline mutations in *APC* or *MUTYH*, but mutation detection rate seems to be declining. The aims of this study were (1) to assess the proportion of these mutations in patients with multiple adenomas and (2) to identify risk factors that predict mutation detection.

Methods. We performed mutation analysis of *APC* and/or *MUTYH* in a Dutch cohort of 1933 patients ascertained from family cancer clinics between 1992 and 2015. Risk factors were examined using (multinomial) logistic regression analyses.

Results. The overall detection rate declined from 54% before to 14% after 2004. The proportion of *APC/MUTYH* carriers in patients with <20 polyps was low (3.5%;25/722). Only one mutation was identified in the patient group (n=198) of 10-19 adenomas diagnosed at age 60<. A younger age at adenoma diagnosis and a first degree relative (FDR) with polyps was associated with higher odds of finding an *APC* mutation, but CRC in a FDR was not. Having CRC was only predictive of finding biallelic *MUTYH* mutations.

	APC/MUTYH (n=332) ³ OR (95%CI)	APC (n=234)* OR (95%CI)	Biallelic MUTYH (n=95)* OR (95%CI)
Adenoma count <10

20-49	6.5 (3.6-12.0)	11.4 (3.9-32.8)	5.4 (2.5-11.6)
50-99	14.7 (7.3-29.5)	19.9 (6.2-63.4)	14.9 (6.2-34.6)
>100	77.6 (40.5-148.7)	202.79 (70.32-584.8)	20.3 (8.5-48.7)
Age at adenoma diagnosis >50			
40-49	6.2 (3.7-10.0)	7.0 (3.8-12.0)	4.6 (2.3-9.2)
30-39	5.7 (3.3-9.7)	8.8 (4.7-16.5)	2.6 (1.1-6.1)
<30	7.7 (4.6-13.0)	15.0 (8.0-28.0)	1.3 (0.4-3.9)
No CRC			
CRC>50	0.74 (0.4-1.4)	0.54 (0.3-1.2)	3.8 (2.0-7.2)
CRC<50	0.55 (0.44-0.90)	0.67 (0.39-1.17)	4.3 (2.7-8.0)
FDR polyps, no			
Yes	1.7 (1.2-2.4)	2.1 (1.3-3.2)	1.2 (0.8-2.0)
FDR CRC, no			
Yes	0.79 (0.55-1.1)	0.77 (0.5-1.2)	0.9 (0.5-1.4)

Discussion. Adenoma count and younger age at adenoma detection are the main predictive factors of finding a mutation, but a FDR with CRC is not. For patients over age 60 with less than 20 adenomas testing does not seem justifiable. Our findings have an important impact on referral policy.

A dual role of sFRP3 modulating molecule in astrocytic brain tumors

A. Kafka^{1,2}, D. Tomas^{3,4}, L. Marković¹, A. Várošanec¹, N. Njirić¹, Ž. Krsnik⁵, G. Mrak⁶, N. Pečina-Slaus^{1,2};

¹Laboratory of Neurooncology, Croatian Institute for Brain Research, School of Medicine University of Zagreb, Zagreb, Croatia, ²Department of Biology, School of Medicine, University of Zagreb, Zagreb, Croatia, ³Department of Pathology, School of Medicine, University of Zagreb, Zagreb, Croatia, ⁴University Hospital „Sisters of Charity“, Zagreb, Croatia, ⁵Department of Neuroscience, Croatian Institute for Brain Research, University of Zagreb School of Medicine, Zagreb, Croatia, ⁶Department of Neurosurgery University Clinical Hospital Zagreb, School of medicine, University of Zagreb, Zagreb, Croatia.

On a sample of 55 astrocytic brain tumors we determined the expression and localization of sFRP3 modulating molecule throughout different malignancy grades. Immunohistochemistry followed by digital scanning (NanoZoomer 2.0RS, Hammamatsu), and ImageJ (NIH, SAD) program were methods of choice for determining the levels of sFRP3 expression. Our results demonstrated that the differences between expression levels and malignancy grades were statistically significant. Moderate (P=0,014) and strong (P=0,028) nuclear expression levels were significantly different with pilocytic and diffuse astrocytomas showing higher expression values. When we divided our sample into two groups, both moderate and high cytoplasmic expression levels were significantly higher in glioblastomas than in the group comprising astrocytomas II and III. We also showed that high grade tumors had lower values of moderate (P=0,002) and strong nuclear (P=0,018) expression comparing to low grade tumors. Analysis of cytoplasmic staining showed that strong cytoplasmic expression was significantly higher in the astrocytomas III and glioblastoma group than in astrocytomas I and II group (P=0,048). Moreover, we found that lower grade astrocytomas had fewer membranous sFRP3 stain than higher grade astrocytomas and that this difference was significant (P=0.036). Our results demonstrated that sFRP3

protein expression levels decreased when located in the nucleus in higher astrocytoma grades, indicating expected behavior as an antagonist of Wnt signaling, whereas when located in the cytoplasm an increase in sFRP3 expression was noted in high grade as compared to low grade astrocytomas. This may suggest that sFRP3 can also act as an agonist of Wnt signaling promoting invasive behavior.

Single nucleotide polymorphism (SNP) array analyses may help to development of personalized medicine in pediatric B-cell acute lymphoblastic leukemia

P. Carrasco Salas¹, J. Nevado¹, I. Vallcorba¹, B. González², D. Bueno², L. Fernández², M. Vela³, J. Valentin⁴, P. Lapunzina⁴, A. Pérez-Martínez²;

¹INGEMM, Hospital Universitario La Paz, Madrid, Spain, ²Unidad de Hemato-Oncología Pediátrica. Hospital Universitario La Paz, Madrid, Spain, ³Centro Nacional de Investigaciones Oncológicas (CNIO). Grupo de Investigación clínica, Madrid, Spain, ⁴Instituto de Investigación Hospital Universitario La Paz (IdiPAZ), Madrid, Spain.

Introduction: B-cell acute lymphoblastic leukemia (B-ALL), the most prevalent cancer in the pediatric population, is a malignant disease resulting from accumulation of genetic aberrations. Knowledge of these aberrations is useful for disease classification, prognosis, therapeutic purposes, and to provide an overall understanding of the pathogenesis of the B-ALL.

Methods: We retrospectively examined bone marrow samples from 32 pediatric B-cell ALL using the Illumina CytoSNP-850K BeadChip in the Illumina HiScan platform.

Results: Except for one, all patients showed copy number alterations (CNAs). Losses were more common than gains. Whole and partial copy neutral loss of heterozygosity (CN-LOH) were observed in 12 cases. Only four recurrent genetic alterations were found: hyperdiploidy (44% of the cases), deletion of *CDKN2A/B* genes (22%), deletion of *PAX5* gene (16%) and deletion of *ETV6* (9%) gene. Several possible target genes were identified, including *SESN1*, *NME1* and *BMP1B*, but additional studies are needed to confirm their implication in the disease. In a deceased high-risk patient, a partial heterozygous deletion of *JAK2* gene were observed, which must be studied to confirm if it provides a gene expression signature similar to BCR-ABL1 pediatric ALL. These *JAK*-mutated cases have been proposed as logical targets for therapeutic intervention with *JAK2* inhibitors.

Conclusions: SNP arrays are a powerful cytogenetic tool to define genetic abnormalities in B-ALL, including CN-LOH, a hidden chromosomal defect by standard methods. In addition, the use of this technology in clinical practice may help to develop individualized treatment plans for affected children.

Genomic analysis identifies novel drivers and progression pathways in skin basal cell carcinoma

X. Bonilla¹, L. Parmentier², B. King³, F. Bezrukov⁴, G. Kaya⁵, V. Zoete⁶, V. B. Seplyarskiy^{7,8,9}, H. J. Sharpe¹⁰, T. A. McKee⁵, A. Letourneau¹, P. G. Ribaux¹, K. Popadin¹, N. Basset-Seguini¹¹, R. Ben Chaabene¹, F. A. Santoni¹, M. A. Andrianova^{7,8,9}, M. Guipponi¹, M. Garieri¹, C. Verdán⁵, K. Grosdemange⁵, O. Sumara¹², M. Eilers¹², I. Aifantis⁵, O. Michielin^{5,13}, E. J. de Sauvage¹⁰, S. Antonarakis^{1,14,5}, S. I. Nikolae^{1,5};

¹University of Geneva, Geneva, Switzerland, ²Hospital of Valais, Sierre, Switzerland, ³NYU School of Medicine, New York, NY, United States, ⁴University of Connecticut, Storrs, CT, United States, ⁵University Hospitals of Geneva, Geneva, Switzerland, ⁶Swiss Institute of Bioinformatics, Lausanne, Switzerland, ⁷Institute of Information Transmission Problems, Moscow, Russian Federation, ⁸Pirogov Russian National Research Medical University, Moscow, Russian Federation, ⁹Lomonosov Moscow State University, Moscow, Russian Federation, ¹⁰Genentech Inc., San Francisco, CA, United States, ¹¹University of Geneva, Paris, France, ¹²University of Würzburg, Würzburg, Germany, ¹³University of Lausanne and Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland, ¹⁴Institute of Genetics and Genomics of Geneva, Geneva, Switzerland.

Basal cell carcinoma of the skin (BCC) is the most common malignant neoplasm in humans. BCC is primarily driven by aberrant activation of the Sonic Hedgehog (Hh) pathway. However, its extensive phenotypic variation remains to be explained. The genetic profiling of 293 BCCs revealed the highest mutation rate observed in cancer (65 Mutations/Mb), with strong prevalence of UV-light signature mutations. 85% of BCCs harbored mutations in Hh pathway genes: mutually exclusive *PTCH1* (73%) and *SMO* (20%) (P=6.6x10⁻⁸), *SUFU* (8%), and in *TP53* (61%). 85% of BCCs also harbored additional driver mutations in other genes implicated in BCC tumorigenesis. Recurrent driver mutations were observed in *MYCN* (30%), *PPP6C* (15%), *STK19* (10%), *LATS1* (8%), *ERBB2* (4%), *PIK3CA* (2%), *RAC1* (1%) and *N/K/H-RAS* (2%). Loss of function (LoF) and deleterious missense mutations were observed in *PTPN14* (23%), *RB1* (8%) and *FBXW7* (5%). In line with the mutational profiles detected by DNA sequencing, we observed activation of the Hh pathway as well as upregulation of target genes of the Hippo-YAP pathway and activation of *MYCN* target genes in RNAseq experiments.

The functional analysis of the novel tumorigenic driver mutations in *MYCN*, *PTPN14* and *LATS1* suggests their potential relevance in BCC tumorigenesis and provides an expanded molecular understanding of BCC.

P12.013

Clinical and genetic features of Birt-Hogg-Dubé syndrome in Spanish families

A. Lopez¹, E. Llistosella², E. Darder¹, A. Velasco¹, D. Sitjà², A. Izquierdo¹, E. Grau³, A. Solanes¹, M. Navarro³, M. Salinas⁴, S. Iglesias⁴, A. Teulé⁴, G. Capellà⁴, C. Lázaro⁴, M. Pineda⁴, L. Feliubadaló⁴, J. Brunet^{1,4,3};

¹Hereditary Cancer Program, Catalan Institute of Oncology, Girona, Spain, ²Dermatology Department, Josep Trueta University Hospital, Girona, Spain, ³Hereditary Cancer Program, Catalan Institute of Oncology, Badalona, Spain, ⁴Hereditary Cancer Program, Catalan Institute of Oncology, L'Hospitalet de Llobregat, Spain.

Introduction: Pathogenic mutations in *FLCN* gene cause Birt-Hogg-Dubé syndrome (SBHD, OMIM #135150). It is inherited in a dominant manner and characterized by the presence of benign hamartomas of hair follicles (fibrofolliculomas and trichodiscomas), lung cysts, spontaneous pneumothorax and increased risk for renal neoplasm.

Materials and Methods: 17 families from our Hereditary Cancer Program were analyzed. Genetic testing identified *FLCN* deleterious mutation in 10 families. To date 30 patients were detected as carriers, all of them are under follow-up. Pathology reports were reviewed in order to classify skin lesions and renal neoplasms. Base line Thoracic CT scan to detect pulmonary bullae was indicated, and renal MRI was performed in all patients to screen for renal tumors.

Results: Focusing on carriers: 21 (70%) have coetaneous affectation (15 have biopsied fibrofolliculomas/trichodiscomas); 8 (26%) developed pneumothorax and 7 were diagnosed of renal cancer (2 cromophob, 3 clear cell and 2 pending pathology results) and kidney sparing surgery could be performed for >3cm lesions. Only one patient shows the triad symptoms (skin, pulmonary and renal manifestations). Three carriers did not manifest any lesion, all of them were under 38 year old.

No previously reported mutations were identified in two families: c.573_574delG>insT and deletion of 1 and 2 exons. The other mutations were: c.1429C>T (nonsense), c.323G>T (missense), c.1733delC, c.3delG (frameshift) and c.1301-1G>A (splicesite)

Conclusions: This data indicate that all carriers over 40 years old have clinical manifestation. Skin lesions appear as the first and more common manifestation. Screening for renal tumors allowed to avoid total nephrectomy.

Differentially expressed long noncoding RNAs in bladder cancer

E. M. Borkowska¹, S. Peter², R. Dryton², C. P. Rakhit², A. P. Noon², W. Chan³, J. W. F. Catto²;

¹Medical University of Łódź Department of Clinical Genetics, Łódź, Poland, ²University of Sheffield Academic Urology Unit and Unit of Molecular Oncology, Sheffield, United Kingdom, ³Max Delbruck Center of Molecular Medicine, Berlin, Germany.

Introduction: Bladder cancer (BC) is the fourth commonest male malignancy and one of the most expensive human cancers to manage. The majority of tumors are urothelial carcinoma in histologic type. Although many reports detail genetic events in urothelial cancer, alterations of epigenetic gene regulation are also important in this disease. Epigenetic gene regulation may occur directly or indirectly through noncoding RNA (ncRNA) species. To date, few data have reported the role of long noncoding RNA (lncRNA) in urothelial cancer and little is known of their function.

Material and methods: The expression of 17112 lncRNAs and 22074 mRNA was determined using microarrays in 83 normal and malignant urothelial samples (discovery step) and selected RNAs with qPCR in 138 samples (validation step). Significantly differentially expressed RNAs were identified and stratified according to tumour phenotype. siRNA knockdown, functional assays, and whole genome transcriptomic profiling were used to identify potential roles of selected RNAs.

Results: We observed upregulation of many lncRNAs in urothelial cancer that was distinct to corresponding, more balanced changes for mRNAs. In general, lncRNA expression reflected disease phenotype. We identified 32 lncRNA with potential roles in disease progression. Focusing upon a promising candidate, we implicate upregulation of AB074278 in apoptosis avoidance and maintenance of a proliferative state in cancer through a potential interaction with EMP1, a tumour suppressor and a negative regulator of cell proliferation.

Conclusion: We have identified many lncRNAs significantly altered in urothelial cancer and associated with disease progression and tumor subtypes.

P12.015

The expression of PIEZO1 and PIEZO2 ion channels in human and mouse bladder carcinoma

E. O. Etem¹, **G. G. Ceylan²**, S. Ozaydin¹, C. Ceylan³, T. Kuloglu⁴, I. Ozercan⁵;

¹Firat University Medical School Department of Medical Biology, Elazığ, Turkey, ²Yildirim Beyazit University Medical School Department of Medical Genetics, Ankara, Turkey, ³Turkey yuksek ihtisas education and research hospital department of urology, Ankara, Turkey, ⁴Firat University Medical School Department of Histology, Elazığ, Turkey, ⁵Firat University Medical School Department of Pathology, Elazığ, Turkey.

Introduction: Action and pressure-sensitive PIEZO ion channels, express in bladder, are cation-selective mechanosensitive channels. PIEZO1 is a MSC protein and it is encoded by PIEZO1 gene in humans. PIEZO2 is a close homolog of PIEZO1. We aim to evaluate PIEZO1/PIEZO2 expression in post-natal period (P0-1) in mice bladder tissue as developmental and bladder cancer (BCa) tissue of mouse and human.

Material/Methods: The detection of developmental expression was performed in P0,P7,P14,P21,P28,P36 and P90 in bladder tissue of BalbC strain mice. Mice were divided into BCa group(n=40) and control group(n=10). BCa in mice was created by using N-butyl-N-(4-hydroxybutyl)nitrosamine (BBN). A total of 50 subjects were included in the study (40=BCa patients, 10=controls). After histopathological evaluation for BCa, expression of PIEZO1/2 genes were examined by RT-PCR and immunohistochemistry in tumor and normal tissues.

Results:PIEZO1 expression increased 21th and 90th days whereas PIEZO2 expression increased 7th day and decreased 90th day as developmentally. It was found in situ carcinoma in 14 samples, adenocarcinoma in 6 samples and benign proliferative changes in 10 samples in mice. Comparing with control group, it was detected significantly increase in expression of PIEZO1/2 in cancer groups in human and mice. Immunoreactivity had been observed against PIEZO1/2 both human and mouse bladder tissue with normal or cancer.

Conclusions: The developmental changes in spesific days of PIEZO expression is demonstrated to play role in BCa development. Although roles of PIEZO1/2 ion channels in BCa isn't known exactly, the dysfunction of PIEZO1/2 ion channels expression may contribute the carcinogenesis of BCa by causing proliferative changes.

P12.016

Genetic and epigenetic profile of tumor cells of 126 patients with diffuse brain gliomas

Z. Zemanova¹, H. Lhotska¹, K. Svobodova¹, H. Cechova², S. Ransdorfova², L. Lizzcova¹, F. Kramar³, Z. Krejci², L. Pavlistova¹, S. Izakova¹, A. Berkova¹, K. Skipalova¹, K. Michalova¹;

¹Center of Oncocytogenetics, Institute of Medical Biochemistry and Laboratory Diagnostics, General University Hospital and 1st Faculty of Medicine, Charles University in Prague, Prague, Czech Republic, ²Institute of Hematology and Blood Transfusion, Prague, Czech Republic, ³Department of Neurosurgery, Central Military Hospital and 1st Faculty of Medicine, Charles University, Prague, Prague, Czech Republic.

Diffuse gliomas are the most common brain tumors and comprise astrocytomas, oligodendrogliomas, and oligoastrocytomas (WHO grades II-III), and glioblastomas (grade IV). Lower-grade gliomas (LGG, grade II-III) have highly variable clinical behavior that is not adequately predicted on the basis of histological classification. Assessment of the genome aberrations will probably allow more robust and prognostically relevant classification of these tumors.

We performed genome-wide analyses of 126 samples of gliomas (100x LGG, 26x glioblastoma) with the aim to investigate the genetic and epigenetic background of different tumor subtypes. The tissues taken from primary tumors were analyzed using I-FISH with VYSIS probes (Abbott), SNP array (Illumina), and MLPA (MRC-Holland) to detect recurrent chromosomal aberrations, copy number variations, IDH mutations and hypermethylation of MGMT and MMR genes promoters.

Mutation of IDH genes was detected in 75.0% LGG. A total of 41.3% LGG patients with mutated IDH had simultaneous co-deletion 1p/19q, which is considered the indicator of better response to radio-chemotherapy. Acquired UPD17p was proven in 65.0% of astrocytomas and 23.1% of glioblastomas. In 46.2% glioblastomas, shattering of different chromosomes (chromothripsis) always in combination with complex changes was observed. In 39.0% LGG, new recurrent finding - hypermethylation of MLH3 gene promoter was detected. In our study, patients with LGG and hypermethylated MLH3 had significantly longer OS (p=0.001).

In conclusion, molecular-cytogenetic diagnostics is a powerful tool to obtain prognostically relevant information in glioma patients and therefore should be an integral part of examination in patients with brain tumors.

Supported by IGA MZCR NT/13212-4, RVO-VFN64165, GACR P302/12/G157.

P12.017

Hereditary breast/ovarian cancer: a systematic screening of 94 cancer associated genes in 500 consecutive index cases

A. Gehrig, I. Schmitt, C. R. Müller;

Department of Human Genetics, Würzburg, Germany.

Introduction: In about 25% of cases, hereditary breast and ovarian cancer (HBOC) is caused by mutations in BRCA1 or BRCA2. Additional DNA repair genes such as CHEK2, ATM, PALB2, RAD51C and others have been implicated in HBOC.

Methods: All 500 patients fulfilled the inclusion criteria defined by the German HBOC Consortium. After target enrichment with the TruSight cancer panel™ (Illumina) designed to simultaneously analyse 94 cancer associated genes - sequencing was performed on a MiSeq (Illumina). Variant analysis was done by GensearchNGS software (PhenoSystems) and the NextGENE CNV detection tool (Softgenetics).

Results: Coverage was at least 50-fold across 93% of all investigated coding regions. We focused on protein truncating mutations since functional data on other variants in these genes are scarce. In addition to BRCA1 and BRCA2, we detected pathogenic mutations (class 4 and 5) in the genes: ATM, CHEK2, NBN, PALB2, RAD51D, BRIP1, TP53, PTEN, CDH1, MSH6, FANCA, FANCC, FANCI, FANCM, XPC, ERCC2, RECQL4, SLX4, WRN, BLM, BUB1B, PMS1 and SBDS. CNVs were found in BRCA1, BRCA2, NBN and WRN.

Conclusions: We identified monoallelic, likely pathogenic mutations in DNA repair genes other than BRCA1/2 in about 10% of HBOC cases. However, the causative association to HBOC and the prospective tumor risks for many of these mutations and genes have yet to be determined. Of note, extending the analysis to a larger number of genes proportionally increases the number of variants of uncertain significance and the workload to survey and classify them.

P12.018

TruSight Enrichment Workflow vs PCR Amplicon Workflow (MASTR) for targeting cancer genes

M. Chatzidakis¹, Y. L. Loukas¹, G. Thodi², E. Molou², Y. Dotsikas¹, K. Schoulpi², O. Triantafylli²;

¹Department of Pharmacy, National and Kapodistrian University of Athens, Athens, Greece, ²Neoscreen LTD, Athens, Greece, ³Department of Mental Health and Social Welfare, Hospital Paidon "Agia Sofia", Athens, Greece.

Introduction: Breast cancer has been associated with mutations in other low and high penetrant genes except of BRCA. This knowledge allow us to identify more women at risk for breast cancer. The purpose of this study was to compare PCR Amplicon Workflow (BRCA HC MASTR Plus) which detects mutations and CNVs in 26 "breast cancer" genes and TruSight Enrichment Workflow (TruSight cancer) which targets 94 "cancer" genes.

Materials/Methods: 30 patients with mild to severe family history were subjected to BRCA HC Plus panel and 12 to the TruSight cancer panel (TC). Three runs were conducted using MiSeq 600V3 reagent kit in the former case, i.e.10 samples per run, while 4 samples each time were loaded on a MiSeq 300V2 kit, regarding the latter panel.

Results: Both panels require a low input of DNA and have an efficient workflow. Regarding hands- on time, it seems that BRCA HC MASTR Plus workflow is shorter and it may be easier for a less experienced user. Considering the quality of the final results, a high Q-score was achieved with both panels. However, the average coverage (read-depth) reached with the former panel was higher i.e. about 500x for most of the targeted genes compared to the one reached with the TC, regarding the common cancer genes.

Conclusion: TC panel could be a solution for cases with a rather inconclusive family history, but for patients with a distinct phenotype BRCA HC MASTR plus panel offers a rather more robust and efficient method for confirming diagnosis.

P12.019

BRCA1 and BRCA2 mutation spectrum in Lebanese women undergoing testing for hereditary breast/ovarian cancer

R. Badra¹, J. Abbas², M. Assaad², F. Boulos¹, N. El Saghir², C. Mounsef², D. Mukherji², Z. Salem², M. Seoud³, C. Farra¹;

¹Department of Pathology and Laboratory Medicine, American University of Beirut Medical Center, Beirut, Lebanon, ²Department of Internal Medicine, American University of Beirut Medical Center, Beirut, Lebanon, ³Department of Obstetrics and Gynecology, American University of Beirut Medical Center, Beirut, Lebanon.

Introduction: In Lebanon, breast cancer is considered the most common malignancy among women. Up to 10% of breast cancers are directly related to germline mutations in BRCA1 or BRCA2 genes. In this retrospective study, we aimed at reporting the prevalence of BRCA mutations in a Lebanese cohort of individuals with personal or strong family history of breast/ovarian cancer, in order to determine the role of BRCA testing in breast cancer risk assessment.

Materials and Methods: Genetic results of all Lebanese patients, who underwent full sequencing of BRCA1/2 at AUBMC between 2011 and 2015, were reviewed. Demographic and personal/family cancer history data were collected.

Results: Deleterious mutations were identified in 10.6% of the families (20/188) (16BRCA1, 4BRCA2). In total, twelve deleterious mutations were recognized, four of them were novel. In 30% (6/20) of the carrier families, the BRCA1 C44F mutation was identified; this is reportedly the most common mutation in our population, suggesting a possible founder effect. Two other mutations BRCA2 IVS24-1G>A and BRCA1 E720X accounted for respectively 15% and 10% of the familial mutations. Twenty five variants were considered of unknown clinical significance (10 BRCA1, 15 BRCA2).

Conclusions: Prevalence of BRCA mutations was found to be high among tested women. Three mutations accounted for more than 55% of the total detected mutations. This study stresses on the importance of BRCA testing in Lebanese women at high risk for breast/ovarian cancer. It also highlights interesting data in terms of prevalence and spectrum of BRCA mutations in our population.

P12.020

Prevalence and reclassification of BRCA1 and BRCA2 variants of uncertain significance in Spanish breast cancer families.

A. Gisbert¹, M. Cornet¹, D. Fisas², C. López², E. Martínez¹, M. Pintor², N. Calvo², T. Ramón y Cajal², A. Lasa^{1,3};

¹Genetics Department. Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, ²Oncology Department. Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, ³U-705, CIBERER, Barcelona, Spain.

INTRODUCTION: In the last two decades, the molecular diagnosis of hereditary breast and/or ovarian cancer has been based on the identification of germline inactivating mutations within the BRCA genes. Unfortunately, variants of uncertain significance (VUS) still occur in 5-10 % of tests. The aim of this study was to reassess the pathogenicity of VUS identified in families counseled at our hospital.

MATERIAL AND METHODS: VUS were reclassified into class I, II, III, IV and V following the International Agency for Cancer Research (IARC) recommendations. This was done by means of a thorough review of online database resources such as BIC (<http://research.nhgri.nih.gov/bic/>), LOVD (<http://www.lovd.nl/3.0/home>) and KConFab (<http://www.konfab.org/Progress/Mutations.aspx>) together with a systematic literature review. The final classification was based on the use of integrated analyses, in vitro transcript assays and in silico tools.

RESULTS: From 1995 to 2015, 1200 families were tested for BRCA1/2 germline mutations. A total of 307 variants were identified in 253 families and 182 were unique.

Our integrative approach allowed us to reclassify 96/182 variants originally categorized as VUS (class III). Eighty of them (83%) were predicted to be non-pathogenic or class I, 7 (7%) were reclassified as class II, 5 (5%) as class IV and 4 (4%) as class V. The other 86 remained as class III.

CONCLUSIONS: The continuous reassessment of VUS remains a challenge for clinicians and geneticists. The wealth of information provided by NGS studies, facilitated the reclassification of more than half of our original VUS, thus allowing us to improve our preventive strategy.

P12.021

Reliable detection of BRCA-mutations in formalin-fixed, paraffin-embedded ovarian carcinomas using smMIP-based next generation sequencing

R. Weren¹, A. Mensenkamp¹, M. Simons¹, A. Sie¹, M. Nelen¹, H. Ouchene¹, M. van Asseldonk¹, A. Eijkelenboom¹, J. Shendure², A. Hoischen¹, B. Tops¹, N. Hoogerbrugge¹, M. Ligtenberg¹;

¹Radboudumc Nijmegen, Nijmegen, Netherlands, ²University of Washington, Seattle, WA, United States.

Introduction. Poly(ADP-ribose) polymerase (PARP) inhibitors are promising novel therapies for ovarian cancer patients who have developed BRCA1 or BRCA2 mutation-positive tumors. Approximately 15% and 8% of these patients have an inactivating germline or somatic BRCA-mutation, respectively. Therefore, assessing the BRCA-mutation status in DNA derived from ovarian carcinomas is crucial to select patients who may benefit from these treatments. However, the detection of germline and somatic mutations in BRCA1 and BRCA2 is hampered by the poor quality of DNA derived from formalin-fixed, paraffin-embedded (FFPE) ovarian carcinomas and the complexity of both genes.

Materials and Methods. We present a single molecule molecular inversion probe-based targeted sequencing approach to detect germline and somatic

mutations in BRCA1 and BRCA2 in DNA derived from FFPE ovarian carcinomas. This method was applied to 107 ovarian carcinomas derived from patients with a BRCA1 (n=24) or BRCA2 (n=14) germline mutation and sporadic patients (n=50) before and after chemotherapy. Calculation of the technical sensitivity and reduction of the levels of sequencing background noise was achieved using molecular barcoding to recognize unique template molecules.

Results. All germline mutations in BRCA1 and BRCA2 were successfully detected. In addition, pathogenic somatic mutations in BRCA1 and BRCA2 were observed in five sporadic patients (10%).

Conclusions. Our approach enables the rapid and reliable detection of both germline and somatic mutations in BRCA1 and BRCA2 in DNA derived from FFPE ovarian carcinomas. Consequently, this method can be applied to select ovarian cancer patients who may benefit from treatments with PARP inhibitors and genetic counseling.

P12.022

Experience of BRCA clinical testing for 3,200 patients: An international perspective

L. Wange¹, S. Wehnelt¹, D. Gebis², J. House², K. Copeland³, L. Esterling², S. Manley², H. C. Cox²;

¹Myriad GmbH, Munich, Germany, ²Myriad Genetic Laboratories, Inc., Salt Lake City, UT, United States, ³Myriad Genetics GmbH, Zurich, Switzerland.

Introduction: Inherited mutations in the BRCA1 and BRCA2 genes are the most common cause of hereditary breast and ovarian cancer (HBOC) across human populations. Clinical screening of germline variants has been routine for over 2 decades in countries such as the USA. However, testing is becoming increasingly accessible on the global scale. We report the outcomes of clinical BRCA genetic testing in a cohort ascertained across 33 countries representing 6 continents.

Methods: This study assessed 3,229 consecutive individuals undergoing BRCA1 and BRCA2 full sequencing and large rearrangement analysis in a DAkkS accredited laboratory in Munich, Germany from 2013 to 2015. Clinical information was obtained from test requisition forms completed by ordering healthcare practitioners, with the majority of patients ascertained on suspicion of HBOC.

Results: Over 98% of patients were female and 72% reported a personal history of cancer. The most frequent female cancer was breast (63%), followed by ovarian (8%). Males comprised <2% of the patients and greater than 50% of them reported a personal history of breast cancer. Overall, 12.7% of patients tested positive for a laboratory classified pathogenic variant. Pathogenic variants were enriched in patients with a personal history of cancer (13.9%) versus no personal cancer history (9.5%); this is especially striking in cancers directly associated with HBOC. Pathogenic variants were detected in patients originating from Europe, Asia, Africa and North and South America.

Conclusion: BRCA clinical testing is valuable at the global level for identifying high-risk patients who would benefit from increased surveillance and medical intervention.

P12.023

Germline and somatic BRCA1/2 mutations in ovarian cancer patients unselected for family history

G. Rodella¹, R. Zuntini^{1,2}, G. Barbero¹, M. G. Tedesco¹, S. Miccoli^{1,2}, L. Godino^{1,2}, A. M. Perrone^{2,3}, D. Santini^{2,4}, B. Corti⁴, C. N. Salvi⁴, F. Buscherini¹, S. Ferrari^{1,2}, P. De Iaco^{2,3}, C. Zamagni^{2,5}, D. Turchetti^{1,2};

Orsola-Malpighi, Bologna, Italy, Bologna, Italy, ⁴SSD UO Anatomia Patologica, AOU di Bologna, Policlinico S. Orsola-Malpighi, Bologna, Italy, Bologna, Italy, ⁵Oncologia Medica, AOU di Bologna, Policlinico S. Orsola-Malpighi, Bologna, Italy, Bologna, Italy.

Ovarian Cancer (OC) is the seventh most common cause of cancer-related death in women. It is estimated that about 15% of OC arise in women carrying germline BRCA1/2 mutations and that 3% of sporadic serous OCs harbour somatic BRCA1/2 mutations; BRCA deficiency is predictive of response to PARP-inhibition.

Since July 2015, we have included for BRCA1/2 testing also women with high grade OC with no suggestive family history. Among 21 patients with apparently sporadic OC who have undertaken testing to date, complete results are available for 12; four of those (33%) carry a deleterious mutation (three in BRCA2, one in BRCA1). In addition, we undertook a research project aimed at analysing BRCA1/2 in fresh-frozen tissue of newly diagnosed OC patients. So far, 15 patients have been enrolled; BRCA1 sequence analy-

sis allowed to identify three mutations out of 14 tested tumors (21%), all showed LOH; moreover, one mutation was found in one out of 13 tumors sequenced for BRCA2, which failed to show LOH. All BRCA1/2 sequence mutations were subsequently found to be germline. BRCA1 MLPA analysis was performed in 11 tumors and detected 8 acquired deletions of the whole gene (three explaining LOH in mutation carriers). Out of eight tumors analyzed with BRCA2 MLPA, two showed deletion of the whole gene (one in a tumor also showing loss of BRCA1). Although preliminary, our results support a relevant frequency of germline BRCA1/2 mutations in OC patients, while somatic mutations appeared to be limited to monoallelic BRCA1 and/or BRCA2 loss.

P12.024

Prevalence of pathogenic gene variants associated with breast and ovarian cancer in Estonia

H. Roomere, Ü. Murumets, P. Laidre, T. Kahre;

Tartu University Hospital, United Laboratories, Department of Genetics, Tartu, Estonia.

Introduction: Breast cancer (BC) is the most common cancer among Estonian women, 650 new cases are diagnosed annually. Ovarian cancer (OC) is less frequent, 150 new cases per year. ~10% of cancers are associated with hereditary predisposition.

Materials and Methods: Altogether 953 individuals (906 females, 47 males) were sent for genetic testing by oncologist or medical geneticist during 2008 - 2015. BC was diagnosed in 339 patients (36%) and OC in 122 (13%), 14 patients had both cancers. 478/953 were high risk family members. 182 patients (19%) were 45y or younger. 654 (69%) had family history of BC/OC. BRCA1/2 genes were analysed either by APEX, Sanger or next generation sequencing (NGS). 314 patients were analysed against BC/OC high and medium risk genes by NGS. Deletions/duplications in BRCA1/2 genes were excluded by MLPA analysis in 547 patients.

Results: 158 patients (17%) were mutation-positive. The prevalence of BRCA1/BRCA2 mutations in BC/OC group (447 patients) was 18%, BRCA1 main mutations ratio was 45%. Interestingly we did not find any deletions/duplications from BRCA1/2 MLPA. In 26 cases (BRCA1/2 negative) the pathogenic variant was found either from PPMID, BRIP1, CHEK2, MSH2, MSH6, PMS1, CDH1, ATM or NBN gene.

Conclusions: Two main mutations in BRCA1 cover ~54% of all BRCA1/2 pathogenic mutations in Estonia: c.4035delA (21%); c.5266dupC (33%). Therefore we recommend start screening with detection of these two relatively common BRCA1 mutations and in case of negative result continue with NGS. BRCA1/2 MLPA analysis is not informative in Estonia.

P12.025

TruRisk® based next-generation sequencing and CNV detection demonstrate the importance of implementing other breast and ovarian cancer-associated genes in routine diagnostics

L. Buelow, B. Bluemcke, E. Pohl, B. Versmold, A. Waha, J. Driesen, K. Keupp, A. Baasner, I. Praulich, J. Hauke, E. Hahnen, B. Wappenschmidt, R. Schmutzler; Center for Hereditary Breast and Ovarian Cancer, Cologne, Germany.

Approximately 24% of familial breast cancer (BC) and/or ovarian cancer (OC) cases analyzed within the framework of the German Consortium for Hereditary Breast and Ovarian Cancer (GC-HBOC) are caused by pathogenic BRCA1/2 mutations. However, the mutation frequencies of non-BRCA1/2 genes associated with familial BC and/or BC/OC are largely unknown. Therefore, panel next-generation sequencing represents a comprehensive approach to simultaneously analyse numerous candidate genes regarding their involvement on BC/OC pathogenesis. Here, we present extended NGS data generated by using the GC-HBOC-designed TruRisk® gene panel. In this study, a cohort of 594 index cases from high-risk BC and BC/OC families, negative regarding deleterious mutations in BRCA1/2 was analyzed. Data analysis was accompanied by CNV detection using the SophiaDDM Version 3.5.0.12-p5.0.0 analysis tool (Sophia Genetics). By focusing on 13 BC and/or OC associated genes (ATM, CDH1, CHEK2, FANCM MLH1, MSH2, MSH6, NBN, PALB2, PTEN, RAD51C, RAD51D, TP53), we identified 25 different pathogenic variants, including large rearrangements, in 25 unrelated mutation carriers (4,2%). Mutations were identified in ATM (n=3), CHEK2 (n=10), FANCM (n=4), PALB2 (n=7) and RAD51C (n=1). 24% of these mutations are large rearrangements, found in ATM, CHEK2 and FANCM. Therefore, our study highlights the importance of comprehensive gene panel testing along with CNV detection to be included in BC and/or OC routine diagnostics. The results of the CNV detection together with further approximately 300 samples, which are already processed, will be evaluated.

P12.027

Easy-to-use online self-test identifies women at high familial risk of breast cancer and decreases anxiety

A. van Erkelens, N. Hoogerbrugge;

Radboud University Medical Center, Nijmegen, Netherlands.

Introduction: Individuals at an increased familial BC risk should be identified, as they and their relatives can receive earlier and more intensive BC surveillance. An online self-test for familial BC can identify women at increased familial risk and may decrease anxiety and distress even in patients at low risk.

Methods: Women invited for population-based screening mammography were also invited for an online self-test and questionnaires. Psychological impact was assessed at baseline (T0), immediately post-test (T1), after two weeks (T2) using the State-trait inventory Dutch Version (STAI-DY) and Hospital Anxiety and Depression Scale (HADS).

Results: In total, 304 completed T0 and T1, 195 completed T2. At T1, a moderate or high familial BC risk was identified in four (1%) and 18 (6%) women. There was a significant reduction in state anxiety at T1 and T2 (T1-T0: mean change = -1.69 (95%CI:-2.21,-1.17), P<0.001; T2-T0: mean change = -2.69 (95%CI:-3.93,-1.45), P<0.001). Similarly, trait anxiety but not distress were reduced at T2 (mean change = -1.31 (95%CI:-2.14,-0.48), P=0.002; mean change = -0.18 (95%CI:-0.78,0.43), P=0.57). Women at moderate or high familial BC risk had slightly higher levels of anxiety and distress at T0, T1 and T2, and similar decreases in psychological outcomes between T1-T0 and T2-T0.

Conclusion: An online self-test for familial BC identified women at moderate or high familial BC risk (prevalence 6%) and decreased anxiety. Adding familial risk assessment to population BC screening may prevent BC in relatives.

P12.028

Founder BRCA1 and BRCA2 mutations in women with breast and/or ovarian cancer from Eastern Europe (Ukraine): application of next generation sequencing

A. Myszka¹, H. Akopyan^{1,2}, N. Kitsera³, F. Hammet³, H. Tsimiklis³, D. Park³, T. Nguyen-Dumont³, M. Southey³;

¹Institute of Obstetrics and Emergency Medicine, University of Rzeszow, Rzeszow,

Poland, ²Institute of Hereditary Pathology of National Academy of Medical Sciences, Lviv,

Ukraine, ³The Genetic Epidemiology Laboratory, Department of Pathology, University of Melbourne, Melbourne, Australia.

Mutations in a small number of genes have been associated with a high risk of breast and ovarian cancer. The frequency of founder mutations in BRCA1 and BRCA2 genes can inform genetic testing strategies for some populations. The main purpose of the study was to search for new pathogenic mutations that are associated with high risk of breast and/or ovarian cancers in the Ukraine population.

The study group consisted of 132 women from West Ukraine diagnosed with breast cancer and/or ovarian cancer. All cases had a positive family history of breast and/or ovarian cancer. DNA samples were isolated from blood. Studies were performed using Hi-Plex technology incorporating massively parallel sequencing (next generation sequencing).

In the group of patients we detected 25 (19%) pathogenic mutations in BRCA1 (5 recurrent and 3 singular mutations) and 9 (7%) pathogenic mutations in BRCA2. The study identified a large number of variants in BRCA1 and BRCA2 that have uncertain or conflicting significance to breast and ovarian cancer risk.

This was the first study of women at high risk of breast and/or ovarian cancer from the West Ukraine population using next generation sequencing and established that there is a high frequency of BRCA1 and BRCA2 mutations in this population. The results will contribute to improved genetic testing in the Ukrainian population that currently relies on the testing of a limited selection of specific mutations in BRCA1 and BRCA2 in clinical genetics practice. Improved genetic risk assessment could also lead to improved cancer prevention in this population.

P12.029

Germline BRCA1, BRCA2, NBN, CHEK2, TP53 mutations in the group of the young Polish patients diagnosed with breast cancer.

D. Nowakowska¹, D. Czupczak², U. Piekarska¹, A. Kluska¹, A. Janiec-Jankowska¹;

¹The Maria Skłodowska-Curie Cancer Center & Institute in Warsaw, Warsaw, Poland,

²The Maria Skłodowska-Curie Cancer Center & Institute of Oncology in Warsaw, Warsaw, Poland.

Breast cancer (BC) at young age is associated with poor prognosis, therefore there is a great need to characterize better this group of patients.

Material/methods: 334 women with BC at/under the age of 35 were of-

ferred genetic counseling and testing. The analysis was performed on DNA from the peripheral blood. The mutations in BRCA1,2 were detected using DHPLC and sequencing of exons in which the Polish founder mutations are found most frequently. TP53 gene was sequenced from exon 2 to 10. All the samples were screened for the Slavic c.657-661del5 mutation in NBN gene and for the most common mutations in CHEK2.

Results: In this group of 334 patients we identified 67(20%)BRCA1,2 mutation carriers and 3 TP53(0,9%), 3 NBN (0,9%),3 CHEK2(0,9%) carriers. Majority of the BRCA1 mutations were founder Polish mutations. Most of the BRCA1 carriers had 1st and/or 2nd degree relatives with breast and/or ovarian cancer. There was no such correlation in the group of BRCA2 and TP53 mutation carriers, however all TP53 carriers had BC with high expression of estrogen and progesterone receptor and overexpression of Her2 („triple positive BC“. **Conclusion:** In Polish women diagnosed with BC at very young age genetic testing for the BRCA1,2 mutations should be offered, even in the absence of relevant family history. Screening for the founder Polish BRCA1 mutations is not sufficient in this group. In the youngest women diagnosed with „triple positive“ BC sequencing of TP53 gene should be considered. Genetic testing may guide important diagnostic and therapeutic decisions in this group of patients.

P12.030

Identification of novel candidate genes for hereditary breast cancer via whole exome sequencing

D. Turchetti^{1,2}, R. Zuntini^{1,2}, F. Isidori¹, C. Diquigiovanni³, F. Buscherini³, F. Palombo³, S. Miccoli^{1,2}, E. Bonora^{1,2};

¹Centro di Ricerca sui Tumori Ereditari, Dipartimento di Scienze Mediche e Chirurgiche,

Università di Bologna, BOLOGNA, Italy, ²Genetica Medica, Policlinico S.Orsola-Malpighi,

Bologna, Italy, ³Genetica Medica, Policlinico S.Orsola-Malpighi, BOLOGNA, Italy.

Hereditary breast cancer (HBC) accounts for 5% of BC cases. Germline BRCA1/2 mutations explain 60% of HBC, but no other major genes have been identified in the remaining 40%.

We decided to perform whole exome sequencing (WES) in affected I-degree cousin-pairs displaying features suggestive of HBC, who tested negative for BRCA1/2. Based on their relationship, I-degree cousins share 1/8 of the entire genome, which helps filter and select candidate variants. To date, 4 cousin-pairs were analyzed through WES and candidate variants were identified in three different genes in 3 pairs, whereas the fourth one shared a BRCA2 deletion not previously identified by Sanger sequencing.

The candidate variants, affecting ROS1, RASAL1 and ICAM5 genes, were confirmed by direct sequencing. Further characterization of the variants is ongoing. In particular, the ROS1 variant affected a predicted canonic splice site, suggesting an effect on the correct splicing of ROS1, a tyrosine kinase receptor that has been implicated in several cancer types. We inserted the wild-type or mutant genomic region into a minigene plasmid, transfected it into COS7 cells, and found that the mutant cells used a cryptic intronic splice site 20 bp downstream, leading to the insertion of a premature stop-codon in the protein. Future studies will explore the effect of the variant on cell growth/proliferation and invasion in CRISP/Cre-modified MCF10A and MCF7 cells.

Our findings support previous evidence that many different genes account for the fraction of HBC not related to BRCA1/2 mutations and led us to identify promising novel variants for HBC.

P12.031

Cluster analysis of breast cancer expression profiles and the search for genes associated with metastatic tumors

K. Grishina¹, T. Muzaffarova¹, N. Pospekhova¹, S. Poyarkov¹, E. Glubokova¹, V. Khaylenko², A. Karpukhin¹;

¹Research Centre for Medical Genetics, Moscow, Russian Federation, ²Blokhin Russian Cancer Research Centre, Moscow, Russian Federation.

The investigation of 75 gene quantitative expression levels in a sample of breast cancer tumors in relation to the normal breast tissue was performed. All patients of the sample were not subject to radiation, neither to chemotherapy. The set of 75 genes was formed on the basis of their participation in the progression of breast cancer. By cluster analysis 3 clusters of gene co-expression were identified. Two of them were enriched by metastasis cases. The frequency of metastasis cases was not significantly different in these clusters that allowed combining them (group 1). A statistically significant difference in the frequency of cases with metastasis in group 1 in relation to the cluster poor in metastasis (group 2) was shown (OR = 20, 95% CI = 1,9 to 218,4 p = 0,01). The 14 differentially expressed genes in group 1 relative to group 2 with significantly different expression level were identified. The 11 of them were differentially expressed in both clusters with metastasis and 3 were specifically expressed only in one cluster. The most highest le-

vel of gene expression revealed in one cluster MMP9 and FN1, and uPAR, PLAUR, ZEB2 in another cluster with metastasis. Excess of the expression level of these genes in cluster with metastasis relative to the group 2 is 10 - 50 times.

P12.033

Evaluation of circulating miRNAs expression as non-invasive biomarker for Breast Cancer in Iranian women

E. Soleimanpour¹, M. Hosseinpour Feizi¹, E. Babaei¹, V. Montazeri²;

¹Tabriz University, Tabriz, Iran, Islamic Republic of, ²Noor Nejat Hospital, Tabriz, Iran, Islamic Republic of.

Introduction: Breast cancer is the most common cause of cancer mortality among women. So, early detection and targeted therapies of cancer can significantly reduce the mortality as well as increase the survival rate. MicroRNAs are a well-known candidate to develop predictive and prognostic biomolecules that can be affordably used as early and non-invasive detection marker. The aim of this study was to evaluate the expression levels of miR-21 and miR-155 in Iranian Breast cancer patients and the potential use of circulating miRs as non-invasive biomarker.

Material and methods: Tumor specimens, paired non-tumoral adjacent tissues and matching plasma samples from 30 Iranian women breast cancer were collected. Plasma of normal women were also used as control. The relative expression of miR-21 and miR-155 was measured by real-time quantitative reverse transcription PCR.

Results: The levels of miR-21 and miR-155 were significantly higher in plasma ($p=0.02$ and 0.01 , respectively) and tissue sample ($p=0.00$ and 0.00 , respectively) of breast cancer patients in comparison with control groups. Receiver operating characteristic curve analysis revealed 0.81 and 0.83 in miR-21 and miR-155 tissue, as well as 0.99 and 0.92 in miR-21 and miR-155 plasma samples respectively. Moreover, there was no relation between the expression level of miRs and clinic-pathologic data.

Conclusion: These finding revealed that the expression patterns of these circulating miRs in Iranian women are the same as their paired tissue groups and also other population over the world. So, circulating miR-21 and miR-155 can be used as non-invasive biomarker for breast cancer detection.

P12.035

Results of BRCA1 and BRCA2 mutation screening with next generation sequencing in a cohort of breast and ovarian cancer patients in Trakya region of Turkey

H. Tozkar¹, S. Demir Ulusal¹, E. Atlı¹, A. Sezer², H. Gürkan¹, N. Tunçbilek³;

¹Trakya University, Medical Faculty, Department of Medical Genetics, Edirne, Turkey,

²Trakya University, Medical Faculty, Department of General Surgery, Edirne, Turkey,

³Trakya University, Medical Faculty, Department of Radiology, Edirne, Turkey.

Introduction: The role of BRCA1 and BRCA2 gene mutations in breast and ovarian cancer risk is supported by a great number of studies worldwide. Here we report a novel mutation in BRCA2 gene in a patient with breast cancer and summarize the BRCA1/BRCA2 mutation screening results of 54 patients (2 males, 52 females) enrolled to our center between November 2014- October 2015.

Methods: Automated DNA isolation was performed from peripheral blood samples of 54 patients using EZ1 DNA isolation kit. Coding regions of BRCA1(NM_007294.3) and BRCA2 (NM_000059.3) genes were captured by Ion Ampliseq Library Kit V2.0. Target enrichment was performed by Ion One Touch OT2 200 kit followed by semiconductor sequencing on Ion Personal Genome Machine. Torrent Suite Software and Ion Reporter Software were used to analyze mutations. IGV was used to visualize the amplicons. At least 100X coverage of the bases in the targeted regions were accepted for precise analysis of the mutations. Sanger sequencing was performed to confirm the presence of the mutations and to screen the other family member if needed.

Results: In total, pathogenic mutations were found in 6 patients. NM_007294.3(BRCA1):c.5266dupC(p.Gln1756Profs*74) (2/54 patients), NM_000059.3(BRCA2):c.67+1G>A (2/54 patients) and NM_000059.3(BRCA2):c.1773_1776delTTAT(p.Ile591Metfs) (1/54 patients) mutations were determined. A novel mutation, NM_000059.3(BRCA2):c.721A>T(p.Lys241Ter) was found in a patient with breast cancer diagnosed at age 22.

Conclusion: Pathogenic mutation frequency was 11.11% in our cohort. We suggest that mutation screening of BRCA1 and BRCA2 genes by next generation sequencing is a practical method for genetic testing of high risk populations.

P12.036

Landscape of the mutation pattern in 4175 HBOC families using NGS panel

L. Castéra^{1,2,3}, S. Krieger^{1,2,3}, N. Goardon¹, A. Ricou¹, A. Rousselin¹, A. Legros¹, O. Bruet¹, C. Quesnelle¹, F. Domin¹, C. San¹, B. Brault¹, R. Fouillet¹, C. Abadie¹, O. Béras⁵, P. Berthet¹, O. Letac¹, T. Frebourg^{6,7,3}, D. Vaur^{1,2,3};

¹Comprehensive Cancer Centre François Baclesse, Caen, France, ²Normandy Centre for Genomics and Personalized Medicine, Caen, France, ³Inserm U1079, Rouen, France,

⁴Comprehensive Cancer Centre Eugène Marquis, Rennes, France, ⁵University Hospital,

Fort de France, France, ⁶Rouen University Hospital, Rouen, France, ⁷Normandy Centre for Genomics and Personalized Medicine, Rouen, France.

In 2012, to optimize the molecular diagnosis of hereditary breast and ovarian cancer (HBOC), we validated a NGS-based routine screening based on the capture of 21 to 33 genes involved in HBOC and paired-end sequencing on Illumina platforms. The bioinformatic pipeline includes CASAVA, NextGENe, CNVseq and Alamut-HT and a custom interfaced database (CanDiD). Using this strategy, we have now analyzed 4175 patients and detected 722 (17%) deleterious mutations. The majority of the mutations (83%) were found in BRCA1, BRCA2, CHEK2, PALB2, ATM, TP53, RAD51C, BRIP1, RINT1 with respective incidences of 4.6%, 4%, 1.2%, 1.1%, 1%, 0.6%, 0.5%, 0.4%, 0.3%. BRCA1 and BRCA2 exhibited 359 mutations including 26 large rearrangements. The 46 mutations detected in PALB2 were mostly found in women with a cancer over 40 years and the 21 RAD51C mutations preferentially in women with ovarian cancer. TP53 was mutated in 23/3865 index cases including only 4 characteristic Li Fraumeni families and preferentially in women with breast cancer before 31 years. These results demonstrate the efficiency of this NGS procedure to perform molecular diagnosis of HBOC, confirms the genetic heterogeneity of HBOC and show that the fraction of potentially deleterious mutations detected within the other genes than BRCA1 and BRCA2 justifies their analysis and additional studies to estimate the associated cancer risks.

P12.037

Parent of origin and prognosis in hereditary non-BRCA breast cancer in Sweden

C. Wendt^{1,2}, A. Lindblom^{3,4}, S. Margolin^{1,5};

¹Department of Oncology-Pathology, Karolinska Institutet, Stockholm, Sweden,

²Department of Oncology, Karolinska Hospital, Solna, Stockholm, Sweden, ³Department

of Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden,

⁴Department of Clinical Genetics, Karolinska University Hospital, Solna, Stockholm,

Sweden, ⁵Department of Oncology, Karolinska University Hospital, Solna, Stockholm, Sweden.

Introduction: Breast cancer prognosis is affected by tumour characteristics and adjuvant treatment. It has been suggested that prognosis in familial breast cancer could be influenced by parent of origin with a worse prognosis when breast cancer is inherited paternally. The aim of this study was to investigate parent of origin effects on prognosis in our cohort of non-BRCA hereditary breast cancer families in Stockholm, Sweden.

Material and methods: Pedigrees from 1782 families were eligible. Index patients were divided into two study groups, paternal and maternal inheritance. Tumour characteristics and survival data for the index patients were collected and analysed.

Results: In total 319 families fulfilled inclusion criteria, 229 and 90 index patients in maternal and paternal group respectively. Affected mothers were excluded to avoid bias. Median follow-up was 11 years. No significant difference in overall survival or recurrence-free survival between maternal and paternal inheritance of breast cancer was observed with hazard ratios 0.99 (95% CI: 0.54 to 1.80) and 1.22 (95% CI: 0.78 to 1.92) respectively.

Conclusion: We found no evidence for a worse prognosis with paternally inherited breast cancer compared to maternal inheritance. However, with this sample size only large differences in prognosis can be detected. In that perspective the tendency towards worse recurrence-free survival (HR 1.22, 95% CI: 0.78 to 1.92) in the group with paternal inheritance is interesting. Also notable is the skew distribution with a predominance of maternally inherited cases indicating that accuracy of self-reported family history is low for paternally inherited breast cancer.

P12.038

A potential role for germline RECQL mutations in breast and ovarian cancer susceptibility

K. De Leeneer, G. Wieme, L. Vergote, I. Coene, F. Malfait, T. Van Maerken, B. Poppe, K. Claes;

CMGG Ghent University Hospital, Ghent, Belgium.

Breast cancer is the most common malignancy among women and the contribution of hereditary susceptibility has been well recognized. However,

since the known moderate-to-high risk genes explain only 5% of breast cancer incidence, the identification of new genetic factors is crucial. Recently, RecQ helicase-like (RECQL) was identified twice as a breast cancer susceptibility gene by whole exome sequencing (Cybulski et al., 2015; Sun et al., 2015). No other data on the prevalence of RECQL mutations in breast cancer susceptibility are currently available.

We evaluated the complete coding and splice site regions of RECQL in 323 unrelated (BRCA1/2 and PALB2 negative) breast and ovarian cancer families referred to our center for genetic testing. Mutation detection was performed with a targeted resequencing approach starting with singleplex PCR, Nextera XT library preparation and sequencing by synthesis on a Miseq instrument. Reads were mapped with the use of CLCbio v7 and called variants annotated by an automated pipeline using VEP and Alamut. Detected variants were confirmed with Sanger sequencing.

In total 12 unique sequence variants were identified, of these, two splice site variants (c.867+3A>T and c.1798-2 A>G) and one missense substitution predicted to be damaging (c.1114G>A; p.Val372Ile) in the helicase domain warrant further investigation. These 3 novel variants were detected in families with a strong predisposition for ovarian cancer, hinting towards a possible role for RECQL in ovarian cancer predisposition in the Belgian population. In a second stage of this study the prevalence of RECQL mutations will be evaluated in ovarian cancer families.

P12.039

Variants in eight cancer genes (AIP, ATM, BLM, BRIP, CHEK2, EXT2, FANCM and RECQL4) and breast cancer risk

M. Jakimovska¹, K. Kubelka², L. Stojanovska³, A. Arsovski³, M. Karagjovov², D. Plaseska-Karanfilska¹;

¹Research Centre for Genetic Engineering and Biotechnology, Skopje, Macedonia, The Former Yugoslav Republic of; ²Acibadem Sistina Hospital, Skopje, Macedonia, The Former Yugoslav Republic of; ³Re-Medika Hospital, Skopje, Macedonia, The Former Yugoslav Republic of.

Recently, a number of moderate and low susceptibility genes have been demonstrated to account for a significant breast cancer (BC) risk. In this study we have screened 12 variants in eight cancer genes (AIP, ATM, BLM, BRIP, CHEK2, EXT2, FANCM and RECQL4) among 180 familial breast cancer patients and 180 controls from the general population, using a multiplex single based extension method. We have previously detected these variants among BC patients during the panel-based NGS screening of 94 cancer genes. Based on ClinVar and/or type of the mutation, five variants were pathogenic, while seven were variants of unknown significance (VUS). All VUS were predicted as deleterious with at least two in silico prediction tools. The variants were either present with very low frequency (<0.3%) or were not found in ExAC database, with the exception of FANCM c.4799C>T (2.7% among Europeans). We have detected higher number of variants (n=27) among BC patients in comparison to the controls (n=13, p=0.0188). The most frequent variant was FANCM c.4799C>T (2.22% in BC and 1.11 in controls), followed by AIP c.47G>A, ATM c.7475T>G and AIP c.911G>A. FANCM c.1972C>T was found in one BC patient and two controls, BLM c.11T>C in one BC patient and one control, while BLM c.1642C>T, BRIP1 c.751C>T, CHEK2 c.1550G>A, EXT2 c.2034+1G>T and RECQL4 c.1868G>A were detected each in only one BC patient. Detection of higher number of variants in these eight genes among BC patients leads to the conclusion that these variants can be considered as risk factor for breast cancer.

P12.040

Impact of low penetrance variants on breast cancer morbidity

M. Ustinova, Z. Daneberga, M. Nakazawa-Miklaševića, L. Kalniņa, E. Miklaševića, J. Gardovskis; Riga Stradiņš University, Institute of Oncology, Riga, Latvia.

Introduction: Four of low-penetrance variants were chosen to test their impact on breast cancer morbidity and prognosis in the given population.

Materials and Methods: Tested population consisted of 2,530 European descent breast cancer patients and 731 healthy gender matched controls. SNP genotyping was carried out by restriction fragment length polymorphism and TaqMan SNP genotyping assays. Data analysis was performed using the program Rv3.1.0.

Results: The diverse effect of variants on breast cancer risk was observed (Table1.).

Table 1. Case-control study results.

SNP	Zygosity	OR	95% CI	P-value
rs9693444	Heterozygous	1.39	1.11-1.75	0.005
	Homozygous	1.51	1-2.34	
rs1436904	Heterozygous	0.79	0.63-1	0.008

rs616488	Homozygous	0.62	0.45-0.87	0.367
	Heterozygous	0.86	0.68-1.09	
rs204247	Homozygous	0.84	0.57-1.25	0.423
	Heterozygous	0.88	0.68-1.14	
	Homozygous	1.04	0.75-1.45	

We observed notably protective effect in the case of rs1436904 positive and rs9693444 wild type genotype compared to rs1436904 wild type and rs9693444 positive allele combination (OR=0.54; 95% CI=0.39-0.73; p<0.001). Disease specific survival rates did not show significant prognostic impact for any of tested variants. Worse prognosis trend (p=0.0877) was observed for rs9693444 positive and rs1436904 wild type genotype compared to rs1436904 positive and rs9693444 wildtype genotype.

Conclusion: Rs9693444 proved association with increased breast cancer risk, rs9693444 has a protective effect, but rs616488 and rs204247 has no impact on breast cancer risk in given population.

Genomic analysis of dual breast cancer tumors for determination of tumor progression and evolution

G. Repiska¹, T. Sedlackova², M. Mego³, J. Radvansky², Z. Cierna⁴, M. Chovanec², F. Duris⁵, N. Muratiova², G. Minarik²;

¹Comenius University in Bratislava, Faculty of Medicine, Institute of Physiology, Bratislava, Slovakia, ²Comenius University in Bratislava, Faculty of Natural Sciences, Department of Molecular Biology, Bratislava, Slovakia, ³Comenius University in Bratislava, Faculty of Medicine and National Cancer Institute, 2nd Department of Oncology, Bratislava, Slovakia, ⁴Comenius University in Bratislava, Faculty of Medicine, Institute of Pathological Anatomy, Bratislava, Slovakia, ⁵Comenius University in Bratislava, Faculty of Mathematics, Physics and Informatics, Department of Computer Science, Bratislava, Slovakia.

Introduction: Cancer as disease is characterized by extreme genetic heterogeneity. Also when it comes to specific cancer types the heterogeneity is still present not only on interindividual basis but also on intratumoral level. The genomic analysis of dual tumors originated from the same patient could bring new information in the field of detection of disease progression and tumor evolution.

Materials and Methods: Dual breast cancer tumors of 4 patients were analyzed with ultradeep genomic sequencing. For genomic sequencing TruSeq Amplicon Cancer Panel and Miseq system were used. Gained genomic data were analyzed using BaseSpace standard analysis tool for TruSeq applications. After variant calling variants with frequency between 10% and 90% were compared between the two samples originated from single patient. Tumor specific variants were subsequently characterized in details.

Results: After variant calling from 147 to 172 variants were identified. From these 13 to 22 variants were present in 10 to 90% variant frequency and except by both tumor samples shared variants in all tumor pairs at least one single tumor specific variant associated with oncogenic effect was recorded. These were represented by variants in *ERBB2* (p. V777L and p.L869R), *TP53* (p.P152fs*14 and p.Y205S) and *PIK3CA* (p.Q546E and p.H1047R) genes.

Conclusions: Identified shared as well as single tumor specific variants with confirmed oncogenic effect could be used in personalized disease progression on molecular testing. Moreover, with addition of future prospectively gained biological samples and clinical information important knowledge about tumor evolution could be added.

Rescuing low tumor-content formalin-fixed paraffin embedded (FFPE) biopsies for whole exome sequencing by DEPArray™ digital sorting technology

C. Forcato¹, J. Laliberte², C. Bolognesi¹, C. Schumacher², G. Buson¹, C. Mangano¹, P. Tononi¹, F. Fontana¹, G. Medoro¹, T. Harkins², N. Manaresi¹;

¹Silicon Biosystems, Bologna, Italy, ²Swift Biosciences, Ann Arbor, MI, United States.

Introduction: According to recent data from ongoing basket trials, about 1 in 5 patients presents with poor biopsies with small sample size, and/or low-tumor content due to admixture of normal cells, preventing them access to precision oncology. Here we describe a workflow for whole-exome sequencing (WES) of pure populations of tumor cells obtained from very low tumor-cellularity FFPE samples using DEPArray™ sorting technology.

Materials and Methods: A FFPE 50µm thick section from breast infiltrating ductal carcinoma, with 10% tumor cellularity, was dissociated into a cell suspension. Using DEPArray™ digital sorter, 419 cells from 100%-pure tumor and 497 cells from normal stromal subpopulations were recovered based on Keratin/Vimentin immunofluorescence and DNA content. After lysis, Illumina® compatible libraries were prepared from cell-sorted or DNA-extracted samples using Accel-NGS® 2S DNA Library Kit from Swift

Biosciences, amplified, enriched using SeqCap EZ MedExome enrichment kit (Roche) and sequenced on a HiSeq 2500.

Results: Matched stromal/tumor analysis of B-allele frequency of heterozygous SNPs precisely identified Loss-of-Heterozygosity (LOH) regions, as well as Copy-gain regions, both undetectable on genomic DNA extracted without sorting. We readily detected a clinically relevant homozygous (23/23=100% reads) TP53:p.L111R somatic mutation in a LOH region of sorted-tumor fraction, missed in unsorted gDNA, where mutation was not called as present in only 1 read out of 20 (5%).

Conclusions: DEPArray™ sorting combined with Accel-NGS® 2S library kit enables WES on pure tumor and stroma of FFPE samples, offering a clear picture of tumor-specific variants including LOH and copy-numbers regardless of tumor cellularity.

Calreticulin gene mutation status in JAK2 and MPL mutation negative essential thrombocytosis and primary myelofibrosis patients

E. O. Ote¹, Y. K. Terzi², S. Karakus², F. I. Sahin¹;

¹Baskent University Faculty of Medicine Department of Medical Genetics, Ankara, Turkey, ²Baskent University Faculty of Medicine Department of Hematology, Ankara, Turkey.

Introduction: JAK2 and MPL mutations are being used for diagnosis of Essential Thrombocythemia (ET) and Primary Myelofibrosis (PMF), but 30-40% of the patients do not carry any mutations of these genes. Recently, another gene called Calreticulin (CALR) has been reported to be involved in development of ET and PMF. In this study, we investigated the CALR mutation frequency, mutation types and their relevance to clinical findings.

Materials and methods: 16 ET and 4 PMF patients were enrolled in this study. All patients were negative for JAK2 V617F, MPL W515K/L and S505N mutations. We investigated CALR mutation status with Sanger sequencing method.

Results: The mutation rate was 25% in general. However, we did not find any mutations in patients with PMF. We detected three different mutations (31.25%) in 5 patients with ET. Three of the mutations were 52 base pairs (bp) deletion (Type I mutation, c.1092_1143del), one was 5 bp insertion (Type II mutation, c.1154_1155insTTGTC) and the last one was 46 bp deletion (c.1094_1139del). All patients with Type I mutation were women and the mean age (23.3y) was found to be significantly lower compared to all groups (p=0.003).

Conclusions: The results showed that the mutation rate and types were similar to the previous reports. New prospective studies with larger cohort will help us to understand the effect of CALR mutations in the development and prognosis of myeloproliferative neoplasms.

This study has been approved by Baskent University Institutional Review Board (Project No: KA14/318) and supported by Baskent University Research Fund.

Germline alterations in cancer patients and unaffected individuals with family history

S. K. Karachanak-Yankova¹, Z. Hammoudeh¹, G. Antov^{1,2}, S. Ivanov³, L. Balabanski³, R. Vazharova³, M. Malinov³, D. Toncheva^{1,3};

¹Department of Medical Genetics, Medical Faculty, Medical University-Sofia, Sofia, Bulgaria, ²Bulgarian Academy of Sciences, Institute of Genetics 'Academician Doncho Kostov', Sofia, Bulgaria, ³Genomic laboratory, SBALGAR "Malinov", Sofia, Bulgaria.

Introduction: Approximately 10% of all types of cancer are hereditary disorders due to germline mutations, which can be transmitted to the offspring. The aim of the present study is to detect germline cancer-associated alterations, which increase the cancer risk among carriers, using next-generation sequencing.

Materials and methods: We have analyzed 17 blood DNA samples from individuals with family history: 6 patients (4 -with breast cancer, 1 -with ovarian and 1 -with colorectal cancer) and 11 unaffected persons (10 with breast cancer relatives and 1 with colorectal cancer relatives). The analysis was performed using the TruSight Cancer Panel, which includes 94 genes and 284 SNPs associated with predisposition to cancer.

Results: We have detected the following alterations: (i) the colorectal cancer patient and the unaffected person with family history both carry probably pathological mutations in the APC gene, namely p.Glu1573LysfsTer3 and p.Ala1283Pro; (ii) the ovarian cancer patient carries the pathological p.Val1663LeufsTer6 mutation in the BRCA2 gene; (iii) three out of four breast cancer patients have pathological mutations in the following genes: TP53 (193H>LH), BRCA2 (p.Ala938ProfsTer21) and BRCA1 (p.Gly1232Glyfs). Among the 10 unaffected persons with breast cancer family history five

are carriers of pathological mutations in BRCA2: p.Thr3033AsnfsTer11 or p.Lys1590SerfsTer27.

Conclusion: In cases with cancer family history, the possibility to detect the pathological mutations running in the pedigree is very high among patients (5 out of 6) and healthy relatives (6 out of 11) and can be determined by using the TruSight Cancer Panel.

A capillary electrophoresis-sequencing based screening solution for identifying and quantifying hotspot mutations in solid tumors

S. Jackson, A. Gerstner, K. Varma;

Thermo Fisher Scientific, South San Francisco, CA, United States.

Sanger sequencing by capillary electrophoresis (CE) offers many advantages over NGS screening, including simplified workflow, faster time-to-answer, less expense, and easier data analysis. Coupled with Applied Biosystems™ Minor Variant Finder (MVF) software to detect low abundance alleles, these features make front-line screening of solid tumors for oncogenic mutations by CE an attractive possibility. We have designed a panel for CE sequencing consisting of 26 amplicons covering 66 COSMIC somatic mutations that are most commonly found in tumor DNA samples. A total 1972 COSMIC sites are covered by the panel. We screened 44 solid tumor FFPE samples from various tissues for these alleles. We found 34 samples with known hotspot mutations. Allele frequencies determined by CE sequencing and MVF at these sites were highly correlative with Ion Torrent™ NGS-determined frequencies. Pathogenic alleles were detected down to frequencies of 5%. Furthermore, minor variants were detectable in as little as 100pg of input DNA. We demonstrated the utility of this approach by screening tissues with unknown mutation profiles with the panel and identified and quantified hotspot mutations in known tumorigenic genes. Therefore, CE sequencing followed by MVF analysis provides a fast and simple first-line screen for pathogenic alleles in FFPE tumor samples.

Whole genome approaches reveal complex genomic rearrangements on a Mesothelioma tumor genome: preliminary findings of a cohort study

T. TUNCEL¹, M. Metintaş², G. Ak², & Değirmenci¹, H. Güneş¹;

¹Eskisehir Osmangazi University Medical Faculty, Department of Medical Biology, Eskisehir, Turkey, ²Eskisehir Osmangazi University Medical Faculty, Department of Chest Diseases, Eskisehir, Turkey.

Malign Mesothelioma (MM) is an aggressive malignancy originating from pleura, pericardium, heart and abdomen layers. Asbestos exposure is the main risk factor for the MM. Individuals with asbestos exposure have the higher risk to get MM. Asbestos exposure has many known pathological effects to the cell, but its effect mechanism and impact on the human genome still remains unclear. It is known that cancer genomes possess many complex genomic anomalies and heterogeneity with patient specific patterns. As the genome-wide scanning technologies and their analyzing methods evolve, our understanding and knowledge of cancer genome structure gain a high-resolution perspective. In this study, we combined Whole genome SNP Array and Whole Genome Sequencing (WGS) methods to map a Mesothelioma genomes' complex genomic architecture. Pleural Tumor of a Malign Mesothelioma patient with known asbestos exposure used for genomic DNA isolation who diagnosed in Eskisehir Osmangazi University Medical Faculty Chest Diseases Department. Tumor genome scanned with a combined effort both SNP array and WGS, as a result, we discovered both massive intra-chromosomal structural anomalies affecting several chromosomes within Chromothripsis patterns on chromosomes 10, 12, 14 and inter-chromosomal rearrangements resulting formation of fusion genes including WDR70-NXP1, SKA3-DDX10, TSHZ2-SLC35A1. We also detected copy number losses of some major cancer-related genes which are confirmed with both two methods. According to our results, we suggest that some genomic anomalies especially fusion genes can be implied as precision medicine targets for future.

The Scientific and Technological Research Council of Turkey (No:115S819) and ESOGU BAP(No:2013-209) supported the study.

DeBakey VAMC, Houston, TX, United States.

Background: microRNAs are associated with regulation of distinct physiopathological processes including development of normal stem cells and carcinogenesis. In this study we aimed to investigate microRNA profile of Cancer stem-like cells isolated from freshly resected larynx cancer (LCA) tissue samples.

Materials and Methods: CD133-high stem-like cells were isolated from freshly resected LCA tumor specimens. MicroRNA profile of 12 pair of CD133-high and CD133-low cells was determined using microRNA microarray and differential expressions of selected microRNAs were validated by quantitative real time PCR (qRT-PCR).

Results: MicroRNA profiling of CD133-high and CD133-low LCA samples revealed that miR-26b, miR-203, miR-200c, and miR-363-3p were significantly downregulated and miR-1825 was upregulated in CD133high larynx CSLCs. qRT-PCR analysis in a total of 25 CD133-high/ CD133-low paired samples were confirmed the altered expressions of these five microRNAs. Expressions of miR-26b, miR-200c, and miR-203 were significantly correlated with miR-363-3p, miR-203, and miR-363-3p expressions, respectively. Furthermore, in silico analysis revealed that these microRNAs target both cancer and stem-cell associated signaling pathways.

Conclusions: Our results showed that certain microRNAs in CD133-high cells could be used as cancer stem cell markers. Based on these results, we propose that this panel of microRNAs might carry crucial roles in LCA pathogenesis through regulating stem cell properties of tumor cells.

A long-term multidisciplinary surveillance program for patients with the Hereditary Diffuse Gastric Cancer Syndrome.

P. R. Benusiglio, D. Lejri, M. Di Maria, P. Burtin, O. Caron, D. Malka; Gustave Roussy Cancer Campus, Villejuif, France.

Introduction. The Hereditary Diffuse Gastric Cancer Syndrome (HDGC) is caused by germline mutations in the E-cadherin gene CDH1. Carriers have a high risk of signet-ring cell carcinoma (SRCC) and lobular breast cancer (LBC, women only). They require long-term multidisciplinary management, as stated in the latest international guidelines, and ideally in centres of excellence. We are about to set up a systematic surveillance program for carriers, and therefore needed a clear picture describing their management at our Institution. Methods. We collected data for patients who had tested positive for a CDH1 mutation at the Gustave-Roussy-Cancer-Campus-Grand-Paris and who were alive as of 11th-Feb-2016. Results. We identified twenty carriers from seven families. Five have a history of SRCC, one of LBC. Of the fifteen with no SRCC history, ten have already had risk-reducing gastrectomy (RRG), three are planning to do so, one is refusing the procedure and one has not collected his test results. Carriers with a history of cancer benefit from regular surveillance. The picture is however more complex for unaffected carriers. For example, follow-up ceased about six months after RRG for all but two. Regarding LBC, formal screening is rarely in place. Conclusion. There is room for improvement in the management of HDGC patients. We are setting up a long-term multidisciplinary surveillance program, in which we aim to address the following issues in particular: 1-the physical, metabolic, and quality-of-life consequences of RRG, 2-SRRC screening and incidence in patients delaying RRG, 3-LBC screening and incidence, and requests for risk-reducing mastectomy.

P12.050

Molecular basis of resistance of chondrosarcomas to conventional therapies

J. J. Aury-Landas, N. Girard, M. Barreau, E. Lhuissier, K. Boumediene, C. Baugé; EA4652 - BioConnecT team - Université de Caen Normandie, Caen, France.

Chondrosarcomas are malignant tumors of bone. They are considered as resistant to both chemotherapy and radiations. This emergent study aims to unravel the molecular mechanisms involved in the resistance of chondrosarcomas to cisplatin or to X-ray treatments by an innovative strategy of comparative functional genomics.

We observed, using five cell lines derived from human chondrosarcomas, that they had distinct responses to cisplatin or to X-ray treatments. To understand the molecular basis of these different sensitivities, we performed whole-exome sequencing on the cell lines. After strict filtration, 245 to 476 rare coding or splice variants per cell line were predicted to have a deleterious functional impact on the protein. We applied targeted, then pangenomic approaches to select relevant variants. We identified 66 mutated genes potentially implicated in the response to therapy. Interestingly, recurrent loss of function mutations of a tumor suppressor gene were identified in the three most resistant cell lines in which no apoptosis is induced by X-rays nor cisplatin. This gene is actionable by targeted chemotherapy. Functional analyses are in progress to validate the role of this very promising gene mutations and of the 65 other genes in resistance to treatments.

In conclusion, chondrosarcoma cell lines respond differently to conventional therapies. In addition, our study is the first one which extensively characterized commonly used human chondrosarcoma cell lines by whole-exome sequencing. Our preliminary results provide essential genetic information on resistance mechanisms through the identification of genes potentially involved in the response to cisplatin and X-ray radiations.

TSC2 mutations in a chromophobe renal cell carcinoma patient with extraordinary response to temsirolimus.

J. Roldán-Romero¹, J. Maroto², G. Anguera², M. Apellániz-Ruiz¹, F. Algaba³, C. Montero-Conde^{1,3}, A. Cascón^{1,3,4}, M. Robledo^{1,3,4}, C. Rodríguez-Antona^{1,3,4}, ¹Hereditary Endocrine Cancer Group, Human Cancer Genetics Programme, Spanish National Cancer Research Centre (CNIO), Madrid, Spain, ²Department of Oncology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, ³Department of Pathology, Fundació Puigvert, Barcelona, Spain, ⁴Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), Madrid, Spain.

Background: Temsirolimus, an inhibitor of the mammalian target of rapamycin (mTOR), is an effective anti-cancer drug. There are large variations in response among patients, in part explained by mutations activating mTOR pathway. Here, we present a metastatic chromophobe renal cell carcinoma patient with complete response at metastatic sites and 80% size reduction of the renal tumor after temsirolimus treatment. After nephrectomy and 5 years after temsirolimus the patient developed a retroperitoneal adenopathy that was resected. Currently, >7 years after temsirolimus, the patient is disease-free.

Patients and Methods: Whole exome sequencing was performed on the primary tumor, the retroperitoneal adenopathy and normal blood. Somatic single nucleotide variants and small insertions or deletions leading to non-synonymous coding or splice site variants were identified. Immunohistochemical detection of TSC2 and phospho-ribosomal protein (pS6) was performed.

Results: Whole exome sequencing revealed two concurrent inactivating mutations in tuberous sclerosis 2 (TSC2), a critical negative regulator of mTOR Complex 1. One was a splicing defect (c.5069-1G>C) in intron 39 of TSC2, and the other consisted on two nucleotide substitutions in exon 28 (c. 3200_3201delinsAA; p.V1067E). These mutations abolished TSC2 activity and increased mTOR pathway activation, as demonstrated by increased phosphorylation of S6, suggesting they constituted the basis for the exceptional temsirolimus response.

Conclusions: Whole exome sequencing in patients with extraordinary drug responses have the potential to uncover mechanisms that underlie drug sensitivity. Specifically, sequencing of mTOR pathway in chromophobe renal cell carcinoma may serve to prioritize mTOR inhibitor treatment and guide therapy in these patients.

Introduction: Chromosomal translocations are rare in the myelodysplastic syndromes (MDS) and chronic myelomonocytic leukemia (CMML). With the exception of t(3q), translocations are not explicitly considered in the cytogenetic classification of the IPSS-R and their impact on disease progression and patient survival is unknown. The present study was aimed at determining the prognostic impact of translocations in the context of the cytogenetic classification of the IPSS-R.

Material and Methods: We evaluated 1,653 patients from the Spanish Registry of MDS diagnosed with MDS or CMML and an abnormal karyotype by conventional cytogenetic analysis.

Results: Translocations were identified in 168 patients (T group). Compared with the 1,485 patients with abnormal karyotype without translocations (non-T group), the T group had a larger proportion of patients with refractory anemia with excess of blasts and higher scores in both the cytogenetic and global IPSS-R. Translocations were associated with a significantly shorter survival and higher incidence of transformation into AML at univariate analysis but both features disappeared after multivariate adjustment for the IPSS-R cytogenetic category. Patients with single or double translocations other than t(3q) had an outcome similar to those in the non-T group in the intermediate cytogenetic risk category of the IPSS-R.

Conclusion: The presence of translocations identifies a subgroup of MDS/CMML patients with a more aggressive clinical presentation that can be explained by a higher incidence of complex karyotypes. Single or double translocations other than t(3q) should be explicitly considered into the intermediate risk category of cytogenetic IPSS-R classification.

Chronic lymphocytic leukemia (CLL) is a cancer of B-lymphocytes, which expands in the bone marrow, lymph nodes, spleen and blood. Many genes have been implicated in CLL development through sequencing the tumor genome. However, these studies do not completely explain the pathogenesis of the disease, nor do they define the early events that lead the B-cells to accumulate the different types of somatic mutations leading to CLL. The aim of this project is to identify the landscape of germline risk factors that can predispose an individual to CLL. In particular, we have designed a rare variant association study based on the hypothesis that rare mutations are more likely to affect the function of the proteins and may modulate risk for complex diseases. We have analyzed exome-sequencing data on 450 CLL cases (normal and tumor samples) respectively, from the Spanish CLL ICGC consortium and performed rare variant association study with 950 controls from our in-house exomes. We identified genes that were enriched in our CLL cohort than in controls. We designed a targeted sequencing panel consisting of 358 genes, 945 cancer susceptible SNPs and 166 microRNAs. Sequencing was performed in a cohort of 95 CLL, 95 prostate cancer and 290 healthy control samples. The most relevant genes we have identified that are associated with susceptibility to CLL are *ERCC4*, *MET* and *NCAPG2*. The results imply an important possible component of CLL pathogenesis and

merit further functional studies for confirmation.

Funding: European Commission (FP7/2007-2013) under grant agreement number 625356.

Detailed analysis of chronic lymphocytic leukemia cases with single TP53 mutation

K. Plevova^{1,2}, J. Malcikova^{1,2}, J. Kotaskova^{1,2}, M. Trbusek², J. Smardova², E. Diviskova², A. Oltova², Y. Brychtova², M. Doubek^{1,2}, S. Pospisilova^{1,2};

¹Central European Institute of Technology, Masaryk University, Brno, Czech Republic, ²University Hospital Brno, Brno, Czech Republic.

Introduction: In chronic lymphocytic leukemia (CLL), somatic defects of TP53 gene represent an adverse prognostic marker. In the majority of affected cases, TP53 is inactivated on both alleles due to the concurrent mutation and deletion. However, in ~30% of cases, only single TP53 mutation (TP53mut) without deletion is detected. We aimed to perform a detailed analysis of the second TP53 allele in these cases and to assess their genomic makeup.

Materials and methods: Separated CLL lymphocytes were investigated. TP53 mutations were analyzed using FASAY assay and direct sequencing. 17p13 deletions were assessed by iFISH. Genome-wide analysis was performed on CytoScanHD arrays (Affymetrix).

Results: We identified 179 CLL cases with TP53 disruption; 56/179 patients (31%) harbored single TP53mut with allelic frequency ranging 10-100%. We selected 22 cases with single TP53mut for CytoScan analysis. Interestingly, copy-neutral loss of heterozygosity (cn-LOH) in a subclone of CLL lymphocytes was detected in 11/22 cases. In 9/22 cases no abnormality in 17p locus was observed. In the remaining 2/22 cases, heterozygous deletion was newly detected. When we compared genomic complexity of leukemic clones with monoallelic vs biallelic (cn-LOH-only) TP53mut, the latter group exhibited significantly more genomic abnormalities (4 vs 6 chromosomal defects, p=0.0121). However, there was no difference in overall survival between the groups.

Conclusion: cn-LOH in 17p locus is a frequent finding in cases with single TP53mut leading to biallelic TP53 inactivation and should be considered in TP53 testing in CLL.

A heritable form of SMARCE1-related meningiomas with important implications for follow-up and family screening

E. H. Gerkes¹, J. Fock¹, W. den Dunnen¹, M. van Belzen², C. van der Lans², E. Hoving¹, I. Fakkert¹, M. Smith³, D. Evans³, M. Olderode-Berends¹;

¹University Medical Center Groningen, Groningen, Netherlands, ²Leiden University Medical Center, Leiden, Netherlands, ³Manchester Centre for Genomic Medicine, Manchester, United Kingdom.

Introduction: Recently, a new hereditary tumor predisposition syndrome has been discovered, resulting in an increased risk for spinal and intracranial clear cell meningiomas (CCMs) in young patients. Heterozygous loss-of-function germline mutations in the SMARCE1 gene are causative, giving rise to an autosomal dominant inheritance pattern.

Case report: We report on an extended family with a pediatric CCM patient and an adult CCM patient and several asymptomatic relatives carrying a germline SMARCE1 mutation.

Discussion: We discuss difficulties in genetic counseling for this heritable condition. Because of the few reported cases so far, the lifetime risk of developing meningiomas for SMARCE1 mutation carriers is unclear and the complete tumor spectrum is unknown. There is no surveillance guideline for asymptomatic carriers nor a long-term follow-up recommendation for SMARCE1-related CCM patients as yet. Until more information is available about the penetrance and tumor spectrum of the condition, we propose the following screening advice for asymptomatic SMARCE1 mutation carriers: neurological examination and MRI of the brain and spine, yearly from diagnosis until the age of 18 and once every 3 years thereafter, or in between if there are clinical symptoms. This advice can also be used for long-term patient follow-up. More data is needed to optimize this proposed screening advice.

Spectrum of BCR-ABL Kinase domain mutations: A cohort study from Saudi Arabia

H. Abalkhail, S. Khalil;

King Faisal Special hospital & RC, Riyadh, Saudi Arabia.

Chronic myeloid leukemia (CML) is a clonal myeloproliferative neoplasm (MPN) associated with a characteristic translocation between chromosome 9 and 22 to form Philadelphia chromosome (Ph). The introduction of tyrosine kinase inhibitors (TKIs) imatinib for CML marked a new era for targeted therapy. In general CML patients in chronic phase (CP) have a very good response to TKIs. A significant proportion harbor molecular residual disease and develop acquired resistance, in which mutations in the Abl kinase domain are the best known cause of resistance. Accelerated phase and blast phase. In this retrospective study, we assessed the ABL kinase domain mutation in 165 patients referred from our clinics between 2011-2015 with Ph positive CML displaying either refractory to TKI or resistance displaying increase BCR-ABL1 levels monitored by Quantitative PCR. Mutation analysis was performed on RNA extracted from either blood or Bone marrows after amplification of the BCR/ABL1 transcript by nested PCR followed by Direct sequencing of the BCR-ABL1 Kinase domain including residues 243-487.

In total, 165 patients (78 Females and 87 males), Age between 10-80 years (median age: 38 years) of which 160 were adults and 5 pediatric patients were analyzed. Among 1653 patients, 35 (21%) were positive for 14 different mutations across the ABL1 Kinase domain mutations (12 patients had T315I, 4 patients had the following: E255K and Y253H, 2 patients had each of the following mutation: H396R, F359 and F317L. Additionally, one patient with each of the following mutations: E355G, V299L, L248V, L298, Y326H, M244V, G250E and E453K).

Exome sequencing data analysis to characterize rare germline copy number variants involved in colorectal cancer predisposition

S. Franch-Expósito¹, C. Esteban-Jurado¹, P. Garre², I. Quintanilla¹, S. Durán¹, M. Cuatrecasas³, E. Samper¹, J. Muñoz², T. Ocaña¹, S. Carballa¹, M. López-Cerón¹, A. Castells⁴, E. consortium¹, M. Vila-Casadesús⁴, E. Serra⁵, S. Beltran⁶, J. Carvajal⁶, L. Bujanda⁷, C. Ruiz-Ponte⁸, J. Camps¹, M. Gironella¹, J. Lozano⁴, F. Balaguer¹, J. Cubiella⁹, T. Caldés², S. Castellvi-Bel¹;

¹IDIBAPS, Hospital Clínic, CIBEREHD, Barcelona, Spain, ²IdISSC, Hospital Clínico San Carlos, Madrid, Spain, ³Pathology, Hospital Clínic, Barcelona, Spain, ⁴Bioinformatics, CIBEREHD, Barcelona, Spain, ⁵CNAG, Barcelona, Spain, ⁶Centro Andaluz de Biología del Desarrollo, Sevilla, Spain, ⁷Gastroenterology, CIBEREHD, Hospital Donostia, Donostia, Spain, ⁸FPGMX, CIBERER, Santiago de Compostela, Spain, ⁹Gastroenterology, CIBEREHD, Hospital de Ourense, Ourense, Spain.

Introduction: Colorectal cancer (CRC) represents the third most common cancer worldwide. On the other hand, copy number variants (CNV) are structural variations larger than 1 kilobase (kb) displaying copy number differences either polymorphic or related with predisposition to disease.

Materials and Methods: Whole-exome sequencing (WES) was performed in germline DNA from 38 families with strong CRC aggregation without alterations in known hereditary genes. To identify rare CNV that could correspond to the mutational event for CRC predisposition, WES data was analyzed with ExomeDepth and CoNIFER tools. Variants shared by family members were prioritized and compared with the Database of Genomic Variants catalogue and our Spanish database. Variants were selected and validation and as well as segregation analysis were performed by comparative genomic hybridization (CGH). Gene expression analysis (arrays and qRT-PCR) were conducted in both germline and tumor cDNA and tumor immunohistochemistry (IHC) was also performed.

Results: Sixteen candidate CNV were detected in 15 families. The most interesting CNV corresponded to a duplication in chromosome 1 spanning 400 kb that was confirmed by CGH and family segregation was correct. TTF2, TRIM45, VTCN1 and miR942 were affected by the duplication. Gene expression data indicated TTF2 and miR942 overexpression in duplication carriers. Tumor IHC showed TTF2 protein overexpression and underexpression of the TMEM158 protein, a predicted target of miR942.

Conclusions: The duplication in chromosome 1 could correspond to the mutational event involved in the predisposition to CRC in the carrier family by overexpressing TTF2 and miR942, which would lead to TMEM158 under-expression.

P12.059

Aberrant DNA methylation in inherited and sporadic colorectal cancer

N. Sahnane¹, F. Magnoli², B. Bernasconi¹, M. Tibiletti¹, M. Pedroni², M. Ponz de Leon², G. Magnani², C. Romualdi³, L. Reggiani-Bonetti², L. Bertario⁴, S. Signoroni⁴, F. Sessa¹, D. Furlan¹, Italian Association for the Study of Familial and Hereditary Gastrointestinal Tumors (AIFEG);

¹University of Insubria, Varese, Italy, ²University of Modena-Reggio Emilia, Modena, Italy, ³CRIBI Biotechnology Center, University of Padova, Padova, Italy, ⁴National Cancer Institute-Milano, Milan, Italy.

Introduction: Aberrant DNA methylation has been widely investigated in sporadic colorectal carcinomas (CRCs) but less information is available about the role of epigenetics in hereditary CRC.

Patients and Material: LINE-1 hypomethylation and gene-specific hypermethylation of 38 promoters were analyzed in multicenter series of 220 CRCs including 71 microsatellite unstable Lynch CRCs (LS-MSI), 23 CRCs of young patients without inherited syndromes (EO-MSS), and 126 sporadic CRCs, comprising 28 MSI-unstable (S-MSI) and 98 microsatellite-stable cases (S-MSS). All tumor methylation patterns were integrated with clinico-pathological and genetic characteristics, namely chromosomal instability (CIN), TP53 loss, BRAF, and KRAS mutations.

Results: LS-MSI mainly displayed absence of extensive DNA hypo- and hypermethylation. A subset of LINE-1 hypomethylated LS-MSI showed G>A transition in the KRAS gene, absence of CIN and TP53 loss and an unfavorable prognosis. S-MSI exhibited extensive gene hypermethylation, MLH1 methylation, BRAF mutation and absence of CIN and TP53 loss. By contrast, S-MSS showed marked LINE-1 hypomethylation and CIN and they had a worse prognosis. EO-MSS were a genetically and epigenetically heterogeneous group. Like LS-MSI, some EO-MSS displayed low rates of DNA hypo- or hypermethylation and frequent KRAS G>A transitions. By contrast, some EO-MSS showed similar features to those observed in S-MSS, such as LINE-1 hypomethylation, CIN and TP53 deletion. In all four classes, hypermethylation of ESR1, GATA5, and WT1 was very common.

Conclusion: Aberrant DNA methylation analysis allows the identification of different subsets of CRCs. This study suggests that LINE-1 hypomethylation may be a useful prognostic marker in both sporadic and inherited CRCs.

Prognostic assessment of colorectal cancer using clustering analysis

N. I. Pospekhova, Y. A. Shelygin, S. I. Achkasov, O. I. Sushkov, S. A. Frolov, O. A. Mainovskaya, A. A. Ponomarenko, A. S. Tsukanov, V. P. Shubin;

State Scientific Centre of Coloproctology, Moscow, Russian Federation.

Colorectal cancer (CRC) is a clinically and molecularly heterogeneous disease. Different subtypes of tumors have different prognosis and sensitivity to target and chemotherapy. The aim of the work was to determine different prognostic subgroups keeping in mind cancer with peritoneal carcinomatosis (PC) to be the worst prognosis group.

Methods: We analyzed samples obtained from 41 patients with PC and 58 CRC stage I-III including 7 patients with Lynch syndrome (LS). 12-gene expression signature has been carried out for all tumors by RT-PCR. RAS/BRAF mutations and MSI were analyzed by sequencing and fragment analysis. Hierarchical clustering has been used for data analysis.

Results: Cluster analysis identified 4 groups of samples. Genes SFRP2, TNC, ZEB1, MUC2, VIM were the most significant for clustering. Seven cases have been included in Cluster 1 (MUC2/TFF3 presence, SFRP2/ZEB1 absence); 36 cases - Cluster 2 (TNC presence, MUC2/TFF3 absence); 24 - Cluster 3 (SFRP2/TNC/VIM presence, MUC2/TFF3 absence); 32 - Cluster 4 (SFRP2/MUC2/TFF3 absence). Distribution of CRC with PC among clusters was 9.8%; 29.3%; 34.1%; 26.8% cases; CRC stage I-III - 5.1%; 41.4%; 17.1%; 36.2% cases, respectively. RAS mutations were more common in Cluster 1 and 3 whereas MSI-H in Cluster 2 and 4. Four from 5 BRAF-V600E were found in Cluster 3.

Conclusion: The prevalence CRC with PC in Cluster 3 and its association with BRAF-mutation confirms aggressiveness, high metastatic potential and poor prognosis of this tumor group. Molecular classification of CRC can serve for disease prognosis assessment suggesting specific treatment for each case.

The Fanconi anemia DNA damage repair pathway in the spotlight for germline predisposition to colorectal cancer

C. Esteban-Jurado¹, S. Franch-Expósito¹, J. Muñoz², T. Ocaña¹, S. Carballa¹, M. López-Cerón¹, M. Cuatrecasas³, M. Vila-Casadesús⁴, J. Lozano⁵, E. Serra⁶, S. Beltran⁷, E. consortium¹, A. Brea-Fernández⁸, C. Ruiz-Ponte⁸, A. Castells⁹, L. Bujanda⁹, P. Garre², T. Caldés², J. Cubiella⁹, F. Balaguer¹, S. Castellvi-Bel¹;

¹IDIBAPS, CIBEREHD, Hospital Clínic, Barcelona, Spain, ²Pathology, Hospital Clínic,

Barcelona, Spain, ³Bioinformatics, CIBEREHD, Barcelona, Spain, ⁴CNAG, Barcelona, Spain, ⁵FPGMX, CIBERER, Santiago de Compostela, Spain, ⁶Gastroenterology, CIBEREHD, Hospital Donostia, Donosti, Spain, ⁷IdiSS, Hospital Clínico San Carlos, Madrid, Spain, ⁸Gastroenterology, CIBEREHD, Hospital de Ourense, Ourense, Spain.

Introduction: Germline mutations in genes from the Fanconi anemia (FA) DNA damage repair pathway are known to cause FA and breast and ovarian cancer predisposition. Very recently, mutations in BRCA2, FAN1 and BLM genes have been postulated to cause familial colorectal cancer (CRC).

Material and methods: Seventy-four patients from 40 families with strong CRC aggregation without alterations in the known hereditary genes were selected from four Spanish hospitals and the EPICOLON consortium. Whole-exome sequencing was performed and variant filtering selected only very rare alterations, shared by individuals from the same family, with a putative loss of function and located in genes with a role compatible with cancer.

Results: We detected enrichment for variants in the FA DNA damage repair pathway genes in our cohort since six families carried heterozygous, rare (<0.01%), potentially pathogenic variants located in BRCA2/FANCD1, BRIP1/FANCF, FANCC, FANCE and REV3L/POLZ. Three of the variants corresponded to frameshift alterations and three to missense variants predicted to be deleterious. Somatic studies also revealed loss of heterozygosity for four of the variants. Interestingly, extracolonic neoplasms including gastric, breast, uterine, and prostate were present in five families.

Conclusions: Although further studies are needed to confirm its contribution, the FA DNA damage repair pathway could play an important role in the inherited predisposition to CRC. It is important to highlight also that pleiotropy is becoming important in germline predisposition to cancer since a higher number genes may be involved in the genetic predisposition to a broader spectrum of neoplasms.

P12.062

Plasma RAS mutations for the selection and monitoring of colorectal cancer patients treated with anti-EGFR therapy

A. Dalmases¹, J. Vidal¹, M. Vela¹, M. Muset¹, G. Piquer¹, L. Visa¹, R. Correa¹, G. López¹, V. Sikri², J. Albanell¹, F. Jones², C. Montagut¹, B. Bellosillo¹;

¹Hospital del Mar, Barcelona, Spain, ²Sysmex Inostics Inc, Mundelein, IL, United States.

Introduction: RAS testing in metastatic colorectal cancer (mCRC) patients in circulating tumor DNA (ctDNA) is being investigated as a new method for detection and monitoring of actionable mutations.

Material and Methods: 38 mCRC patients with known RAS status in tissue sample were analysed. Plasma mutations were determined with Sysmex Inostics BEAMing34 RAS mutation panel and compared to standard-of-care (SOC) RAS testing in tissue samples.

Results: Plasma and tissue results showed a concordance of 89.5% (table). In 2 patients in which a RAS mutation was identified in plasma but not in tissue, one was treated with anti-EGFR therapy and did not respond; in the other, the mutation was also detected in tissue by BEAMing re-examination. In one of two cases in which a RAS mutation was detected in tissue but not in plasma, BEAMing determination in tissue confirmed the same mutation detected by SOC.

Longitudinal analysis of RAS mutations in serial plasma samples from 5 patients that progressed to anti-EGFR, showed emergence of RAS mutations in 2 patients (40%).

Conclusions: The high overall concordance between tissue and plasma BEAMing determination supports the blood-based testing to determinate the eligibility of CRC patients for anti-EGFR treatment. The detection of RAS mutations in plasma at progression to anti-EGFR suggests that BEAMing 34 RAS mutation panel may be used to monitor resistance.

Plasma RAS Result	Tissue RAS Result			Total
	Positive	Negative		
Positive	17	2		19
Negative	2	17		19
Total	19	19		38

Expression analysis of PTEN in colorectal cancer

M. Nemati¹, E. Sakhinia², N. Ajami³, S. Rezapour²;

¹Tabriz Genetic Analysis Center (TGAC), Tabriz University of Medical Sciences, Tabriz, Iran, Islamic Republic of, ²Department of Medical Genetics, Tabriz University of Medical Sciences, Tabriz, Iran, Islamic Republic of, ³Department of Biology, Faculty of Basic Science, Khoy Payam Noor University, Khoy, Iran, Islamic Republic of.

Introduction: The tumor suppressor phosphatase and tensin homolog (PTEN) is involved in many important biological processes related to cell survival, proliferation, and growth. Reduced expression of the PTEN is observed in several human cancers, indicating a critical role in carcinogenesis and a potential as a tumor marker in cancer. In this prospective study, we compared PTEN expression levels in colorectal tumor tissues with adjacent

non-tumor tissues to assess the diagnostic value of this biomarker in colorectal cancer and its relationship with the clinicopathological features of patients.

Methods: Total RNA was extracted from 48 pairs of colorectal tumor tissue and adjacent non-tumor tissue. Afterwards cDNAs were synthesized and the expression level of PTEN was quantified by real time PCR. The Correlation between the expression level of PTEN and clinicopathological features was studied and the capability of PTEN to function as a CRC tumor marker was also explored.

Results: The expression levels of PTEN (P<0.001) were significantly decreased in colorectal tumors compared to adjacent non-tumor tissues. The Receiver operating characteristic (ROC) curve analysis on PTEN showed that the area under the ROC curve was high (0.83). No correlation was observed between PTEN expression levels and clinicopathological features of patients.

Conclusion: Our results suggest that PTEN can serve as an important prognostic indicator in colorectal cancer and may provide valuable information to diagnosis and targeted therapy purposes.

P12.064

Expression of inhibitors of TRAIL apoptotic pathway in colorectal tumours

S. Tsikalakis¹, I. Chatziandreu¹, O. Dimopoulou¹, N. V. Michalopoulos², G.

Theodoropoulos², E. Patsouris¹, A. Saetta¹;

¹National and Kapodistrian University of Athens, Medical School, Department of Pathology, Athens, Greece, ²National and Kapodistrian University of Athens, Medical School, 1st Department of Propaedeutic Surgery Hippokrateion Hospital, Athens, Greece.

Introduction: TRAIL (TNF related apoptosis inducing factor) is a member of the tumor necrosis factor superfamily which has been considered as a promising drug target for cancer therapy due to its ability to selectively induce apoptotic death in transformed cells. Inhibitors of TRAIL induced apoptosis include c-FLIP, XIAP, Mcl-1, Bcl-2, Bcl-xL genes.

Methods: 106 colorectal tumours (63 males, 43 females, median age 70 years) along with 20 normal tissues were analysed using RT-PCR, for relative mRNA expression analysis with $\Delta\Delta Ct$ method for total c-FLIP, XIAP, Mcl-1, Bcl-2, Bcl-xL. Statistical analysis was performed in order to correlate relative mRNA levels with clinicopathological characteristics and with previous data on relative mRNA expression of TRAIL, DR4, DR5, DcR1, and DcR2 genes.

Results: Elevated mRNA levels were observed as follows: Bcl-2 16%, Mcl-1 8.7%, XIAP 4.9% and total c-FLIP 2.2%. Additionally, reduced mRNA levels were observed for: total c-FLIP 88%, Bcl-2 84%, Bcl-xL 80%, XIAP 38.7% and Mcl-1 96%. XIAP reduced mRNA levels were correlated with older patients (over 70 years old) and with smaller tumour size, T1/2. Finally, TRAIL ligand mRNA levels were correlated with stage and DcR1 elevated mRNA levels with patients' age.

Conclusions: Apart from decoy receptors' over expression, a small subset of cases showed elevated mRNA levels of apoptosis resistance genes. Our results depict a potential significant role of XIAP expression in limiting tumour growth during colon tumorigenesis. TRAIL expression emerged as an early event, possibly delaying disease progression.

P12.065

Field synopsis of genetic variation and colorectal cancer: unified 2016 update

J. Little¹, E. Theodoratou², W. Zheng³, Z. Montazeri¹;

¹University of Ottawa, Ottawa, ON, Canada, ²University of Edinburgh, Edinburgh, United Kingdom, ³Vanderbilt University School of Medicine, Nashville, TN, United States.

Background: According to current predictions of global demographic changes, the WHO estimates a 77% increase in colorectal cancer (CRC) incidence and 80% increase in CRC-related deaths by 2030 (Bray et al., 2012). Identifying genetic variants that influence susceptibility to disease potentially can inform the development of approaches for primary and secondary prevention. Two groups have published field synopses on genetic variants associated with CRC, in JNCI in 2012 and Gut in 2013. These groups are now working together on an update.

Methods: We have searched all published (and some unpublished) genetic association data - including candidate gene and GWAS- for CRC to the end of 2015. Furthermore, we have access to 4 GWAS datasets. We are conducting meta-analyses. We have reached a consensus on the operationalization of the Venice guidelines on the credibility of genetic association, which had differed between the two previous field synopses.

Results: More than 200 genes in about 770 SNPs were identified as putatively associated with CRC. For 450 SNPs, there was a single study only; for 90 SNPs, two studies; and for 230 SNPs, 3 or more studies. Meta-analysis will be carried out for SNPs with 3 or more studies, and credibility of association assessed according to the Venice criteria.

Conclusions: The identification of genetic variants with influence on CRC risk may reflect an importance of genes involved in colorectal cancer risk. Our data should help results of genetic associations studies to be placed in context and interpreted appropriately and should help direct future research effort.

P12.066
Genomic imbalances in tumor and surrounding tissue detected by MLPA in Brazilian patients with colorectal cancer

M. Rocha^{1,2}, A. T. Dias², E. A. Zanardo², T. V. M. M. Costa², F. A. R. Madia², J. Damasceno², C. Milani², F. Balsamo¹, S. D. F. Boratto¹, S. H. C. Horta¹, C. E. R. Corsi¹, B. A. Bianco¹, D. M. Christofolini¹, C. P. Barbosa¹, J. Waisberg¹, L. D. Kulikowski^{1,2};
¹Faculdade de Medicina do ABC, São Paulo, Brazil, ²Faculdade de Medicina da USP, São Paulo, Brazil.

Gains and losses of chromosome arms are usually detected in colorectal cancer (CRC) samples and may be linked to progression of this disease. Thus, we investigated specific genomic unbalances associated with CRC in Brazilian patients who underwent surgery without previous neoadjuvant treatment. The tumors were histologically classified as low and high grade according to Brazilian Society of Pathology. The total of 30 tissue samples from neoplastic and non-neoplastic colorectal tissues was obtained from 10 patients. Paired peripheral blood samples were used as controls. The DNA was extracted using the QIAamp DNA Blood Midi Kit (QIAGEN, Valencia, California) and investigated by MLPA method (MRC-Holland®, Amsterdam, The Netherlands) with combination of specific kits for CRC basic research (P413 and P146). The results were analyzed using the software GeneMarker® (SoftGenetics, LLC, State College, PA - www.softgenetics.com). The results revealed alterations of several different regions: genomic gains in the long arm of 20 chromosome including probes located in ADMR1, OPRL1, MAPRE1, TPX2, ZNF217 genes and gains in the short arm of 17 chromosome including MNT and OVCA2 gene. In addition we found losses in short arm of chromosome 8 including markers of CDCA2, NKX3, LPL genes and losses in long arm of 13 chromosome including RB1, DACH, PSpC, ZMYM2 genes. Unexpectedly, we also detected similar genomic imbalances in adjacent control tissues for some patients suggesting that there is a field of chromosomal instability surrounding the tumor. Therefore the accurate genomic characterization of these tissues is critical to screening the progression of this disease.

P12.067
Analysis of complex karyotypes in patients with haematological neoplasms

H. Podgornik, U. Mlakar, M. Sever, P. Černelč;
 Department of Hematology, Ljubljana, Slovenia.

Background. Most studies define complex karyotype (CK) as ≥3 or ≥5 independent abnormalities. In the last few years a new definitions have arisen as structurally CK and monosomal (MCK). The mentioned CKs have been claimed to be the strongest predictor of an inferior outcome in patients with haematological neoplasms. We analysed subgroups of CKs in our patients. Methods. GTG banding, FISH and spectral karyotyping were combined to resolve karyotypes. CKs were subdivided according to the number of aberrations (3, 4, ≥5), to monosomal (M), and structurally rearranged (S). Results. 147 CKs were observed in the last 4 years. The majority of cases (77%) corresponded to AML and MDS followed by CLL patients. Frequency of different subtypes of CKs is given in Table 1. 73% of CKs had ≥5 aberrations. 89% of them were also structurally rearranged. 56% of CKs corresponded to monosomal and structurally complex at the same time (CKMS). All monosomal CKs with ≥5 aberrations were also structurally rearranged (CKMS5). This was the main group of CKs in MDS and AML. Structurally rearranged karyotypes (CKS4 and CKS5) were significantly more frequent in CLL than in AML or MDS (P<0.05). Conclusions. In MDS a distinction between CK with 3 and 4 aberrations is already crucial for prognostification. To give comprehensive information to clinicians CKs should be analysed even more extensively.

Karyotype subtype	Frequency of CK subtypes.			
	All patients (N=147)	AML (N=56)	MDS (N=46)	KLL (N=17)
CK3	1 (1%)	1 (2%)	0 (0%)	0 (0%)
CKS3	18 (12%)	8 (14%)	5 (11%)	2 (12%)
CKM3	4 (3%)	2 (4%)	2 (4%)	0 (0%)
CKMS3	2 (1%)	1 (2%)	1 (2%)	0 (0%)
CK4	2 (1%)	1 (2%)	1 (2%)	0 (0%)
CKS4	9 (6%)	2 (4%)	1 (2%)	4 (24%)
CKM4	2 (1%)	0 (0%)	1 (2%)	1 (6%)
CKMS4	2 (1%)	0 (0%)	2 (4%)	0 (0%)
CK5	2 (1%)	3 (5%)	3 (7%)	0 (0%)
CKS5	26 (18%)	3 (5%)	5 (11%)	4 (24%)

P12.068
Connexin43 Gap Junctions and Melatonin Receptors as Independent Marker for Prostate Cancer

A. Tavartkiladze^{1,2}, R. Khutsishvili¹, D. Khijakadze²;
¹Institute For Personalized Medicine, Tbilisi, Georgia, ²Tbilisi State Medical University, Tbilisi, Georgia.

Gap junctions are intercellular channels that are formed from members of a family of proteins, the connexins (Cx). Gap junctions play an important role in vital functions, including the regulation of cell growth and cell differentiation. Here, we examined the expression of Cx43, a major Cx in prostate tissue, in 27 surgical specimens obtained from prostate cancer patients who underwent a primary surgical castration prior to hormonotherapy or radiotherapy treatments. The expression of Cx43 gap junctions was compared to the levels of testosterone, melatonin (MLT1), and erbB2 tyrosine kinase receptors. In addition, a panel of prostate cancer cell lines and a series of normal rat prostate tissues and rat prostate tumors induced in vivo by N-Methylnitrosurea were studied. We demonstrated that the lack of Cx43 gap junctions is a common feature of human prostate cancer tissues compared to nonneoplastic prostate tissues surrounding primary tumors. Cx43 gap junctions were not observed in prostate adenocarcinomas, and they seem to be independent of testosterone, melatonin, and erbB2 receptor status. In prostate cancer cell lines and rodent prostate carcinoma tissues, down-regulation of Cx43 occurs at the mRNA level, suggesting a transcriptional mechanism for the decrease of Cx43 protein in prostate cancer. In summary, this study provides evidence of decreased expression of Cx43 gap junctions in prostate cancer at various stages of progression as well as prostate cancer cell lines and raises the possibility that Cx43 may be a useful marker for detecting early oncogenesis in the prostate.

P12.069
Identification of two novel cases of constitutional mismatch repair deficiency syndrome in a spanish consanguineous family

Y. Rodriguez¹, D. Parraga², I. Rey³, M. Gallego³, N. Carrizo³, J. Perea⁴, O. Toldos¹, M. A. Martinez Gonzalez¹, J. L. Vivanco⁵, V. Perez Alonso⁵, L. Robles⁶, D. Rueda³;
¹Pathology Department, Doce de Octubre Hospital, Madrid, Spain, ²Hereditary Cancer Genetic Diagnostics Laboratory, Madrid, Spain, ³Hereditary Cancer Genetic Diagnostics Laboratory, Doce de Octubre Hospital, Madrid, Spain, ⁴Surgery Department, Doce de Octubre Hospital, Madrid, Spain, ⁵Pediatric Oncology and Hematology Department, Doce de Octubre Hospital, Madrid, Spain, ⁶Familial Cancer Unit, Doce de Octubre Hospital, Madrid, Spain.

Introduction: The Constitutional Mismatch Repair Deficiency (CMMRD) syndrome (OMIM #276300) is a rare autosomal recessive cancer predisposition disease caused by inactivating biallelic germline mutations in mismatch repair (MMR) genes. Carriers develop in their childhood hematologic malignancies, central nervous system tumors or colorectal tumors, as well as other neoplasia. Many patients overlap neurofibromatosis type I features such as cafe-au-lait spots. Patient and Methods: MMR genes were studied by amplicon based NGS on a suspected CMMRD patient belonging to a consanguineous Spanish family. Directed genetic study was extended to other family members, collecting clinical and pathological data. Microsatellite Instability (MSI) status and immunohistochemical (IHC) studies on mismatch repair complex proteins was performed on tumor and normal tissues. Results: Two siblings carrying homozygous nonsense mutation on MSH6 gene were identified: one developed an abdominal B-cell non-Hodgkin lymphoma and two lymphoblastic T-cell lymphoma, and the other a nephroblastoma. Both of them were diagnosed at early age and presented cafe-au-lait macules. IHC on different tumors showed absence of staining for the MSH6 protein both in malignant and normal tissues. However, MSI was only observed in tumor but not in blood or oral epithelium controls. Conclusions: Our results confirm previous clinical and molecular observations for CMMRD patients. Remarkably both homozygous carriers scored positive for the indication criteria for CMMRD testing suggested by the European Consortium „Care for CMMRD“. Additional molecular studies are currently being performed in order to better characterized this poorly known cancer syndrome.

P12.070
Expression of Contactin 4 is associated with malignant behaviour in pheochromocytomas and paragangliomas

L. Evenepoel^{1,2}, F. H. van Nederveen³, L. Oudijk⁴, T. G. Papatomas^{5,6}, D. F. Restuccia⁴, E. J. T. Belt⁴, G. J. H. Franssen⁴, R. A. Feelders⁴, A. Perren⁶, S. van Eeden⁷, H. J. L. M. Timmers⁸, W. W. de Herder⁴, L. Vroonen⁹, S. Aydin¹⁰, M. Vikkula¹, R. R. de Krijger^{4,11}, W. N. M. Dinjens⁴, A. Persu², E. Korpershoek⁴;
¹de Duve Institute, Brussels, Belgium, ²Institut de Recherche Expérimentale et Clinique, Brussels, Belgium, ³Laboratory for Pathology, Dordrecht, Netherlands, ⁴Erasmus MC Cancer Institute, Rotterdam, Netherlands, ⁵King's College Hospital, London, United Kingdom

Kingdom, ⁶Clinical Pathology Division, Bern, Switzerland, ⁷Academic Medical Center, Amsterdam, Netherlands, ⁸Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, ⁹Centre Hospitalier Universitaire de Liège, Liège, Belgium, ¹⁰Cliniques universitaires Saint Luc, Brussels, Belgium, ¹¹Reinier de Graaf Hospital, Delft, Netherlands.

Introduction: Pheochromocytomas and paragangliomas (PPGL) are rare and mostly benign tumours. Approximately 10% of PPGL are malignant, as defined by the presence of metastases, i.e. chromaffin tissue at a location that usually does not contain chromaffin cells. However, up to 35% of tumours in patients carrying an SDHB mutation appears to be malignant. No reliable marker allows prediction of whether a PPGL is, or will become malignant. In addition, there are no curative treatments if metastases occur.

Materials and methods: In order to identify genetic markers allowing to distinguish benign from malignant tumours, 40 benign and 11 malignant PPGL were investigated for differences in mRNA expression with Affymetrix arrays. Expression data were normalized according to Affymetrix recommendations. Then, using Pomelo II (<http://pomelo2.bioinfo.cnio.es/>), a Limma t-test was performed, to assess which genes were differentially expressed between benign and malignant PPGL. Clustered and non-clustered analysis were performed, and 15 genes with a False Discovery Rate (FDR) below 0.05 and a relative overexpression ratio of at least 4 were found. They were further investigated using qRT-PCR, and immunohistochemistry on Tissue Micro Array including 88 benign and 13 malignant PPGL. Subsequently, slides of malignant and benign tumours (n= 32 respectively) were stained.

Results: Contactin 4 (CNTN4) was significantly overexpressed (FDR=0.001, and p=0.004 for the IHC) in malignant compared to benign tumours.

Conclusion: CNTN4 overexpression is associated with malignant PPGL, and may thus predict metastatic dissemination in patients with PPGL. Notably, CNTN1 has been shown to be associated with malignancy in different tumours including gliomas.

P12.071

Panel gene testing identified PTEN mutation in family that did not fulfill criteria for clinical diagnosis. Are we considering PTEN screening as often as we should?

D. Georgiou, V. Kiesel;
GeneHealth UK, Cambridge, United Kingdom.

The majority of colorectal cancer is sporadic; however up to 10% may be inherited; with Lynch syndrome, Familial Adenomatous polyposis and MUTYH associated polyposis the most common known hereditary colorectal cancer syndromes. Other conditions, such as Cowden syndrome are rare causes of colorectal cancer and colorectal polyps; hence genetic testing is not routinely offered. Historically, genetic counselling has involved performing a risk assessment based on an individual's family history of cancer and sequential single gene testing. With the advent of panel testing it is becoming possible to simultaneously examine multiple genes, which is eliciting unusual phenotypes.

This case report presents an individual tested through GeneHealth UK due to a personal history of colorectal polyps and a family history of colorectal cancer and polyps. No history of learning difficulties, skin lesions, other cancers/tumours was noted. The proband was counselled and offered Bowel-Gene panel testing, which tests 11 genes associated with colorectal cancer and colorectal polyps using NextGeneration sequencing on an illumine platform. A pathogenic mutation was found in the PTEN gene, which confirmed a diagnosis of Cowden syndrome, which is thought to affect 1 in 200 000 individuals in the population.

This report illustrates the importance of learning more about established phenotypes, clinical diagnostic criteria and the impact of panel testing. It explores challenges in identifying patients with unexpected mutations and the importance of recommending validated cancer screening. Reflection on such cases can be helpful in improving our understanding of panel testing, rare cancer susceptibilities and improving patient and family experiences.

Telomeric length analysis in CRC tumors

P. Mogollón Arroyo^{1,2}, J. Pérez¹, J. Perea², J. García⁴, M. Urioste⁵, D. Rueda⁶, M. Arriba², R. González-Sarmiento^{1,2,7}.

¹Centro de Investigación del Cáncer, Salamanca, Spain, ²Department of medicine, University of Salamanca, Salamanca, Spain, ³Centre for biomedical research of 12 de Octubre University Hospital, Madrid, Spain, ⁴Institute of Molecular and Cellular Biology of Cancer (IBMCC), Salamanca, Spain, ⁵Centre for Biomedical Network Research on Rare Diseases (CIBERER), Institute of Health Carlos III, Madrid, Spain, ⁶Molecular biology laboratory, 12 de Octubre University Hospital, Madrid, Spain, ⁷Biomedical Research Institute of Salamanca (IBSAL), Salamanca, Spain.

Early-onset Colorectal Cancer (ECRC) represents a significant and increa-

sing proportion of Colorectal Cancer (CRC) and it is a heterogeneous entity that probably encompasses specific subclasses. It has been reported that shortening of telomere length is associated with an increased risk of cancer. Telomeres are the protective end-complexes of eukaryotic chromosomes since they are involved in the maintenance of normal chromosome structure and function. It has been demonstrated that telomerase is crucial for controlling telomere length, however, telomeres undergo a shortening with each cell division. In addition, it has been reported that telomeric shortening is associated with an early onset cancer.

Initially, we performed a cytogenetic study (CGH-Array) 46 tumors of late-onset CRC patients (over 70 years) and 45 tumors of early-onset CRC patients (under 45). We identified a group of tumors (mostly early-onset) that had a similar cytogenetic profile so the aim of our study was to analyze differences in telomeric length between tumors with the same cytogenetic profile (early and late-onset) versus tumors with a different profile.

Our results show that telomere length correlates with the cytogenetic profile in early-onset CRC tumors. Interestingly, there are not significant differences when compare the telomeric length of early-onset CRC tumors with the same cytogenetic profile versus late-onset CRC tumors.

These results reinforce the hypothesis that early-onset CRC cancer represents a specific subgroup of colon cancer.

Using of droplet digital PCR for tumor heterogeneity testing in gastrointestinal stromal tumors

K. Jasek¹, P. Szepe², L. Plank², Z. Lasabova¹;

¹Biomedical Centre, Martin, Slovakia, ²Department of Pathological Anatomy, Martin, Slovakia.

Introduction: Gastrointestinal stromal tumors (GISTs) are characterized by KIT/PDGFRα mutations. However, around 10-15% of all diagnosed GISTs are referred to as wild-type (WT) GISTs and V600E mutation in BRAF was in <5% of cases. The aim of this study was to confirm and quantify the presence of BRAF mutation using sensitive droplet digital PCR (ddPCR) in GISTs samples previously positive for V600E by allele-specific approach and/or dideoxysequencing.

Material and methods: DNA was extracted from 9 FFPE tissue section of V600E positive GISTs patients. Different amount of DNA - 130/100/10ng were used to prepare master mix with ddPCR Mut Assay BRAF and droplets were generated. Serial dilutions of V600E- positive RKO cell line DNA in wild-type DNA were used for calibration.

Results: The average number of droplets was 13696/PCR. The mutation could be detected in a dilution of 0.08%. The presence of V600E mutation in the 8 tested samples (positive by allele-specific PCR) was 1.9 % up to 0.34%. Sample positive for 1.9 % and 0.34% showed positivity and negativity by Sanger sequencing, respectively. One sample shows positivity below the limit of the detection of 0.06%, however was positive by allele-specific PCR.

Conclusions: The BRAF mutation in GISTs occur in a very low number of cells, however, the detection of these mutations is particularly important in terms of propped treatment and targeted therapy. The method should be evaluated to higher sensitivity and used in order to improve the therapy opportunities of patients.

The excision of centromere as stabilization mechanism of dicentric chromosomes in bone marrow cells of two patients with acute myeloid leukemia

I. Sarova^{1,2}, J. Brezinova¹, S. Ransdorfova¹, Z. Zemanova², L. Pavlistova², K. Svobodova², J. Cermak¹, A. Jonasova³, K. Michalova^{1,2};

¹Institute of Hematology and Blood Transfusion, Prague, Czech Republic, ²Center of Oncocytogenetics, IMBLD, General University Hospital and First Faculty of Medicine, Prague, Czech Republic, ³1st Department of Internal Medicine of General University Hospital and 1st Faculty of Medicine, Prague, Czech Republic.

Dicentric chromosomes (DCs), have been observed in variety types of malignancies. Barbara McClintock (1939) first described their unstable behavior during cell division. The segregation of centromeres to opposite spindle poles can result in a cascade of chromosomal damages (the breakage-fusion-bridge cycle) and consequently in a complex unbalanced rearrangement of the karyotype. Three possible mechanisms of dicentric stabilization have been observed: epigenetic inactivation, reduction in the intercentromeric distance, and shortening/deletion of a centromere, resulting in a secondarily monocentric chromosome.

We describe two patients with acute myeloid leukemia and complex karyotype involved derivative chromosomes: der(11)(11pter→11q25::11q23→1

1q25::9p24→9p23::11q14→11q25::11q23→11q25::9p23→9p11::11q14.3→11q14.3::9q11→9qter) in one case and der(17)(17qter→17p11.2::11p11.2::11q11.2→11qter) accompanied by the separately localized centromere of chromosome 11, present as a small marker chromosome, in the second one. On the basis of molecular cytogenetic results (FISH, mFISH, mBAND), we inferred that the derivative chromosome der(11), respective der(17) were primary dicentric chromosomes, stabilized by the excision of centromere 9, respective 11.

In 2011, MacKinnon and Campbell first described centromere deletion in naturally occurring cancer chromosomes. Some studies suggest that the centromere excision is under-diagnosed, because centromere as a small marker chromosome can be usually detected by FISH only. Not in all cases, the centromere fragment is preserved as we present in patient 1. In conclusion, the centromere excision is an important stabilization mechanism of DCs however further analyses on the larger cohort of patients are needed to establish its true incidence.

DICER1 cancer predisposition syndrome: Expanding the phenotype

J. J. O'Byrne, M. Duff, A. J. Green, L. Bradley;

Department of Clinical Genetics, Dublin 12, Ireland.

Introduction: DICER1 is a cancer predisposition syndrome. Although germline mutations are known to increase the risk of many diverse, rare tumours such as pleuropulmonary blastoma and sertoli leydig cell tumours and multinodular goitre, the complete phenotype is still poorly understood. The variability in expression and the lack of penetrance data continues to make DICER1 a difficult condition to diagnose and counsel around. In this study a cohort of three families with known pathogenic mutations is presented which expands the known phenotype.

Materials and Methods: Clinical review and pedigree analysis of three families with a known DICER1 pathogenic mutation was conducted and the phenotypes tabulated.

Results:

Table: Familial DICER mutations and phenotypes

Family No	Mutation	Pathology in Family members with confirmed DICER mutation (age of onset - yrs)		Pathology in family members not yet tested for DICER mutation (age of onset - yrs)
		Cancer	Non Cancer	
1 (Irish/Caribbean)	c.5003dupA; p.Asn1668fs (exon 25-3)	1 Bilateral SLCT (18/20)	1 MNG (50s)	1 Cervical Cancer (age unknown)
2 (UK)	c.5493G>A; p.Trp1831* (exon 27)	OSCT Gynadroblastoma (15)	3 MNG (19,21,22) 1 "abnormal womb cells" (age unknown)	1 SLCT (17yrs) 1 Ovarian Cyst (6) 1 Bone Tumor (16) 1 Brain Tumor (40s)
3 (Irish)	c.2233C>T; p.Arg745* (exon 16)	ASK(6)		1 Aevolar RMS(9) 1 Brain Cancer (1) 1 Renal Cancer (8) 1 Leukaemia (9) 1 MNG (35) 1 Lung Cyst (age unkown)

ASK - Anaplastic sarcoma of the kidney; MNG - multinodular goitre; OSCT - Ovarian Sex Chord Stromal Tumor; RMS- Rhabdomyosarcoma

Conclusions:

In this study:

- multinodular goitre and SLCT are confirmed as frequent phenotypes in people with DICER1 pathogenic mutations but no case of PPB was documented.
- rare or very rare phenotypes such as OSCST, gynadroblastomas, ASK were observed, suggesting these may occur more frequently than expected.
- the penetrance is estimated to ~70%, while literature suggests a low penetrance¹.
- the DICER1 cancer predisposition syndrome phenotype is extended which may guide the development of, much needed, tumour screening recommendations.

Constitutional PTEN expression in women with early-onset breast cancer

M. G. Tedesco¹, S. Martini¹, R. Zuntini^{1,2}, S. Miccoli^{1,2}, L. Godino^{1,2}, A. Belardinelli³, G. Lanzoni¹, A. Vaisfeld¹, M. Romagnoli¹, D. Turchetti^{1,2};

¹U.O.Genetica Medica, Policlinico S.Orsola-Malpighi, Bologna, Bologna, Italy, ²Centro di Ricerca sui Tumori Ereditari, Dipartimento di Scienze Mediche e Chirurgiche, Università di Bologna, Bologna, Italy, ³Immunopatologia e medicina trasfusionale, Policlinico Sant'Orsola-Malpighi, Bologna, Italy.

Breast cancer (BC), the most common malignancy in women, mostly arises in peri-post menopausal age, while early age at onset may suggest genetic

susceptibility. However, germline mutations are identified only in a minority of patients, suggesting a role for different risk factors. Among those, we considered PTEN levels, which in mouse models were associated to BC risk. We assessed PTEN expression in 31 women with early-onset BC (26-35 years), who had tested negative for BRCA1/2 mutations, using q-real time PCR. Expression levels were compared to the mean level of 23 healthy female blood donors aged 50 or older. Patients were then subdivided into three groups: 13 patients under-expressing PTEN (≤80%), 8 over-expressing PTEN (≥125%) and 10 with expression similar to controls. If compared to patients with normal or lower levels, patients overexpressing PTEN had a more recent diagnosis (7,38 vs 8,10 vs 11,15 years, respectively), larger tumors (mean diameter: 21,7 mm vs 17,6 vs 18, respectively), with a T2 stage in 50% of the group compared to 22.2% and 16.7% in normal and low expression groups, respectively. These differences, however, did not reach the statistical significance; no other differences were detected between the groups. To explore the mechanisms underlying different PTEN levels, PTEN mutations and defect of methylation were analyzed, with no alterations detected.

Our findings seem to exclude that PTEN levels may be a relevant risk factor for BC occurrence, but might suggest the presence of regulatory mechanisms raising PTEN levels after BC diagnosis, especially for larger size tumors.

P12.078

The experience of EGFR-genotyping for the individualization in treatment of the patients with lung cancer in Federal State Budgetary Institution "RCRC named after N.N. Blokhin" of the Ministry of Health of the Russian Federation

O. Arkhipova, M. Filippova, A. Semyanikhina, T. Dubrovina, K. Laktionov, L. Lyubchenko; FSBI „Russian cancer research center named after N.N. Blokhin“, Moscow, Russian Federation.

Introduction: Activating somatic mutations in the *EGFR* gene can be detected in up to 30% cases of non-small-cell lung cancer (NSCLC). According to clinical guidelines *EGFR*-genotyping is a routine diagnostic procedure before prescribing tyrosine kinase inhibitors. Aside *EGFR*-testing the detection of *ALK-EML4* gene rearrangements which occur in 4-10% of all adenocarcinoma cases is recommended prior to initiating targeted therapy.

Methods and materials: *EGFR*-genotyping and *ALK*-testing of the DNA derived from the FFPE NSCLC samples were carried out. The specimens were collected from the 279 patients with NSCLC (179 women and 100 men). The median age at diagnosis was 57 years. Adenocarcinoma was diagnosed in 87%. DNA-testing was performed using Cobas *EGFR* Mutation Test Kit. To confirm the results Sanger sequencing was performed. *ALK* screening was carried out using the VENTANA anti-*ALK* (D5F3) assay.

Results: Mutations in the *EGFR* gene were detected in 28,5% of all tested samples. Mutations in exon 19 were found in 41%, L858R in 35%, T790M in 12%, G719C in 5% and an insertion in exon 20 in 7%. The combination of two activating mutations was revealed in two patients. We identified two *ALK*-positive samples.

Conclusion: Our data on the frequency and distribution of the mutations in the *EGFR* gene and *ALK*-rearrangements is comparable with the results previously reported. The cases with two activating but functionally different mutations confirm the heterogeneity of NSCLC but further research is necessary to determine the frequency of this phenomenon for a better understanding of the mechanisms of responsiveness to targeted therapy.

P12.079

Hereditary Breast and Ovarian Cancer Syndrome: Screening ERCC4 (FANCO) when BRCA Mutations are not the Origin

C. Velázquez Pérez¹, M. Durán Domínguez¹, E. Esteban Cardeñosa¹, M. Tascón Torres¹, E. Lastra Aras², G. Marcos García², L. Hernández Sanz¹, N. Martínez Martín¹, M. Infante Sanz¹;

¹IBGM, Valladolid, Spain, ²Servicio de Oncología, Complejo Hospitalario Burgos, Burgos, Spain, ³Servicio de Oncología, Hospital Río Hortega, Valladolid, Spain.

ERCC4 is a versatile protein implicated in several DNA repair via: nucleotide excision repair (NER) pathway and Fanconi Anemia (FA) pathway. FA genes products are involved in DNA interstrand crosslink repair. Biallelic mutations in ERCC4 cause FA subtype Q whereas monoallelic mutations contribute to inherited risk of Hereditary Breast and Ovarian Cancer Syndrome (HBOC). In a clinical scope, via NER alterations conferred platinum sensitivity, the standard therapy for breast and ovarian cancer.

To investigate the role of ERCC4 in HBOC we screened this gene for mutations in 125 Spanish ovarian cancer patients or breast cancer cases with ovarian history in their pedigrees. All samples were negatives for BRCA mutations. Mutation screening was performed by HA-CAE and subsequently

Sanger Sequencing of altered pattern. Missense mutations were evaluated using CONDEL software that combines tools as SIFT, Polyphen and MutationAssessor.

Our study identified two novel variants (c.338+13A>G, c.1524 A>T) and eleven previously described (c.251C>T, c.974-7A>G, c.974-53delTG, c.1244G>A, c.1251T>A, c.1563C>G, c.1727G>C, c.1812-103G>A, c.1905-35T>C, c.1905-28G>A and c.2505T>C). In Silico analysis predicted c.1244 G>A and c.1727G>C as probably damaging.

We have identified ERCC4 inactivating mutations in 0.8% of our population, which is similar to other FA-BRCA genes. Hence, genetic testing of this gene should be considered in high risk HBOC families as far as ERCC4 mutations, that compromise DNA repair, could preserve sensitivity to continuous platinum therapy.

Clinical and pathogenetic features of ETV6-related thrombocytopenia with predisposition to childhood ALL

F. Melazzini¹, F. Palombo², A. Balduini³, D. De Rocco⁴, C. Marconi², P. Noris¹, C. Gnan⁵, T. Pippucci², V. Bozzi¹, **M. Faleschini⁴**, C. A. Di Buduo⁶, C. Alfano⁷, M. Seri², C. L. Balduini¹, A. Pecci¹, A. Savoia^{8,9};

¹Department of Internal Medicine, University of Pavia-IRCCS Policlinico San Matteo Foundation, Pavia, Italy, ²Department of Medical and Surgical Sciences, University of Bologna Medical Genetic Unit, Sant'Orsola Malpighi Hospital, Bologna, Italy, ³Laboratory of Biotechnology, IRCCS San Matteo Foundation, Pavia, Italy, ⁴Institute for Maternal and Child Health – IRCCS Burlo Garofolo, Trieste, Italy, ⁵Department of Medical Sciences, University of Trieste, Trieste, Italy, ⁶Department of Molecular Medicine, University of Pavia, Pavia, Italy, ⁷Maurice Wohl Institute, King's College London, London, United Kingdom.

Inherited thrombocytopenias (ITs) are genetic disorders characterized by reduced blood platelet count. In addition to spontaneous bleedings, IT can be associated with other features, including risk of leukemias as in the ITs caused by mutations of RUNX1 and ANKRD26. Thanks to an international collaboration, we have recently identified another form of IT with increased risk of hematological malignancies (ETV6-related thrombocytopenia; ETV6RT) that is caused by mutations of ETV6, a relatively well-known tumor-suppressor gene (Noetzli et al., 2015). We searched for ETV6 mutations in a series of 130 consecutive probands with ITs of unknown origin and found 5 causative variants in 7 of them. Although the study of family members revealed that degree of thrombocytopenia and bleeding tendency were mild, 4 patients had childhood B-cell acute lymphoblastic leukemia (ALL), confirming that ETV6-RT is a ALL predisposition syndrome. In vitro studies revealed that patient megakaryocytes have defective maturation and proplatelet formation, while platelet have reduced ability to spread on fibrinogen; however clinical and laboratory findings did not identify any peculiar defect that can be used to suspect this disorder and also platelet size (usually enlarged in ITs) was normal. For these reasons, we suggest that mutation screening of ETV6 is performed in subjects with dominant ITs and normally sized platelets.

Polymorphisms associated with everolimus pharmacokinetics, toxicity and survival in metastatic breast cancer

M. Apellániz-Ruiz¹, T. Pascual-Martínez², C. Pernaut³, C. Cueto-Felgueroso⁴, P. Villalba⁴, C. Álvarez¹, L. Manso³, L. Inglada-Pérez^{1,5}, M. Robledo^{1,5}, C. Rodríguez-Antona^{1,5}, E. Ciruelos³;

¹Spanish National Cancer Research Centre (CNIO), Madrid, Spain, ²Medical Oncology Department, La Princesa University Hospital, Madrid, Spain, ³Medical Oncology Department, 12 de Octubre University Hospital, Madrid, Spain, ⁴Biochemistry Department, 12 de Octubre University Hospital, Madrid, Spain, ⁵Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), Madrid, Spain.

Background: Metastatic breast cancer (MBC) progressing after endocrine therapy frequently activates mTOR pathway. The BOLERO-2 trial showed that everolimus-exemestane achieves increased progression free survival (PFS) compared with exemestane. However, there is great inter-patient variability in toxicity and response to exemestane-everolimus treatment. The objective of this study was to explore the implication of single nucleotide polymorphisms (SNPs) on outcomes from this treatment through a pharmacogenetic analysis.

Patients and Methods: Blood was collected from 90 postmenopausal women with hormone receptor-positive, HER2-negative MBC treated with exemestane-everolimus following progression after prior treatment with a non-steroidal aromatase inhibitor. Everolimus pharmacokinetics was measured in 37 patients. Twelve SNPs in genes involved in everolimus pharmacokinetics and pharmacodynamics were genotyped and associations assessed with drug plasma levels, clinically relevant toxicities (non-infectious pneumonitis, mucositis, hyperglycemia and hematological toxicities), dose reductions

or treatment suspensions due to toxicity, progression free survival (PFS) and overall survival.

Results: We found that CYP3A4 rs35599367 variant (CYP3A4*22 allele) carriers had higher everolimus blood concentration compared to wild type patients (P=0.019). ABCB1 rs1045642 was associated with risk of mucositis (P=0.031), while PIK3R1 rs10515074 and RAPTOR rs9906827 were associated with hyperglycemia and non-infectious pneumonitis (P=0.016 and 0.024, respectively). Furthermore, RAPTOR rs9906827 was associated with PFS (P=0.006).

Conclusions: CYP3A4*22 allele influenced plasma concentration of everolimus and several SNPs in mTOR pathway genes were associated with treatment toxicities and prognosis. These results require replication, but suggest that germline variation could influence everolimus outcomes in MBC.

P12.082

Mutational status of EZH2 and CD79B hot spots in mature B-cell non-Hodgkin's lymphomas: novel CD79B variations have been revealed

G. Cetin¹, I. Baris², **V. Caner³**, B. Sarikepe¹, N. Sen Turk³, E. Tepeli¹, S. Hacioglu⁴, I. Sari⁴, G. Bagci¹, A. Keskin⁴;

¹Pamukkale University School of Medicine Department of Medical Genetics, Denizli, Turkey, ²Pamukkale University School of Medicine Department of Medical Biology, Denizli, Turkey, ³Pamukkale University School of Medicine Department of Medical Pathology, Denizli, Turkey, ⁴Pamukkale University School of Medicine Department of Hematology, Denizli, Turkey.

OBJECTIVE: We aimed to determine the hot spot mutational frequencies of Enhancer of Zeste homolog 2 (EZH2) and cluster of differentiation 79B (CD79B) genes in a cohort of mature B-cell non-Hodgkin's lymphomas.

MATERIALS AND METHODS: DNA samples from formalin-fixed and paraffin embedded (FFPE) tissues from a total of 37 patients with mature B-cell non-Hodgkin lymphomas were included in the study. Molecular genetic analysis was performed by direct sequencing of the DNA samples.

RESULTS: We analyzed FFPE tumor tissue samples from 17 female and 20 male patients with a median age of 63.7 years at the time of diagnosis. None of the patients had previously reported hot spot mutations in EZH2 and CD79B, but previously unreported single nucleotide variations of CD79B were present in nine patients. rs779833118 was the most frequent variation (7/37 patients, 18.9%). A non-synonymous variation rs757407417, which could have a potentially damaging outcome, was detected in two patients.

CONCLUSIONS: None of the patients had well-known hot spot mutations in EZH2 and CD79B. However, we detected novel CD79B variations in mature B-cell non-Hodgkin's lymphoma patients.

Grant Reference: This study was supported by the Pamukkale University Scientific Research Unit (Grant No: 2015HZL009).

P12.083

Extracolonic tumors as presenting symptoms of FAP in probands with a family history of FAP

C. Vinkler¹, K. I. Dayan², A. Singer³, R. Berger⁴, D. Lev¹;

¹Institute of Clinical Genetics Wolfson Medical Ctr, Holon, Israel, ²Dpt of Surgery, Wolfson Med Ctr, Holon, Israel, ³Department of Community Genetics Ministry of Health, Jerusalem, Israel, ⁴Institute of Oncology Wolfson Medical Ctr, Holon, Israel.

Sporadic desmoid tumors is estimated at 1 to 2 per million, whereas more than 15% of patients suffering from familial adenomatous polyposis (FAP) develop desmoid tumors.

Nonmedullary Thyroid Cancer (NMTC) has an incidence of 12.1:100,000. 5-10% are familial cases caused by germline mutations in specific genes. A small number are associated with known syndromes. Rarely NMTC is an extracolonic manifestation of FAP.

FAP is a colon cancer susceptibility syndrome in which hundreds to thousands of colonic polyps develop. By 35y, 95% of individuals with FAP have polyps.

We report two patients with FAP presenting first with extracolonic manifestation.

A 33 y old woman with thyroid goiter whose sister and her father have NMTC. Her 35y old brother had GI bleeding and three adenomatous polyps removed on colonoscopy. Sequencing of APC gene in the brother revealed a frame shift mutation p.Arg332fs*

A 53-year-old male presented first with intestinal obstruction. Two small adenomatous polyps were found during colonoscopy. A large peritoneal desmoid tumor was removed and symptoms were alleviated. FAP has been diagnosed previously in other family members. He was found to carry a frameshift mutation in the APC gene p.Ser299Cysfs*.

This unusual presentation demonstrates the clinical importance of a comprehensive evaluation of familial cancer cases. It also shows the intrafamilial variability in the phenotypic manifestations of the familial mutations. It may

be postulated that difference in genetic background along with environmental factors may be involved in modifying the phenotypic expression in these cases.

P12.085

Identification of susceptibility genes to define the genetic basis of familial testicular cancer by whole exome sequencing

B. Paumard Hernandez¹, M. Urioste^{1,2}, E. Gonzalez Billalabeitia³, I. Marquez-Rodas⁴, J. Maroto⁵, G. Anguera Palacios⁶, N. Romero-Laorden⁷, J. Triviño⁸, H. Tejero¹, J. Benítez^{9,2};
¹Spanish National Cancer Research Center (CNIO), Madrid, Spain, ²Center for Biomedical Network Research on Rare Diseases (CIBERER), Madrid, Spain, ³Hospital Universitario Morales Meseguer, Murcia, Spain, ⁴Instituto de Investigación Sanitaria Gregorio Marañón, Madrid, Spain, ⁵Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, ⁶Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, ⁷Centro Integral Oncológico Clara Campal, Madrid, Spain, ⁸Sistemas Genómicos, Valencia, Spain, ⁹Spanish National Cancer Research Center (CNIO), Madrid, Spain.

Introduction: Testicular cancer represents ~1-1.5% of male tumors, with a peak incidence between 15 and 45 years. Human Testicular germ cell tumors (TGCT) have a strong genetic component, familial aggregation is observed in ~1% of cases, although no high penetrance genes have been identified so far. The aim is the identification of high-/moderate susceptibility genes by WES technique.

Materials and Methods: Currently, 20 families with at least two affected members were selected, from them, 8 have already been sequenced using a HiSeq2000. Data was analyzed according to the specific pipeline described by our group based on different filters. Considering the recent findings in the genetic background of the TGCTs and our preliminary results, we are working on the hypothesis of a polygenic model of inheritance, making a family-based association test in parallel with a population-based association test with the FB-SKAT test, to evaluate the level of additive effect that our variants could have with the familial aggregation of the disease.

Results: 87 variants were identified in candidate genes, whose functions have been implicated in pathways involving male germ cell development, spermatogenesis, microtubule assembly, DNA damage response, steroid hormone signaling or telomerase function. From them, 65 were validated by Sanger sequencing and segregation analysis performed.

Nine, seven and one variants are shared between 2, 3 and 4 different families, respectively.

Conclusion: Our preliminary results show that a number of moderate-low susceptibility alleles from specific pathways could be involved in this type of familial tumors.

B.Paumard holds a Caixa Fellow grant.

¹Institut d'Investigació Biomèdica de Bellvitge-Institut Català d'Oncologia, L'Hospitalet de Llobregat, Spain, ²Spanish National Cancer Research Center (CNIO), Madrid, Spain, ³Department of Genetics and Microbiology, Universitat Autònoma de Barcelona, Bellaterra, Spain, ⁴Institut d'Investigació Germans Trias i Pujol-Institut Català d'Oncologia, Badalona, Spain, ⁵Institut d'Investigació Biomèdica de Girona Doctor Josep Trueta-Institut Català d'Oncologia, Girona, Spain, ⁶University Hospital Vall d'Hebron and Vall d'Hebron Institute of Oncology, Barcelona, Spain, ⁷Santa Creu i Sant Pau Hospital, Barcelona, Spain.

Introduction: In about 55% of individuals harboring mismatch repair (MMR) deficient tumors, germline mutations or somatic methylation in MMR genes are not identified, being referred as Lynch-like syndrome (LLS) patients. Recently FAN1 germline mutations have been associated to MMR proficient colorectal cancer (CRC) and pancreatic cancer predisposition. The aim of this study was to determine whether germline FAN1 play also a role in LLS. Patients and methods: Germline analysis of FAN1 was performed in 30 LLS unrelated individuals showing MSH2 loss of expression in tumors. Pathogenicity assessment of identified variants was performed using computational and cosegregation analyses.

Results: We identified three rare missense variants in 3 unrelated LLS patients (10% of the studied sample). Two of the 3 identified variants, c.434G>A [p.(R145H)] and c.1129C>T [p.(R377W)], cosegregated with colorectal cancer-affected relatives. The remaining variant, c.1856T>A (p.M619K), for which no cosegregation data was available, was classified as likely pathogenic based on functional and computational analyses.

Conclusion: The obtained results suggest the involvement of the FAN1 gene in MSH2-deficient LLS.

Funding: SAF2012-33636, AECC, 2014SGR388.

Recently, Kiiski et al. reported a significant association between the truncating FANCM mutation p.Gln1701Ter and BC risk in the Finnish population (OR 1.86, 95% CI = 1.26-2.75; P = 0.0018). By analyzing the exomes of 24 BRCA1/2-negative index cases from high-risk BC/OC families of German origin, we also found the p.Gln1701Ter mutation. Mutational analysis of the FANCM gene by NGS in 2,211 familial BRCA1/2-negative BC and/or OC index cases identified 7 different truncating alterations in 26 cases (1x p.Gln156Ter, 12x p.Gln1701Ter, 1x p.Arg1030Ter, 1x p.Arg185Glufs, 5x p.Arg1931Ter, 5x p.Arg658Ter, 1x p.Val1095Tyrfs; 26/2,211 CF=1.176%). We were able to calculate an OR of 2.24 (95%CI=1.26-3.95 p=0.004) by comparing our findings to the FANCM mutation load in 5,335 control individuals of which 28 were tested positive (28/5,335 CF=0.525%). In an extended cohort of 6,117 familial BRCA1/2-negative BC and/or OC index cases of German origin we genotyped the p.Gln1701Ter mutation 20 times (20/6,117, CF=0.327%) and 14 times in 9,786 control individuals (14/9,786, CF=0.143%), resulting in an OR of 2.29 (95%CI=1.10-4.77 p=0.013). The mean age at first BC diagnosis of individuals carrying truncating FANCM alterations was 49 years with predominantly ER+, PR+, HER2-tumours of grade 2. Due to the apparently low FANCM mutation frequency, a large collaborative international study group was founded (FANCM study group), including research groups from Finland, Germany, Italy and the USA to quantify the risk for BC and possibly other cancer entities associated with deleterious FANCM alterations.

Modelling the Fanconi anemia/BRCA pathway by TALEN and CRISPR/Cas9 engineered nucleases

A. Aza^{1,2}, M. Bogliolo^{1,2}, M. Marín^{1,2}, L. Mina^{1,2}, Á. Muñoz¹, M. Ramírez^{1,2}, J. Surrallés^{1,2};
¹Department of Genetics and Microbiology, Universitat Autònoma de Barcelona, Barcelona, Spain, ²Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), Barcelona, Spain.

Introduction: Fanconi anemia (FA) is a rare genome instability disorder clinically characterized by developmental abnormalities, high predisposition to cancer and bone marrow failure. Many of the available cell lines from FA anemia patients are difficult to manipulate and are not isogenic.

Objectives: Due to current limitations of FA cell models, we decided to knock-out (KO) genes implicated in the FA/BRCA pathway (FANCA, FANCD1, FANCO and FAN1) in the genetically amenable human HEK293T cell line.

Methods: We used TALENs and CRISPR/Cas9 for gene KO. Specific gene disruption was proven by genetic complementation with the corresponding wildtype gene using lentiviral vectors or transient transfection.

Results: We successfully generated FANCA, FANCD1 and FAN1 KO HEK293T cells using engineered nucleases. All these cells are sensitive to DNA crosslinking agents, thus mimicking cells from patients with defects in the FA/BRCA pathway. Moreover, all FA genes KO cells get blocked in the G2/M phase upon treatment with DNA crosslinkers, a typical FA cellular phenotype. Finally, these FA cells reproduce gene-specific defects: FANCA/- cells have impaired FANCD2 monoubiquitination, FANCD1/- cells are unab-

le to form Rad51 foci after irradiation and are sensitive to PARP inhibitors, and FANCD1/- cells are sensitive to UV-light radiation.

Conclusion: Genome editing with targeted engineered nucleases is a valuable tool to generate isogenic and genetically amenable FA cell models. The generated FA/BRCA KO isogenic cells will facilitate translational studies including the analysis of pathogenicity of variants of unknown significance, large-scale drug screenings or proteomic projects to identify new FA/BRCA pathway genes.

Germline TP53 mutation in a patient with fibrolamellar carcinoma: new association to Li-Fraumeni Syndrome?

R. C. Andrade¹, M. A. F. D. Lima², P. A. S. Faria³, F. R. Vargas^{1,4,5},

¹Genetics Division, Instituto Nacional de Câncer, Rio de Janeiro, Brazil, ²Programa de Internato em Genética, Universidade UnigranRio, Rio de Janeiro, Brazil, ³Pathology Division, Instituto Nacional de Câncer, Rio de Janeiro, Brazil, ⁴Genetics and Molecular Biology Department, Universidade Federal do Estado do Rio de Janeiro, Rio de Janeiro, Brazil, ⁵Birth Defects Epidemiology Laboratory, Fundação Oswaldo Cruz, Rio de Janeiro, Brazil.

Li-Fraumeni (LFS) syndrome is a rare hereditary cancer predisposition syndrome associated with germline mutations in *TP53* gene. We performed *TP53* mutation screening in a cohort of 14 probands whose family cancer histories presented at least one LFS core cancer before age 45, and a second cancer of any type before age 45, irrespective of degree of kinship. These features are reminiscent of LFS, yet not compatible with LFS or Li-Fraumeni like (LFL) published criteria. A pathogenic *TP53* mutation was identified in 1/14 probands (7.1%), a 14 year-old female diagnosed with fibrolamellar carcinoma (FLC). FLC is a rare variant of hepatocellular carcinoma with distinct molecular features. The proband is a heterozygote carrier of the *TP53* c.467G>A (p.Arg156His) in exon 5, and her mother is an asymptomatic carrier. Analysis of tumor DNA disclosed an additional alteration (c.461G>A; p.Gly154Asp) in *TP53*. This is the first case of a proband with FLC exhibiting a germline and a somatic *TP53* pathogenic mutation, possibly acting as driver alterations. This report adds information to the molecular etiology of FLC, and to the continuously growing spectrum of tumors related to LFS. Importantly, probands with family history reminiscent of LFS/LFL should be considered for *TP53* screening.

Cloud-based informatics enables the design and analysis of massively multiplex custom gene fusion panels for next-generation sequencing on FFPE RNA samples.

R. Gottimukkala, E. Ballesteros, H. Brev, Y. Lou, S. Myrand, M. Hogan, K. Bramlett, G. Liu, S. Sadis, F. Hyland, F. Hernandez-Guzman; Thermo Fisher, South San Francisco, CA, United States.

Gene fusions, a combination of two genes, are caused by structural DNA rearrangements. Many gene fusions are strong driver mutations in neoplasia, and are important in understanding interaction with targeted therapy and risk stratification.

Massively multiplex Amplicon gene fusion assays with next-generation sequencing enable enrichment of fusion transcripts using 10 ng of RNA extracted from FFPE samples, with sensitive detection of particular fusion isoforms for defined gene pairs. Ion Torrent sequencing reveals the full sequence of the gene fusion.

We developed cloud-based software to enable the design of a custom Amplicon gene fusion panel, with up to 1,000 fusions and gene expression assays. We extensively mined the scientific literature and the COSMIC database for fusions. We rigorously curated this data, including correction of reported sequence to obtain genomic coordinates, breakpoints, exon junctions, and selected wet lab testing. We created a database containing over 1000 high quality fusion isoforms, including 70 ALK, 60 RET, 26 ROS1, and 21 NTRK1 fusions. We designed multiplexable Amplicon primers for all fusions.

We developed cloud-based analysis software to analyze sequencing data, utilizing the rich annotation information. The reads are mapped to a custom fusion reference sequence; an optimized algorithm selects confidently mapped reads using overlap and breakpoint information, and sensitively detects gene fusions. Software QC steps for total number of mapped reads, number of reads for gene expression controls, and elimination of cross-talk artifacts result in a highly sensitive and specific detection of fusions, with LOD below 1%. Fusion results can be viewed, annotated, exported.

Genetic susceptibility to gastric cancer: Immunohistochemical characterization of genes significantly associated with gastric cancer

A. V. Sanchez Romero¹, N. Garcia Lozano¹, M. Paúles Villar², L. Luján Barroso¹, M. Galán Guzmán¹, N. Sala Serra¹;

¹Catalan Institute of Oncology-Bellvitge Institute for Biomedical Research (ICO-IDIBELL), Hospitalet de Llobregat, Barcelona, Spain, ²University Hospital of Bellvitge-IDIBELL, Hospitalet de Llobregat, Barcelona, Spain.

Introduction: From previous studies, we confirmed the association between gastric cancer (GC) in Europeans and variants in different genes, of which *MUC1*, *TFF1*, *NQO1* and *PTPN11* were selected for further characterization of their role in gastric carcinogenesis.

Objectives: To analyze the immunohistochemical (IHC) expression of these four genes in paired samples of tumor-normal gastric mucosa, according to the genotypes of their GC associated variants.

Methods: IHC staining was performed on tissue slides of 100 pairs of FFPE tissue blocks of tumor and adjacent non-tumor gastric mucosa from 100 patients with GC. Samples were grouped in three categories according to the percentage of IHC stained cells in gastric mucosa: 0-10%, >10-50% and >50-100%. The kappa statistic was used to evaluate the agreement between tumor and paired non-tumor tissues. The Fisher exact test was used to analyze differences between the histological subtypes of gastric cancer in tumor samples. Association between IHC expression of *TFF1*, *MUC1* and *NQO1* and *TFF1* rs2839488 and rs9976977, *MUC1* rs3814316 and rs4072037 and *NQO1* rs7359387, was analyzed by logistic regression.

Results: *TFF1* was significantly decreased or absent in tumor mucosa. *MUC1* and *NQO1* were expressed in both normal and tumor mucosa, particularly of the intestinal-type, but expression decreased in tumor samples. *PTPN11* expression was absent in 95% of the samples. None of the analyzed genetic variants was associated with the IHC expression of their genes.

Conclusion: The genotype of the analyzed GC-associated genetic variants does not contribute to the IHC expression of their genes.

Grants: ISCIII PI12/01187 and MICITT/FI-049B-14

Profiling of mutations in gastric cancer

K. I. Kirillova^{1,2}, V. V. Strelnikov^{1,2}, M. V. Nemtsova^{1,3}, I. I. Bykov⁴, A. S. Tanas^{1,2};

¹Research Centre for Medical Genetics, Moscow, Russian Federation, ²Pirogov Russian National Research Medical University, Moscow, Russian Federation, ³Russian Medical Academy for Postgraduate Education, Moscow, Russian Federation, ⁴I.M.Sechenov First Moscow State Medical University, Moscow, Russian Federation.

Introduction: Gastric cancer (GC) is one of the most common oncological diseases with high morbidity and mortality. Genetic factors may increase the risk of developing GC. The aims of this study are to identify new genes involved in the development of GC and to characterize mutations in these genes. **Materials and methods:** The study included GC 52 patients aged 35-59 years, who had given the tumor material, normal gastric tissue and venous blood. Search for mutations in 52 cancer related genes was carried out by high-throughput parallel DNA sequencing. For the validation of the detected mutations we used Sanger sequencing. Determination of germline or somatic nature of the identified mutations was done by DNA sequencing of normal tissues of the same patients.

Results: Mutations were found in 22 out of 52 genes. We show that diffuse and intestinal GC types are distinguished by the spectra of somatic mutations: somatic mutations in the *CDH1* gene are more common in the diffuse type (p=0.04) and mutations in the *TP53* gene are more common in the intestinal type of GC (p=0.04). Germline mutations in patients with GC were for the first time detected in the genes *MET* (p.N375S, p.R970C), *RB1* (p.H686N), *EGFR* (p.V292M), *JAK3* (p.V722I), *APC* (p.I1289K), *ATM* (p.F858L), *CDKN2A* (p.D86N). New mutations were discovered in the *CDH1* gene (c.-71C>G, p.K182N, p.T303P, p.S838G, c.1320+2T>G).

Conclusions: Our results suggest that germline mutations in genes other than *CDH1* might contribute to GC development.

P12.094

MAP3K6 expression and methylation profile in sporadic Gastric Cancer

A. S. Valente¹, P. Oliveira¹, P. Ferreira¹, J. Carvalho¹, H. Pinheiro¹, C. Oliveira^{1,2};

¹Ipatimup/i3S, Porto, Portugal, ²Medical Faculty of the University of Porto, Porto, Portugal.

Introduction: Every year, >1 million new Gastric Cancer (GC) cases are diagnosed and around 700.000 GC-related deaths are reported. Despite all efforts, much remains to be known on the molecular events involved. Important lessons can be learned from studies of familial cases as the genes and mechanisms are frequently shared with those found in the sporadic setting. Recently, we described MAP3K6 germline mutations in hereditary GC. Somatic hypermethylation of an intragenic CpG island, overlapping a DNase-

hypersensitive site predicted to harbour a promoter-associated regulatory element, has been presented as a putative second-hit. The aim of the present work was to evaluate the relevance of MAP3K6 in sporadic GC. **Materials and Methods:** MAP3K6 expression was evaluated by qRT-PCR in RNA from sporadic GC cases and corresponding adjacent normal mucosa. Methylation profile of MAP3K6 promoter and gene-body was assessed by RRBS. **Results:** Overall, MAP3K6 was consistently downregulated in GC samples in comparison to corresponding adjacent mucosa. Promoter hypomethylation was a common event in tumours, but the methylation profile at the intragenic CpG island was unchanged compared to normal. **Conclusions:** MAP3K6 down-regulation seems to be a common event in GC, correlating with promoter hypomethylation. These observations suggest the existence of a repressor binding site within MAP3K6 promoter, which becomes active upon demethylation. Further studies are warranted to corroborate these findings as well as to disclose the role of MAP3K6 in gastric carcinogenesis.

The study was supported by FCT Fellowships (SFRH/BPD/89764/2012; SFRH/BPD/86543/2012; SFRH/BPD/79499/2011), iFCT Programmes 2014, POPH—QREN Type 4.2, European Social Fund and Portuguese MC-TES.

The tumorigenic pathways of MSI and CIN sporadic gastric cancers

J. Carvalho^{1,2}, P. Ferreira^{1,2}, P. Oliveira^{1,2}, G. M. Almeida^{1,2}, H. Pinheiro^{1,2}, S. Rocha^{1,2}, D. Ferreira^{1,2}, A. S. Valente^{1,2}, M. Santos^{1,2,3}, F. Carneiro^{1,2,4}, C. Oliveira^{1,2,3,4},

¹Expression Regulation in Cancer Group, IPATIMUP, Institute of Molecular Pathology and Immunology of the University of Porto, Porto, Portugal, ²Instituto de Investigação e Inovação em Saúde, Universidade do Porto, Porto, Portugal, ³Department of Medical Sciences and Institute of Biomedicine – iBiMED, University of Aveiro, Aveiro, Portugal, ⁴Medical Faculty of the University of Porto, Porto, Portugal.

Introduction: Gastric cancer (GC) kills ~700.000 people per year and 5-year overall survival is below 25%, due to late diagnosis and lack of effective therapies. Surgery is the single curative treatment, however helpful only for early-stage tumors. Targeted therapies are just starting to be applied with limited success. Recently, NGS technology provided the spectrum of somatic alterations in several GC series but its usefulness for decision-making in clinical practice is still scarce. We aimed at characterizing two GC molecular subgroups and predict targetable molecular signatures, which may guide better therapy selection strategies. **Material and Methods:** Fifty GC tumour/normal pairs either showing Chromosomal Instability (CIN=25) and bad prognosis, or Microsatellite Instability (MSI=25) and better prognosis, were analyzed by Whole genome and Methylation sequencing and integrative bioinformatics. Data was validated in independent TCGA datasets. **Results:** MSI tumours displayed hypermethylated tumour suppressor genes and activating point mutations in oncogenes. CIN tumours displayed gene amplification at oncogenes and drug-resistance genes and hypomethylation on oncogene promoters. The same type of differential mechanisms was found for Chromatin remodeling, and Cell cycle control, but Splicing factors and RNA-binding proteins were affected similarly in both subgroups. Despite differences in mechanisms, genes encoding targetable oncogenic signalling proteins were similarly affected in both subgroups. **Conclusions:** These data demonstrate that most tumors present similar tumorigenic pathways independently of the molecular subgroup, and that differences in prognosis and drug response are likely related with the action of modifier proteins.

P12.096

Gene expression analysis of Gastric cancer Patients from Saudi Arabian Population

F. Bibi¹, M. I. Nasser², S. Akhtar², E. I. Azhar^{1,3}, M. Yasir⁴, A. A. Jiman-Fatani⁵, A. Sawan⁶; ¹Special Infectious Agents Unit, King Fahd Medical Research Centre, King Abdulaziz University, Jeddah, Saudi Arabia, ²Center of Excellence in Genomic Medicine Research (CEGMR), King Abdulaziz University, Jeddah, Saudi Arabia, ³Department of Medical Laboratory Technology, Faculty of Applied Medical Sciences, King Abdulaziz University, Jeddah, Saudi Arabia, ⁴Special Infectious Agents Unit, King Fahd Medical Research Centre, King Abdulaziz University, Jeddah, Saudi Arabia, ⁵Department of Medical Microbiology and Parasitology, Faculty of Medicine, King, Jeddah, Saudi Arabia, ⁶Department of Anatomical Pathology, Faculty of Medicine, King, Jeddah, Saudi Arabia.

The role of small non-coding microRNAs (miRNAs) in several types of cancer has been evident. However, its expression has not been studied in Saudi population in gastric cancer (GC) patients. First time this study was conducted to identify miRNAs that are differentially expressed in gastric cancer patients compared with normal controls using miRNA microarray analysis and validated the results by Real-time quantitative PCR (qPCR). Our objective was to investigate the role of microRNAs in GC patients from Saudi population using formalin-fixed paraffin-embedded (FFPE) tissues of 34 samples from GC patients and 15 from normal control. We obtained expression data of 1082 expressed genes, from cancer tissues and noncancerous tissues (48 samples in total). Where 129 genes are up-regulated ($P > 0.05$) and 953 genes ($P > 0.05$) are down-regulated in 45 FFPE tissue samples. After candi[Unsupported Character - Codename ­]date miRNAs were selected, qPCR further confirmed that four miRNAs (hsa-miR-361-5p, hsa-miR-3687, hsa-miR-3613-3p, hsa-miR-1263) were significantly aberrant in GC tissues compared to the normal gastric tissues. In this study we provide miRNAs profile of GC where many miRNAs showed aberrant expression, suggesting the involvement of these genes in the development and progression of gastric cancer. Taken together, the results provided potential roles of these candidates' miRNAs in the diagnosis, prognosis biomarkers, or therapy targets of gastric cancer in Saudi population.

P12.097

Stomach Specific eQTLs represent Risk Factors for the Development of Gastric Carcinoma

T. Hess^{1,2}, U. Gyvyte², J. Becker^{1,2}, S. Heinrichs^{1,2}, S. Lindenberg², M. Leja⁴, M. Venerito⁵, J. Kupcinskas³, J. Schumacher¹;

¹Institute of Human Genetics, University of Bonn, Bonn, Germany, ²Department of Genomics, Life & Brain Center, Bonn, Germany, ³Department of Gastroenterology, Lithuanian University of Health Sciences, Kaunas, Lithuania, ⁴Digestive Diseases Center GASTRO, Riga East University Hospital, University of Latvia, Riga, Latvia, ⁵Department of Gastroenterology, Hepatology and Infectious Diseases, University of Magdeburg, Magdeburg, Germany.

Introduction: Gastric carcinoma (GC) represents the fourth most common cancer type worldwide. To find genetic risk factors priming for GC development, GWAS in Asian populations have been performed already with success. However, genetic GC studies in patients of European origin are scarce and so far have focused on small sets of candidate loci only.

Materials and Methods: To identify germline variants playing a role in the development of GC in patients of European descent, we genotyped a set of 27 SNPs in a Eastern European sample comprising 502 GC cases and 507 controls. As disease associated variants often reside in gene regulatory elements, we selected the SNPs based on the latest data release of the Genotype-Tissue Expression (GTEx) consortium, focusing on strong stomach specific expression quantitative trait loci (eQTLs).

Results: Three of the tested SNPs showed at least nominal significance for the development of GC ($P < 0.05$). SNP rs2976397 showed the strongest GC association signal ($P = 2 \times 10^{-8}$) at the same time influencing the expression of *PSCA*. SNP rs198408 showed GC association ($P = 1.67 \times 10^{-2}$) and regulates the expression of *NPPA*. Additionally, SNP rs10771539 was GC associated ($P = 2.31 \times 10^{-2}$) regulating the transcription of *KLRB1*.

Conclusion: In summary, using stomach specific eQTLs we identified three SNPs that are associated with GC development. Further replication studies in a large independent European sample are currently performed to further elucidate the role of eQTLs in the development of this fatal disease.

Deciphering the genetic bases of gastric carcinoids: from human to mouse model. A knockin mouse model with a missense mutation in the ATP4a gene mimics an aggressive familial form of gastric neuroendocrine tumor type I in humans

O. Calvete¹, A. Varro², P. Vargiu², S. Dodd², D. Pritchard², M. Garcia¹, J. Reyes⁵, S. Ortega², J. Benitez²;

¹Centro Nacional de Investigaciones Oncológicas (CNIO), Madrid, Spain, ²Department of cellular and molecular physiology. Institute of translational medicine. University of Liverpool, Liverpool, United Kingdom, ³Transgenic mice core unit. Spanish national cancer research center (CNIO), Madrid, Spain, ⁴Animal facility core unit. Spanish national cancer research center (CNIO), Madrid, Spain, ⁵Department of gastroenterology. Hospital INCA, Majorca, Spain.

Introduction: The H,K-ATP4a proton pump acidifies the gastric lumen in tight coordination with gastrin. We recently identified a missense mutation in the human ATP4a gene that causes an aggressive form of familial gastric neuroendocrine tumor characterized by early age of onset, hypoacidity, hypergastrinemia, iron-deficiency anemia, muscular infiltration, intestinal metaplasia and adenocarcinoma. Total gastrectomy was undertaken as the final treatment for the affected patients.

Materials and Methods: We constructed a knockin mouse model for this mutation to better understand the pathology developing and search for new therapies

Results: Mice mimic most of the alterations described in human patients, including achlorhydria, iron-deficiency anemia and hypergastrinemia, which validate the mutation as the primary responsible for this disease. While mice developed severe hyperplasia, dysplasia and glandular metaplasia in the stomach, gastric neuroendocrine tumors or adenocarcinomas as observed in humans were not observed. Interestingly, gastric acidification by treatment with 3% HCl in drinking water, both prevented (treatment since birth) and reverted (treatment starting at 150 or 250 days after birth) the glandular metaplasia and severe dysplasia phenotype of mice and partially restored the biochemical parameters in stomachs.

Conclusions: Preliminary preclinical experiments with HCl drinking water prevent and revert the gastric pathology in mouse model. These results suggest a therapeutic alternative for the treatment of human patients. Furthermore, the knockin mouse model represents a unique and novel tool for studying pathologies related to stomach acid disturbances.

This work is partially funded by CIBERER, H2020 BRIDGES and the Spanish Ministry of Health PI12/00070 supported by FEDER.

Genomic classification of oral squamous cell carcinoma: the role of copy number alterations

I. P. Ribeiro^{1,2}, F. Caramelo³, F. Marques^{2,4,5}, A. Santos¹, L. Barroso⁶, M. Mesquita⁶, T. Lopes⁶, M. J. Julião⁷, A. Ferreira⁸, I. P. Baptista^{2,4}, J. B. Melo^{1,2}, I. M. Carreira^{1,2};

¹Cytogenetics and Genomics Laboratory, Faculty of Medicine, University of Coimbra, Coimbra, Portugal, ²CIMAGO - Center of Investigation on Environment, Genetics and Oncobiology - Faculty of Medicine, University of Coimbra, Coimbra, Portugal, ³Laboratory of Biostatistics and Medical Informatics, IBILI - Faculty of Medicine, University of Coimbra, Coimbra, Portugal, ⁴Department of Dentistry, Faculty of Medicine, University of Coimbra, Coimbra, Portugal, ⁵Stomatology Unit, Coimbra Hospital and University Centre, CHUC, EPE, Coimbra, Portugal, ⁶Maxillofacial Surgery Unit, Coimbra Hospital and University Centre, CHUC, EPE, Coimbra, Portugal, ⁷Department of Pathology, Coimbra Hospital and University Centre, CHUC, EPE, Coimbra, Portugal.

Introduction: Oral Squamous Cell Carcinoma (OSCC) is a phenotypic, aetiological, biological and clinical heterogeneous malignancy. The current attempts of risk stratification do not have utility in clinical routine and consequently in the patients survival. We aimed to molecularly discriminate these heterogeneous OSCC patients based in chromosomal gains and losses and consequently find a clinical meaning to the molecular groups identified. **Material and Methods:** Array-comparative genomic hybridization in 93 OSCC samples was performed using an Agilent oligonucleotide microarray 4x180K. Healthy donors were used as controls. **Results:** Our results confirmed the regions previously reported as altered in these tumors, including gain of chromosomes 3q, 8q and 11q13 and loss in 3p, 5q and 9p. The presence or absence of metastasis/relapses is one of the most important predictors of disease outcome. Using cluster analysis based only in the genomic profile we were able to separate our cohort in two groups, one of which was correlated with a high risk of metastasis/relapses development during or after treatment, ($\chi^2(1)=6.7610637$; $p=0.0093168$ and $OR=3.868$, $IC95\%$ (1.478; 10.12). This specific genomic signature identified seems to have the power to predict outcome in OSCC with huge implications in terms of treatment choices, disease control and prevention. **Conclusions:** These results represent a significant step forward in the translation of genomic biomarkers for OSCC management in the clinical daily use.

genetic investigation of familial hematological malignancies

W. Hamadou¹, S. Besbes¹, R. El abed¹, V. Bourdon², Y. Ben youssef³, M. Laatiri⁴, S. Jemni⁵, T. Noguchi⁶, A. Khelif⁶, H. Sobol⁶, Z. Soua¹;

¹Faculty of Medicine of Sousse, Sousse, Tunisia, ²Institut Paoli-Calmette, marseille, France, ³Service of Clinical Hematology, CHU Farhat Hached, Sousse, Tunisia, ⁴Service of Clinical Hematology, CHU Fattouma Bourguiba, monastir, Tunisia, ⁵Regional center of Blood transfusion . CHU F. Hached, Sousse, Tunisia, ⁶Institut Paoli-Calmette, Marseille, France.

Introduction: Familial aggregation among patients with several hematological malignancies has been revealed. This emphasizes the importance of genetic factors. Only few genes predisposing to familial hematological malignancies have been reported until now due to the low occurrence. Few variants that might contributing to the background of genetic factors were reported, this fact encourage us to extend our investigations to other co-operating genes. We target several genes previously reported in sporadic hematological malignancies as apoptotic genes (*FAS*, *FASLG*, *CASP8*, *CASP10*, *PRF1*), proto-oncogenes (*CRAF*, *BRAF*, *CBL*), tumor suppressor genes (*CEBPA*, *TP53*, *RUNX1*) and genes involved in several cell process (*YY1*, *ASXL1*, *NPM1*, *JAK2*). **Materials and Methods:** In this study, we investigated these 15 candidate genes by direct sequencing in 20 Tunisian familial cases with aggregated hematological malignancies. **Results:** We report a new *ASXL1* germline missense substitution p.Arg402Gln in two related patients that we describe it for the first time in non-Hodgkin lymphoma. We report also a *PRF1* p.Ala211Val variant in two related patients both diagnosed with Hodgkin lymphoma. *In silico* analysis has predicted potential deleterious effect of these two variants and were totally absent in 200 control chromosomes. We report also two intronic substitutions: c.1641+6 T>C in *JAK2* gene and 559+1 G>A in *TP53* gene in familial cases diagnosed respectively with Hodgkin lymphoma and acute lymphoblastic leukemia. This two substitutions may disrupt the splice site and impact the normal protein function. **Conclusion:** From an extended candidate genes analyzed in the field of familial hematological malignancies, *ASXL1*, *TP53*, *JAK2* and *PRF1* might be involved. These variants should be considered as potential candidate genes since a potential damaging effect was predicted.

Establishment and characterization of a primary glioblastoma multiforme human cell line with C176F TP53 mutation

L. Muñoz-Hidalgo¹, C. López-Ginés², R. Gil-Benso², S. Rodríguez², J. Mejías², T. San Migue², M. Cerdá-Nicolás²;

¹Foundation for research HCU-INCLIVA, Valencia, Spain, ²University of Valencia, Valencia, Spain, ³Spanish National Cancer Research Centre (CNIO), Madrid, Spain.

Introduction: Primary glioblastoma (GBM) is the most frequent and most malignant neoplasm of the human brain tumors which, despite current therapies, usually causes the patient's death within one year following diagnosis. Cell lines derived from primary tumors represent an important tool for studying the biological behavior of these malignant neoplasms and searching for new drugs and treatments. The objective of the present work was the immunohistochemical and genetic characterization of a new human cell line established from a primary GBM, named GBM-HC-44.

Material and Methods: We have analyzed immunohistochemical markers, cytogenetics and molecular characteristics of the cell line and the primary tumor. We have analyzed the variation in the number of copies and the methylation status of genes involved in cancer by MLPA technique (MLPA P105-D1 gliomas and ME001-C2 tumor suppressor-1). EGFR /CEP7 expression was analyzed by FISH technique. Likewise, sequencing for TP53, SKY and CGH array were performed.

Comments: We report the characterization of GBM-HC-44 cell line, derived from a primary GBM with C176F mutation in TP53 and without EGFR amplification. Numerical and structural alterations in chromosomes as trisomies 7, 14, 15, 18, 20 and 21, and further deletions in chromosomes regions 10, 13, 16 and 19 were detected. The study of GBM-HC-44 cell line and its comparison with features of the primary tumor may improve the knowledge about these neoplasms and could be a very useful material for basic research of GBM.

P12.102

Early onset of Glioblastoma in Indian consanguineous family is caused by R802X PMS2 homozygous mutation

S. E. Antonarakis¹, G. Chetan², M. Adrianova², V. Zoete⁴, M. Sabin², K. Narasinga Rao⁵, O. Michielin⁶, P. Ribaux¹, V. Seplyarskiy³, S. I. Nikolae⁷; ¹University of Geneva, Geneva, Switzerland, ²Department of human genetics. Nimhans, Bangalore, India, ³Institute of Information Transmission Problems, Russian Academy of Sciences, Moscow, Russian Federation, ⁴SIB, Lausanne, Switzerland, ⁵Department of Neurosurgery. Nimhans, Bangalore, India, ⁶SIB, CHUV, Lausanne, Switzerland, ⁷University Hospitals of Geneva, Geneva, Switzerland.

We have performed exome sequencing of two second cousin patients with the early onset of glioblastoma and their parents from a consanguineous family with likely autosomal recessive inheritance. 1.3% of the patients genomes were identical by descent and homozygous; the homozygous segment included a germline p.R802X variant in the PMS2 gene. We have confirmed that the mutation segregated with the phenotype. Additionally, we have performed the exome sequencing of the tumors, and revealed extremely high somatic mutation rates: one tumor contained 12621 somatic mutations including truncating in PARP1, ARID2, CREBBP and TP53; and the other - 6764 mutations including two drivers in PIK3CA (p.R88Q and p.T1025A) and truncating mutations in APC and in NF1. Interestingly both tumors harbored somatic mutations in the proofreading domain of POLE (p.P436H and p.L424V), polymerase that replicates the leading strand during DNA replication. In-silico modeling suggested these mutations cause significant structural instability of the protein. Most interestingly we have observed in both cancers that the vast majority of mutations were consistent with the signature of PoLE exo-: C>A and C>T mutations which occurred on the leading strand. This genetic analysis revealed the cause and functional mechanism of familial glioblastoma and provided additional diagnostic opportunity in the studied family.

P12.103

Over expression of hMSH2 mRNA is associated with poor prognosis in high grade glioma

C. K. Ghati;

National Institute of Mental Health and Neurosciences, Bangalore, India.

Introduction: Glioblastoma and anaplastic oligodendroglioma are high grade gliomas (HGG). Human MutS homolog2 (*hMSH2*) is the most consistently expressed MMR gene and a key component for mismatch recognition. Proficient expression of *hMSH2* mRNA is important for efficient functioning of MMR, thereby maintaining micro-satellite and genomic stability. We studied the expression levels of *hMSH2* and its role in progression free survival (PFS) in high grade glioma.

Materials and Methods: Our study group consisted of 39 glioma patients (frontal lobe) and 8 non-glioma patients. Expression of *hMSH2* mRNA was studied using qRT-PCR (ABI Taqman Gene expression assay). Kruskal Wallis test was used for comparison of mRNA expression between various groups. Kaplan Meier survival analysis was used for variables with prognosis and Cox proportional hazard regression was used for multivariate analysis.

Results: Over expression of *hMSH2* with median fold change of 2.48 (Range-0.01-114.98) was found in 51.5% cases significantly different from non-glioma tissues (p=0.036). Positive correlation was seen between *hMSH2* gene expression and age [r = +0.4 (p=0.01)]. Age, histological type, grade, extent of resection and post surgery adjuvant therapy (RT+CT) were associated with PFS of patients in univariate analysis (p<0.05). Low *hMSH2* expression with RT+CT was seen to have significantly better prognosis (median=22months), when compared to high expression with RT+CT (median=10months, p=0.011). Tumor type, grade and effective therapy independently predicted PFS (p<0.05) using multivariate analysis.

Conclusion: Over expression of *hMSH2* mRNA suggests higher number of mispair DNA mutations in high grade glioma. This can be used as a potential prognostic biomarker.

Methylated MGMT alleles are distributed heterogeneously in glioma, irrespective of IDH status and chromosome 10q deletion

C. Pesenti^{1,2}, L. Fontana², S. Tabano², E. Bonaparte^{1,2}, R. Falcone^{1,2}, G. Marfia^{2,3}, M. Caroli¹, S. Guernerì¹, M. Baccarin¹, N. Carlessi¹, S. Sirchia², S. Bosari^{1,2}, M. Miozzo^{1,2}; ¹Fondazione IRCCS Cà Granda-Ospedale Policlinico di Milano, Milano, Italy, ²Università degli Studi di Milano, Milano, Italy, ³Fondazione IRCCS Cà Granda-Ospedale Maggiore Policlinico di Milano, Milano, Italy.

INTRODUCTION: The evaluation of molecular markers in glioma is part of clinical assessment and glioma classification.

Mutations in the dehydrogenases IDH1-IDH2 are prognostic markers in glioma, strongly associated with the epigenetic silencing of the O6-me-

thylguanine-DNA-methyltransferase (MGMT). Little is known about the timing of MGMT silencing during gliomagenesis, the distribution of MGMT methylated alleles and the potential association with MGMT deletion (10q LOH). We investigated the associations among MGMT methylation levels, IDH genotyping and 10q allelic loss.

METHODS: We quantitatively assessed by pyrosequencing the IDH1 R132H allele frequency and the MGMT methylation percentages in 208 primitive glioma samples. The 10q LOH was determined by Short Tandem Repeats genotyping or array-CGH.

RESULTS: 1. IDH1 was heterozygously mutated in virtually all cancer cells, whereas MGMT methylated alleles were not homogeneously distributed in tumor cells.

2. The MGMT methylation percentages directly correlated with increasing OS.

3. The MGMT LOH acts as a late event during gliomagenesis, not related to methylation.

CONCLUSION: The incomplete overlap between the percentages of IDH1 mutated and MGMT methylated alleles in tumor cells suggests that only a fraction of tumor cells undergo MGMT silencing, indicating an incomplete association between the two events. Nevertheless, MGMT methylation is a positive prognostic marker irrespective of IDH1 status. Finally, MGMT can be considered a tumor suppressor completely inactivated by 10q LOH and methylation in more advanced tumors.

Identification of GPRC5A as a novel risk factor for the triple negative tumor phenotype in BRCA1 and BRCA2 mutation carriers

K. Klaschik^{1,2,3}, E. Pohl^{1,2,3}, J. Hauke^{1,2,3}, G. Neidhardt^{1,2,3}, S. Kröber^{1,2,3}, S. Heilmann-Heimbach^{4,5}, H. Hellebrand⁶, H. Surowy⁷, J. Altmüller^{8,9}, P. Nürnberg^{9,10}, C. Engel¹¹, B. Wappenschmidt^{1,2,3}, K. Rhiem^{1,2,3}, A. Meindl⁶, R. Schmutzler^{1,2,3}, E. Hahnen^{1,2,3}; ¹Center for Familial Breast and Ovarian Cancer, Cologne, Germany, ²Center for Integrated Oncology (CIO), Cologne, Germany, ³Center for Molecular Medicine Cologne (CMMC), Cologne, Germany, ⁴Institute of Human Genetics, University of Bonn, Bonn, Germany, ⁵Life&Brain Center, Bonn, Germany, ⁶Department of Gynaecology and Obstetrics, Klinikum rechts der Isar at the Technical University, Munich, Germany, ⁷Molecular Epidemiology, German Cancer Research Center (DKFZ) and Molecular Biology of Breast Cancer, Heidelberg, Germany, ⁸Cologne Center for Genomics, Cologne, Germany, ⁹Institute of Human Genetics, University of Cologne, Cologne, Germany, ¹⁰Cologne Excellence Cluster on Cellular Stress Responses in Aging-Associated Diseases (CECAD), Cologne, Germany, ¹¹Institute for Medical Informatics, Statistics and Epidemiology (IMISE) Center for Familial Breast and Ovarian Cancer, Leipzig, Germany.

GPRC5A encodes an orphan G-protein coupled receptor highly expressed in lung tissue. *Gprc5a* knockout mice spontaneously develop lung adenomas and adenocarcinomas suggestive of a role in cancer predisposition. Within a consanguineous breast cancer (BC) family from Turkey, we identified a homozygous frameshift mutation (c.183delG; p.R61Sfs*59) in the first coding exon of *GPRC5A* in two affected sisters via exome sequencing, suggesting an autosomal recessive trait. Interestingly, Sokolenko et al. (2014) reported a ten-fold increase of the heterozygous *GPRC5A* p.R61Sfs*59 mutation in *BRCA1* c.5266dupC BC patients compared to *BRCA1*-negative BC patients. Thus, we hypothesized that *GPRC5A* acts as recessive BC gene and disease modifier when heterozygously inactivated. While the search for homozygous or compound heterozygous *GPRC5A* mutation carriers is ongoing, we genotyped the p.R61Sfs*59 mutation in a large series of *BRCA1/2* mutation carriers (n=1,841), *BRCA1/2*-negative familial cases (n=5,841) and control individuals (n=8,305). The detailed analysis of the *BRCA1/2* mutation carriers, consisting of 1,282 BC, 131 ovarian cancer (OC), 106 BC/OC patients and 322 healthy mutation carriers, revealed that the 17 *GPRC5A* mutation carriers solely coincide with the BC subgroup (CF=1,33%). Remarkably, the mutation was particularly frequent in *BRCA1/2*-positive triple negative BC cases (11/540, CF=2.04%) and presented a statistically significant association with this BC subtype (odds ratio: 2.362; 95%CI=1.177-4.627; p=0.007). In summary, we provide evidence for *GPRC5A* p.R61Sfs*59 as a disease modifier in *BRCA1/2* mutation carriers, especially in BC cases affected by the triple negative subtype. We are now starting functional analyses to elucidate the molecular mechanisms of *GPRC5A* p.Arg61fs in BC pathogenesis.

Prostate cancer susceptibility assessed by GWAS risk variants in Finnish men

C. Sipeky¹, T. L. J. Tammela², A. Auvinen³, t. PRACTICAL consortium⁴, J. Schleutker^{1,5};
¹Department of Medical Biochemistry and Genetics, University of Turku, Turku, Finland, ²Department of Urology, Tampere University Hospital and Medical School, University of Tampere, Tampere, Finland, ³Department of Epidemiology, School of Health Sciences, University of Tampere, Tampere, Finland, ⁴Members from the Prostate Cancer Association Group to Investigate Cancer Associated Alterations in the Genome (PRACTICAL) consortium are provided in the Supplement/foot notes., ⁵Finland, ⁶Tyks Microbiology and Genetics, Department of Medical Genetics, Turku University Hospital, Turku, Finland.

Introduction: Prostate cancer (PrCa) is the most common cancer in males in Finland with 5043 new cases in 2015. Genome-wide association studies (GWAS) identified 101 common PrCa susceptibility loci, explaining 33% of familial risk of prostate cancer predominantly in mixed European population. Our aim is to assess the association of selected GWAS “hot hits” with PrCa specifically in Finnish men.

Materials and methods: In order to subset GWAS variants with strong risk effect we applied the per allele odds ratio (OR) of ≥ 1.1 , and with strong protective effect the OR ≤ 0.9 . Effect allele frequency was chosen as > 0.1 . By applying these criteria we selected 37 known risk and 13 known protective variants from 101 GWAS hits in PrCa. Germline DNA samples for common PrCa risk loci were genotyped for 5165 Finnish subjects (n=2764 unselected cases, n=2401 controls) within the Collaborative Oncological Gene-Environment Study (COGS) using Illumina iSelect custom SNP genotyping platform. Statistical analyses of case-control logistic regression model was performed by using PLINK software.

Results and Conclusions: 13 of 37 common European risk variants (1/3), and 4 of 13 common European protective variants were not found as statistically significant on GWAS level in Finnish samples. The highest PrCa susceptibility variant is at 8q24 CASC8 gene region ($p=5.26 \times 10^{-12}$), which seems to play an important role in PrCa genetics in Finns.

Post-mortem testing: Germline variant detection in genes related to hereditary breast, ovarian and colorectal cancer using archival non-tumor tissue

T. D. Jensen, A. Petersen, M. Joergensen, A. Bojesen;
 Department of Clinical Genetics, Lillebaelt Hospital, Vejle, Denmark.

Introduction: A sufficient evaluation of cancer risk in a family suspected of e.g. hereditary breast and ovarian cancer (HBOC) or Lynch syndrome very often requires genetic testing. The task of identifying the disease-causing mutation in a family is difficult without affected living family members. Identifying a mutation in tissue-derived DNA from deceased is technically challenging and because of that, this diagnostic approach has not been offered on a regular basis by diagnostic departments or companies.

Materials and Methods: DNA was extracted from 9x15 μm FFPE tissue sections per sample, and DNA integrity was estimated. DNA samples were subjected to HaloPlex Target Enrichment using a custom design (Agilent Technologies). After enrichment, HaloPlex libraries were diluted, pooled, denatured and 10 pM library pool was subjected to paired-end (2x150 bp), single index (8 bp) DNA sequencing on a MiSeq (Illumina).

Results: In clinical use, a total of 304 samples (0-43 years) were investigated using our HBOC and colorectal cancer NGS panels. We identified 16 pathogenic and 1 likely pathogenic BRCA1 variants, 11 pathogenic and 1 likely pathogenic BRCA2 variants, 7 pathogenic and 1 likely pathogenic CDH1 variants and 1 pathogenic PALB2 variant. Furthermore, we identified 5 pathogenic APC variants. We did not detect any pathogenic variants in the Lynch syndrome-associated genes MLH1, MSH2, MSH6, PMS2 and EPCAM.

Conclusions: The possibility of identifying pathogenic mutations in deceased family members is a new and important tool in the process of determining or evaluating the risk of certain cancers of family members who receive genetic counseling.

OBJECTIVES: Characterize the frequency of mutations in patients with clinical criteria for Hereditary Breast and Ovarian Cancer (HBOC) using a 25-gene panel in a Spanish population (FAMOSA study).

PATIENTS: Patients with breast or ovarian cancer who met the NCCN criteria for genetic testing with a) prior testing for BRCA genes with NO mutation identified; or b) recently diagnosed (<6 months) and not genetically tested, were enrolled for multiplex cancer testing.

RESULTS: From November 14 to February 15, 210 patients were included in the FAMOSA study (109 HBOC). 61 (56%) patients were previously tested for BRCA1/2 gene mutations with conventional techniques; median age: 44y (22-77); gender: 3 males / 106 females; cancer types: breast 96 (87.3%); ovary 14 (12.7%). Overall 23 (21%) pathogenic variants were identified in 19 patients; 10 BRCA1, 2 BRCA2, 2 PALB2, 3 MYH, 1 CDKN2A; 3 ATM, 1 BRAD1, 1 BRIP1. One patient had an unexpected mutation in CDKN2A gene (gluteus sarcoma age 20; bilateral breast ca; ages 45 and 50; father lung ca, age 70; brother melanoma, age 35). Of 61 patients previously tested, 1 had a pathogenic variant in BRCA1 and 17/19 patients with VUS were classified negative in BRCA genes with the 25-gene panel.

CONCLUSIONS: Panel testing in patients with HBOC yielded a 21% mutation rate, increasing the yield of genetic mutations beyond BRCA; one unexpected finding in CDKN2A was identified.

P12.109

Identification of novel candidate genes for Hereditary Breast Cancer via Whole Exome Sequencing

D. Turchetti^{1,2}, R. Zuntini^{1,2}, F. Isidori¹, C. Diquigiovanni¹, F. Buscherini¹, F. Palombo¹, S. Miccoli^{1,2}, E. Bonora^{1,2};

¹U.O.Genetica Medica, Policlinico S.Orsola-Malpighi, Bologna, Italy, ²Centro di Ricerca sui Tumori Ereditari, Dipartimento di Scienze Mediche e Chirurgiche, Università di Bologna, Bologna, Italy.

Hereditary breast cancer (HBC) accounts for 5-10% of breast cancer cases. Germline BRCA1/2 mutations explain 60% of HBC, but no other major genes have been identified in the remaining 40%.

We decided to perform whole exome sequencing (WES) in affected first-degree cousin-pairs displaying features suggestive of HBC, who tested negative for BRCA1/2. Based on their relationship, cousins share 1/8 of the entire genome, which helps filter and select candidate variants. To date, 4 cousin-pairs were analyzed through WES and candidate variants were identified in three different genes in 3 pairs, whereas the fourth one shared a BRCA2 deletion not previously identified by Sanger sequencing.

The candidate variants, affecting ROS1, RASAL1 and ICAM5 genes, were confirmed by direct sequencing. Further characterization of the variants is ongoing. In particular, the ROS1 variant affected a predicted canonic splice site, suggesting an effect on the correct splicing of ROS1, a tyrosine kinase receptor that has been implicated in several cancer types. We inserted the wild-type or mutant genomic region into a minigene plasmid, transfected it into COS7 cells, and found that the mutant cells used a cryptic intronic splice site 20 bp downstream, leading to the insertion of a premature stop-codon in the protein. Future studies will explore the effect of the variant on cell growth/proliferation and invasion in CRISP/Cre-modified MCF10A and MCF7 cells.

Our findings support previous evidence that many different genes account for the fraction of HBC not related to BRCA1/2 mutations and led us to identify promising novel variants for HBC.

P12.110

Search for new high susceptibility genes in hereditary breast cancer families with a recessive pattern of inheritance

A. Tavera¹, M. de la Hoya², A. Macías³, A. Barroso¹, M. Urioste¹, J. Benitez¹, A. Osorio¹; ¹CNIO, Madrid, Spain, ²Hospital Clínico San Carlos, Madrid, Spain, ³Hospital Morales Meseguer, Murcia, Spain.

Only two high-risk genes involved in hereditary breast and ovarian cancer (HBOC) have been identified, BRCA1 and BRCA2, that do not explain more than 20% of HBOC cases. In the last years, Whole Exome Sequencing (WES), has been used to find novel susceptibility genes.

So far, dominant or polygenic patterns of inheritance have been considered, however, some publications have implemented simulations with different models of segregation in a large number of families which suggests that a part of them could be explained by a model of recessive inheritance, a hypothesis that has remained unexplored.

Five families showing an apparent pattern of recessive inheritance were selected based on: presence of two or more affected siblings with BC at young age, absence of familial antecedents of the disease, availability of the samples and no mutations in BRCA1/BRCA2 genes. Through WES, 23 candidate variants following an apparent recessive inheritance model were identified and validated by Sanger sequencing. Segregation and loss of heterozygosity analyses in tumors samples are being performed. A further analysis considering a dominant inheritance pattern was also performed. 30 candidate variants were found in this analysis, including a truncating mutation in ATM, a known HBOC moderate risk gene, which lead us to the conclusion that we cannot rule out other models of inheritance. Case-control association study in Spanish population is being performed to get insights about the transcendence of these variants in the disease.

P12.111

Introducing multigene panel testing for hereditary breast and ovarian cancer into routine practice: frequency of detected mutations in Slovene patients

A. Blatnik, M. Krajc, V. Stegel, P. Cerkovnik, S. Novaković; Institute of Oncology, Ljubljana, Slovenia.

Introduction: Next generation sequencing (NGS) of breast/ovarian cancer susceptibility genes has recently been shown to be an accurate and cost-effective method of performing genetic testing. NGS offers the possibility of screening patients for mutations in high and moderate risk genes other than BRCA1/2. Subsequently, it increases the detection rate of variants of uncertain significance. Our study aimed to determine the frequency of germline mutations found in Slovene patients using an NGS multigene panel.

Methods: We retrospectively collected and analyzed data from a group of 306 patients selected in accordance with standard BRCA1/2 testing guidelines and sequenced at our institution between October 2014 and November 2015. We assessed the frequency of mutations in genes associated with a predisposition to breast/ovarian cancer, such as BRCA1, BRCA2, TP53, PTEN, STK11, CDH1, CHEK2, PALB2 and ATM.

Results: Pathogenic variants were detected in 29.4% of our patients. Most mutations were identified in BRCA1 (16.7%) and BRCA2 (7.8%). In addition, 5.2% carried a mutation in another breast/ovarian cancer susceptibility gene: 1.9% in CHEK2, ~1% in PALB2, ~1% in ATM, ~1% in CDH1 and 0.3% in TP53. One patient carried mutations in both BRCA2 and ATM.

Conclusions: With NGS panel testing we were able to detect pathogenic variants in genes other than BRCA1/2 in ~5% of our patients. CDH1 mutations were detected in patients with no family history of diffuse gastric cancer and a TP53 mutation was seen in a family with no Li-Fraumeni cancers apart from early-onset breast carcinoma, highlighting the benefits of this new approach.

Oncology Department, Hospital Universitari Arnau de Vilanova, Lleida, Spain, ⁷Medical Oncology Department, Vall d'Hebron University Hospital, Barcelona, Spain, ⁸Unitat de Consell Genètic, Corporació Sanitària Parc Taulí, Consorci Sanitari de Terrassa, Sabadell, Spain, ⁹Departament d'Oncologia Mèdica, Corporació Sanitària Parc Taulí Institut Universitari-UAB, Sabadell, Spain, ¹⁰Departament d'Oncologia Mèdica, Consorci Sanitari de Terrassa, Terrassa, Spain.

Pathogenic variants of the BRCA1 and BRCA2 genes (BRCA1/2) mostly include small insertions or deletions and nucleotide substitutions that generate a premature stop codon. Besides, large genomic rearrangements (LGRs) account for 5-10% of all deleterious variants in BRCA1/2.

Molecular characterization of LGRs is essential to know their genetic mechanisms, identify recurrent alterations, and investigate genotype/phenotype relationships.

We used multiplex ligation-dependent probe amplification (MLPA) or multiple amplicon quantification (MAQ) to identify BRCA1/2 LGRs in 1542 hereditary breast/ovarian cancer families referred to three hospitals in Catalonia.

We used long-range PCR, CGH arrays, and cDNA analyses to characterize the alterations at molecular level. We found 12 LGRs in BRCA1 and five in BRCA2.

Breakpoints were fully characterized in fourteen of them. Six LGRs were novel: deletions targeting exons 1-2, exon 8, exons 16-17, two different deletions of exon 24 in BRCA1 and one duplication of exon 21 in BRCA2. The BRCA1 deletion of exons 16-17 appears to be a Catalan founder mutation explaining five independent families.

Both non-homologous and homologous events were involved in the aetiology of the rearrangements. The cDNA analyses showed chimeric RNAs expressed by BRCA1 alleles carrying exons 1-2 or exon 24 deletions.

Our study substantially increases the spectrum of BRCA1/2 LGRs fully characterized at the molecular level. Also highlights the relevance of cDNA analysis for a reliable prediction of protein effect of LGRs involving 5' and 3'UTR expression regulatory regions.

Transcriptional analysis of 36 BRCA1/BRCA2 variants with potential effects on splicing

G. Montalban^{1,2}, S. Bonache¹, A. Tenés³, E. Carrasco⁴, N. Tuset⁵, I. Esteban⁴, N. Gadea⁶, J. Balmaña^{6,9}, O. Díez^{1,3}, S. Gutiérrez-Enríquez¹;

¹Oncogenetics Group, Vall d'Hebron Institute of Oncology-VHIO, Barcelona, Spain, ²Universitat de Barcelona, Barcelona, Spain, ³Area of Clinical and Molecular Genetics, Vall d'Hebron University Hospital, Barcelona, Spain, ⁴High Risk and Cancer Prevention Group, Vall d'Hebron Institute of Oncology-VHIO, Barcelona, Spain, ⁵Medical Oncology Department, Hospital Universitari Arnau de Vilanova, Lleida, Spain, ⁶Medical Oncology Department, Vall d'Hebron University Hospital, Barcelona, Spain.

Introduction: Molecular diagnosis of BRCA1 and BRCA2 genes (BRCA1/2) often identifies variants of unknown significance (VUS). An evaluation of their effect on mRNA splicing becomes essential to elucidate their clinical impact. In this study we perform experimental and bioinformatic analysis to assess the role in disease development of a set of 36 VUS identified in Spanish high-risk breast/ovarian cancer families.

Methods: Bioinformatic tools were used to select 15 BRCA1 and 21 BRCA2 VUS with potential splicing effects from 1200 patients screened for BRCA1/2 pathogenic variants in genomic DNA. RNA from VUS carriers and 10 control samples was isolated from blood leukocytes. All variants are assessed by RT-PCR, agarose gels and direct sequencing. A semiquantitative capillary electrophoresis of fluorescent amplicons is performed to estimate the proportion of aberrant and normal transcripts. The allele-specific transcript expression will also be determined.

Results: Aberrant splicing patterns were observed in 5/15 BRCA1 and in 7/21 BRCA2 variants. A preliminary semiquantitative analysis of the BRCA1 c.4675+1G>C and BRCA2 c.8023A>G shows differences in the abundance of the Δ15 and Δ18 isoforms compared to control samples, respectively. In both cases, the full-length transcript exhibits a significant reduced expression compared to controls, supporting the hypothesis that the variant alleles only generate aberrant transcripts.

Conclusions: Our findings highlight semiquantitative capillary electrophoresis as an essential tool to allow the clinical classification of VUS.

P12.114

Genetic testing for hereditary cancer: is exome sequencing ready or there is still room for ad hoc designed panels?

M. Gausachs¹, L. Feliubadaló¹, R. Tonda^{2,3}, J. Trotta^{2,3}, E. Castellanos⁴, A. López-Doriga¹, A. Teulé¹, E. Tornero¹, J. del Valle¹, B. Gel¹, M. Gutiérrez¹, M. Pineda¹, S. González¹, M. Menéndez¹, M. Navarro¹, G. Capellá¹, I. Gutiérrez¹, E. Serra¹, J. Brunet¹, S. Beltran^{2,3}, C. Lázaro¹; ¹Hereditary Cancer Program, Joint Program on Hereditary Cancer Catalan Institute of Oncology, IDIBELL, Hospitalet de Llobregat, Spain, ²Centro Nacional de Análisis Genómico (CNAG-CRC), Center for Genomic Regulation, Barcelona Institute of Science and Technology (BIST), Barcelona, Spain, ³Universitat Pompeu Fabra (UPF), Barcelona, Spain, ⁴Genetic Variation in Cancer Group, Joint Program on Hereditary Cancer, Institut de Medicina Predictiva i Personalitzada del Càncer, Badalona, Spain.

Introduction: Several Next Generation Sequencing (NGS) panels have been developed for hereditary cancer diagnosis, although there is a debate about its cost-effectiveness compared to exome sequencing. The performance of two hereditary cancer panels is compared to exome sequencing.

Materials and Methods: Twenty-four patients were selected: ten with identified pathogenic mutations (control set) and 14 suspicious of hereditary cancer but without any identified mutation (discovery set). Two panels, TruSight-Cancer (94 genes) and a custom panel (122 genes), were assessed alongside exome sequencing.

Results: Eighty-three genes were targeted by all approaches. More than 99% of the bases had read depth over 30x (C30) in the panels whereas exome covered 94% of these positions at C30. Variant calling identified the 10 pathogenic mutations in the control set except for MSH6 mutation c.255dupC in TruSight-Cancer. Two hundred and forty unique non-silent coding and canonical splice-site variants were identified in the remaining 14 samples in the 132 panel genes, 7 of them putatively pathogenic in ATM, BARD1, CHEK2, ERCC3, FANCL, FANCM and MSH2. The three approaches identified a similar number of variants in the shared genes. In contrast, WES provides additional information. Exomes were on average three times more expensive than panel analyses.

Conclusions: Ad hoc panels are an option for genetic diagnostics for hereditary cancer. Benefits include lower cost and higher depth resulting in more positions covered sufficiently for clinical interpretation. However WES identifies variants in genes that are not currently targeted by panels.

Introduction: Inherited factors account for over 20% of all colorectal cancers (CRC), but less than 6% can be explained by rare high-penetrance mutations in known genes. We aimed at identifying novel hereditary cancer genes by performing whole-exome sequencing in individual hereditary CRC families.

Materials and Methods: Exome enrichment (Agilent SureSelect Human All Exon 50Mb) followed by massively parallel sequencing (Illumina Hi-Seq2000) was performed on blood DNA from at least 3 cancer-affected family members. Three Amsterdam-positive families were studied. Data analysis was performed using conventional algorithms. Validation studies in familial cancer series and in silico and in vitro functional studies were also carried out.

Results: One family harbored two mutations in the MUTYH gene -known polyposis (recessive) gene-, one recurrent in the European population and

the other novel, for which functional studies demonstrated its deleterious nature. The family showed an atypical phenotype for MUYTH, characterized by the absence of polyps, apparent autosomal dominant inheritance, and presence of a mismatch repair-deficient tumor.

The study of the second family allowed us to identify a novel hereditary CRC gene, FAN1. Functionally relevant mutations were identified in almost 3% of Amsterdam-positive families.

The third family carried of two mutated genes: a splice-site mutation in a tumor suppressor gene, and a missense mutation in a previously-proposed cancer-predisposing gene.

Conclusions: The analysis of exomes in individual high-risk families allowed us to identify two novel genes for hereditary CRC, as well as mutations in previously-known or -proposed CRC-predisposing genes.

P12.116

Increased utilization of multi-gene panel testing for hereditary cancer: overcoming initial barriers

E. K. Dalton, K. Fulk, A. F. Yussuf, R. McFarland, H. LaDuca, J. S. Dolinsky; *Ambry Genetics, Aliso Viejo, CA, United States.*

Multi-gene panels (MGP) for hereditary cancer susceptibility became commercially available in the United States in 2012. Both genetics and non-genetics providers experienced initial concerns regarding utility and implementation of MGP. However, research has demonstrated multiple benefits of MGP, such as a higher diagnostic yield. This study analyzes the utilization of MGP over a three-year period at a clinical diagnostic laboratory in the U.S.

Quarterly ordering trends for single-syndrome tests were compared to smaller and larger MGP from the third quarter (Q3) of 2013 to Q3 2015. Ordering provider (OP) specialties and genetics provider (geneticist, genetic counselor, advance practice nurse, or other clinician with genetics training) extent of involvement was also noted. Statistical analysis was performed using the Fisher's exact test.

Comparison of single-syndrome tests in Q3 2013 versus Q3 2015 revealed that larger MGP significantly increased in frequency from 39% to 65% (p<0.01). MGP have been utilized more frequently across all OP specialties in 2015 compared to 2013. Genetics provider involvement significantly increased the utilization of MGP across all specialties (p<0.01).

Consistent with recent literature, this study demonstrates markedly increased utilization of MGP compared to 2012 when initially available. However, despite the overall decrease, single-syndrome and smaller MGP tests still account for 34% of total tests in Q3 2015, demonstrating clinicians' desires for tiered testing options. Additional research is needed to directly investigate OP attitudes towards MGP, however this study indicates that initial concerns surrounding MGP have lessened over time, particularly when genetics providers are involved in the ordering process.

Technological innovation in hereditary cancer risk assessment

A. Kulkarni¹, A. Kenney², V. Tripathi¹, C. Compton¹, S. Rose¹, E. Haque¹, D. Ruddy¹, L. Izatt¹, A. Shaw¹; ¹Guy's Hospital, London, United Kingdom, ²UBQO Limited, London, United Kingdom.

Guy's Cancer Genetics guidelines are used across Southeast London, Kent & East Sussex and updated in line with national standards. However they are currently presented in 'non-interactive' .pdf format that is not always readily accessible. It is also difficult to ensure clinicians are using the most recent version of the guidelines.

The Cancer Genetics application (App), developed by Guy's Clinical Genetics department and UBQO with funding from Guy's and St Thomas' Charity, provides streamlined hereditary cancer risk assessment and referral guidance for clinicians.

The aim is to address inequity in referrals and improve patient access to our service by targeting several key factors, including clinicians' limited understanding of hereditary cancer, lack of time, confusion about where to refer patients and use of outdated guidance.

The App contains a risk assessment tool and succinct reference guide, enabling clinicians to easily decide who requires genetic assessment of their cancer risk and who can be managed in primary or secondary care. Patients thereby have quicker access to cancer surveillance, genetic counselling, pharmacoprevention and surgical options.

Cancer Genetics is freely available on iOS and android platforms and via a public website. It is certified as a Class 1 medical device and a secure content management system allows quick central updates.

We will present the development process, user feedback and integration of

the App into primary and secondary care. Our goal is that Cancer Genetics will promote timely, evidence-based management of those at risk of hereditary cancer.

P12.118

Exome sequencing identified potential causative candidate genes for hyperplastic polyposis syndrome

S. Peters¹, I. Spier¹, C. Trueck¹, J. Altmueller^{2,3}, K. Kayser¹, M. Kloth⁴, S. Holzapfel¹, R. Adam¹, H. Thiele², M. M. Noethen^{1,5}, S. Aretz¹;

¹Institute of Human Genetics, University of Bonn, Bonn, Germany, ²Cologne Center for Genomics, University of Cologne, Cologne, Germany, ³Institute of Human Genetics, University of Cologne, Cologne, Germany, ⁴Institute of Pathology, University of Cologne, Cologne, Germany, ⁵Department of Genomics, Life & Brain Center, Bonn, Germany.

Hyperplastic polyposis syndrome (HPS) is a poorly defined colorectal cancer predisposition characterized by the occurrence of multiple and/or large serrated lesions throughout the colon. To date, only few molecular signatures have been described and neither the etiology of the syndrome nor the distinct genetic alterations have been identified.

To uncover predisposing causative genes, the exomes of 31 clinically well characterized HPS patients have been sequenced (Illumina HiSeq) using leukocyte DNA. The variants were filtered for rare (homozygous/compound heterozygous: MAF ≤ 1%, heterozygous: 0.01% according to dbSNP, EVS, and ExAC), truncating, and missense germline mutations (pathogenic by ≥ 2/3 prediction tools). For data analysis and filtering the GATK software and the Cartagena Bench Lab NGS Software were applied. In a first preliminary analysis, known cancer genes and candidate genes were analyzed.

After stringent filtering steps and manual inspection of the variants, potentially biallelic variants were found in 289 genes. However, none of the cancer genes contained a biallelic mutation that met the criteria. All in all, 943 genes harbored heterozygous mutations in at least two patients, eight of which are cancer genes (*ATM*, *CHEK2*, *ERCC4*, *JAK2*, *MET*, *NUP214*, *RNF43*, *USP6*). *ATM* and *RNF43* harbored recurrent mutations. These patients had variants in several cancer or candidate genes.

Preliminary data indicate that exome sequencing might identify relevant genes for HPS. However, the number of variants per patient is also in line with an oligogenic etiology of polyp predisposition. The current work-up includes the inclusion of non-cancer genes and validation of variants by Sanger sequencing.

P12.119

Multilocus Inherited Neoplasia Alleles Syndrome (MINAS) - A Case Series and Literature Review

J. Whitworth¹, A. Skytte², L. Sundé³, D. Lim³, M. Arends⁴, L. Happerfield⁵, I. Frayling⁶, R. van Minkelen⁷, E. Woodward⁸, M. Tischkowitz¹, E. Maher¹;

¹University of Cambridge, Cambridge, United Kingdom, ²Aarhus University Hospital, Aarhus, Denmark, ³Birmingham Women's Hospital, Birmingham, United Kingdom, ⁴University of Edinburgh and Institute for Genetics and Molecular Medicine, Edinburgh, United Kingdom, ⁵Cambridge University Hospitals, Cambridge, United Kingdom, ⁶Cardiff University School of Medicine, Cardiff, United Kingdom, ⁷Erasmus Medical Center, Rotterdam, Netherlands, ⁸Central Manchester University Hospitals, Manchester, United Kingdom.

Mendelian causes of inherited cancer susceptibility are mostly rare and characterised by variable expression and incomplete penetrance. Phenotypic variability may result from a range of causes such as allelic heterogeneity or genetic modifier effects. Another potential cause is the presence of two or more inherited cancer predisposition alleles in the same individual, an occurrence that may feasibly have a number of phenotypic consequences. Although the frequency of such occurrences might be predicted to be low, such cases have probably been under-ascertained because standard clinical practice has been to test candidate inherited cancer genes sequentially until a pathogenic mutation is detected. However, recent advances in sequencing technologies now provide the opportunity to perform simultaneous parallel testing of large numbers of inherited cancer genes.

We describe five newly identified patients who harbour pathogenic variants in multiple inherited cancer genes. Three cases involve *FLCN* mutations in combination with those in *NF1*, *TP53* and *MSH2* while combinations of *MLH1/XPA* and *BRCA2/NF1* account for the remaining cases. We also undertook a review of previously published examples to illustrate the complex genotype-phenotype relationships in these cases. We suggest that clinicians should proactively consider the likelihood of this phenomenon (referred to as multilocus inherited neoplasia alleles syndrome [MINAS]) in patients with unusual inherited cancer syndrome phenotypes. To facilitate the clinical management of novel cases of MINAS, we have established the term as a phenotypic tag in the Leiden Open Variant Database to collect information on what is likely to be an increasingly recognized cohort of such individuals.

P12.120

Novel NRAS mutation and clonal evolution detected by next-generation sequencing in a patient with juvenile myelomonocytic leukemia

S. Lavrina¹, V. Brilliantova¹, I. Mersyanova¹, I. Shipitsina¹, M. Kurnikova^{1,2}, I. Kalinina¹, A. Panfyorova¹, E. Raykina¹, A. Maschan¹, M. Maschan¹;

¹Federal Research Centre of Children Hematology, Oncology and Immunology named after D.Rogachev, Moscow, Russian Federation, ²The Pirogov Russian National Research Medical University, Moscow, Russian Federation.

Juvenile myelomonocytic leukemia (JMML) is a myeloproliferative neoplasm of childhood with a poor prognosis. The only curative therapy is hematopoietic stem cell transplantation (HSCT), with relapse being the most common reason for treatment failure. The patient is a 5-year-old boy with a 3,5 year history of JMML. The disease had progressed to acute leukemia after low-dose chemotherapy, so the patient received allogeneic HSCT, and he relapsed after the transplantation. We performed the genetic work up at 3 points: at initial evaluation, at progression and at post-transplant relapse. DNA extracted from bone marrow was sequenced using Illumina TruSight Myeloid sequencing panel on the MiSeq platform, with following validation using Sanger sequencing. Analysis of the first point revealed a novel NRAS mutation NM_002524: c.29_31dupGAG (NP_002515: p.Gly10dup) with 48% mutated allele frequencies. The point at progression revealed SETB1 c.2612T>C (p.Ile871Thr), ZRSR2 c.557+2T>G, ASXL1 c.2131insA (p.Thr711fs) and the same NRAS mutations in 24%, 96%, 45% and 49% of reads respectively. Relapse point revealed the same ZRSR2, ASXL1 and NRAS mutations in 83%, 39% and 48% of reads respectively. NRAS mutation was not found in buccal smear cells DNA samples indicating its somatic origin. NRAS is known to be one of the key genes in JMML pathogenesis, and this novel mutation is in the hot spots region for JMML, while SETBP1, ASXL1 and ZRSR2 are among targets for secondary mutations. The assessment of the mutational burden and clonal evolution in JMML can provide insight into the unfavorable outcome for the patient.

P12.121

Detection of KRAS gene mutation by liquid biopsy in patients with colorectal cancer

P. Riera¹, D. Pérez^{2,3}, M. Cornet¹, A. Sebío², A. Lasa^{1,3};

¹Genetics Department, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, ²Oncology Department, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, ³U-705, CIBERER, Barcelona, Spain.

INTRODUCTION: Tumour KRAS mutational status is an important determinant of the response of metastatic colorectal cancer to targeted treatments with anti-EGFR-antibodies. Molecular analyses of somatic mutations are usually performed on tissue biopsies. However, repeat biopsies are difficult, invasive and the results may be limited by intra-tumour heterogeneity. In light of these limitations, liquid biopsy has been proved to be a noninvasive way to detect cancer mutations.

The aim of this study was to investigate the use of plasmatic cell-free tumour DNA (ctDNA) to detect and quantify KRAS mutations using a digital PCR platform in a series of clinically relevant samples.

MATERIAL AND METHODS: A total of ten colon cancer patients with a KRAS mutation in the tumour sample were included in the study. Positive and negative control samples were also analyzed.

DNA was extracted from 3ml of plasma with the QIAamp Circulating Nucleic Acid Kit (Qiagen). PCR was performed with the Droplet Digital PCR (ddPCR) from BIO-RAD.

RESULTS: The following table shows the ddPCR events obtained analyzing ctDNA of patients and the different controls. As we expected, it seems that samples at diagnosis have a higher number of KRAS mutated copies.

CONCLUSIONS: Cell-free tumour DNA (ctDNA) may be a surrogate for tumour DNA obtained from tissue biopsies. It constitutes a potential tool for identification and monitoring of KRAS somatic mutations during the course of therapy.

Genotype - Phenotype spectrum in a large Indian Li-Fraumeni Syndrome (LFS) cohort

M. Haque¹, P. Kowal¹, D. Parchure², G. Pandit¹, R. Sarin¹;

¹Advanced Centre for Treatment Research and Education in Cancer, Tata Memorial Centre, Navi Mumbai, India, ²National Institute of Immunohaematology, Mumbai, India.

Introduction: LFS is a rare autosomal dominant hereditary syndrome with early onset of diverse type of cancers, caused due to germline mutations in TP53 gene. Li-Fraumeni-like (LFL) syndrome has relaxed criteria for age and type of cancers. The IARC database has about 900 families with germline TP53 mutation with vast majority being from North America, Europe, Brazil, Australia and Japan. As there are no reports from South Asia, we have done comprehensive clinical & genetic characterization in a large Indian cohort.

Materials and methods: Sanger sequencing and Multiplex Ligation-dependent Probe Amplification (MLPA) of TP53 gene was done in 8 classical LFS, 125 LFL and 97 familial cancer probands not fulfilling LFS/LFL criteria.

Results: We identified 37 distinct deleterious germline TP53 mutations (2 novel) including 4 LGRs in 42/230 (18%) families. TP53 mutations were identified in 87.5% of classical LFS and 17.6% of LFL families. Surprisingly, deleterious TP53 mutations were identified in 8/97 (8%) families with familial cancers not fulfilling any LFS/LFL criteria. Comparing with the IARC database, the genotype phenotype differences in this Indian cohort include 1) Absence of hotspot codon 337 mutation; 2) high frequency of splice site, frameshift and LGRs and low frequency of missense mutations; 4) rarity of adrenocortical cancer and skin cancer.

Conclusions: Our study on the largest LFS/LFL Indian cohort reveals distinct clinical and genetic features and highlights the need for TP53 sequencing including MLPA for large genomic rearrangement in suspected LFS/LFL families for counseling and risk management.

Fellowship and Funding: ACTREC-TMC, Navi Mumbai, India

P12.123

Colonic polyps assessment in TP53 germline mutation carriers: case series report from a tertiary cancer center in Brazil

T. Teixeira, E. Palmero, D. Guimarães, H. Galvão;

Hospital de Câncer de Barretos, Barretos, Brazil.

Introduction: Li-Fraumeni syndrome (LFS), associated with germline TP53 mutation, leads to predisposition to multiple malignancies. Core tumors described in LFS are breast cancer, soft tissue and osteosarcoma, adrenocortical and central nervous system tumors. In addition, various other types of cancer are also mentioned, including colorectal cancer (CRC). Thus, annual colonoscopy is recommended for patient screening, starting from 25 years of age. However, current scientific data does not provide robust information on what type of lesions may be present at exams.

Objective: To describe the prevalence of polyps detected by colonoscopy in patients with LFS assessed at Hospital de Câncer de Barretos, Brazil, from November/2009 to October/2015.

Results: From 110 TP53 mutation carriers followed, we have assessed 58 patients (from 24 families) who underwent CRC screening (total of 95 colonoscopies). TP53 germline mutations identified in these families were: c.1010G>A (in 20/24 families), c.158G>A, c.814G>A, c.869G>A and c.997C>T (1/24 families, each). In 34 (58.6%) patients, polyps were found. Hyperplastic polyps were found in 21 (36.2%) patients, sessile serrated polyp was described in one (1.7%) patient, adenomas with low-grade dysplasia in 20 (34.5%), adenomas with high-grade dysplasia in five (8.6%), and adenocarcinoma was found in one (1.7%) patient. In 36 screened individuals, the most recent colonoscopy was performed before 50 years, and 58.3% of them already had polyps detected on exam.

Conclusion: Considering reports of early CRC in LFS and evidence that polyp excision reduces CRC incidence, this study corroborates the recommendation of CRC screening for LFS patients.

P12.124

ChIP-Seq analysis of lymphocytes from Li-Fraumeni patients reveals the drastic impact on p53 DNA binding of heterozygous TP53 mutations associated with early-onset cancers

Y. Zerdoumi, R. Lanos, I. Tournier, S. Raad, S. Baert-Desurmont, G. Bougeard, J. Flaman, T. Frebourg;

Inserm U1079, Rouen University and Department of Genetics, Rouen University Hospital, Normandy Centre for Genomics and Personalized Medicine, Rouen, France.

Li-Fraumeni Syndrome (LFS) results from heterozygous germline mutations of TP53, encoding a key transcriptional factor activated in response to DNA damage. We have recently shown, from a large LFS series including 415

TP53 mutation carriers, that the most severe form of the disease, characterized by childhood tumours, is associated with missense mutations with dominant-negative activity (Bougeard et al., J Clin Oncol 2015). Thanks to a new p53 functional assay that we developed in lymphocytes (Zerdoumi et al., Hum Mutat 2013), we found that dominant-negative missense mutations, in comparison to null mutations, drastically alter the p53 transcriptional response to DNA damage and this assay has now been used to classify 56 distinct TP53 germline alterations. To study, at the genome scale, the functional impact of heterozygous TP53 mutations on DNA binding, we performed chromatin immunoprecipitation followed by massive parallel sequencing (ChIP-seq) analysis on lymphocytes exposed to doxorubicin, a powerful DNA damaging agent. ChIP-seq analyses of exposed control wild-type TP53 lymphocytes accurately mapped 706 p53 binding sites. New p53 binding sites were validated using a functional assay in yeast. ChIP-seq analysis of LFS lymphocytes with TP53 dominant-negative missense mutation reveals only 25 binding sites and, for these sites, the depth of the corresponding peaks was drastically reduced. Altogether, our results show that the clinical severity and predominance of TP53 dominant-negative missense mutations are explained by a global alteration of p53 binding at the genome scale and support that LFS results from a defect of the transcriptional response to DNA damage.

P12.125

Phenotypic heterogeneity of Bannayan-Riley-Ruvalcaba syndrome - two cases from one family

A. Kutkowska-Każmierczak¹, M. Gos¹, M. Rychłowska-Pruszyńska², E. Obersztyn¹;

¹Department of Medical Genetic, Institute of the Mother and Child, Warsaw, Poland,

²Clinic of Oncologic Surgery, Institute of the Mother and Child, Warsaw, Poland.

Introduction: Bannayan-Riley-Ruvalcaba syndrome (BRRS, OMIM 153480) belonging to the PTEN Hamartoma Tumor Syndrome family, is an autosomal dominant genetic disorder characterized by macrocephaly and high birth weight, benign mesodermal hamartomas (cutaneous and visceral lipomas, multiple hemangiomas and intestinal polyps), pigmented macules of the glans of penis. Intellectual delay, myopathic process and skeletal abnormalities (joint hyperextensibility, pectus excavatum and scoliosis) are observed in some patients. PTEN gene mutations located at 10q23.3 are identified in approximately 60% of BRRS patients. Individuals with BRRS and PTEN pathogenic variants have higher cancer risk and should be offered tumor surveillance protocols.

Patients and methods: We present phenotypic manifestation in father and daughter affected with BRRS. The child at the age of 11 with developmental delay, macrocephaly and lipomas was admitted to the genetic unit. Her father presented with high stature, macrocephaly, multinodular thyroid goiter and subcutaneous fibromas but without lipomas. Because of the suspicion of BRRS the PTEN gene was analysed using classic Sanger sequencing technique.

Results: The molecular analysis confirmed the diagnosis of BRRS. The mutation c.209+1G>A in intron 3 of PTEN gene was identified in both patients. We present the detailed clinical data of these two cases of BRRS in comparison with cases reported in medical literature.

Conclusions: The correct diagnosis of BRRS allowed for the offering of tumor surveillance protocol to both patients and for proper genetic counseling with risk assessment.

Children presenting with lipomas should be examined for other signs of BRRS and the family pedigree should always be thoroughly analysed.

P12.126

Techniques for measuring cancer burden in liquid biopsy samples

T. Harkins, H. Fiske, L. Kurihara, C. Schumacher, J. Laliberte, S. Sandhu, J. Irish, V.

Makarov;

Swift Biosciences, Ann Arbor, MI, United States.

Liquid biopsy is a non-invasive sample source that can be utilized to assess cancer burden by measuring the tumor-derived fraction of circulating, cell-free DNA (cfDNA) from plasma. We evaluated two assays to monitor cancer burden using cfDNA: whole genome bisulfite sequencing (WGBS) and targeted amplicon sequencing for 56 oncology-related genes. We tested samples with both assays to characterize their efficacy across a broad spectrum of cancer types, stages, and treatment regimens. cfDNA was extracted from tumor-bearing patients and normal controls. To monitor methylation density, WGBS was performed using 5 ng of bisulfite-converted cfDNA with the Accel-NGS® Methyl-Seq DNA Library Kit. To detect tumor-specific mutations, 10 ng of cfDNA was used for the Accel-Amplicon™ 56G Oncology Panel. Six out of eight cancer samples demonstrated significant hypomethylation in cfDNA, ranging from 2-40% when compared to healthy controls. The 56 gene amplicon panel identified point mutations in the cfDNA of only three

samples, but which also had the highest observed hypomethylation (18-40%). For all but two cancer samples, corresponding mutations were also found in the primary tumor at allele frequencies significantly higher than in the cfDNA fraction (e.g., 22% in tumor vs. 5% in cfDNA). The three cancer samples that had primary tumor mutations that were not detected in cfDNA also had the lowest observed hypomethylation. Therefore, a correlation between hypomethylation and detection of tumor mutations in the cfDNA fraction may exist. Further studies will elucidate which assay is more sensitive at detecting tumor burden in cfDNA.

The Mallorca Group was formed by European members of the International Society for Gastrointestinal Hereditary Tumours (InSiGHT), to facilitate and coordinate European research on inherited colorectal cancer syndromes and issue clinical guidelines (<http://www.ncbi.nlm.nih.gov/pubmed/23408351>), and this year it has transformed into The European Hereditary Tumour Group (EHTG), open for world-wide membership (Gabriela.Moeslein@helios-kliniken.de).

The European MMR cDNA Working Group focuses on in-vitro testing for determining pathogenicity of MMR gene variants affecting splicing (elkeholinski-feder@t-online.de). Ultimate classification of mutations (http://chromium.lovd.nl/LOVD2/colon_cancer/) is made by the InSiGHT Variant Interpretation Committee. (johnpaul.plazzer@gmail.com)

The Prospective Lynch Syndrome Database (moller.pal@gmail.com), established 2013, is open for all to join. The goal is to upgrade knowledge on Lynch Syndrome (LS) from educated guesses based on retrospective series invalidated by selection biases, to prospectively obtained empirical knowledge and revise clinical guidelines accordingly. Large numbers allow reliable results: the database includes ~3,200 LS patients prospectively observed for ~25,000 years.

Results currently published (<http://www.ncbi.nlm.nih.gov/pubmed/26657901>) or in preparation include: Colonoscopy with removal of adenomas does not prevent colorectal cancer as assumed, but survival is excellent. Less than 3 years between colonoscopies was neither associated with lower incidence of colorectal cancer nor worse survival. Endometrial cancer has the highest incidence and has excellent survival. Ovarian cancer is seen early in life but most are cured. These results call for a reconsideration of clinical guidelines for identification of, and health care to, LS patients. The web-site <http://lscarisk.org> shows the risk for cancer according to age, genotype and gender for a LS patient at any age.

Lynch syndrome (LS) is an inherited autosomal dominant susceptibility to colorectal cancer (CRC) due to a germline mutation in mismatch repair (MMR) genes. The main aim of this study was to identify the underlying risk variants in 20 LS families from the R.Macedonia selected by the clinical Amsterdam criteria and MSI status, BRAF V600E/K mutation and MLH1 promoter methylation in tumor samples. Using targeted NGS of the coding regions of MLH1, MSH2, MSH6 and PMS2 genes we families of which 4 in MLH1 gene [p.S131X (c.392C>G), p.Thr82Ala (c.244A>G), p.Ala21Val (c.62C>T) and IVS12+8G>C (c.1409+8C>G)], 2 in MSH2 gene [MSH2 IVS14-2A>C (c.2211-2A>C) and c.68_-72del] and one in PMS2 gene [p.Ser128Leu (c.418 G>A)]. Three new mutations [MLH1 p.S131X (c.392C>G) and p.Thr82Ala (c.244A>G and MSH2 IVS14-2A>C (c.2211-2A>C)] were detected in 5, 3 and 3 families, respectively, accounting for ~60% of the molecular defects suggesting that they are founder mutations in our population. It was noted that the disease onset was earlier for 7-10 years in each successive generation in these families, suggestive for the anticipation mechanism. Our data indicate that all new LS patients from the R. Macedonia should be initially screened for these 3 frequent variants and that CRC screening of carriers should start >10 years earlier in each successive generations.

Abnormal Immunohistochemistry (IHC) and Microsatellite Instability (MSI) have been observed both in tumoural and normal endometrial biopsies in Lynch Syndrome (LS). The potential use of these findings as markers for endometrial cancer progression was confirmed in a pilot and is being investigated in a prospective multicentre study: the LynCE.

Methods:

58 Lynch Syndrome (LS) carriers are now enrolled and are being followed using gynaecological/ US exam, and endometrial biopsies, accounting for a median follow-up of 10.11 months. Endometrial samples are being histologically diagnosed and evaluated for IHC, MSI, and Methylator phenotype (CIMP-MMR).

Results:

- All 112 gynaecological/US exams have been normal. 86/87 biopsies resulted in normal endometrium and 1/87 in endometrial cancer. All (63/63) biopsies were MSI-Stable. 32/36 showed normal while 4/36 had CIMP-MMR hypermethylation (all from a single constitutional MLH1 epimutation carrier).

- 33% (12/36) patients had abnormal IHC biopsies, 11/12 matching the underlying germline genetic defect. All abnormal IHC samples were heterogeneous, 15/16 also showing adjacent normal IHC areas.

- 3 patients progressed from normal to abnormal IHC (median=13 months) but no other clinical, ultrasound, pathological, MSI or CIMP-MMR sign accompanied this progression.

Conclusion:

Heterogeneous abnormal IHC is present in a subset of normal endometrium biopsies from Lynch Syndrome patients, sometimes evolving from normal IHC. Other abnormalities as MSI (in the pilot study), CIMP-MMR, and pathology changes could follow this IHC abnormality anticipating the progression to endometrial cancer.

Introduction: The role of multigene panels for hereditary cancer risk assessment is yet to be established. We aimed at describing the prevalence of cancer predisposition gene mutations identified by a multigene panel in individuals with suspected Lynch syndrome.

Patients and methods: We performed germline analysis with a next-generation sequencing 25-gene panel (Myriad myRisk™ Hereditary Cancer) using DNA from 95 patients with suspected Lynch syndrome (endometrial cancer <50 y-o and/or fulfillment of revised Bethesda criteria) from Nov-2014 through March-2015 within the FAMOSA study. We classified all identified germline variants for pathogenicity and calculated the prevalence of pathogenic mutations and variants of uncertain clinical significance (VUS). We analyzed data on patients' personal and family history of cancer.

Results: We included 95 patients [female: 46 (48.5%), mean age: 48.6±12]: 8 (8.5%) patients with endometrial cancer and 87 (91.5%) with colorectal cancer. Multigene panel testing identified 20 (21%) patients with Lynch syndrome mutations (8 MLH1, 7 MSH2, 4 MSH6, 1 PMS2) and 1 (1%) with a mutation in BRCA2 in a 35 y-o woman without personal/familial history of breast/ovarian cancer. In patients diagnosed with mutations in the MMR genes and prior molecular screening (n=9), two displayed MMR proficiency and five patients had a negative prior genetic result by conventional techniques.

Conclusions: In individuals with suspected Lynch syndrome, multigene panel testing identified unexpected high-penetrance mutations in 1% of cases. Parallel sequencing also detected a meaningful number of cases with previous false negative results.

P12.131

Elucidating the molecular basis of MSH2-deficient tumors in Lynch syndrome suspected patients

G. Vargas¹, E. Dámaso¹, T. Pons¹, J. del Valle¹, S. Iglesias¹, À. Velasco¹, A. Solanes¹, A. Valencia², J. Brunet³, L. Feliubadaló¹, C. Lázaro¹, M. Navarro¹, **M. Pineda¹**, G. Capellà¹;

¹Institut d'Investigació Biomèdica de Bellvitge-Institut Català d'Oncologia, L'Hospitalet de Llobregat, Spain, ²Spanish National Cancer Research Center (CNIO), Madrid, Spain, ³Institut de Investigació Biomèdica de Girona Doctor Josep Trueta-Institut Català d'Oncologia, Girona, Spain, ⁴Institut d'Investigació Germans Trias i Pujol-Institut Català d'Oncologia, L'Hospitalet de Llobregat, Spain.

In about 55% of individuals harboring mismatch repair (MMR) deficient tumors, germline mutations or somatic methylation in MMR genes are not identified, being referred as Lynch-like syndrome (LLS). Mutations in *POLE* and *MUTYH* and double somatic events in MMR genes have been found in a proportion of these patients. The aim of this study was to elucidate the molecular basis of MSH2-deficient LLS cases by means of a comprehensive analysis of colorectal cancer (CRC) associated genes at germline and somatic level.

Eighteen LLS individuals harboring MSH2-deficient tumors were included. A customized NGS subexome panel including CRC associated genes was designed. PBL and matched FFPE DNA from available tumors (4 colorectal, 1 endometrial) were analyzed.

Predicted pathogenic germline heterozygous variants in *MSH2*, *BUB1*, *SETD2*, *FAN1* and *MUTYH* were identified in 6 of the 18 (33%) cases analyzed. The somatic analysis of tumors demonstrated the presence of: double somatic hits in *MSH2* or *MSH6* in 2 cases; and apparent loss of heterozygosity in *MSH2* locus and coexistence of double somatic mutations in other MMR and/or *POLE*/*POLD1* genes in the remaining ones. Also, somatic mutations in other cancer genes (*APC*, *AXIN2*, *BMP1A*, *PTEN* or *BUB1B*) coexisted with the above mentioned alterations. In all, alterations putatively responsible for LLS were detected in 60% of the cases.

The evaluation of germline and somatic mutational status of CRC-associated genes by means of a subexome panel is useful for the elucidation of the molecular basis of LLS-suspected cases.

¹Department of Human Genetics, Leiden University Medical Center, Leiden, Netherlands, ²Department of Pathology, Leiden University Medical Center, Leiden, Netherlands, ³Department of Clinical Genetics, Leiden University Medical Center, Leiden, Netherlands, ⁴Department of Clinical Genetics, Erasmus University Medical Center, Rotterdam, Netherlands, ⁵Department of Medical Genetics, University Medical Center Utrecht, Utrecht, Netherlands, ⁶Department of Clinical Genetics, University Hospital Maastricht, Maastricht, Netherlands, ⁷Department of Gastroenterology and Hepatology, Leiden University Medical Center, Leiden, Netherlands.

Introduction: Lynch Syndrome (LS) is caused by pathogenic germline variants in one of the mismatch repair (MMR) genes. However in up to 60% of MMR-deficient colorectal cancers no pathogenic germline MMR variant is found. Clinical management of these suspected Lynch Syndrome (sLS) cases remains difficult.

Materials and Methods: Using targeted next-generation sequencing, we analyzed the entire non-repetitive genomic sequence, including intronic and regulatory sequences, of 15 CRC susceptibility genes in 34 unrelated sLS patients and 11 patients with MLH1 hypermethylated tumors with a clear family history for LS. In addition, tumor DNA from 28 sLS patients was analyzed for somatic MMR variants.

Results: Of 1979 germline variants found in 34 sLS patients, one was a predicted pathogenic variant (MLH1 c.1667+1delG). The 11 MLH1 hypermethylated tumors were negative for germline variants in CRC susceptibility genes and for germline MLH1 hypermethylation. However, somatic DNA analysis of 28 sLS tumors identified nine (32%) cases of biallelic somatic inactivation and nine cases with (32%) one (likely) pathogenic somatic variant.

Conclusions: This is the first study in sLS patients to include the entire genomic sequence of CRC susceptibility genes. An underlying somatic or germline MMR gene defect was identified in ten of 34 sLS patients (29%). In the remaining sLS patients, the underlying genetic defect explaining the MMR-deficiency in tumors might be found outside the genomic regions harboring the MMR and other known CRC susceptibility genes. Classification of 8 mismatch repair variants identified in MSH2 and MSH6 genes using multifactorial likelihood analysis

M. González Acosta¹, **B. A. Thompson²**, M. Navarro¹, A. Fernández¹, G. Vargas¹, S. Iglesias¹, A. Velasco¹, A. Solanes¹, J. Balmaña³, C. Lázaro¹, J. Brunet³, G. Capellà¹, M. Pineda¹;

¹Bellvitge Biomedical Research Institute - Catalan Institute of Oncology (IDIBELL-ICO), Hospitalet de Llobregat, Spain, ²Huntsman Cancer Institute, University of Utah, Circle of Hope, Salt Lake City, UT, United States, ³Catalan Institute of Oncology, IDIBGI, Girona, Spain, ⁴Catalan Institute of Oncology, Hospital Germans Trias i Pujol, Badalona, Spain, ⁵University Hospital Vall Hebron - Vall Hebron Institute of Oncology, Barcelona, Spain.

Introduction: Up to 30% of the DNA variants identified in mismatch repair (MMR) genes are variants of unknown significance (VUS). A standardized classification scheme based on quantitative and qualitative algorithms has recently been proposed for their interpretation according to the five class IARC scheme. The aim of this study was to assess the pathogenicity of MSH2 and MSH6 variants by means of multifactorial likelihood calculations.

Patients and Methods: Eight variants (5 missense, 2 intronic and 1 small in-frame duplication), identified in multiple families or associated to multiple tumors, were selected. Four of them had previously been classified as probably pathogenic whereas the remaining were VUS. Frequency in control population was searched in public databases. Variants were screened in DNA samples from available relatives by Sanger sequencing. Pathological information was collected. Multifactorial likelihood analysis based on estimated prior probabilities of pathogenicity, likelihood ratios for segregation and microsatellite instability in colorectal tumors was conducted as described (Thompson et al. 2013).

Results: None of the selected variants were reported in control population. The collected tumor data and the results of cosegregation analysis were used in likelihood ratio calculations. Posterior probability of pathogenicity resulted >0.999 for all the analyzed variants, allowing reclassification as pathogenic mutations of the 8 variants analyzed.

Conclusions: These results highlight the benefit of collecting segregation and tumor data for variant classification. Current multifactorial models will likely be improved when information concerning IHC patterns and MSI/IHC results of extracolonic tumors are included.

The role of 22 common susceptibility loci in phenotype variability in Lynch Syndrome patients carrying a germline PMS2 mutation

S. W. ten Broeke¹, F. A. Elsayed¹, L. Pagan¹, M. J. W. Berends-Olderode², E. Gomez Garcia³, H. J. P. Gille⁴, L. P. van Hest⁴, T. G. W. Letteboer⁵, F. H. Menko⁶, A. R. Mensenkamp⁷, T. A. van Os⁸, L. Spruijt⁹, B. J. W. Redeker⁹, Y. J. Vos², A. Wagner⁹, C. M. Tops¹, J. T. Wijnen¹, T. van Wezel¹, M. Nielsen¹;

¹Leiden University Medical Center, Leiden, Netherlands, ²University Medical Center Groningen, Groningen, Netherlands, ³Maastricht University Medical Center, Maastricht, Netherlands, ⁴VU Amsterdam, Amsterdam, Netherlands, ⁵University Medical Center Utrecht, Utrecht, Netherlands, ⁶The Netherlands Cancer Institute, Amsterdam, Netherlands, ⁷Radboud University Medical Center, Nijmegen, Netherlands, ⁸Academic Medical Center, Amsterdam, Netherlands, ⁹Erasmus Medical Center, Rotterdam, Netherlands.

Background: Lynch syndrome (LS) patients are at high risk of developing colorectal cancer (CRC). Notably, LS families show a marked intra- and inter-familial phenotype variability. This might in part be explained by common susceptibility loci, or single nucleotide polymorphisms (SNPs). Previous studies have shown conflicting results and have mainly focused on MLH1, MSH2 and MSH6 carriers. We now aim to investigate the role of these SNPs in a large cohort of PMS2 carriers.

Methods: Twenty-two candidate SNPs from previous Genome Wide Association studies (GWAS) were selected (rs6687758, rs6691170, rs10936599, rs1321311, rs16892766, rs6983267, rs10795668, rs3802842, rs3824999, rs4444235, rs9929218, rs4939827, rs12953717, rs10411210, rs961253, rs4925386, rs1569686, rs2736100, rs1800734, rs1799945, rs36053993, rs1048943), which have previously been associated with (sporadic) CRC. These SNPs were genotyped in 353 PMS2 carriers ascertained from family cancer clinics (77 cases, 276 controls). Hazard ratios were corrected for familial clustering and calculated using a weighted cox regression analysis to correct for ascertainment bias. Possible effects were examined using both a dominant/recessive and an additive (per allele) model.

Results: We found no evidence of an association between CRC risk and cumulative number of risk alleles (HR=0.99 (95%CI: 0.90-1.08)). Moreover, none of the SNPs individually showed a risk modifying effect.

Discussion: There was no evidence of a risk modifying effect of twenty-two analyzed SNPs in PMS2 carriers, thus they do not appear to be of any clinical utility. Other explanations for phenotype variability that warrant further exploration include gene-environment interaction and risk modification by other genetic variants.

Lymphoid malignancies and myeloproliferative neoplasms concurrently diagnosed: the experience of a single center

M. S. Dencic Fekete, M. Peruničić-Jovanović, J. Jovanović, V. Đorđević, S. Bižić, D. Šefer, D. Antić, B. Anđelić, A. Bogdanović;

Clinic of hematology, Belgrade, Serbia.

The coexistence of lymphoproliferative and myeloproliferative neoplasms (LPN/MPN) is a rare event and has been sporadically reported in the literature. We retrospectively analyzed the clinical and biological characteristics of 7 patients with concomitant LPN and MPN - 3 chronic lymphocytic leukemia (CLL) with Polycythemia Vera (PV), 2 CLL with Essential thrombocytosis (ET), 1 diffuse large B-cell lymphoma (DLBCL) with PV and one multiple myeloma (MM) with ET - who presented to our clinic between 1995 and 2013. The average time to secondary malignancy was 62 months: LPN was diagnosed as a first disease in 1 patient (pt) and as a second in 6 patients (pts). Five patients were treated for MPN and two for LPN. Both of the patients treated for LPN achieved complete remission. After a median follow-up from MPN diagnosis of 149 months, 6 pts are still alive and 1 died. Cytogenetics was done in 6 patients: 5 pts had normal karyotype, while one pt had abnormal karyotype with derivative chromosome 18. Interphase FISH analysis was performed with CLL panel probes in three patients, showing del(13)(q14.3) in all of them. One patient with MM was analyzed with FISH probes for D13S319, TP53, IGH/FGFR3 and IGH/MAF genes and showed no rearrangements. Four patients were tested for JAK 2 mutation: 3 with PV were positive while 1 with ET was negative. This retrospective analysis showed that MPN was diagnosed before LPN in a majority of our patients. Coexistence of LPN/MPN does not appear to predict worse outcome.

P12.137

Mitotic kinesins are important players in the pathogenesis of malignant peripheral nerve sheath tumours

E. Terribas¹, B. Gel¹, J. Biayna¹, J. Fernández-Rodríguez², C. Lázaro², E. Serra¹;

¹Institut de Medicina Predictiva i Personalitzada del Càncer, Badalona, Spain, ²Catalan

Institute of Oncology (ICO-IDIBELL), L'Hospitalet de Llobregat, Spain.

Around half of malignant peripheral nerve sheath tumours (MPNSTs) develop in the context of neurofibromatosis type 1 (NF1), normally progressing from pre-existing benign plexiform neurofibromas (pNFs). A genomic characterization of a set of MPNSTs confirmed the acquisition of hyperploid genomes and recurrent somatic copy number alterations for these tumours. To study the impact of these regional alterations on the transcriptome, microarray expression data was used. Mapping on the genome the differential gene expression between MPNSTs and pNFs, we identified transcriptional imbalances (TIs), genomic regions with a significant abundance of over- or underexpressed genes. Using information from TIs, some mitotic kinesin genes were identified as potential candidates for MPNST pathogenesis, which were functionally characterized in vitro using MPNST-derived cell lines.

Most of these kinesin genes were significantly overexpressed in MPNSTs in the microarray. Expression knockdown by siRNA of KIF23, involved in telophase and cytokinesis, showed that KIF23 is essential for cell survival and cell cycle progression of MPNST cell lines. Chemical inhibition of the early mitotic kinesins KIF11 and KIF10 with ispinesib and GSK923295, respectively, reduced cell viability in a set of MPNST cell lines. Moreover, according to their IC50 values, these lines were more sensitive to these compounds, especially for ispinesib, than a fibroblast cell line. Although in vivo validation is needed, our results suggest that mitotic kinesins are important players in the pathogenesis of MPNSTs, and we propose KIF11 as a new potential therapeutic target for these tumours.

Gene copy number variation analysis in male breast cancer

L. Rollán Manso^{1,2}, I. Aurrekoetxea Rodríguez^{1,2,3}, J. García Hernández^{1,3}, E. Sánchez Tapia^{1,3}, A. Pascual Rodríguez^{1,2,3}, E. Lumbresas¹, J. Hernández Rivas^{1,4,3}, J. Cruz Hernández^{5,3}, T. Martín Gómez⁶, R. Martín⁷, R. González Sarmiento^{1,2,3};

¹Centro de Investigación del Cáncer, Salamanca, Spain, ²Departamento de Medicina, Facultad de Medicina, Universidad de Salamanca, Salamanca, Spain, ³IBSAL (Instituto de Investigación Biomédica de Salamanca), Salamanca, Spain, ⁴Servicio de Hematología, Hospital Universitario de Salamanca, Salamanca, Spain, ⁵Servicio de oncología médica, Hospital Universitario de Salamanca, Salamanca, Spain, ⁶Servicio de Oncología médica, Hospital Universitario de Salamanca, Salamanca, Spain, ⁷Servicio de Anatomía Patológica, Hospital Nuestra Señora de Sonsoles de Ávila, Ávila, Salamanca, Spain.

Introduction: Male breast cancer (MBC) is a rare disease and little is known about its etiology. So, there is limited knowledge of the disease at both genetic and molecular levels. The identification of DNA copy number variations (CNV) on MBC may result in an appropriate strategy to understand tumor pathogenesis. Therefore, the aim of this study was to analyze DNA imbalances using aCGH.

Materials and methods: Twelve FFPE tissue blocks of male breast cancer were used for analyze CNA utilizing Affymetrix® CytoScan 750K Array.

Results: All cases of male breast cancer samples displayed some chromosomal instability. An average of 179 segmented altered per cases were observed (range 16-339). Gains were most frequent than losses (1570 vs 369). The most frequent chromosome regions affected by gains were 1q21-q44, 8q11-q24, 16p13-p11 and 20q, (5/12), 17q and Xq (3/12). Deletions of 8p23-p12 and X were observed in 2 cases. Minimal common regions (MCRs) were detected on 7q11.23 (11/12), 8q21.11 (4/12), 8q24.3 (4/12), 16p11.2 (8/12), Xq21.3 (6/12) and 1q41 (5/12). MCR on 1p13.3, 6q15 21q21 and Xq13.1 (3/12) were the most frequent affected by loss.

Conclusions: the analysis of genomic changes by aCGH and the detection of recurrent MCRs can lead to the identification of functional important genes involved in MBC. In view of our results, male breast cancer could be considered as a different molecular entity than female breast cancer.

Mutated MCM9 is associated with predisposition to hereditary mixed polyposis and colorectal cancer in addition to primary ovarian failure

Y. Goldberg;

Hadassah Medical Center, Jerusalem, Israel.

Mutations in MCM9 encoding DNA helicase were recently shown to cause a clinical phenotype of primary ovarian failure and chromosomal instability. MCM9 plays an essential role in homologous recombination-mediated double-strand breaks repair. We describe a multiplex family with early colorectal carcinoma and mixed polyposis associated with primary hypergonadotropic hypogonadism. A combination of whole genome homozygosity

mapping as well as exome sequencing and targeted gene sequencing identified a homozygous c.672_673delGGinsC mutation which predicts a truncated protein, p.Glu225Lysfs*4. Our data expands the phenotypic spectrum of MCM9 mutations and suggests a link between MCM9 and inherited predisposition to mixed polyposis and early onset colorectal cancer.

P12.140 Investigation of gene expression alterations in metastatic colorectal cancer

V. P. Shubin, A. Ponomarenko, A. Tsukanov, Y. Shelygin, O. Mainovskaya, E. Rybakov, N. Pospekhova;
Ministry of Health / State Scientific Center of Coloproctology, Moscow, Russian Federation.

Metastases of colorectal cancer (CRC) are main cause of patients' death. Data concerning gene expression alteration in primary tumors and liver metastases can served for prognosis of disease outcome.

Methods. The materials for the study were 30 CRC tumors (T3-4N0-2cM1) and corresponding liver metastases. Expression the most important (according scientific literature data) genes CFTR, FLNA, PROM1, SFRP2, PLS3, BMI was investigated by RT-PCR. Analysis of gene expression was performed by clustering.

Results. As a result of cluster analysis all tumors and metastases were divided into 3 groups. The first cluster of tumors (6 cases) characterized by: CFTR +, FLNA-, PROM1 +, SFRP2 +, PLS3-, BMI +; the second cluster (8 cases): CFTR +, FLNA +, PROM1-, SFRP2-, PLS3 +, BMI +; the third cluster (17 cases): CFTR +, FLNA +, PROM1, SFRP2 +, PLS3 +, BMI +. The first cluster of metastases (11 cases) characterized by: CFTR +, FLNA +, PROM1 +, SFRP2-, PLS3 +, BMI +; the second cluster (8 cases) by: CFTR +, FLNA +, PROM1-, SFRP2-, PLS3 +, BMI +; the third cluster (12 cases) characterized by: CFTR +, FLNA +, PROM1-, SFRP2 +, PLS3 +, BMI +.

Conclusion. The most significant alterations of expression were detected for FLNA, PROM1, SFRP2, PLS genes in primary tumors and for PROM1, SFRP2 genes in metastases.

P12.142 Gene expression profile in melanoma cell lines carrying BRAF and NRAS mutations

P. Giménez-Xavier^{1,2}, E. Martínez-Barrios³, J. A. Puig-Butillé^{2,3}, G. Tell-Martí^{1,2}, M. Potrony¹, C. Badenas^{2,3}, J. Malvehy^{1,2}, D. Benítez⁴, S. Puig^{1,2};
¹Dermatology Department, Melanoma Unit, Hospital Clínic of Barcelona and Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain, ²Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), Barcelona, Spain, ³Biochemical and Molecular Genetics Service, Hospital Clínic of Barcelona and Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain, ⁴Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBEREHD), Barcelona, Spain.

Introduction: Malignant melanoma is one of the most aggressive human cancers due to its high metastatic propensity. It is well known that somatic oncogenic alterations in *BRAF* or *NRAS*, members of the MAPK (mitogen-activated protein kinase) pathway, are a common and initial event in melanocyte transformation. The oncogenic p.V600E *BRAF* mutation is found in 50% of melanomas, while mutations in *NRAS* gene are found in 20% of melanomas. Thus, identifying a gene expression profile associated with the presence of *BRAF* or *NRAS* mutations in melanoma cell-lines can provide a better understanding of their role in melanoma development and progression.

Materials and Methods: A panel of 12 melanoma cell lines derived from cutaneous melanoma or melanoma metastases was used. Cell lines were classified according to the mutational status of *BRAF* and *NRAS* genes. Analysis of whole genome expression of the cell lines was conducted by gene expression microarrays (SurePrint G3 Human Gene Expression v3 8x60K, Agilent) and differential expression was analyzed using limma. Transcripts with an adjusted p-value (FDR) <0.05 were selected.

Results: We found a genomic signature associated with p.V600E *BRAF* (36 transcripts) and another associated with *NRAS* mutations (42 transcripts). Moreover, 103 transcripts were found deregulated between p.V600E *BRAF* cell lines and *NRAS* mutated cell lines.

Conclusions: We have identified a *BRAF* and *NRAS* associated gene expression profile in a set of melanoma cell lines. These profiles can help to improve our knowledge of the role of *BRAF* and *NRAS* mutations in melanoma progression and treatment response.

P12.144 Qualitative analysis of RET protooncogene mutations responsible for Multiple endocrine neoplasia type 2 syndrome in Lithuania

L. Juodele¹, D. Serapinas², L. Kucinskas², V. Asmoniene², E. Juozaityte³;
¹Lithuanian university of Health sciences, Kaunas, Lithuania, ²Department of Genetics and molecular medicine, Lithuanian university of Health sciences, Kaunas, Lithuania, ³Institute of Oncology, Lithuanian university of Health sciences, Kaunas, Lithuania.

Introduction. Multiple endocrine neoplasia type 2 (MEN2) is a rare syndrome, inherited in an autosomal dominant pattern, characterized by combination of medullary thyroid carcinoma with pheochromocytoma, tumors of the parathyroid glands and more rare tumors. The aim of the study was to determine and evaluate RET protooncogene mutations in patients with MEN2 syndrome in Lithuania.

Materials and Methods. A total of 47 unrelated patients with medullary thyroid carcinoma were enrolled into the study. Patients underwent genetic testing by DNA sequencing, detecting germline mutations causing MEN2 syndrome.

Results. RET protooncogene mutations causing MEN2 syndrome were detected in 8 patients of the 47 medullary thyroid carcinoma cases - 17.02% (CI 95% 6.4 - 27.7%). The most frequent RET protooncogene mutations (in 611 (n=2), 618(n=1), 634 (n=2) codons) were detected to cause MEN2A syndrome (62.5%), less frequent mutation in 918 codone (n=2) that caused MEN2B syndrome, most rare - familial medullary thyroid carcinoma syndrome causative mutation in 791 codone (n=1). In patients with detected MEN2 syndrome causative mutations in RET protooncogene, medullary thyroid carcinoma manifested in younger age - 29.8 ±16.1 years, comparing with sporadic cases - 49.5±10.7 years (p<0.05).

Conclusions. In unrelated patients with medullary thyroid carcinoma detected frequency of probands and germline RET protooncogene mutations causing MEN2 syndrome was 17.02 (CI 95% 6.4 - 27.7%).

P12.145 Epigenetic inactivation of tumor suppressor genes correlates with tumor recurrence in histologically benign meningiomas

T. San-Miguel¹, L. Navarro¹, J. Megías¹, L. Muñoz-Hidalgo², R. Gil-Benso¹, M. Cerdá-Nicolás¹, C. López-Ginés¹;
¹Department of Pathology, University of Valencia, Valencia, Spain, ²INCLIVA, Valencia, Spain.

Meningiomas are the most frequent tumors of the central nervous system. Histologically, they are divided in three grades according to their aggressiveness. Grade I tumors are the most common, and they are usually slow-growing tumors, curable by surgery. Nevertheless, in absolute numbers, they cause the majority of recurrences. Despite cytogenetic and genetic approaches for meningioma progression, prediction of recurrence in histologically benign meningioma remains a challenge.

The aim of this work was to characterize epigenetic changes in recurrent versus non-recurrent grade I meningiomas. We completed the study comparing primary meningiomas with tumor recurrences, in order to determine characteristic changes in progressed tumors. Formalin-fixed paraffin-embedded specimens were used for DNA extraction and studied by Methylation-Specific Multiplex Ligation-dependent Probe Amplification with ME001-C2 tumor suppressor genes (TSG) kit (MRC-Holland). This technique provides promoter hypermethylation information of several genes in just one reaction.

The study revealed a statistically significant increase in the global number of hypermethylated TSG in grade I recurrent tumors in a similar way that happens in the recurrences analyzed versus primary tumors. Specifically, epigenetic changes of MLH1, RASSF1A and CDKN2B correlated to the tendency to recur. In addition, the epigenetic landscape of grade I-recurrent tumors resembled to the one found on recurrences.

Our results suggest that TSG hypermethylation is an early event in the acquisition of aggressiveness in benign meningioma and the role of these genes that are implicated in DNA-repair, neovascularization and cell-cycle control should be further studied.

P12.146

Evaluation of Microsatellite Instability in Tumor and Tumor Marginal Samples of Sporadic Colorectal Cancer Using Mononucleotide Markers

J. Nouri Nojadeh, E. Sakhinia, S. Hashemzadeh, S. Behrouz Sharif; Tabriz University of Medical Science, Tabriz, Iran, Islamic Republic of.

Background: Microsatellite instability in tumor DNA is defined as the presence of alternate sized repetitive DNA sequences that are not seen in the corresponding germline DNA. Microsatellite instability (MSI) is a molecular phenotype due to a defective DNA mismatch repair system. The presence of MSI is found in sporadic colon, gastric, sporadic endometrial and the majority of other cancers. Determination of MSI status in CRC has a clinical use in the form of identifying patients with germline defects predisposing to MMR-deficiency. Additionally, MSI status has prognostic and therapeutic implications, due to MSI CRCs typically exhibiting a better prognosis. For these reasons microsatellite instability analysis is becoming more important in detecting sporadic primary tumors.

Material and methods: In this study we investigated tumoral DNA and tumor marginal DNA of 50 sporadic CRC patients who have not received chemotherapy. Five mononucleotide markers, BAT-25, BAT-26, NR-21, NR-22 and NR-27 were used as a pentaplex PCR panel to evaluate for microsatellite instability status.

Results: Our primary finding showed that MSI was detected in about 40% of specimens. Instability was observed in the tumoral DNA compared to the DNA from the normal DNA sample. Our primary results showed that the frequency of instability NR-21, BAT-25 and NR-27 markers more than other markers and its frequency almost were similar.

Conclusion: Our study showed NR-21, BAT-25 and NR-27 were the most useful markers for diagnosing sporadic CRC. Therefore these markers have shown promise in their potential use for determining MSI status in patients with sporadic colorectal cancer.

P12.147

The phenotype of the POLE germline mutation p.(Val411Leu) overlaps with constitutional mismatch repair deficiency syndrome

K. Wimmer¹, A. Beilken², R. Nustedde³, T. Ripperger⁴, B. Ure³, D. Steinmann⁵, J. Zschocke¹, C. Fauth¹, C. Kratz²;

¹Division Human Genetics, Medical University Innsbruck, Innsbruck, Austria, ²Pediatric Hematology and Oncology, Hannover Medical School, Hannover, Germany, ³Department of Surgery, Childrens Hospital, Hannover Medical School, Hannover, Germany, ⁴Institute of Human Genetics, Hannover Medical School, Hannover, Germany, ⁵Department of Radiotherapy and Special Oncology, Hannover Medical School, Hannover, Germany.

There are three adenomatous polyposis and colorectal cancer (CRC) susceptibility syndromes that result from constitutional DNA repair defects. The phenotypes of the constitutional base excision repair defect, MUTYH-associated polyposis (MAP), and of impaired exonuclease function of replicative polymerases, polymerase proofreading-associated polyposis (PPAP), are characterized by multiple adenomas and/or carcinoma usually diagnosed in adulthood. Constitutional mismatch repair deficiency (CMMRD) confers a more penetrant phenotype with a high risk for childhood or adolescence onset of polyposis and CRC as well as for other malignancies. Despite the presence of multiple café-au-lait macules (CALM) and one pilomatricoma, which serve as diagnostic signposts for CMMRD in young cancer patients, this diagnosis was ruled-out by gMSI and mutation analysis of the four MMR genes in a 14-year-old boy with polyposis and a rectosigmoid cancer expressing all four MMR genes. The only functionally-relevant variation found by analysis of eight polyposis genes is p.(Val411Leu) in POLE (NM_006231.3). This somatic hot-spot mutation recurrently found in 'ultramutated' sporadic CRC was never before observed as germline alteration. It impairs Pole's exonuclease activity and, therefore, is considered responsible for the phenotype of this youngest reported CRC patient with PPAP. This PPAP case reminiscent of CMMRD raises the question of a skin phenotype that is common to different types of constitutional DNA repair defects and results from post-zygotic mutations secondary to the repair defect. Together with anecdotal reports of multiple CALM and pilomatricomas in MAP patients, this case supports this notion and should prompt investigations for skin features in MAP and PPAP patients.

P12.148

Mitochondrial DNA mutational changes in glioma

M. M. González¹, C. Santos¹, A. Ramos¹, M. Cos², C. F. Alarcón³, J. J. Acebes³, M. P. Aluja⁴;

¹Unitat d'Antropologia Biològica, Departament BABVE, Universitat Autònoma de Barcelona, Cerdanyola del Vallès, Barcelona, Spain, ²Servei de Neuro-radiologia, Institut de Diagnòstic per la Imatge, Centre Bellvitge, Hospital de Llobregat, Barcelona, Spain, ³Servei de Neurocirurgia, Ciutat Sanitària i Universitària de Bellvitge, Hospital de Llobregat, Barcelona, Spain.

Mitochondrial anomalies have been linked to carcinogenic processes. The production of reactive oxygen species (ROS) increases the probability of suffering oxidative damage and, consequently, the accumulation of mitochondrial DNA (mtDNA) mutations, affecting conserved positions probably contributing to the development of disease. This study aims to characterize the whole mitochondrial genome in patients affected by glioma. A total of 27 glioma cancer patients were studied. Brain tumour and blood samples were collected for each patient and 10 brain samples from healthy individuals were added to the study. mtDNA was sequenced using Nextera XT kit with MiSeq sequencer from Illumina. Comparing tumour and blood samples from the same patient, results show that the vast majority of the mutations were present in both tissues (87.02%), assuming a high representation of germinal mutations. Somatic mutations in brain tumours (12.98%) are mainly in heteroplasmy (70.59%). The comparison between brain tumour samples and brain samples from healthy individuals shows that both present a low percentage of mutations in heteroplasmy and their frequencies are very similar (18.32% in brain tumour samples; 18.18% in brain samples from healthy individuals). The study could contribute to understanding the implication of mtDNA in cancer development, specifically its role in glioma tumorigenesis.

The genomic landscape of mitochondrial DNA mutations in chronic myeloid leukaemia

I. S. Pagani^{1,2}, C. H. Kok^{1,3}, V. Saunders¹, J. Goyne¹, J. McLean¹, M. VanderHoek¹, S. Heatley⁴, A. P. Schwarer⁴, T. P. Hughes^{1,3,5}, D. L. White^{1,3}, D. M. Ross^{1,5,6};

¹South Australian Health and Medical Research Institute, Adelaide, Australia, ²The University of Milan, Milano, Italy, ³School of Medicine, University of Adelaide, Adelaide, Australia, ⁴Box Hill Hospital, Melbourne, Australia, ⁵Department of Haematology, SA Pathology, Adelaide, Australia, ⁶Flinders University and Medical Centre, Adelaide, Australia.

Introduction: Genomic instability in BCR-ABL1-positive chronic myeloid leukaemia (CML) is reported to be associated with increased reactive oxygen species (ROS). The mitochondrial (mt) genome is susceptible to ROS-induced mutations due to oxidative stress in the mitochondrion and limited DNA-repair mechanisms.

Rationale: To describe the mt-genomic landscape in CML, and to identify diversity in the apparently uniform leukemic clone.

Methods: We performed targeted next-generation sequencing on mt-genome in 27 CML patients at diagnosis and after 12 months of therapy. Patients were selected as good (n=15) or poor (n=12) responders based on achievement of major molecular response (BCR-ABL1^{IS} ≤0.1%) at 12 months. Mesenchymal stem cells or hair follicles were used to exclude germline polymorphisms.

Results: We identified 87 somatic mutations at diagnosis, in 14/15 good responders and in 9/12 poor responders. The number of somatic mutations per patient tended to be higher in good responders than in poor responders. All somatic mutations identified at diagnosis were heteroplasmic, reverting to wild type at follow up. Seven good responders and 5 poor responders had new heteroplasmic mutations detected in follow-up samples. The distribution of mutations across the mt-genome did not differ between good and poor responders, and did not show an excess of G>T transversions that are considered the hallmark of ROS-induced damage.

Conclusions: MtDNA mutations are common in CML, and identify clonal diversity both at diagnosis and follow up. Mitochondrial mutations are not directly related to ROS damage or clinical outcome. The significance of mutations in remission requires further study.

Molecular characterization of constitutional MLH1 epimutations

E. Dámaso¹, A. Castillejo², M. Arias³, G. Vargas⁴, P. Mur⁴, M. Genuardi⁴, D. Rueda⁵, Á. Alonso³, J. Soto², M. Pineda¹, G. Capellá¹;

¹Bellvitge Biomedical Research Institute - Catalan Institute of Oncology, L'Hospitalet de Llobregat, Spain, ²Elche University Hospital, Elche, Spain, ³Complejo Hospitalario de Navarra, Pamplona, Spain, ⁴Catholic University of the Sacred Heart, Rome, Italy, ⁵Doce de Octubre University Hospital, Madrid, Spain.

Introduction: Constitutional epimutations in MLH1 have been identified in a subset of Lynch syndrome patients (0-2%). Little is known about their mechanistic basis and consequently its inheritance pattern. The aim of this study was to perform a genetic and epigenetic characterization of constitutional MLH1 epimutations.

Methods: Twelve patients carriers of constitutional MLH1 epimutations were recruited (8 previously reported). Mutational analysis of MLH1 promoter and intron 1 was performed by Sanger sequencing. The presence of structural alterations was evaluated using a customized array with 15K probes (Agilent Technologies), surrounding MLH1 gene. Clonal bisulfite sequencing of the promoter was used to determine the methylated allele. Inheritance pattern was determined by haplotype and MS-MLPA analyses in probands' first-degree relatives. Global methylome analysis was performed using Infinium 450K array (Illumina).

Results: The variant c.-234_-236del was identified in one of 12 cases analyzed and rearrangements in the locus surrounding MLH1 were found in 4 of the 11 analyzed patients. Methylation was confined to a single allele in two analyzed cases, associated to MLH1 transcriptional inactivation. Subsequent methylation and haplotype analyses in relatives revealed intergenerational erasure. Global methylome analysis in the 12 cases revealed that MLH1-EP-M2AIP1 promoter CpG island is the most differentially methylated region of MLH1 epimutants when compared with 21 MLH1 mutation carriers.

Conclusions: Structural alterations are found in a significant proportion of MLH1 constitutional epimutations. Further studies are needed to assess its putative causal relationship. Refined molecular characterization is needed to elucidate their mechanistic basis and heritability.

P12.151

A novel mutation in hMLH1 causing positive hMLH1 immunohistochemical staining, but defective binding to and loss of hPMS2

A. Stella, M. Patrino, D. C. Loconte, S. Di Tommaso, C. Ranieri, C. Simone, D. Varvara, R. Bagnulo, P. Lastella, N. Resta; Division of Medical Genetics- Department of Biomedical Sciences and Human Oncology, University of Bari, Bari, Italy.

Introduction: The advent of NGS has caused the identification of novel variants in Lynch syndrome patients, whose clinical consequences are difficult to predict especially when associated with conflicting results of immunohistochemistry analyses. We here report a novel mutation in hMLH1 which, albeit leading to normal hMLH1 expression impairs its ability to bind to hPMS2 causing PMS2 lack of expression

Materials and Methods: The index case was represented by a 23 years old male diagnosed with a pT3N1M1 colon adenocarcinoma. DNA isolated from PBL was deep sequenced using an Ion AmpliSeq custom panel on an Ion Torrent PGM. IHC for MLH1, MSH2, PMS2 and MSH6 was done according standard methods. In silico analysis was performed using the following software prediction tools: Variant Effect Predictor (VEP), PredictProtein, and i-Mutant.

Results: NGS analysis revealed the presence of a c.122C>T, p. D41V in the hMLH1 coding sequence as the most likely pathogenic variant. IHC demonstrated positive staining for MLH1, MSH2, MSH6 but not for PMS2. In silico analysis showed the following results: VEP returned a moderate score for the pathogenicity of this variant with all predictions from SIFT, Polyphen, and MutationTaster either deleterious or probably damaging. PredictProtein computed for the mutant protein the loss of five binding sites, the reduction in length of additional two, while three novel binding sites were gained. Finally, i-mutant predicted a stability decrease for the mutant protein

Conclusions: The identified variant falls in the ATPase domain where 50% of missense variants cluster despite accounting for less than 25% of amino acid sequence.

Unclassified sequence variants: a challenge for molecular oncogenetic diagnostics

L. Negura¹, A. Chicos¹, D. Azoicai¹, A. Negura²;

¹Gr. T. Popa Medicine and Pharmacy University, Iasi, Romania, ²Alexandru Ioan Cuza University, Iasi, Romania.

Oncogenetics was developed 20 years ago as a clinical and psychological follow-up addressing to patients and families with hereditary risk of cancer. Oncogenetic approach developed together with the identification of predisposition genes to breast, ovarian or colorectal cancer, and with the progress in molecular diagnosis abilities. Today, the only molecular technique accepted and validated for oncogenetic diagnosis is Sanger sequencing of all exons and exon-intron boundaries for the known predisposition genes. When completely sequencing and decrypting thousands of DNA nucleotides, many sequence variants are identified, most of them being single nucleotide polymorphisms. Current practice classifies sequence variants in a 5-levels frame, from deleterious pathogenic to polymorphic benign. Unfortunately,

more than 40% of the sequence variants found in routine analysis are of unclear pathogenicity. While several biochemical, molecular, genetics and *in-silico* analysis may help in interpreting such variants, there still rest an important percentage with unclear clinical value.

Here we present several distinct unclassified variants (UV) and how they could be interpreted for a clinical purpose. Case 1: Validating a UV to benign by *in-silico* or *in-trans* analysis; Case 2: Validating a UV to benign by functional tests; Case 3: doubts persisting when the result is level 2 "probably benign"; Case 4: Segregation and linkage analysis for results level 4 "probably benign"; Case 5: The ultimate challenge - the level 3 absolute unclassified variant.

Interpreting such variants, as well as communicating the diagnosis results both to patients, families or clinicians, are the biggest challenges for present molecular diagnosis.

Introduction: Multiple Myeloma (MM) is the hematological disease characterized by transformation of B cells into malignant cells. Our aim of the study was to investigate transcriptome profiles in bone marrow myeloma cells by next generation sequencing technology.

Method: In this study we performed RNA-Seq using the Ion Torrent PGM platform to compare the transcriptome profiles of untreated four MM patients and four healthy donors. Myeloma cells (CD38+, CD138+, CD19-, CD56+) and healthy B cells (CD38+, CD138+, CD19+, CD56-) from bone marrow were selected using cell surface marker in FACSAria II Cell Sorter. Transcriptome libraries were prepared from rRNA depleted RNA extracted from pool of myeloma cells and healthy donors B cells. These libraries were sequenced and aligned the reads to the human genome (GRCh37/hg19) and mapped sequences to the RefSeq database.

Result: Here, we characterize transcriptional profiles in MM patients. In addition, 18806 transcript (17760 of transcripts were reported), 490 deletion, 1397 insertion, 8402 single nucleotide variants 415 reported fusion gene, 983 novel fusion gene were detected. The genes found differentially expressed underwent Gene Set Enrichment Analysis by MSigDB. We identified significant overlap between EEF1A1, UBC, UBB, CALR, CXCR4, JUN, FOS, PIM2, JUN, GAPDH, HSP90B1 that was previously reported upregulation of MM.

Conclusion: We were determined some variations and different mRNA expression pattern in some previous reported genes that especially in ubiquitin-proteasomal pathway. Possible candidate genes detected in this study should be confirmed with real time PCR and sanger sequencing in a large groups of patients.

P12.154

Clonal evolution in bone-marrow cells of patients with myelodysplastic syndromes (MDS) and deletion 5q

K. Svobodova¹, Z. Zemanova¹, H. Lhotska¹, M. Novakova¹, M. Belickova², J. Brezinova², I. Sarova^{1,2}, S. Izakova¹, L. Lizcova¹, A. Berkova¹, A. Jonasova³, J. Cermak², K. Michalova^{1,2};

¹Center of Oncocytogenetics, IMBLD, General University Hospital and 1st Faculty of Medicine, Charles University in Prague, Prague 2, Czech Republic, ²Institute of Hematology and Blood Transfusion, Prague 2, Czech Republic, ³First Medical Department, General University Hospital and First Faculty of Medicine, Charles University in Prague, Prague 2, Czech Republic.

The most common recurrent chromosomal change in bone-marrow cells of patients with myelodysplastic syndromes (MDS) is interstitial deletion of the long arm of chromosome 5. Finding of the sole del(5q) is associated with good prognosis. Acquisition of additional aberrations during clonal evolution usually leads to rapid disease progression. The aim of our study was to thoroughly analyze bone-marrow cells of five MDS patients with sole del(5q) in the original clone and with successive linear or divergent clonal evolution proved in ancestral cell clones.

Bone-marrow samples were analyzed by conventional G-banding, I-FISH/mFISH/mBAND (MetaSystems) and aCGH/SNP microarray (Illumina). To detect TP53 mutations, NGS (GS Junior system, Roche) was used.

In all five patients, interstitial del(5q), extending between 5q13.4 and

5q35.2, encompassed commonly deleted regions 5q31 and 5q33. Clonal evolution concerning 5q included the duplication of deleted chromosome 5 in one sample and new translocation t(X;5)(q13;q12) in the other one. However, additional chromosomal changes acquired during clonal evolution were identified across the whole genome. Most frequently affected chromosome arms were 11q (9x), 11p (6x) and 17p (6x). In four of five patients copy number neutral loss of heterozygosity (CN-LOH) of 17p and corresponding missense mutations of TP53 gene (17p13.1) were found. The evaluation of primary and secondary aberrations is important for identification of mechanisms involved in clonal evolution of pathological cells, which can contribute to better understanding of the disease progression and is indeed very important for prognosis of the patients. Supported by RVO-VFN64165, GACR P302/12/G157, PRVOUK-P27/LF1/1.

The expression analysis of F2R gene in JAK2V617F mutation positive Polycythemia Vera (PV)

I. Uslu¹, H. Hekimoglu¹, A. S. Yavuz², S. Sözer Tokdemir¹;

¹Department of Genetics, Institute of Experimental Medicine, Istanbul University, Istanbul, Turkey, ²Istanbul Faculty of Medicine, Internal Medicine Division, Department of Hematology, Istanbul University, Istanbul, Turkey.

Introduction: Myeloproliferative neoplasms (MPN) are stem cell originated diseases associated with high risk of thrombosis. 50- 98% of patients carry JAK2V617F. F2R gene, has a role as a receptor regulates thrombotic response. The aim of this study is to analyze the F2R gene expression levels both in CD34+ and mononuclear cells (MNC) of patients related with the JAK2V617F.

Materials-Methods;

MNCs were isolated from peripheral blood of 5 patients who were diagnosed with PV and one cord blood (CB). The cells were stained and sorted against CD34. JAK2V617F were investigated in CD34+ and MNCs using allele-specific nested PCR. F2R gene expression evaluation were performed by real-time RT-PCR in MNCs, CD34+ and HEL. The analysis was performed by using 2-ΔCT.

Results: The analysis for JAK2V617F in patients revealed that four were heterozygous JAK2V617F and one was wild type(wt) JAK2 allele. F2R gene expression analysis of CD34+ between patients and CB revealed the 60.1 ± 49.1 fold increase whereas the MNCs of the same patients has 4.5± 5.7 fold increase compared to CB. There was no difference between JAK2V617F-/+ patients regarding to F2R. HEL, homozygous for JAK2V617F, has 4.1 fold increase.

Conclusion: The analysis of the F2R gene expression has revealed that the CD34+ of patients has statistically significant increase compared to controls. This is the first investigation in literature demonstrating the role of F2R in MPN related with the JAK2V617F. The further studies are needed to address the exact role of F2R and its relationship between disease and pathophysiology.

P12.156

Association between NBN mutation and lung cancer - a new risk factor

J. S. Nowak¹, E. Kałużna¹, J. Rembowska¹, I. Ziółkowska-Suchanek¹, B. Świątek-Kościelna¹, P. Gabryel², W. Dyszkiewicz³;

¹Institute of Human Genetics, Poznan, Poland, ²Department of Thoracic Surgery University of Medical Sciences, Poznan, Poland, ³Department of Thoracic Surgery University of Medical Sciences, Poznan, Poland.

The NBN gene, also known as NBS1, is located on chromosome band 8q21.3 and encodes 754-amino acids protein called nibrin. This protein is a member of the MRN nuclear complex, and is involved in numerous cell processes essential for maintaining genomic stability. Heterozygous variants in the NBN gene, including p.I171V, c.657del5 and p.R215W, have been described as a risk factors for the development of several malignancies. However, there is no report regarding the association of these mutations with lung cancer thus far. Therefore, the present study aimed to evaluate whether there is an association between heterozygous p.I171V, c.657del5 and p.R215W variants of the NBN gene and the risk of developing lung cancer.

The frequency of these variants was estimated in a group of 453 adults diagnosed with non-small cell lung cancer and in healthy controls (2,400 for p.I171V, 2,090 for c.657del5 and 498 for p.R215W). The p.I171V was assessed by restriction fragments length polymorphism analysis of polymerase chain reaction (PCR) products, using MunI (MfeI) restriction enzyme, whereas the c.657del5 and p.R215W were assessed by PCR-single-strand conformation polymorphism method.

A significantly increased risk of developing lung cancer was observed for the p.I171V variant, which was present in 17 (3.75%) of the 453 cases of lung cancer and in 12 (0.5%) of the 2,400 healthy individuals (odds ratio,7.759; P<0.0001).

The results obtained indicated an association between the p.I171V mutation and the development of lung cancer. Therefore, this variant may be considered as a risk factor for non-small cell lung cancer.

tient characteristics of children with a NET. We aimed to investigate the role of genetic predisposition in the etiology of pediatric NETs by collecting data of second primary malignancies and comorbidities suggestive of genetic predisposition.

Patients and methods: Using the nationwide pathology database PALGA, we collected patient- and tumor data of all children diagnosed with a NET in the Netherlands between 1991 and 2013 (N=483).

Results: The incidence of NETs in children in the Netherlands is 5.40 per one million per year. The majority of NETs were appendiceal tumors (N=441; 91.3%). In only 16 patients (3.3%) either locoregional lymph node or distant metastases were present. Three patients with pancreatic NETs were diagnosed with the known tumor predisposition syndromes Von Hippel Lindau disease (N=2) and Multiple Endocrine Neoplasia syndrome type 1 (N=1). One additional patient with NETs in the stomach and pancreas had MEN-1 syndrome. In one patient with an appendiceal NET Familial Adenomatous Polyposis was diagnosed. A role of genetic predisposition was suggestive in several others, e.g. in patients with second primary malignancies (N=6, 1.2%) or multiple NETs (N=5, 1.0%).

Conclusion: We identified a significant number of patients with a confirmed or suspected tumor predisposition syndrome and show that pediatric pancreatic NETs in particular are associated with cancer prone syndromes.

P12.160

NF1 and SPRED1 mutational spectrum of 1.100 unselected patients suspected of having Neurofibromatosis Type 1

B. Campos¹, O. Abad², J. Gardenyes², P. Fabregas², E. López-Toledano², V. Volpini²;
¹Reference Laboratory Genetics, L'Hospitalet de Llobregat, Spain, ²IDIBELL, L'Hospitalet de Llobregat, Spain.

Introduction: Neurofibromatosis type 1 (NF1) [MIM 162200] is a common dominant autosomal disorder, affecting 1 in 3500 individuals and caused by mutations in the *NF1* gene at 17q11.2. Legius syndrome [MIM 611431], caused by mutations in *SPRED1* gene (15q13.2), is characterized by clinical manifestations that overlap NF1, as café-au-lait spots and freckling. **Materials and Methods:** We screened 1.100 unrelated NF1 patients for mutations in *NF1* and *SPRED1* genes, using direct cDNA sequencing complemented with MLPA analysis. **Results:** We identified 710 mutations in *NF1* and 19 in *SPRED1*. Among the 710 changes in *NF1*, 184 (26%) nonsense, 180 (25%) were frameshift mutations, 173 (24%) splice errors, 105 (15%) were missense and 12 (2%) were in frame amino acid deletions/insertions. Furthermore, using MLPA approach we found 55 mutations (8%): 29 total gene deletions, 23 multiexon deletions and 3 multiexon duplications. The subset analysis of *SPRED1* mutated group (n=19) showed 8 (42,5%) missense mutations, 6 (31,5%) frameshift, 2 (10,5%) nonsense, 2 (10,5%) splice errors and 1 (5%) total gene deletion. RNA analysis allowed us to identify 80/729 (11%) mutations that we would not be able to detect or characterize using DNA-based methodologies, as deep intronic mutations or other intronic changes out of canonical GT-AG splice sites. **Conclusions:** Our results confirm that RNA analysis together with MLPA provide a sensitive and specific method for the rapid identification of *NF1* and *SPRED1* mutations. RNA analysis improved our sensitivity over DNA-based methodologies, allowing accurate genetic counselling.

P12.161

Genetic diagnosis of NF1: A 5-year retrospective study evaluating different technologies

M. Lazaro, M. Molero, L. Rausell, A. Gomez, A. Artech, M. Bermejo, C. Ruiz, J. Garcia-Planells, M. Garcia-Hoyos;
 Instituto de Medicina Genómica (IMEGEN), Paterna, Spain.

Neurofibromatosis type 1 (NF1; MIM#162200) is the most common autosomal-dominant neurocutaneous disorder associated with tumor predisposition. The primary clinical features of NF1 are multiple café-au-lait spots, axillary and inguinal freckling, Lisch nodules in the eye and benign peripheral nerve sheath tumors or neurofibromas. This disorder is caused by defects in the tumor suppressor gene *NF1* (MIM*613113). Mosaicism has been described to have important clinical implications in a large number of different diseases; therefore, it also plays an important role in some cases of NF1. During the last 5 years, we have analysed the *NF1* gene in more than 150 patients using different techniques and approaches, including Sanger sequencing at mRNA level, NextGeneDX® (a post-PCR NGS methodology developed and validated by IMEGEN), and MLPA (Multiplex-Ligation Probe Amplification) at DNA level.

We have identified the disease-causing mutation in more than 60% of our studied cohorts and detected all types of truncated germline mutations: nonsense, splicing-site, and small and large deletions/duplications. Besides, NGS technologies enable the detection of disease-causing variations in mosaic. We describe the presence of mosaicism in different tissues and cell

lines in two cases. In one case, nonsense mosaicism disease-causing change (c.3916C>T; p.Arg1306*) was detected. In the other case, two different changes in the same position of the cDNA, in at least two different cell lines (c.7806+2T>G and c.7806+2T>A), were detected

The combination of different techniques that includes NGS DNA sequencing, mRNA Sanger sequencing, and MLPA provides higher diagnostic yield for the detection of disease-causing mutations in *NF1* patients.

Comprehensive analysis of NF1 gene by using targeted resequencing and multiplex ligation-dependent probe amplification in patients with neurofibromatosis type 1

S. Demir Ulusal¹, H. Gürkan¹, E. Atlı¹, D. Eker¹, S. A. Öza², H. Tozkar¹;
¹Trakya University Faculty of Medicine Department of Medical Genetics, Edirne, Turkey, ²Trakya University Faculty of Medicine Department of Ophthalmology, Edirne, Turkey.

Introduction:

NF1 gene consists 57 exons (NM_000267.3) and involvement of various pathogenic variants including single nucleotide variants, in/dels and copy number variants makes difficult to analyse it. We aimed to summarize genetic analysis results of 17 neurofibromatosis patients studied between November 2014-January 2016.

Methods:

Genomic DNA was isolated from peripheral blood samples. *NF1* coding regions were captured with IonAmpliseq DNA Library Preparation Kit and enriched by OT2 200 Kit. Resequencing performed on the Ion Personal Genome Machine. P081.B2 /P82.B2 and P373-B1 multiplex ligation dependent probe amplification (MLPA) probes were used to detect large deletions. ACMG 2015 guidelines, Human Genome Mutation Database, ClinVar, and Leiden Open Variation Database, were used for evaluation of the variant pathogenicity.

Results:

4 splice mutations, 2 frameshift deletions, 1 missense and 3 nonsense mutations defined. Additionally, *NF1* whole gene deletion was found in a patient with MLPA. 27,2% of the mutations found were not previously reported.

Conclusion:

NF1 mutation frequency detected by genomic DNA sequencing was reported to be about 61% compared to our study (58,8%, Table1). MLPA increased the diagnostic yield up to 64,7%. There was at least one additional symptom to café-au-lait spots in most of the *NF1* mutant patients (72.7%) compared to the patients without a mutation or deletion. We suggest that targeted resequencing and MLPA together offer a powerful diagnostic approach for neurofibromatosis in addition to clinical examination.

Until recently, the molecular diagnosis of hereditary breast and ovarian cancer (HBOC) was mostly based on BRCA1/2 testing. Next generation sequencing and the recent discovery of new genes involved in HBOC progressively permitted the transfer of genomic capture targeting multiple candidate genes from research to diagnosis. However, the implication for the management of patients and their families has not been extensively studied. We studied 583 consecutive patients originated from Burgundy (France) fulfilling the criteria for BRCA testing using a next generation sequencing 25-gene panel including 20 candidate predisposition genes for breast and/or ovarian cancer. A pathogenic BRCA1/2 mutation was found in 51 patients (9%). Besides, we found 37 pathogenic or likely pathogenic mutations in 10 different high to low-risk genes in 34 patients (6%). The most fre-

quently mutated genes were CHEK2 (n=12; 2 %), ATM (n=9; 1.5 %), and PALB2 (n=4; 0.6%). Three double-hits and four mutations in MMR genes were also found. Most of mutations were consistent with the spectrum of cancers observed in the patient and/or family (89%). The analysis of clinical actionability performed among the mutation-positive individuals other than BRCA revealed that additional disease specific screening and/or prevention measurers beyond those based on personal and family history alone have been recommended in most of cases (84%). In conclusion, multigene panel testing is a powerful tool for identifying high to low-risk HBOC susceptibility genes. The penetrance and spectrum of cancer associated to these other genes remain sometimes undefined, and further collaborative work is needed to address this question.

P12.164

Targeted next generation sequencing identifies a novel mutation in FANCA gene

M. Dimishkovska¹, S. A. Kocheva², D. Plaseska-Karanfilska¹;

¹Research Center for Genetic Engineering and Biotechnology "Georgi D. Efremov", Skopje, Macedonia, The Former Yugoslav Republic of, ²Pediatric Clinic, Medical Faculty, Skopje, Macedonia, The Former Yugoslav Republic of.

Fanconi anemia (FA) is a rare autosomal recessive or X-linked disorder characterized by clinical and genetic heterogeneity. Characteristic clinical features include developmental abnormalities in major organ systems, bone marrow failure and genomic instability resulting to cancer predisposition. Analysis of three unrelated gypsy families in Macedonia had revealed a homozygous deletion of exon 3 in FANCA gene (c.190-256_283+1680del2040dupC) as a founder mutation in Macedonian FA patients of Gypsy-like ethnic origin (Acta Hematol 2014;132:15-21).

Case report: We report a girl from gypsy minority who was referred to the pediatric clinic at the age of 2,5. The patient had normochromic anemia with thrombocytopenia, increased level of fetal hemoglobin (10.4%) and no skeletal or organ systems abnormalities. After a few months the disease progressed and the intracranial hemorrhage resulted in death.

Due to suspicion of FA, we analyzed the proband for the known founder mutation (deletion c.190-256_283+1680del2040dupC) but we detected the deletion in a heterozygous state. In order to clarify the diagnosis, a targeted resequencing was performed using an Illumina kit TruSight One sequencing panel.

Our filtering approach revealed an undescribed heterozygous mutation c.3446_3449dupCCCT (p.Met1151ProfsTer65) in FANCA gene, located in the region of interaction with the protein FAAP20 important for the functional integrity of the FA pathway.

In conclusion, using targeted NGS we detected a novel mutation in FANCA gene in a patient with Fanconi anemia from Macedonia with gypsy ethnic origin.

P12.165

Multiple gene panel testing unravels rare aspects of cancer genetics

F. Fostira, I. Konstantopoulou, P. Apostolou, I. Konstanta, V. Mollaki, A. Vagena, M. Papamentzelopoulou, D. Yannoukakos;

Molecular Diagnostics Laboratory, INRASTES, NCSR, Demokritos, Athens, Greece.

Next-generation sequencing (NGS) and more specifically, customized gene panels, have replaced conventional Sanger sequencing and became the gold standard for hereditary cancer diagnostics. Through this technology, we report a number of interesting findings, which would have been missed by other methods.

Case 1. A female with early onset breast cancer was found to be a double heterozygote for loss-of-function mutations in both PTEN and PALB2 genes. Case 2. A rare case of TP53 mosaic event has been detected in a man who was previously diagnosed with four primary cancers. The TP53 missense mutation, located in the DNA binding domain, has been identified in 9.2% of the total reads.

Case 3. Family relatives within a family with multiple cases of ovarian cancer were found to carry two different BRCA1 deleterious mutations.

Case 4. Two sisters diagnosed with early onset breast cancer. One of them carries a PALB2 missense mutation with potential pathogenicity, while the other carries a BRCA2 pathogenic mutation.

Case 5. In a family with three cases of premenopausal breast cancer, proband tested negative, while a MEN1 pathogenic mutation was detected in the second member tested. Subsequently, her daughter was diagnosed with neuroendocrine pancreatic cancer and was also found to carry the MEN1 mutation.

All the above highlight the different aspects in genetics that arise through the evolution of NGS technologies, from explaining missing heritability and

elucidating unclear phenotypes, to raising new questions about whether to report incidental findings and whether predictive testing versus full testing is always sufficient.

Molecular diagnosis of inherited colorectal cancer using NGS panel

S. Baert-Desurmont, F. Charbonnier, S. Coutant, M. Vezain, R. Lanos, J. Bou, E.

Bouvignies, S. Fourneau, S. Manase, S. Vasseur, G. Bougeard, J. Mauillon, I. Tournier, T. Frebourg;

Department of Genetics Rouen University Hospital and Inserm U1079, Rouen University, Normandy Centre for Genomics and Personalized Medicine, Rouen, France.

We have developed and optimized a massive parallel sequencing strategy for the diagnosis of inherited forms of colorectal cancer (CRC). This strategy is based on (1) a panel of 10 genes involved in Mendelian forms of CRC (MLH1, MSH2, MSH6, PMS2, APC, MUTYH, STK11, SMAD4, BMPR1, PTEN), (2) a quick capture of exonic and intronic sequences using Sureselect Agilent QXT, (3) sequencing on MiSeq and NextSeq 500 Illumina platforms, (4) double bioinformatics pipelines including CASAVA (Illumina) and BWA-GATK (Broad Institute) softwares for alignment and variant calling, Alamut Batch (Interactive BioSoftware) for annotation, completed by CANOE software for the rearrangement detection, (5) automatically generated quality reports and (6) systematic control of the genotypes, using Sanger sequencing or QMPSF for the positive cases and Multiplex SnapShot analysis of SNPs for the negative cases. Analysis of 1200 index cases allowed us to identify a deleterious mutation in 18% of the patients and the mutation detection rate reached 32% in Lynch syndrome suspected by tumour analyses. The main advantages of this strategy are the reduction of molecular diagnosis delay, the correction of the diagnosis in cases of overlapping phenotypes (MUTYH biallelic mutation mimicking Lynch syndrome) and the detection of mosaics and cryptic alterations.

Comprehensive identification of genes driven by ERV9-LTRs reveals TNFRSF10B as a re-activatable mediator of testicular cancer cell death

U. Beyer^{1,2}, S. K. Kroenung¹, A. Leha³, L. Walter⁴, M. Döbelstein¹;

¹University Goettingen, GZMB, Department of Molecular Oncology, Goettingen, Germany,

²Medical University Hannover, Department of Human Genetics, Hannover, Germany,

³University Goettingen, Department of Medical Statistics, Goettingen, Germany, ⁴German Primate Center, Primate Genetics Laboratory, Goettingen, Germany.

The long terminal repeat (LTR) of human endogenous retrovirus type 9 (ERV9) acts as a germline-specific promoter that induces the expression of a proapoptotic isoform of the tumor suppressor homologue p63, GTAp63, in male germline cells. Testicular cancer cells silence this promoter, but inhibitors of histone deacetylases (HDACs) restore GTAp63 expression and give rise to apoptosis. We show here that numerous additional transcripts throughout the genome are driven by related ERV9-LTRs. 3' Rapid amplification of cDNA ends (3' RACE) was combined with next-generation sequencing to establish a large set of such mRNAs. HDAC inhibitors induce these ERV9-LTR-driven genes but not the LTRs from other ERVs. In particular, a transcript encoding the death receptor DR5 originates from an ERV9-LTR inserted upstream of the protein coding regions of the TNFRSF10B gene, and it shows an expression pattern similar to GTAp63. When treating testicular cancer cells with HDAC inhibitors as well as the death ligand TNF-related apoptosis-inducing ligand (TRAIL), rapid cell death was observed, which depended on TNFRSF10B expression. HDAC inhibitors also cooperate with cisplatin (cDDP) to promote apoptosis in testicular cancer cells. ERV9-LTRs not only drive a large set of human transcripts, but a subset of them acts in a proapoptotic manner. We propose that this avoids the survival of damaged germ cells. HDAC inhibition represents a strategy of restoring the expression of a class of ERV9-LTR-mediated genes in testicular cancer cells, thereby re-enabling tumor suppression.

P12.168

Germline mutations in 94 cancer predisposition genes among large epithelial ovarian cancer cohort

R. Janavičius^{1,2}, V. Rudaitis³, N. Archipova¹, L. Griškevičius¹;

¹Vilnius University Hospital Santariskiu Clinics Hematology, Oncology and Transfusion Medicine Center, Vilnius, Lithuania, ²State Research Institute Innovative Medicine Center, Vilnius, Lithuania, ³Vilnius University Hospital Santariskiu Clinics, Dept. of Oncogynecology, Vilnius, Lithuania.

INTRODUCTION. Recent advances in massive parallel DNA sequencing led to the generation and application of various cancer predisposition genes (CPG) panels, improving the stratification of genetic cancer subtypes for better

management and targeted therapy. To determine the utility of multigene testing approach we assessed the frequency of pathogenic variants in 94 pan-CPGs in a large epithelial ovarian cancer (EOC) cohort from a homogenous population of Lithuania.

METHODS. Patients with EOC (n=586) w/wo family history (FH) were recruited through single hospital center (VUHSC HOTC) and germline DNA was sequenced and analysed using Illumina Miseq multigene panels of 94 CPGs, including BRCA1 and BRCA2.

RESULTS. Deleterious (class IV/V) mutations were identified in 35,6% all EOC patients. Of these, 29,4% had mutations in BRCA1 (26,5%) and BRCA2 (2,9%) genes, whereas 6,3% harboured mutations in other CPG, including RAD51C, BRIP1, ATM, STK11, MUTYH, MLH1, MSH6, TP53, CHEK2, WRN, FANCI. In patients w/o FH pathogenic BRCA1/2 mutations were found in 18,3% and 4,2% harboured mutations in other genes. EOC patients with pathogenic CPG mutations were diagnosed at an earlier age (p<0,001).

CONCLUSION. The heritable component of EOC due to mutations in other genes than BRCA1/2 genes is less prevalent and not affected by FH. Clinical utility for newer genes remains to be established.

P12.169

Analysis of germline HABP2 G534E variant in Spanish families with Nonmedullary Thyroid Cancer

M. Ruiz-Ferrer^{1,2}, R. M. Fernández^{1,2}, E. Navarro^{3,2}, G. Antiñolo^{1,2}, S. Borrego^{1,2};

¹Department of Genetics, Reproduction and Fetal Medicine, Institute of Biomedicine of Seville (IBIS), University Hospital Virgen del Rocío/CSIC/University of Seville, Seville, Spain, ²Centre for Biomedical Network Research on Rare Diseases (CIBERER), Seville, Spain, ³Department of Endocrinology, Institute of Biomedicine of Seville (IBIS), University Hospital Virgen del Rocío/CSIC/University of Seville, Seville, Spain.

Nonmedullary thyroid cancer (NMTC) comprises thyroid cancers of follicular cell origin and accounts for more than 95% of all thyroid cancer cases. Recently, using NGS technologies and further functional studies, the G534E variant in *HABP2* gene has been implicated in familial NMTC. However, the role of this variant has generated the latter scientific comments due to the higher reported frequencies in public database. Subsequently, several cohorts of patients from different ethnical origin have been evaluated with different results reported. Therefore, the added collaborative effort of testing this variant in NMTC families has been requested to further clarify its role. In this sense, we have evaluated the G534E variant in 14 Spanish families with NMTC (13 papillary thyroid cancer, PTC; and 1 follicular thyroid cancer, FTC), including 30 affected and 46 unaffected individuals. As a result, we only found two heterozygous variant carriers, both in the same family, but clearly showing no segregation between PTC and the G534E variant. Specifically, there was one PTC patient in this family who does not carry the *HABP2* variant and one of the identified carrier was an unaffected individual. In addition, we examined this variant in 267 Spanish controls exomas available in the context of the Medical Genome Project. Among them, 6 individuals (2.24%) were heterozygous for the variant (MAF = 0.0112). According to this, our results suggest that the G534E variant in *HABP2* might not be associated with familial NMTC in the Spanish population.

Oral squamous cell carcinoma: can the genes predict a second primary tumor?

I. M. Carreira^{1,2}, I. P. Ribeiro^{1,2}, F. Marques^{2,3,4}, F. Caramelo⁵, A. Santos¹, M. J. Julião⁶, J. P. Baptista^{2,3}, J. B. Melo^{1,2};

¹Cytogenetics Laboratory, Faculty of Medicine, University of Coimbra, Coimbra, Portugal, ²CIMAGO - Center of Investigation on Environment Genetics and Oncobiology, Coimbra, Portugal, ³Department of Dentistry, Faculty of Medicine, University of Coimbra, Coimbra, Portugal, ⁴Stomatology Unit, Coimbra Hospital and University Centre, CHUC, EPE, Coimbra, Austria, ⁵Laboratory of Biostatistics and Medical Informatics, IBILI - Faculty of Medicine, University of Coimbra, Coimbra, Portugal, ⁶Department of Pathology, Coimbra Hospital and University Centre, CHUC, EPE, Coimbra, Portugal.

Introduction: Oral squamous cell carcinoma (OSCC) patients are at elevated risk of second primary tumors (SPT) with significant reduction of 5-year survival. For OSCC management the identification of molecular markers with predictive value of relapse risk development and of response to the treatment is pivotal. **Material and Methods:** We identified the genomic and epigenetic profile of a primary tongue tumor and of a SPT in the floor of the mouth of the same patient, diagnosed four years and eight months later. Primary tumor, SPT and macroscopically tumor free tissue from SPT were analyzed. This study was conducted using array-Comparative Genomic Hybridization and Methylation-Specific Multiplex Ligation-dependent Probe

Amplification. Results: The patient was 49 years old male at the time of the primary tumor diagnosis and a heavy smoker (≥20 cigarettes/day). Treatment of primary tumor was radiochemotherapy and surgery for SPT. SPT presented more aberrations than primary tumor. However, primary tumor and SPT shared several genomic imbalances, namely at 17 and 19 chromosomes. Copy number alterations in genes related with radioresistance and worse prognosis were identified. WT1, CHFR and GATA5 methylated in tumor and macroscopically tumor free tissue of SPT were detected. Three months after SPT diagnosis the patient presented a tumor in larynx. **Conclusions:** Genomic and epigenetic profile of tumors in different anatomic subsites seems to be different, even in the same patient exposed to the same risk factors. The molecular signatures seem to be pivotal to help in the early detection of SPT, to predict tumor behavior and response to therapy.

Ovarian carcinomas and hereditary cancer syndromes

L. Libera¹, I. W. Carnevali², L. Cimetti², N. Sahnane³, T. Rossi³, G. Formenti³, A. Chiaravalli², D. Furlan¹, C. Riva¹, M. G. Tibiletti²;

¹University of Insubria, Varese, Italy, ²Ospedale di Circolo, Varese, Italy, ³Ospedale del Ponte, Varese, Italy.

Introduction: About 23% of ovarian carcinomas (OC) are related to hereditary conditions, mainly Hereditary Breast Ovarian Cancer (HBOC) and Lynch syndrome (LS). The identification of germline mutation represents a fundamental step in the management of these patients and their relatives. Patients: 126 women affected by OC referred to our Genetic Counseling Service for a suspected inherited cancer syndrome. 110/126 patients underwent BRCA1/2 or MMR germline genetic test based on their family history and/or somatic analyses for MMR defects.

Results: Somatic MMR analysis was performed on 45 OC and 14 of these resulted MMR defective. Six of 14 patients revealed MMR pathogenetic germline variants, 5 showed variants of uncertain significance (VUS) and 3 had sporadic cancers. In the remaining 96 patients with OC, the germline BRCA test was performed and a pathogenetic variant of BRCA1 or BRCA2 genes was identified in 43 women. The global detection rate (DR) of hereditary syndromes was 45% (49/110). Mutated and wildtype patients had the same age of OC onset (50.2ys). Interestingly, the mean age of OC onset in LS patients was lower than that of HBOC patients (45ys vs 51.6ys). Regard to histological types of OC, in both LS and HBOC patients, endometrioid, serous, clear cells and mixed carcinomas and carcinosarcomas were observed suggesting that in these syndromes is not involved an exclusive OC histological type.

Conclusions: The OC is a sentinel cancer for inherited cancer syndromes identification independently to histological type and age of onset.

P12.172

A Hot-spot of In-frame Duplications Activates the Oncoprotein AKT1 in Juvenile Granulosa Cell Tumors

A. Todeschini¹, L. Bessière¹, A. Auguste¹, S. Sarnacki², D. Flatters³, B. Legois¹, A. Zider¹, S. Caburet¹, C. Sultan⁴, N. Kalfa⁴, L. Galmiche², R. A. Veitia¹;

¹Institut Jacques Monod/CNRS/Université Paris Diderot-Paris VII, PARIS, France, ²Hôpital Necker Enfants-Malades/Université Paris Descartes-Paris V, PARIS, France, ³INSERM UMR973/Université Paris Diderot-Paris VII, PARIS, France, ⁴University Hospital of Montpellier/Hôpital Lapeyronie, MONTPELLIER, France.

Ovarian granulosa cell tumors are the most common sex-cord stromal tumors and have juvenile (JGCTs) and adult forms. The molecular basis of JGCTs is poorly understood although mutations in the *GNAS* gene have been reported but only in 30% of the analyzed JGCTs. We have searched for alterations in other proteins involved in ovarian mitogenic signaling. This led us to detect in-frame duplications within the oncogene *AKT1* in >60% of the JGCTs studied and point mutations affecting highly conserved residues in tumors without duplications. Subcellular localization analyses of the mutated proteins and functional explorations using Western-blot and luciferase assays showed that *AKT1* variants bearing the duplications located at the plasma membrane and were hyperactive. To gain insights into the effects of these mutations and the existence of potential co-driver alterations, we performed transcriptome of four JGCTs. RNA-Seq data analyses showed that the duplications were the sole lesions common to the four tumors suggesting a causative role. They also pinpointed a series of differentially expressed genes, involved in cytokine and hormone signaling and cell division-related processes. Our results suggested that most of the transcriptomic dysregulation might be mediated by a limited set of transcription factors perturbed by *AKT1* activation. Finally, we show that commercially available *AKT* inhibitors can modulate the in vitro activity of various mutated forms. Our study incriminates somatic *AKT1* mutations as a major event in the pathogenesis of JGCTs and provide therapeutic leads for a targeted treatment.

P12.173

Exploring the non-randomness of somatic mutations in cancer genomes

M. D. Stobbe^{1,2}, **D. Kedra**^{1,2}, **M. Oliva**^{1,2,3}, **E. Raineri**^{1,2}, **I. G. Gut**^{1,2}, *Pan-Cancer Analysis of Whole Genomes study of the International Cancer Genome Consortium; ¹CNAG-CRG, Centre for Genomic Regulation (CRG), Barcelona Institute of Science and Technology (BIST), Barcelona, Spain, ²Universitat Pompeu Fabra (UPF), Barcelona, Spain, ³University of Chicago Department of Medicine & Institute for Genomics and Systems Biology, Chicago, IL, United States.*

Mutation rates in tumors are higher than basal mutation rates in unaffected tissues. However, given the sheer size of the human genome it is still improbable that identical mutations are recurrent by chance. To explore this hypothesized non-randomness of somatic mutations we used a pilot dataset of 2049 cancer genomes from the Pan-Cancer Analysis of Whole Genomes project of the International Cancer Genome Consortium, for which the somatic mutation calls were available from one of the pipelines used in this project. We first normalized the mutation calls to make them comparable across samples and applied the filters provided by the pipeline. To reduce false positives, we removed all calls found in Kaviar or dbSNP, two variant databases. This left us with ~31 million unique Somatic Single-base Mutations (SSMs) of which ~43.000 are recurrent, i.e. present in 3 or more tumours, and ~2 million unique Somatic Insertion/deletion Mutations (SIMs) of which ~130.000 are recurrent. We selected the top 10 ranking recurrent SSMs, SIMs and 2bp deletions, which define 30 sets of samples, to identify genomic and phenotypic events that co-occur with the selected recurrent mutation.

Multiple sets of samples share, i.e., more mutations between them than randomly selected samples without the specific mutation. Nearly all sets contain samples from different cancer types suggesting relevant pan-cancer commonalities. In one such case with samples from colon, stomach and uterine cancer, the processes behind the non-randomness of the mutations may be the DNA damage repair pathways that are often defective in these three cancers.

P12.174

The pancreatic master genes expression in Panc1 cells stimulated with TGFβ1

L. Kondratyeva¹, **A. Sveshnikova**^{1,2}, **I. Chernov**¹, **E. Kopancev**¹, **E. Sverdlov**^{1,2,3}; *¹M.M. Shemyakin and Yu.A. Ovchinnikov Institute of bioorganic chemistry of the Russian Academy of Science, Moscow, Russian Federation, ²Lomonosov Moscow State University, Moscow, Russian Federation, ³Institute of Molecular Genetics Russian Academy of Sciences, Moscow, Russian Federation.*

Introduction: One of the most important events of cancer progression is an epithelial-mesenchymal transition (EMT). Activation of EMT program is realized by mean growth factors, for instance, TGFβ1. The goal of this project was expression level analysis of genes of master factors that manage developing pancreas in cell line Panc1 stimulated with TGFβ1

Materials and Methods: To perform this study we cultivated Panc1 cells during 120 hours with TGFβ1. Changes in the cells were analyzed by Western blot test and qRT-PCR for the 4 genes marked EMT and the 13 master factors genes.

Result: Stimulation of Panc1 with TGFβ1 has resulted in changing cell epithelial to mesenchymal morphology, increasing level of SNAIL and decreasing level of E-cadherin. Besides the relative expression levels of *SNAI1* and *SNAI2* genes increased 6- and 25-fold, respectively, expression levels of *CDH1* and *KRT8* decreased 25- and 15-fold, respectively. For the selected master genes suppression of expression level *SOX9* twice, *FOXA2* 5-fold and *GATA4* 4-fold was revealed. Expression of *PTF1A*, *PDX1*, *HNF1b*, *NEUROG3* genes was not detected, expression level of *GATA6*, *HES1*, *NKX6.1*, *NRSA2*, *RBPJL* and *ONECUT1* has not changed.

Conclusion: Visual observation during 120 hours and changing profiles of protein and genes marked EMT after incubation with factor prove that addition of TGFβ1 in the cell medium induce EMT process. Among the 13 selected genes of master factor of pancreas development *SOX9*, *FOXA2* and *GATA4* genes changed their expression levels.

Regulation of GAD expression in human pancreatic cancer cell lines

M. L. Svirtlih^{1,2}, **D. Drakulic**¹, **Z. Katarova**², **M. Mojsin**¹, **Z. Mate**², **M. Stevanovic**¹, **G. Szabo**²; *¹Institute of Molecular Genetics and Genetic Engineering, University of Belgrade, Belgrade, Serbia, ²Division of Medical Gene Technology, Institute of Experimental Medicine, Hungarian Academy of Sciences, Budapest, Hungary.*

Introduction: Pancreatic ductal adenocarcinoma (PDAC), most common

type of pancreatic cancer is an aggressive disease with dismal prognosis mainly because it is generally discovered very late and it is resistant to chemotherapy. Aside from the role as a major inhibitor neurotransmitter in the brain, GABA (γ-aminobutyric acid) has emerged as a stem and cancer cell signaling molecule in different tissues. Glutamic acid decarboxylase (GAD), the biosynthetic enzyme for GABA, exists in two forms- GAD65 and GAD67 that are usually co-expressed in various ratios in the GABAergic cells but differ in subcellular localization, kinetics and cofactor binding.

Materials and Methods: The RT-PCR and immunocytochemistry assays were used to access the gene and protein expression in three PDAC cell lines, Panc1, MiaPaCa2 and HPAF II.

Results: Our results show that, in contrast to healthy exocrine pancreas PDAC cell lines express the GAD isoforms, GABA receptors and accumulate GABA. Specific activation of GABA receptors significantly increased the proliferation rate of these cells. Finally, following the treatment with the chemotherapeutic agent retinoic acid we detected altered expression of GAD65/GAD67 genes, as well as cancer stem cell transcription factor, SOX2.

Conclusion: The identification of molecules and proteins involved in development and progression of PDAC is critical to develop novel active drugs. Our data provide new insights into the role of GABA in pancreas as a modulator of cellular proliferation and/or differentiation during tumorigenic cell transformations. Expression of survivin and its splice variants in pediatric acute lymphoblastic leukemia

E. Eren-Keles¹, **H. G. Karabulut**², **H. F. Cakmakli**³, **B. Adakli-Aksoy**³, **S. K. Kose**⁴, **H. Dincaslan**³, **L. G. Yavuz**³, **M. Ertem**³, **A. Tukun**²;

¹Ankara University Institute of Biotechnology, Ankara, Turkey, ²Ankara University School of Medicine, Department of Medical Genetics, Ankara, Turkey, ³Ankara University School of Medicine, Department of Pediatric Hematology and Oncology, Ankara, Turkey, ⁴Ankara University School of Medicine, Department of Biostatistics, Ankara, Turkey.

Introduction: Survivin (BIRC5) is a member of the inhibitor of apoptosis protein family and involved in inhibition of apoptosis and regulation of cell division. High expression of survivin mRNA has been shown in several human cancers including hematological malignancies. However, expression level of survivin in pediatric acute lymphoblastic leukemia (ALL) and its prognostic value has not been well studied.

Materials and Methods: 41 pediatric B-precursor ALL patients and six healthy donors were included in this study. Expression of survivin and its splice variants including ΔEx3, 2B, 3B and 2α was investigated by real-time PCR both at first diagnosis and in remission periods of patients divided into high (n=16) and standard risk (n=25) groups according to age, white blood cell count and genetic risk factors. In addition, survivin variant(s) that may affect the response to the treatment was also investigated.

Results: Expression levels of survivin and survivin-ΔEx3 were found to be higher in patient group than controls, and survivin-3B was found at increased levels in high risk group both at first diagnosis and remission periods. The ratio of survivin-2α/3B expression was also higher at diagnosis than remission period.

Conclusion: Our results suggest that survivin and survivin-ΔEx3 may be a risk factor for childhood ALL. On the other hand, survivin-3B can be used in risk classification and as a therapeutic target. Survivin-2α/3B and survivin-ΔEx3/WT may also be taken into consideration in risk classification.

Microdeletion 19p13.3 including STK11 gene in a patient with Peutz-Jeghers syndrome and dysmorphic features

C. Machado, **P. Dias**, **J. Dupont**, **R. Silveira-Santos**, **S. Serafim**, **A. Sousa**; *Serviço de Genética Médica, Departamento de Pediatria, Hospital de Santa Maria, Centro Hospitalar Lisboa Norte, Centro Académico de Medicina de Lisboa, Lisboa, Portugal.*

Introduction: Peutz-Jeghers (PJS) is an autosomal dominant cancer predisposition syndrome characterized by gastrointestinal hamartomatous polyposis and mucocutaneous pigmentation. Germline point mutations and partial/whole exon deletions in STK11 can be identified in about 70% and 30% of patients with PJS, respectively. Only a few carriers of large genomic deletions at 19p13.3 encompassing STK11 have been previously reported.

Case presentation: A 31 year-old woman was referred for genetic evaluation for dysmorphism. Family history was unremarkable. She had normal intel-

lect. In her late teens, a jejunal villous polyp and pseudopolyps of the ileus and cecum had been removed. She had also been noticed to have lip pigmentation. However, sequencing of STK11 found no mutation. On observation, she presented thick eyebrows, long down-slanting palpebral fissures, ocular proptosis, high nasal bridge, hanging columella, black-pigmented spots on the lips and a sandal gap.

Results: MLPA using DNA extracted from peripheral blood revealed a probable total deletion of one copy of STK11: c.(?-1100)(_*3276_?); array-CGH (NimbleGen CGX 135K, Perkin Elmer) confirmed the presence of a clinically significant interstitial deletion (410.30kb) within 19p13.3. The deletion was de novo and involved 13 OMIM genes, including STK11.

Conclusion: PJS features in our patient are a consequence of STK11 haploinsufficiency. Dysmorphisms common to our patient and similar reported cases in the literature support the notion that genes in the neighborhood of STK11 are responsible for a clinically recognizable phenotype. This case strengthens the need to screen for large deletions in patients presenting with PJS together with dysmorphic and/or other atypical clinical features.

P12.178

Whole-genome microarray analysis to establish genetic profiles of pilocytic astrocytomas

J. N. Sanmann¹, A. T. Calleroz², J. M. Stevens¹, M. Nelson¹, P. A. Althof¹, D. L. Pickering¹, N. Lu¹, C. Lettieri³, L. J. Starr⁴, D. Perry⁵;

¹Human Genetics Laboratory, Munroe-Meyer Institute at the University of Nebraska Medical Center, Omaha, NE, United States, ²Department of Pathology and Microbiology, University of Nebraska Medical Center, Omaha, NE, United States, ³Department of Pediatrics Hematology/Oncology, University of Nebraska Medical Center, Omaha, NE, United States, ⁴Department of Genetic Medicine, Munroe-Meyer Institute at the University of Nebraska Medical Center, Omaha, NE, United States, ⁵Department of Pathology, Children's Hospital & Medical Center, Omaha, NE, United States.

Introduction: Pilocytic astrocytomas, the most common pediatric brain tumor, are low-grade gliomas. Although distinct clinical features exist, the histopathological diagnosis of pilocytic astrocytoma can be challenging because of the wide morphologic spectrum and histopathological overlap with high grade malignancies. A MAPK pathway aberration involving *BRAF* has been reported in pilocytic astrocytomas, but nearly one-third lack the presence of a unique, detectable genetic hallmark. This study aimed to molecularly characterize a cohort of pilocytic astrocytomas for identification of additional genetic signatures that may provide additional information to assist in making the correct pathologic diagnosis.

Methods: DNA was extracted from archived paraffin-embedded tissue from 18 pediatric pilocytic astrocytomas. Microarray was performed using the Affymetrix OncoScan® FFPE Assay according to standard protocol (Santa Clara, CA) for identification of clinically-relevant copy number variants (CNVs) and regions of copy-neutral loss of heterozygosity (CN-LOH).

Results: CNVs involving *BRAF* were identified in 13/18 (72%) of cases: gain encompassing both *KIAA1549* and *BRAF* loci (n=12) and deletion in *BRAF* (n=1). Whole chromosome gains were the next frequent CNV noted, with recurrent involvement of chromosomes 5 and 6 (n=2). Additional, less frequent CNVs and CN-LOH were present throughout the cohort.

Conclusions: Microarray analysis is a cost-effective tool for the identification of the hallmark genetic aberrations reported in pilocytic astrocytomas, including deletions and duplications of *BRAF*. Additionally, the whole-genome platform allows for characterization of additional neoplastic markers that may have diagnostic and prognostic implications.

Analytical challenges in the study of PMS2 for Lynch syndrome genetic diagnosis. Long range PCR matters

V. M. Barberá, M. I. Castillejo, A. Castillejo, J. L. Soto;
Hospital Universitario Elche, Elche, Spain.

Introduction: Genetic tests for Lynch Syndrome are well standardized and broadly used, although there remain some specific difficulties that need to be addressed to reach an optimal diagnosis. The analysis of PMS2 gene is especially complex because of the high number and homology with several pseudogenes. We report the problem raised by differences in sensibility and specificity to detect genetic variants depending on polymerases enzyme blends and master mixes used for long range PCRs (LR-PCR).

Materials and Methods: Two cases with suspicious of Lynch Syndrome were tested for mutations in PMS2 using two different commercial LR-PCR kits in parallel (LongRange_PCR_kit, QIAGEN and Expand_LonRange_dNT-Pack, Roche). The amplicons generated by LR-PCR contained the exons 1-5 (9.964bp), exons 11-12 (8812bp) and exons 13-15 (9804bp). Next, we performed nested PCR by the same master mix (AmpliTaQ Gold 360, Life Tech-

nologies).

Results: Using the first LR-PCR kit we detected a new pathogenic variant: 97bp deletion in I01-E02 boundary (c.24-12_109del) that was confirmed in independent experiments and both strands. This mutation could not be detected using the second LR-PCR kit. Moreover, the analysis of a second case showed a missense variant in E02:c.137G>T;p.(Ser46Ile) detected by the second, but not with the first LR-PCR kit. This variant could not be confirmed in both strands and was considered as an artifact.

Conclusions: LR-PCR can be used to amplify the PMS2 gene and avoid pseudogene interference previously to sequence (Sanger or NGS) although a detailed validation analysis is needed to provide a clinically useful analysis of PMS2.

P12.180

Germline POLD1 mutation can mimic Lynch syndrome

M. Castillejo¹, A. Castillejo¹, E. Hernández-Illán¹, I. Tena², J. Soto¹;

¹Hospital Universitario Elche, Elche, Spain, ²Hospital Provincial Castellón, Castellón, Spain.

Introduction: Lynch syndrome (LS) is caused by pathogenic germline variants in one of the mismatch repair (MMR) genes and patients have a high risk of developing colorectal cancer and other tumors. Microsatellite instability (MSI) and loss of MMR protein expression are the molecular hallmarks of LS tumors. Recently, it has been suggested that mutations in *POLE* and *POLD1* genes might explain part of the suspected LS cases without mutations in MMR genes.

Materials/Methods: We analyzed germline mutations at *POLE* (exon 13) and *POLD1* (exon 11) genes in 327 unexplained suspected LS cases. From these, 158 tumors had normal expression and 165 tumors had loss of expression of MMR proteins. Analysis of *MLH1* somatic mutations in tumor was performed in one case of interest.

Results: We found three mutated individuals among cases with normal MMR protein expression (1.9%). Two cases had *POLD1_Leu474Pro* mutation and one case had *POLE_Leu424Val* mutation. These three cases fulfilled Amsterdam II criteria.

Another individual with the *POLD1_Leu474Pro* mutation was found among cases with loss of MMR protein expression (0.6%). This patient was diagnosed of colorectal cancer at age 51 with no family history of cancer. His tumor showed loss of *MLH1* expression without *MLH1* promoter methylation and wild-type for *BRAF_V600E* mutation. Germline analysis of *MLH1* did not show any pathogenic alteration. Tumor analysis of *MLH1* showed a homozygous/hemizygous nonsense pathogenic variant [(c.1279C>T; p.(Glu427*)] suggesting somatic inactivation of *MLH1* as a consequence of *POLD1* deficiency.

Conclusion: Mutations at *POLD1* can induce tumorigenesis via MSI-pathway mimicking Lynch syndrome.

P12.181

Combined mismatch repair and POLE/POLD1 defects explain unresolved suspected Lynch Syndrome cancers

A. M. L. Jansen^{1,2}, T. van Wezel¹, B. E. W. M. van den Akker¹, M. Ventayol Garcia¹, D. Ruano¹, C. M. J. Tops³, A. Wagner⁴, T. G. W. Letteboer⁵, E. B. Gómez-García⁶, P. Devilee⁷, J. T. Wijnen^{2,3}, F. J. Hes⁵, H. Morreau⁴;

¹Department of Pathology, Leiden University Medical Center, Leiden, Netherlands,

³Department of Clinical Genetics, Leiden University Medical Center, Leiden, Netherlands,

⁴Department of Clinical Genetics, Erasmus University Medical Center, Rotterdam, Netherlands,

⁵Department of Medical Genetics, University Medical Center Utrecht, Utrecht, Netherlands,

⁶Department of Clinical Genetics, University Hospital Maastricht, Maastricht, Netherlands,

⁷Department of Pathology, Leiden University Medical Center/Department of Human Genetics, Leiden University Medical Center, Leiden, Netherlands.

Introduction: Many suspected Lynch Syndrome (sLS) patients who lack mismatch repair (MMR) germline gene variants and *MLH1* or *MSH2* hypermethylation are currently explained by somatic MMR gene variants or, occasionally, by germline *POLE* variants.

Materials and Methods: To further investigate unexplained sLS patients, we analyzed leukocyte- and tumor DNA of a cohort of 62 sLS patients using gene panel sequencing including the *POLE*, *POLD1* and MMR genes.

Results: Forty tumors showed either one, two or more somatic MMR variants predicted to affect function. Nine sLS-tumors showed an ultramutated phenotype and were found to carry germline- (n=2) or somatic variants (n=7) in the *POLE/POLD1* exonuclease domain (EDM). Six of these *POLE/POLD1*-EDM mutated tumors also carried somatic MMR variants. Four of these tumors showed low or high microsatellite instability.

Conclusions: Our findings suggest that faulty proofreading may result in

loss of MMR and thereby in microsatellite instability. While literature mainly addresses POLE/POLD1 variant in microsatellite stable tumors, somatic POLE/POLD1 variants in sLS patients are likely to be overlooked. Our results further emphasize the importance of POLE/POLD1 germline and somatic screening in unexplained MSI-H and MMR-deficient tumors. Promoter methylation profiling of head and neck squamous cell carcinoma

S. Stangler Herodez¹, B. Zagradisnik¹, B. Cizmarevic², N. Kokalj Vokac^{1,3};
¹Laboratory of Medical Genetics, UKC Maribor, Maribor, Slovenia, ²Department of Otorhinolaryngology and Maxillofacial Surgery, UKC Maribor, Maribor, Slovenia, ³University of Maribor, Faculty of Medicine, Maribor, Slovenia.

Introduction Silencing of tumor suppressor genes by DNA promoter hypermethylation is an early event in carcinogenesis and a potential target for personalized cancer treatment. In head and neck squamous cell carcinoma (HNSCC) limited knowledge is available about the role of promoter hypermethylation in cancer progression.

Materials and methods In present work we have investigated DNA methylation of 24 different tumor suppressor genes in 62 patients with various stages of HNSCC (34 oral squamous cell carcinoma (OSCC) and 28 oropharyngeal squamous cell carcinoma (OPSCC)) with methylation specific multiplex ligation-dependent probe amplification (MS-MLPA). We analyzed genomic DNA extracted from homogenized fresh-frozen HNSCC tissue specimens.

Results Promoter hypermethylation (≥ 2 genes) was observed in 48 of the 62 cases (77%). HNSCC showed frequent promoter hypermethylation in ATM (67%), TIMP3 (67%), RARB (65%), DAPK1 (55%), CDH13 (55%), APC (36%) and IGSF4 (36%). Total number of hypermethylated genes in OSCCs did not differ statistically from the number of total hypermethylated genes in OPSCCs ($P=0.7866$). Promoter hypermethylation in OSCC didn't reveal statistically significant differences between the early and advanced tumor stage ($P=0.5081$). Similarly OPSCC early onset cases didn't differ from advanced stage cancers ($P=0.6911$).

Conclusion Promoter methylation profiling of HNSCC using MS-MLPA identified ATM, TIMP3, RARB, DAPK1, CDH13, APC and IGSF4 as frequent epigenetic events. Observed findings permit the identification of the nature of the tumor but they don't allow the differentiation according to the tumor stage. Validation of these findings in larger HNSCC units would support these genes as relevant biomarkers for cancer management.

P12.183
Functional analysis of RAD51B and RAD23B SNPs using Circular Chromosome Conformation Capture (4C) in human prostate cell lines.

C. Cieza-Borrella¹, S. Stephens¹, Q. Karlsson¹, R. Eeles^{1,2}, Z. Kote-Jarai¹;
¹The Institute of Cancer Research, Sutton, United Kingdom, ²The Royal Marsden Hospital NHS Trust, London, United Kingdom.

INTRODUCTION: Prostate Cancer (PrCa) is the most frequently diagnosed cancer among men in developed countries. Genome-wide association studies (GWAS) have identified over 100 common, low penetrance PrCa susceptibility variants, some near or within RAD51B and RAD23B genes. Our aim is to better understand associations between these variants and PrCa risk, analysing their interactions with the whole genome, by Circular Chromosome Conformation Capture (4C).

MATERIAL AND METHODS: Genomic interactions of 10 single nucleotide polymorphisms (SNPs), selected from previous GWAS and fine mapping studies, were investigated in five human prostate epithelial cell lines (LN-CaP, DuCaP, PC3, PNT1a and RWPE-1) presenting diverse phenotypes and genotypes. 4C assay design was carried out using 4C Primer Designer for 4C viewpoints program. Libraries were run on an Illumina HiSeq 2500 (RAPID chemistry). Bioinformatics analysis was performed using the program 4C-ker.

RESULTS: Preliminary results show numerous interactions between analysed SNPs and the rest of the genome. Of particular interest; a significant cis association was observed, in all three adenocarcinoma cell lines, between rs7141529 and rs767127 (both RAD51B SNPs) with FUT8. Interaction between rs767127 and the RAD51B promoter region was also detected. In addition rs767127 also presented cis interactions with FOS, YY1 and EVL. We will also present data on the RAD23B SNPs as analysis is currently ongoing. **CONCLUSION:** 4C analysis showed interactions in adenocarcinoma prostate cell lines between rs7141529 and rs767127 and various regions of high interest due to their implications in cancer development. Further analysis, using Chromosome Conformation Capture (3C), will be conducted to validate results.

P12.185
HOXB13 gene exon 1-2 mutations among patients with prostate cancer

D. Alptekin¹, M. A. Erkoç¹, F. Gökalp², M. İzmirlir², Y. Bayazit², N. S. Ilgaz¹, N. Satar², H. Ü. Lüleyp¹;
¹Cukurova University, Medical Faculty, Dept. of Medical Biology, Adana, Turkey, ²Cukurova University, Medical Faculty, Dept. of Urology, Adana, Turkey, ³Mustafa Kemal University, Medical Faculty, Dept. of Medical Biology, Hatay, Turkey.

Introduction: Prostate cancer susceptibility gene is located on chromosome 17q21-22 which is reported to be associated with Homeobox (HOX) gene family. HOX genes' proteins resulting from transcription of this gene is associated with prostate cancer which plays important role in regulation of Androgen receptors. One of the most important members of HOX family is HOXB13. G84E codon mutation of HOXB13 is reported to be associated with prostate cancer. This study aimed to investigate relationship between prostate cancer and HOXB13 exon 1-2 mutations.

Materials and Methods: In this study, 64 prostate cancer patients are involved. After DNA isolation, sequence analysis is performed with Big Dye Cycle sequencing PCR technique. HOXB13 exon 1-2 are amplified and sequence analysis is performed with ABI PRISM® 3100 Genetic Analyzer.

Results: We couldn't determine any G84E mutation. However, 44 normal homozygote(CC), 16 heterozygote(CT) and 4 mutant homozygote(TT) genotypes have been found in 366 base position of the coding region of HOXB13 gene. In addition, 63 normal homozygote and 1 mutant heterozygote(CT) genotypes have been found in 411 position of coding region. Also, 45 normal homozygote(TT), 12 heterozygote(TC) and 7 mutant(CC) genotypes have been found. There was no mutation in exon 2.

Conclusions: Previously described 366 and 513 base mutations have been thought as a polymorphism because of no amino acid substitution in protein of HOXB13. Due to this reason, there is no association between these mutations and prostate cancer. However, it has been thought that there is an association between 411 base mutations and prostate cancer.

P12.186
The prognostic importance of the MGMT and RARβ gene hypermethylation in Primary Glioblastoma

R. Kalkan¹, E. I. Atli², M. Özdemir³, H. E. Aydın³, A. Arslantaş³, S. Artan³;
¹Near East University, Nicosia, Cyprus, ²Trakya University, Turkey, Turkey, ³Eskişehir Osmangazi University, Eskişehir, Turkey.

Background: We screened RARβ and MGMT methylation in 40 primary glioblastoma multiforme (GBM) sample. We used MS-HRM for evaluation of methylation levels in primary GBM samples. This study indicates a potential prognostic value for GBM treatment planning.

Results: MGMT methylation was detected in 13 of the 40 patients (32,5%) and the overall survival time is 19 months for methylated MGMT patients, it is 15 months for unmethylated MGMT patients. MGMT methylation did not significantly associate ($p > 0,05$) with overall survival time MGMT-promoter methylation did not correlate with overall survival (OS; $p > 0,05$).

RARB methylation was detected in 24 of the 40 patients (60%). The overall survival time of the patients with methylated RARβ was 19 months, and nonmethylated RARB was 15 months. The statistical analysis shows that the patients who received both chemotherapy and radiotherapy treatment combined had a survival time of 25 months. The patients who received only radiotherapy or had no treatment protocol had a survival time between 15-20 months, which demonstrates a significant difference ($P < 0.05$). Statistical difference was observed between the survival times of the patients receiving both radiotherapy and chemotherapy treatment and the cases with no applied treatment protocol.

Conclusion: In summary, our results demonstrated that the positive correlation between RARβ methylation status and radio/chemotherapy treatment. Furthermore MGMT promoter methylation had no prognostic value and lower frequency in primary glioblastomas.

Comprehensive Analyses of the Variants of the Oncogene, FAT10 in Hepatocellular Carcinoma (HCC) patients

C. G. Lee^{1,2,3}, C. C. T. Sim², J. Yu^{1,2}, S. S. Theng^{1,2}, S. S. Chong²;
¹National Cancer Centre, Singapore, Singapore, ²National University of Singapore, Singapore, Singapore, ³Duke-NUS, Singapore, Singapore.

Hepatocellular Carcinoma (HCC) is a deadly disease due its late presentation and limited therapeutic options. Our laboratory previously reported FAT10 as an oncogene that is highly up-regulated in HCC.

FAT10 gene is 4,314 bp long located on chromosome 6. Since FAT10 is an

oncogene, and mutations/polymorphisms can influence susceptibility to cancer, we hypothesized that mutations/polymorphisms within the FAT10 gene will modulate the expression / function of the FAT10 protein and be associated with differential risk for the development of HCC and/or differences in clinical outcome.

The architecture of polymorphisms in the FAT10 gene is noteworthy. For such a small gene like FAT10 with an open reading frame of ~500 bp, it has ~9 single-nucleotide polymorphisms within its coding region of which 8 were non-synonymous and 4 were also non-conservative changes. This observation suggests that many of these polymorphisms can potentially affect function and perhaps even modulate its tumorigenic properties. Interestingly, the haplotype of polymorphisms in the different ethnic population as well as between healthy individuals and HCC patients are also different suggesting that variability of the polymorphisms in the different ethnic groups may account for variability in susceptibility to cancer development. The polymorphisms within the coding region had been recapitulated in cells and characterized.

This work is supported by grants from National Cancer Centre (NCC), National Medical Research Council (NMRC) (NMRC/1306/2011) and the Ministry of Education Academic Research Fund (MOE AcRF) Tier 1 FRC (T1-2015 Apr -05).

A large fraction of pathogenic BRCA2 variants impairs mRNA splicing in hereditary breast/ovarian cancer. Missense, synonymous or in frame-deletion/insertion variants are usually classified as variants of uncertain significance. The best method to identify splicing aberrations is based on the study of patient RNA, but that is often difficult to obtain. Minigene-based technology is an alternative approach to test candidate splicing variants without the need of patient samples. To study this process we constructed a large minigene in the pSAD plasmid with exons 14 to 20 (MGBR2_ex14-20) to keep the genomic context. Here, we focus on exons 17 y 18 because of the atypical GC donor in exon 17. The intronic GT dinucleotide is the most conserved element of the donor splice signal. However, in a small fraction of the donor sites (<1%), GT is replaced by GC that are rather located in alternatively spliced introns. A total of 226 variants were analysed with NN-Splice and HSF so that 48 of them were selected to assay. They were introduced into MGBR2_ex14-20 by site-directed mutagenesis. Minigenes were transfected into HeLa and MCF7 cells to examine their transcripts. We found that 22 variants (45.8%) produced abnormal transcripts. Moreover, micro-deletion assays showed that the 3' region of exon 17 and the 5' of exon 18 were essential for exon recognition and might contain splicing enhancer sequences. Actually, five reported variants mapping in these intervals disrupted splicing.

Relative gene amplification analysis of FGFR1, MET, DCUN1D1 and BCL9 gene in squamous cell carcinomas of the lung

A. A. Psaraki, I. Chatziandreou, I. Mourkioti, P. Korkolopoulou, E. Patsouris, A. A. Saetta; National and Kapodistrian University of Athens, Medical school, Department of Pathology, Athens, Greece.

Background: The discovery of new biomarkers and therapeutic targets is of great importance for the clinical benefit of NSCLC patients. Since gene amplification is regarded as an important oncogenic target in lung Squamous Cell Carcinoma, we performed relative amplification analysis of FGFR1, MET, DCUN1D1 and BCL9 genes in lung squamous cell carcinomas, and searched for correlations with KRAS mutations and clinicopathological characteristics.

Materials and Methods: DNA was isolated from 73 lung Squamous Cell Carcinoma FFPE tissues. Real time- PCR using GAPDH as a reference gene was performed and Relative gene amplification was calculated using the normalized ratio. Statistical analysis was performed using SPSS v21 statistical package.

Results: Relative gene amplification was detected as follows: FGFR1 12.3%, MET 15.1%, DCUN1D1 38.4% and BCL9 43.8%. KRAS was found mutated in 2 cases, whereas no EGFR mutations or ALK rearrangements were detected. In addition, DCUN1D1 and BCL9 were correlated with low tumor differentiation. A subset of cases 22% displayed co-amplification of two genes.

Discussion: The percentages of gene amplification of suggested new drug-gable target genes FGFR1, MET, DCUN1D1 and BCL9 are in accordance with recent findings. DCUN1D1 and BCL9 relative amplification emerged as possible markers of low tumor differentiation. Interestingly, a high percentage of the samples showed co-amplification of at least 2 genes.

P12.191

High complexity libraries and targeted NGS panels to access sequencing information of limiting samples

M. Hymes, C. Schumacher, S. Sandhu, L. Kurihara, S. Chupreta, J. Irish, J. Laliberte, J. Lenhart, J. RoseFigura, T. Harkins, V. Makarov; Swift Biosciences, Ann Arbor, MI, United States.

Targeted sequencing by hybridization capture provides a cost effective method for performing Next Generation Sequencing (NGS) on selected regions of the genome. While formalin-fixed, paraffin-embedded (FFPE) samples are utilized in targeted sequencing, the amount and quality of their DNA is typically compromised. Library preparations that maximize complexity and coverage uniformity across the genome are especially valuable for these limiting samples, which would otherwise produce high duplicate rates and poor coverage metrics when pursuing the deep sequencing required to call somatic variations. Here we present a library preparation method to enable high quality libraries for target enrichment, utilizing a variety of sample types.

For hybridization capture, libraries were constructed from 1-100 ng of Coriell HapMap samples, clinical FFPE, circulating cell-free DNA (cfDNA) and Horizon Discovery reference DNA using a novel library preparation method. Hybridization capture was performed using commercially available panels from three different vendors.

A Pan-Cancer Panel yielded <3% duplicates and ≥40X coverage on 10 ng and 100 ng samples of Coriell DNA, while maintaining 30X coverage at 1 ng inputs. Additionally, kidney samples that underwent formalin fixation for 6, 24, and 48 hours were compared to fresh frozen. While fresh frozen samples performed equivalently to Coriell DNA samples, formalin fixed samples demonstrated <8% duplicates at 10 ng and 100 ng, and <45% duplicates and ≥22X coverage at 1 ng, illustrating the effects of fixation on DNA quality. Somatic variant calling down to 1% allele frequency was evaluated at various DNA quantities with reference samples.

P12.192

Next generation sequencing of patients with familial papillary thyroid carcinoma and their relatives

D. N. Nikolova¹, Z. Hammoudeh¹, L. Balabanski², S. Ivanov², R. Vazharova², S. Weidner³, D. Toncheva^{1,2};

¹Medical University, Sofia, Bulgaria, ²Genomic Laboratory, SBALGAR "Malinov", Sofia, Bulgaria, ³Bern University Hospital, Bern, Switzerland.

Introduction: The incidence of thyroid cancer is steadily growing worldwide. It develops and progresses through accumulation of genetic alterations the most common being point mutations in BRAF and RAS genes and RET/PTC rearrangements, all of which activate the MAPK pathway. We used NGS technology for analysis of potentially pathologic mutations predisposing to the development of familial papillary thyroid carcinoma (FPTC) in affected families.

Materials and Methods: DNA from peripheral blood was isolated from 23 individuals (11 patients with FPTC, 2 patients with other thyroid disorders and 10 unaffected relatives). We used TruSight Cancer sequencing panel (Illumina) targeting 94 genes and 284 SNPs.

Results: In our study we selected 44 missense variants, four of which are pathogenic or potentially pathogenic. In our first family we determined the variant FANCD2_c.1137G>T associated with Fanconi anemia. In the second family we proved three variants associated with Fanconi anemia: FANCA_p.Ser1088Phe, FANCD2_c.1137G>T and SLX4_p.Pro245Leu. In the third family we defined the same Fanconi anemia variants FANCA_p.Ser1088Phe, FANCD2_c.1137G>T and the variant HOXB13_p.Gly84Glu predisposing to prostate and colorectal cancer. In the fourth family again the same HOXB13_p.Gly84Glu was carried.

Conclusion: Mutations in three of the genes (FANCA, FANCD2, and SLX4) belong to Fanconi anemia complementation group and cause cytogenetic instability, hypersensitivity to DNA crosslinking agents, increased chromosomal breakage, and defective DNA repair. Mutations in the fourth gene

HOXB13 predispose to carcinomas. The results suggest a possible role of these mutations in causing genetic predisposition to familial papillary thyroid carcinoma.

P12.193

Mutations in MYO1F cause familial non-medullary thyroid cancer (FNMTC)

C. Diquigiovanni¹, C. Bergamini², C. Evangelisti³, A. Costanzini², F. Isidori¹, H. Anbunathan⁴, A. Bowcock⁴, R. Casadio⁵, G. Babbi⁵, K. J. Rhoden¹, G. Lenaz², R. Fato², M. Seri¹, G. Romeo¹, E. Bonora¹;

¹Department of Medical and Surgical Sciences, St. Orsola-Malpighi Hospital, University of Bologna, Bologna, Italy, ²Department of Pharmacy and Biotechnology, University of Bologna, Bologna, Italy, ³Department of Biomedical and Neuromotor Sciences, University of Bologna, Bologna, Italy, ⁴National Heart and Lung Institute, Imperial College, London, United Kingdom, ⁵Biocomputing Group, University of Bologna, Bologna, Italy.

Familial Non-Medullary Thyroid Cancer (FNMTC) accounts for 5-7% of all NMTC. Since these patients develop more aggressive tumours with worse outcomes compared to the sporadic counterparts, the identification of the susceptibility genes is crucial for treatment and surveillance.

Whole exome sequencing in a multigenerational family affected by FNMTC with oncocytic features, revealed a novel heterozygous mutation in MYO1F gene, encoding for an unconventional myosin and mapping to chromosome 19p13.2, where our group previously identified a predisposing locus. Cell lines stably expressing mutant MYO1F showed more mitochondria, an altered mitochondrial network and increased levels of endogenous and extracellular ROS, compared to cells overexpressing the wild-type protein or the empty vector. The mutation also conferred a significant increase in colony formation, invasion and anchorage-independent growth, along with an over-activation of ERK1/2 pathway. These results suggest that the MYO1F variant is the mutation underlying the linkage locus previously mapped at chromosome 19p13.2.

192 independent FNMTC patients were screened to identify additional predisposing variants in MYO1F. We identified a rare silent change (rs184748543G>A) altering an Exonic Sequence Enhancer (ESE) in one patient and his affected sister. In vitro transcription analysis using a mini-gene containing-plasmid showed that the rare A allele determines an exon skipping, leading to an in-frame deletion of 43 amino acids, which alters the ATP-binding domain in MYO1F.

These results suggest that rare variants in MYO1F may predispose to FNMTC susceptibility.

P12.194

Novel germline TP53 mutations in the Swedish constitutional TP53 cohort

P. Kharazima^{1,2}, C. Larsson¹, E. Tham^{3,4}, S. Bajalica-Lagercrantz^{1,2};

¹Department of Oncology-Pathology, Cancer Center Karolinska (CCK), Karolinska Institutet, Stockholm, Sweden, ²Department of Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden, ³Clinical Oncology, Karolinska University Hospital, Stockholm, Sweden, ⁴Clinical Genetics, Karolinska University Hospital, Stockholm, Sweden.

Introduction: Individuals with a constitutional TP53 mutation have a high risk of cancer in childhood and/or early adulthood, but show a large phenotypic variation. In some families, pediatric tumors are more frequent while in others only breast cancer is seen. The underlying cause for this variation is unknown. However, this question is of utmost importance for which surveillance should be offered to mutation carriers. It is therefore a large need for further molecular characterization of the genomic landscape with regard to both the TP53-mutations, as well as of genetic modulating factors, in order to understand the genotype-phenotype correlation.

Materials and Methods: We have generated cDNA expression constructs for all nine novel germline TP53 mutants.

Results: In the Swedish cohort of 32 families, we found 25 different mutations in the TP53 gene. Nine have not been reported previously as germline mutations according to the HGMD or IARC databases. Five of these have not even been reported as somatic mutations in the IARC or cosmic databases and are thus truly novel. Transfection in p53 null H1299 cells have demonstrated a wide range of activities among the constructs in terms of induction of apoptosis in response to 12 G irradiation, as well as variable impact on the cell cycle regulation.

Conclusions: We showed that all novel mutations were expressed stably in cell lines and decrease spontaneous apoptosis and have a poorer response to therapy which indicate that affected individual has higher risk of tumorige-

nesis and less response to radiotherapy.

Mutational biases drive elevated rates of substitution at regulatory sites across cancer types

V. B. Kaiser, M. S. Taylor, C. A. Semple;

IGMM, MRC Human Genetics Unit, University of Edinburgh, Edinburgh, United Kingdom.

Disruption of gene regulation is known to play major roles in carcinogenesis and tumour progression. Here, we comprehensively characterize the mutational profiles of diverse transcription factor binding sites (TFBSs) across 1,574 completely sequenced cancer genomes encompassing 11 tumour types. We assess the relative rates and impact of the mutational burden at the binding sites of 81 transcription factors (TFs), by comparing the abundance and patterns of single base substitutions within putatively functional binding sites to control sites with matched sequence composition. There is a strong (1.43-fold) and significant excess of mutations at functional binding sites across TFs, and the mutations that accumulate in cancers are typically more disruptive than variants tolerated in extant human populations at the same sites. CTCF binding sites suffer an exceptionally high mutational load in cancer (3.31-fold excess) relative to control sites, and we demonstrate for the first time that this effect is seen in essentially all cancer types with sufficient data. The sub-set of CTCF sites involved in higher order chromatin structures has the highest mutational burden, suggesting a widespread breakdown of chromatin organization. However, we find no evidence for selection driving these distinctive patterns of mutation. The mutational load at CTCF-binding sites is substantially determined by replication timing and the mutational signature of the tumor in question, suggesting that selectively neutral processes underlie the unusual mutation patterns. Pervasive hyper-mutation within transcription factor binding sites rewires the regulatory landscape of the cancer genome, but it is dominated by mutational processes rather than selection.

P12.196

Contribution of misreading Serine tRNAs to tumor growth in vivo

M. R. Santos^{1,2,3}, P. M. Pereira^{1,2,3}, S. Varanda^{1,2,3}, J. Carvalho^{2,3}, M. Azevedo², D. D. Mateus², N. Mendes^{2,3}, P. Oliveira^{2,3}, M. T. Pinto^{2,3}, R. Bordeira-Carriço^{2,3}, F. Carneiro^{2,3,4}, M. A. S. Santos¹, C. Oliveira^{2,3,4};

Pathology and Oncology, Faculty of Medicine, University of Porto, Porto, Portugal.

Introduction: Upregulation of protein synthesis, deregulation of tRNA expression and amino acid starvation are common features of cancer. The occurrence of these events raises the hypothesis that translational fidelity is compromised in tumors(1,2). However, the relevance of tRNA misreading in cancer is still unknown. To clarify the role of tRNA misreading in cancer development, we expressed misreading tRNAs in a near-normal cell line and studied UPR and cancer-associated signaling pathways.

Materials and Methods: NIH3T3 cell line was stably transfected with pIRES2-DsRED plasmids containing the tRNA^{Ser}(WT), tRNAs that misincorporate Serine(Ser) at Alanine(Ala)-GCU or Leucine(Leu)-CUU sites and also an empty plasmid. Cell lines were injected in mice and their tumorigenic potential was evaluated. tRNA expression both in cell lines and in tumors was determined by SNaPshot sequencing. Alterations in UPR and cancer-related pathways were accessed by western blot.

Results and Conclusions: We report an unexpected role for misreading tRNAs in tumor growth. Our data show that expression of misreading tRNAs produce tumors with similar growth rate to K-ras-induced tumors. Remarkably, expression of misreading tRNAs increases in vivo, suggesting advantageous features of this phenotype. Our results also showed that Akt and UPR pathways are activated in a microenvironment-dependent manner. Accumulating evidence has demonstrated that UPR activation and decrease in translation fidelity are required for cancer cells to maintain malignancy and acquire therapy resistance, suggesting that compromising translation fidelity may select adaptive mutations. Our results support the hypothesis that mistranslation phenotypes have a role in tumor growth, worth to explore further.

Interstitial 10q21.1-q23.31 duplication due to a meiotic recombination of a paternal balanced complex rearrangement: cytogenetic and molecular fine characterization

V. Orlando^{1,2}, V. Alesi¹, C. Surace¹, D. Pompili¹, F. Restaldi^{1,2}, M. Dentici³, M. Digilio³, A. Novelli¹;

¹Laboratory of Medical Genetics, "Bambino Gesù" Children's Hospital, Roma, Italy, ²Department of Experimental Medicine, Sapienza University, Rome, Italy, ³Medical Genetics, "Bambino Gesù" Children's Hospital, Roma, Italy.

Chromosome structural rearrangements, such as translocations, inversions and insertions, are aberrations involving one or more chromosomes and are relatively common in human population. They are defined as "balanced" if they do not lead to a gain or a loss of genetic material and "unbalanced" when they are associated with duplications or deletions at breakpoints or as a consequence of malsegregation during cell division. Rearrangements associated with more than two breakpoints are rare and they have a higher probability of a pathological outcome, because of gene disruption or of a not correct segregation pattern.

We describe a complex rearrangement involving chromosomes 7 and 10 with 4 different breakpoints in an asymptomatic man and in his son, the latter presenting with developmental delay, speech delay, growth retardation, microcephaly, hypospadias and dysmorphic features. The child inherited both the paternal derivatives but the rearranged chromosome 10 also harboured an interstitial duplication due to a recombination event. During paternal meiosis, two different crossing-over occurred upstream and downstream the 10q21.1q23.31 region, between the derivative 10 chromosome and the normal chromosome 10 homologous, bringing back a copy of the missing portion in its original position. As a consequence the child harboured a 32.4 Mb duplication of chromosome 10, characterized by array-CGH. The involved region completely overlaps the critical 10q22.3q23.3 region, whose duplication is described in association with microcephaly, developmental delay, speech delay, growth retardation and dysmorphic features.

P13.02

The malsegregation of a cryptic paternal chromosomal rearrangement results in two 5q noncontiguous microduplications: evidences of a reciprocal phenotype of the 5q31.3 deletion syndrome.

S. Loddo¹, V. Alesi¹, M. G. Giuffrida², M. T. Liambo¹, M. Grispo¹, L. Bernardini², M. C. Digilio³, A. Novelli¹;

¹Laboratory of Medical Genetics, "Bambino Gesù" Children's Hospital, Rome, Italy, ²Mendel Laboratory, Casa Sollievo della Sofferenza Hospital, IRCCS, Rome and San Giovanni Rotondo, Italy, ³Medical Genetics, "Bambino Gesù" Children's Hospital, Rome, Italy.

The great majority of apparently balanced translocation are associated with normal phenotype, although a small percentage of carriers shows abnormal phenotypes. One of the mechanisms proposed to explain this phenomenon is the presence of a cryptic complex chromosomal rearrangement (CCR). CCRs are structural anomalies involving at least three chromosomes or three breakpoints. The use of FISH assays and DNA microarray technologies for the characterization of CCRs has allowed the identification of cryptic imbalances at breakpoints sites.

We report a girl, carrier of an apparently balanced translocation t(3;11) inherited from her healthy father, showing psychomotor delay, dysmorphic features, microcephaly, hypertrichosis, hypotonia, seizures and precocious puberty. Array-CGH analysis highlighted the duplication of two not contiguous regions of the long arm of a chromosome 5, extended 6 Mb (5q31.1q31.3) and 3,2 Mb (5q34) respectively. FISH assay, also performed on paternal chromosomes, revealed a more complex rearrangement involving chromosomes 3, 5 and 11. The child inherited the derivative chromosomes 3 and 11 and the normal chromosome 5, therefore showing the two duplicated regions of 5q as consequence of malsegregation of the paternal balanced CCR.

Of note, 5q31.1q31.3 duplication overlapped the critical region of 5q31.3 microdeletion syndrome characterized by hypotonia, seizures, developmental delay and facial dysmorphisms. Our patient shared many of these features, suggesting the existence of a distinct phenotype associated with the reciprocal duplication of the 5q31.3 microdeletion syndrome.

Genetic studies reveal five new mutations in the CP gene in patients affected by autosomal recessive aceruloplasminemia

A. Barqué¹, A. Negro¹, N. Wood², E. Jové-Buxeda³, J. Sanchez-Delgado⁴, B. Burnytc⁵, N. Baena-Díez⁶, J. Limon⁷, F. Fuster¹, J. Aranda¹, M. Sanchez¹;

¹Diagnostics in Iron Metabolism Diseases (D•IRON), Josep Carreras Leukaemia Research Institute (IJC), Badalona, Spain, ²National Hospital for Neurology and Neurosurgery, London, United Kingdom, ³Internal Medicine Department, University Hospital Parc Taulí, Sabadell, Spain, ⁴Hepatology and Digestive Department, University Hospital Parc Taulí, Sabadell, Spain, ⁵Center for Medical Genetics, Hospital Santariskiu Klinikos, Vilnius, Lithuania, ⁶Genetic Department, University Hospital Parc Taulí, Sabadell, Spain, ⁷Department of Biology and Genetics, Medical University of Gdansk, Gdansk, Poland.

Aceruloplasminemia is a rare autosomal recessive genetic disease with an adult onset characterized by iron-refractory anemia, retinal degeneration, diabetes mellitus and various neurological symptoms (including ataxia, involuntary movements, parkinsonism, depression and cognitive dysfunction) due to iron accumulation in the brain and viscera. It is caused by the absence of ceruloplasmin ferroxidase activity due to mutations in the ceruloplasmin (CP) gene.

Diagnosis is based on the absence of serum ceruloplasmin and some combination of low serum copper concentration, low serum iron concentration, high serum ferritin concentration as well as hepatic iron overload. The diagnosis is strongly supported by characteristic MRI findings of abnormal low intensities reflecting iron accumulation on the brain and liver. Genetic testing can confirm the diagnosis.

Treatment is based on intravenous and oral iron chelators, which have been associated with improvement in diabetes and neurological symptoms. Combined intravenous desferrioxamine and fresh-frozen human plasma (FFP) is effective in decreasing iron content in the liver. Antioxidants such as vitamin E and oral administration of zinc may prevent tissue damage.

Here we will discuss the clinical and genetic aspects of 6 new cases of aceruloplasminemia, (including two young case <40 years old) presenting 5 previously not described mutations (one missense, three frameshifts and one intronic mutation).

P13.04

Evidence of high pathogenicity of a de novo mutation in polycystin-1 gene

J. F. Rocha, R. Pinto Leite, M. Martins, M. Fructuoso, T. Morgado; Centro Hospitalar de Tras-os-Montes e Alto Douro, Vila Real, Portugal.

Introduction: Autosomal Dominant Polycystic Kidney Disease (ADPKD) is the main inherited cause of Chronic Kidney Disease (CKD). Mutations in polycystin-1 gene are responsible for 85% of the cases. The variant c.7837_7839del (p.Leu2613del) is an in-frame deletion of three nucleotides, resulting in the deletion of one amino acid in polycystin-1. It was already described in Human Gene Mutation Database but its pathogenicity was so far undetermined.

Cases Presentation: we describe an ADPKD family with several members affected by a de novo genetic mutation. CKD was diagnosed in the mother at 38y, who started hemodialysis at 41y. The first son presents CKD at 33y. The second son had CKD since 24y, having started hemodialysis at 28y. A niece had the diagnosis at 13y without Renal Failure yet. The variant c.7837_7839del (p.Leu2613del) was found in all patients. The mutation was not found in a daughter who did not present disease criteria. Awaiting genetic study are sixteen relatives with ADPKD (6 started dialysis early).

Conclusion: The mutation variant c.7837_7839del in the polycystin-1 gene was the only one found in four affected family members (three in first degree) and was absent in a relative without the disease, confirming its pathogenicity. Many cases developed early severe CKD, in favor of a mutation with high pathogenicity. The early and severe manifestations of ADPKD make relatives seek reliable prenatal diagnosis. Therefore, every new case of a rare genetic mutation should be reported in order to obtain a more precise genotype/phenotype correlation, improving risk evaluation and genetic counseling.

Association of FAS promoter gene polymorphism in alopecia areata

E. Ensari¹, O. Ates¹, G. Kalkan²;

¹Gaziosmanpasa University, Medical Faculty, Department of Medical Biology, Tokat, Turkey, ²Yildirim Beyazit University, Medical Faculty, Department of Dermatology, Ankara, Turkey.

Introduction: Alopecia areata (AA) is a T cell-mediated autoimmune disease characterized non-scarring, patchy loss of hair in the scalp and elsewhere. Onset of AA may occur at any age. Incidence is equally distributed across races and genders. It's etiopathogenesis is exactly uncertain yet. AA has a multifactorial etiology that both several genes and environmental factors come together with a different weight in triggering the pathology. Fas cell surface death receptor (FAS), a member of the tumor necrosis factor (TNF) receptor super-family, is a transmembrane receptor involved in apoptotic signal transmission in many cell types and play essential roles in many human autoimmune diseases. The aim of this study was to evaluate the possible association between the 1377 G>A promoter polymorphism in the FAS gene and risk of AA.

Materials and methods: The study group included 200 patients with AA and 165 healthy volunteers. Genotyping for the FAS-1377 G>A polymorphism was performed by Polymerase Chain Reaction-Restriction Fragment Length Polymorphisms (PCR-RFLP) method.

Results: A statistically significant difference was observed between patients and controls according to genotype and alleles frequencies of FAS gene 1377 G>A polymorphism ($p = 0.007$ and $p = 0.000$, OR 1.98, 95 % CI 1.35-2.92, respectively).

Conclusion: According to our findings, the FAS-1377 G>A polymorphism is associated with AA. The presence of the A allele is thought to be protective to AA. This work was supported by Gaziosmanpasa University, Unit Of Scientific Research Projects

P13.06

Identification and molecular characterization of new variants of SERPINA1 gene in Spanish patients with Alpha1- Antitrypsin Deficiency

N. Matamala¹, D. Retana¹, T. Fernandez¹, A. Muñoz-Callejas¹, B. Lara², R. Sáez³, S. Castillo⁴, M. Molina⁵, A. Texido⁶, E. Lopez del amo⁷, G. Tirado⁸, J. Lopez-Campos⁹, I. Blanco¹⁰, B. Martinez-Delgado¹;

¹Institute of Health Carlos III (ISCIII), Madrid, Spain, ²Royal Exeter & Devon Hospital, Exeter, Devon, United Kingdom, ³Hospital Donostia, San Sebastián, Spain, ⁴Hospital Clínico de Valencia, Valencia, Spain, ⁵Bellvitge University Hospital-IDIBELL, Hospitalet De Llobregat, Spain, ⁶Hospital Universitario Sant Joan de Reus, Tarragona, Spain, ⁷Hospital La Laguna, Tenerife, Spain, ⁸Hospital Cádiz, Cádiz, Spain, ⁹Hospital Virgen del Rocío, Sevilla, Spain, ¹⁰Alpha1-Antitrypsin Deficiency Spanish Registry (REDAAT), Spanish Society of Pneumology (SEPAR), Barcelona, Spain.

Alpha-1 antitrypsin deficiency (AATD) is caused by mutations in the *SERPINA1* gene predisposing to early onset emphysema and liver cirrhosis. The most common mutations known to cause AATD are the deficient Z (Glu-342Lys) and S (Glu264Val) variants. Nevertheless, *SERPINA1* gene is very polymorphic, and more than one hundred genetic variants have been described. We aimed to identify and characterize new variants of *SERPINA1* gene in patients with decreased levels of serum AAT that cannot be explained by the genotype after analysis of Z and S alleles. We selected eight patients who fulfilled these criteria and performed sequence analysis of all coding exons of *SERPINA1* by Sanger sequencing. We found seven previously unidentified missense variants, four of them located in exon 2, two in exon 3 and one in exon 4. Molecular characterization of these variants was performed by *in vitro* expression of mutant proteins generated after directed mutagenesis. We evaluated by western blot analysis the expression of monomeric AAT protein and the formation of polymers. In addition, protein aggregates were detected by Periodic acid-Schiff (PAS)-positive staining. Finally, an elastase assay was conducted in order to evaluate the inhibitory activity of the mutants. In conclusion, we have identified novel variants of *SERPINA1* gene that can help to explain the discrepancies found between serum AAT levels and genotype. These results suggest that rare variants might be more frequent than expected, and therefore standardized PCR screening of the S and Z alleles should be complemented with sequencing of the gene in discordant cases.

The coexistence of two causative mutations leads to reconsider Alport syndrome pattern of inheritance

C. Fallerin¹, M. Baldassari^{1,2}, E. Frullanti¹, M. Mencarelli^{1,2}, A. La Manna³, G. Garosi⁴, D. Del Prete⁵, A. Pinto^{1,2}, F. Ariani^{1,2}, F. Mari^{1,2}, A. Renieri^{1,2};

¹Medical Genetics, University of Siena, Siena, Italy, ²Genetica Medica, Azienda

Ospedaliera Universitaria Senese, Siena, Italy, ³Department of Pediatrics, Second University of Napoli, Napoli, Italy, ⁴Nephrology, Dialysis and Transplantation, Azienda Ospedaliera Universitaria Senese, Siena, Italy, ⁵Division of Nephrology, Department of Medicine DIMED, Laboratory of Histomorphology and Molecular Biology of the Kidney, University of Padova, Siena, Italy.

Alport syndrome (ATS) is a clinically heterogeneous progressive nephropathy, characterized by extreme phenotypic and genetic variability. Monogenic inheritance model is well known and different patterns of inheritance have been previously recognized ranging from autosomal to X-linked models. We have recently reported digenic inheritance for the disease. Here, we go further and we describe a new series of cases with more complex mechanism of inheritance for ATS unmasked by the increased use of high throughput sequencing which keeps unveiling unexpected combinations of pathogenic mutations lying either on the same allele or on different genes. Families with X-linked inheritance and unusual severity in females harbor two pathogenic mutations on the same COL4A5 allele. Families with apparent dominant pattern of inheritance are rather due to a digenic transmission of two causative mutations inherited in cis and lying in the two collagen 4 genes linked on chromosome 2 (COL4A3/COL4A4). Moreover, two distinct mutations on the same two genes, inherited in trans, are responsible for ATS following an apparent autosomal recessive mode of inheritance and intermediate severity. A more complex inheritance is shown when an autosomal mutation is combined with an X-linked mutation. Overall, these results reveal that ATS transmission pattern overcomes the Mendelian inheritance, which can thus easily trick the clinical geneticist. This finding leads to reconsider the recurrence risk and opens new perspectives in the management of genetic and prenatal counseling for ATS.

P13.08

MALAT1: a long non-coding RNA involved in alternative splicing regulation and potentially implicated in multiple sclerosis

E. M. Paraboschi¹, G. Cardamone², V. Rimoldi^{2,3}, D. Gemmati⁴, M. Spreafico⁵, S. Duga^{2,3}, G. Soldà^{2,3}, R. Asselta^{2,3};

¹Università degli Studi di Milano, Dipartimento di Biotechnologie Mediche e Medicina Traslazionale, Milano, Italy, ²Humanitas University, Department of Biomedical Sciences, Rozzano, Italy, ³Humanitas Clinical and Research Center, Rozzano, Italy, ⁴University of Ferrara, Center Haemostasis & Thrombosis, Department of Medical Sciences, Ferrara, Italy, ⁵Azienda Ospedaliera della Provincia di Lecco, Alessandro Manzoni Hospital, Department of Transfusion Medicine and Hematology, Lecco, Italy.

Introduction: Multiple sclerosis (MS) is an autoimmune neurodegenerative disease, characterized by chronic inflammation, demyelination, and axonal damage. Accumulating evidence suggests the existence of pathogenic links between MS and abnormalities in alternative splicing (AS). Among splicing regulators, besides hnRNPs and SR proteins, long noncoding RNAs (lncRNAs) are emerging as critical players in pre-mRNA AS. Here, we aimed at exploring the role of MALAT1, an abundant lncRNA reported to influence AS through its interaction with pre-mRNA splicing factors.

Materials and Methods: The expression levels of several splicing regulators, as well as the AS pattern of specific MS-related genes, were evaluated in HEK293, HeLa, and SH-SY5Y cells after MALAT1 overexpression or downregulation. Gene expression analysis was performed by real-time RT-PCR and RNAseq analysis.

Results: Upon MALAT1 modulation, expression levels of splicing regulatory genes, such as HNRNPF and CELF1, were significantly dysregulated in a cell-specific manner. Furthermore, we demonstrated that MALAT1 overexpression/silencing influence also the AS pattern of IL7R and PRKCA genes, previously associated with MS susceptibility and characterized by the presence of a SNP acting on splicing. Intriguingly, we also detected a significant upregulation (1.4-fold) of MALAT1 in peripheral blood mononuclear cells of MS patients respect to controls ($P < 0.05$).

Conclusion: In this work, we provide evidence of a functional link between the lncRNA MALAT1, AS regulation and MS-associated AS events, suggesting a potential role of MALAT1 in MS pathogenesis.

P13.09

Expression Assay of BMPR2 gene in Pulmonary Arterial Hypertension

G. Pousada¹, M. Lago¹, S. Prado-López¹, A. Baloiñá², R. Varela-Calviño³, D. Valverde¹;

¹Universidad de Vigo, Vigo, Spain, ²Complejo Hospitalario de Pontevedra, Pontevedra, Spain, ³Universidad de Santiago de Compostela, Santiago de Compostela, Spain.

Pulmonary Arterial Hypertension (OMIM 178600) is rare disease characterized by pulmonary vascular resistance increase and vascular remodelling. Symptoms include fatigue, shortness of breath and syncope. The most implicated gene is BMPR2, with a reduced expression in PASMC cells. The aim was to analyze the BMPR2 gene expression, in different cell cycle phases, in B-Lymphocytes.

We select seven patients with mutations and eight controls without mu-

tations in BMPR2. B-lymphocytes from patients and controls were aised from peripheral blood by Ficoll method. B cells were immortalized using Epstein-Barr Virus and grown. Lymphoblastoid Cell line were analyzed by flow cytometry and separated based on the cell cycle phase by Sorting. With patients and controls RNA, we realized a RT-PCR and we analyzed BMPR2 gene expression with TaqMan assay.

After analysis of BMPR2 gene expression by qPCR, we detected expression for BMPR2 gene in Lymphoblastoid Cell line from controls. The normalized gene expression results in BMPR2 gene, using GAPDH as reference gene, shows a greater expression levels in G2/M phase, followed by G0/G1 phase and, finally, in S phase. However, sorting cell analysis show changes in ploidy from patients relative to controls. The results of BMPR2 gene expression in patients, will tell us if there are any expression differences between patients and controls.

Although the availability of a tissue that express BMPR2 like lung is a problem, the expression analysis of the mutated gene by this technique, allowed us to analyzed how mutations in BMPR2 could interfere in the expression levels of this protein.

P13.10

WGS contribution to two cases of complex chromosomal rearrangements suggesting a chromothripsis mechanism

N. Chatron^{1,2}, J. Lauer¹, P. Rollat Farnier¹, A. Labalme¹, F. Prieur³, F. Diguët¹, M. Till¹, R. Touraine², C. Bardel^{1,4}, P. Roy^{1,4}, C. Schluth-Bolard^{1,2}, D. Sanlaville^{1,2}; ¹HCL, BRON Cedex, France, ²INSERM U1028 CNRS UMR 5292, UCBL, CRNL, GENDEV Team, Lyon, France, ³CHU Saint-Etienne, Saint-Etienne, France, ⁴UMR 5558, LBBE, Service de Biostatistique et plateforme de séquençage NGS, CNRS, Lyon, France.

Chromothripsis was first described in 2011 in somatic cells and is proposed to constitute the basis for complex chromosomal rearrangements (CCR) seen in 2-3% of all cancers. These CCR were rarely reported in constitutional field. Here, we report CCR discovered in two patients harboring syndromic intellectual disability. The first case is a young boy with growth retardation, moderate intellectual disability, delayed speech, oral dyspraxia, hair ichthyosis, thin nails and facial dysmorphism. Karyotyping showed a ring 21 chromosome with 8 CNVs: 3 losses of 1.2 to 7.4 Mb and 5 gains of 162 kb to 2.8 Mb revealed by array CGH (aCGH) and confirmed by FISH. To reach basepair resolution of these anomalies, paired-end whole genome sequencing (WGS) (2x100bp) was performed on a NextSeq500 (Illumina). WGS confirmed all CNVs previously identified and pointed out three additional small CNVs (2 losses, 1 gain) and the presence of 4 inversions for a total of 23 chromosomal breakpoints. The second patient is an adult with mild intellectual disability, language delay and cleft palate carrier on the karyotype of a double chromosome 3 inversion (46,XX, inv(3)(p13; p22), inv(3)(p12; q26.3)) without pathogenic imbalance identified using aCGH. WGS revealed a more complex rearrangement with 12 breakpoints. The disruption of FOXP1 gene can explain Patient 2's phenotype. Overall, while Patient 1's phenotype is due to a large copy number change (losses and gains), the second case shows the importance of breakpoints' characterization of balanced chromosomal rearrangement and the potential underestimation of CCRs incidence

P13.11

Does the genomic architecture amongst Irish Travellers predispose to chromosome 17q12 microduplication?

S. A. Lynch, J. McDaid, D. R. Betts, E. Crushell, J. P. Casey; National Centre for Medical Genetics, Dublin 12, Ireland.

Certain regions of the human genome are predisposed to non-allelic homologous recombination (NAHR) resulting in copy-number-variants (CNVs). Ethnic differences have been observed with some CNVs. We previously reported a consanguineous Irish Traveller family with PCD and laterality due to homozygous mutations in CCDC103 (17q21.31). The mother (patient-A) and affected children had a co-existing chromosome 17q12 duplication. The 17q12 duplication and CCDC103 mutation are in cis, ~6Mb apart. Patient-A's husband (her first cousin) does not carry the 17q12 duplication indicating that a) this was a recent evolutionary CNV event either in patient-A or her mother (husband's maternal aunt) or b) there has been a recent recombination event.

We now report a second Irish Traveller family with a 17q12 duplication, identical to the first. This child (who has autism) also has a de novo neurexin-1 deletion (2q13.1). The families are not related and come from different geographical areas. Further analysis revealed that family-2 do not carry the CCDC103 mutation suggesting that a) the duplication arose as an independent de novo event in family 2 or b) recombination has separated the CCDC103 mutation from the duplication in previous generations.

A review of 17q12 duplications identified within our centre revealed only three other cases, all in non-Traveller families.

Conclusions: The Irish Traveller population number ~40,000, out of a total population of 4.6 million, within the Irish Republic. Our discovery of two unrelated Irish Traveller families with a 17q12 duplication suggests that the genomic architecture at 17q12 in this population may predispose to this CNV.

P13.12

A comprehensive genome analysis of three constitutional chromothripsis rearrangements: a new mechanism for complex karyotype disorders

A. Provenzano¹, V. Orlandini¹, M. Pantaleo², G. Traficante¹, L. Xumerle³, F. di Leva⁴, G. Bacci⁵, S. Stagi⁶, S. Guarducci⁷, S. Bargiacchi¹, O. Zuffardi⁷, M. Delledonne^{3,4}, S. Giglio¹; ¹Medical Genetics Unit, Department of Biomedical Experimental and Clinical Sciences „Mario Serio“, University of Florence, Firenze, Italy, ²Medical Genetics Unit, Meyer Children's University Hospital, Firenze, Italy, ³Personal Genomics srl, Verona, Italy, ⁴Department of Biotechnologies, University of Verona, Verona, Italy, ⁵Ophthalmology Unit, Meyer Children's University Hospital, Firenze, Italy, ⁶Department of Health Science, University of Florence, Firenze, Italy, ⁷Department of Molecular Medicine, University of Pavia, Pavia, Italy.

Chromothripsis is a novel phenomenon in the structural variation landscape of cancer genomes. We analyzed the genomes of three patients with congenital disease without apparent karyotype anomalies. The rearrangements displayed unanticipated complexity resembling chromothripsis. The array-CGH analysis identified complex chromosomal rearrangements involving chromosome 17 (Case-1), 12 (Case-2) and 1 and 4 (Case-3). Case-1 presented a complex clinical phenotype in which coexisted 3 known disorders: Potocki-Lupski syndrome, Charcot-Marie-Tooth disease and neurofibromatosis type 1. Case-2 showed intellectual disabilities with autistic traits and a particular stromal corneal dystrophy, at the moment described only in adult subjects. Case-3 exhibited a complex clinical picture, not immediately framed with 1p36 deletion syndrome (array-CGH revealed a 3 Mb deletion in 1p36). With whole genome sequencing we investigated the genetic architecture of these constitutional complex chromosomal rearrangements (CCRs), copy number profiling, and breakpoint-junctions proving that the rearrangements (deletions/duplications/inversions) identified in our cases were not clustered on a single chromosome region, but on the whole length of the chromosomes. These findings provide additional information suggesting that chromosome shattering and nonhomologous repair may be a common mechanism underlying chromothripsis rearrangements associated with developmental malformations.

P13.14

Short read paired end and long range mate pair genome sequencing characterization of complex and chromothriptic chromosomal aberrations

D. Nilsson¹, J. Eisfelt¹, M. Pettersson¹, F. Vezzi², S. Lundin³, V. Wirta³, M. Käller³, M. Nordenskjöld¹, E. Syk Lundberg¹, A. Lindstrand¹;

¹Karolinska institutet, Solna, Sweden, ²SciLifeLab, Department of Biochemistry and Biophysics, Stockholm University, Stockholm, Sweden, ³SciLifeLab, KTH Royal Institute of Technology, Stockholm, Sweden.

Complex chromosomal rearrangements, including chromothripsis, are emerging as important phenomena in both somatic and constitutional disease. Whole genome sequencing technologies capable of base pair level resolution of chromosomal fusion events, rearrangements and copy number changes now allow us to understand complex aberrations in fine detail. We present results from five complex cases using a combination of Illumina Nextera mate pair sequencing and PCR-free paired end (PE) sequencing. Two are cases of intrachromosomal chromothripsis affecting chromosome 1 and chromosome 21 respectively. The chromothriptic chromosome 21 was identified in a patient with heart anomalies and dysmorphic features, deceased at 5 mo. Molecular cytogenetic characterization with customized array comparative hybridization (CGH) and fluorescence in situ hybridization (FISH) had previously identified four deletions and five duplications. Whole genome sequencing elucidated break and fusion events at basepair resolution. BioNano Genomics IRYs nano-channel single molecule mapping was applied for corroboration. CNVs were estimated in excellent concordance with CGH using low pass short read coverage data, but at higher resolution, corroborating uncertain single probe signals. Discordant read pair data from low pass mate pair sequencing was sufficient to give a clear overall picture, improving over FISH reactions in all five cases. The added full coverage paired-end sequence data improves fine detail of complex rearrangements in fusion points. SNVs further add information with runs of autozygosity in deletions, and fractional allele ratios as expected from duplications. In summary, genome sequencing technologies elucidate even highly complex chromosome rearrangements, reducing analysis time, labour and increasing resolution over hybridisation based methods.

P13.15

Whole genome, mate-pair sequencing reveals additional cryptic breakpoints in a family with a complex chromosomal rearrangement

C. Aristidou^{1,2}, M. Mehrjouy³, M. Bak³, N. Tommerup³, C. Sismani^{1,2};

¹Cytogenetics and Genomics Department, The Cyprus Institute of Neurology and Genetics, Nicosia, Cyprus, ²The Cyprus School of Molecular Medicine, The Cyprus Institute of Neurology and Genetics, Nicosia, Cyprus, ³Wilhelm Johanssen Centre for Functional Genome Research, Department of Cellular and Molecular Medicine, University of Copenhagen, Copenhagen, Denmark.

Accurate characterization of complex chromosomal rearrangements (CCRs) in non-affected individuals is crucial as their presence may result in reproductive failure, recurrent miscarriages or children with malformations. Here, we present a family, initially referred 10 years ago, where the non-affected father and daughter were found, using FISH and karyotyping, to be carriers of a balanced three-way translocation [t(6;7;10)(q16.2;q34;q26.1), de novo in the father]. The family suffered from two stillbirths, one miscarriage, and has a son with severe intellectual disability.

In the present study, the family was revisited using whole-genome mate-pair sequencing (MPS) and Sanger sequencing to further characterize the CCR in the father and daughter.

MPS allowed accurate reconstruction of all derivative chromosomes involved in the translocation. Interestingly, it revealed an additional cryptic translocation breakpoint on der(6) (1.37Mb proximal to the 1st breakpoint) rendering the rearrangement even more complex. The interstitial segment created was translocated onto der(10) proximal to the translocated segment from chromosome 7.

SIM1, GRIK2, CNTNAP2, and PTPRE genes were disrupted at the breakpoints. As some of these genes have been proposed as candidate dominant genes for developmental delay, clarifying the consequences of the disruption at the protein level will provide important information about the function of the genes.

In conclusion, MPS proved highly successful in identifying additional complexity, not detectable by FISH, in two non-affected complex translocation carriers. We propose that such CCRs should be studied with NGS in combination with other methods to aid in correct prenatal, preimplantation genetic diagnosis and counselling in couples with reproductive problems.

P13.16

Complex deletion of 18q revealed by array CGH - the significance of high resolution analysis method in patients with known abnormal karyotype

M. Czakó, K. Hadzsiev, A. Szabó, A. Lócsei-Fekete, B. Melegh;

University of Pécs, Department of Medical Genetics, Pécs, Hungary.

Introduction: Inverted duplications with terminal deletions have been described with different chromosomes involved. Since the widespread use of array CGH increasing number of publications revealed the possible mechanisms of its development as non-allelic homologous recombination or nonhomologous end joining resulting in a dicentric chromosome, in which a breakage-fusion-bridge cycle and telomere formation lead to this type of rearrangement. In the vast majority of the known cases the duplicated region is larger than the deleted segment. In the patient presented here the situation is exactly the opposite.

Methods: Routine cytogenetic investigation was indicated in a 5 year old child because of muscle hypotonia, clubfoot, genital hypoplasia, minor anomalies and delayed development. The deletion of terminal 18q detected by karyotyping (450 bands), however, didn't provide sufficient explanation for the severity of the symptoms, therefore array CGH analysis using Agilent Sureprint 8x60K oligo-array (ISCA v.2) was performed.

Results: Array CGH detected a 2,166 Mb duplication affecting 18q21.31q21.32 and a 21,5 Mb contiguous deletion of 18q21.32q23. In possession of the results the more complex clinical features compared to "pure" deletion 18q syndrome could be explained, allowing for a more thorough genotype-phenotype analysis.

Conclusions: The application of high-resolution molecular cytogenetic analysis methods is of great importance even in cases where the karyotyping detects abnormalities which correlation with the clinical picture is clear. In order to understand the formation of chromosomal rearrangements better, the use of array CGH analysis providing copy number data for the regions adjacent to the breakpoints is recommended.

P13.17

Conserved non-coding elements and Topologically Associated Domains, a correlation story

B. Ambrose, J. C. Fischer, L. E. Hunt, G. Elgar;

The Francis Crick Institute, London, United Kingdom.

The recent development of genome wide chromosome conformation capture (Hi-C) has permitted the study of chromatin interactions within the nucleus. The resulting interactions maps show that genomes can be divided into large local chromatin domains termed Topologically Associated Domains (TADs). Within TADs, the genome appears to be organized to favour strong internal chromatin interactions rather than external interactions with neighbouring TADs. It has also been suggested that TADs might help to de-lineate basic genomic functions such as gene regulation. Interestingly, TADs also appear to be conserved across species and cell types.

Comparative genomics has revealed the existence of conserved non-coding elements (CNEs) in vertebrates. Multiple lines of evidence suggest that these non-coding units are cis-regulatory elements associated with key developmental genes.

Using CNEs clusters extracted from the CONDOR database, we investigated whether CNEs and TADs were spatially correlated in the human genome. We looked at different parameters such as absolute and relative distances, overlap of the regions and correlation of the boundaries. In addition, we performed 10,000 simulations to measure the statistical robustness of our analysis.

Preliminary results show a strong correlation between the boundaries of CNE clusters and TADs. This indicates that CNEs are not randomly distributed across the genome but are organized with respect to the TAD architecture. Furthermore, this reinforces the role of CNEs as potential cis-regulatory modules of genes.

P13.18

A case of potential human chimerism detected by the concomitant presence of both derivative chromosomes from the same translocation.

M. E. Mansilla^{1,2}, F. García-Santiago^{1,2}, M. A. Mori^{1,2}, S. García-Miñaur^{1,2}, J. Nevado^{1,2}, L. Fernández^{1,2}, B. Fernández^{1,2}, M. I. Gómez^{1,2}, P. Lapunzina^{1,2};

¹INGEMM, IdiPaz. Hospital Universitario la Paz., Madrid, Spain, ²CIBERER. Instituto de Salud Carlos III, Madrid, Spain.

A complex genetic diagnosis of a 2-year-old girl with growth delay, congenital renal anomalies, and developmental delay was revealed by combined a-CGH and FISH studies. The reported girl was born single to healthy non-consanguineous parents.

Methods and results: oligonucleotide-based microarray analysis was performed on genomic DNA (KaryoArray®, Bluegenome, Illumina). A mosaicism of a 8,84 Mb terminal deletion on 10q26 and a 511 Kb terminal duplication on 18q initially suggested an unbalanced derivative chromosome 10. Subtelomeric 10q (Vysis) and subtelomeric 18q (Kreatech) FISH probes were applied to establish mosaicism degree, resulting in a major cell line (171 metaphases) with the derivative chromosome 10 (one signal for subtelomeric 10q region and three signals for subtelomeric 18q region) and a minor one (8 metaphases) with the derivative chromosome 18 (three signals for subtelomeric 10q region and one signal subtelomeric for 18q region). No metaphases with the balanced translocation was detected. Parents' karyotype and FISH studies were normal.

Conclusions: The mosaicism observed by a-CGH is the result of the dosage compensation between the two chromosome derivative. The FISH techniques are essential for the full characterization of genomic rearrangements. We discuss the possible genetic mechanism involving the occurrence of at two independent events: germinal mosaicism and human chimerism in a single pregnancy after an initial twin dizygotic conception

P13.19

Highly restricted Down syndrome critical region identified on human chromosome 21

M. C. Pelleri¹, E. Cicchini¹, C. Locatelli¹, L. Vitale¹, M. Caracausi¹, A. Piovesan¹, A. Rocca², G. Poletti², M. Seri², P. Strippoli², G. Cocchi²;

¹Department of Experimental, Diagnostic and Specialty Medicine (DIMES), Unit of Histology, Embryology, Bologna, Italy, ²Neonatology Unit, St. Orsola-Malpighi Polyclinic, Bologna, Italy, ³Medical Genetics Unit, St. Orsola-Malpighi Polyclinic, Department of Medical and Surgical Sciences (DIMEC), University of Bologna, Bologna, Italy, ⁴Neonatology Unit, St. Orsola-Malpighi Polyclinic, Department of Medical and Surgical Sciences (DIMEC), University of Bologna, Bologna, Italy.

Introduction: A „Down Syndrome critical region“ (DSCR) sufficient to induce the most constant phenotypes of Down syndrome (DS) had been identified by studying partial (segmental) trisomy 21 (PT21) as an interval of 0.6-8.3 Mb within human chromosome 21 (Hsa21), although its existence was later

questioned.

Materials and Methods: We propose an innovative, systematic reanalysis of all described PT21 cases (from 1973 to 2015). In particular, we build an integrated, comparative map from 126 cases with or without DS fulfilling stringent cytogenetic and clinical criteria. The map allowed to define or exclude as candidates for DS fine Hsa21 sequence intervals, also integrating duplication copy number variants (CNVs) data.

Results: A highly restricted DSCR (HR-DSCR) of only 34 kb on distal 21q22.13 has been identified as the minimal region whose duplication is shared by all DS subjects and is absent in all non-DS subjects. Also being spared by any duplication CNV in healthy subjects, HR-DSCR represents a strong candidate for the typical DS features, the intellectual disability and some facial phenotypes. HR-DSCR contains no known gene and has homology only to the chimpanzee genome. **Conclusion:** Our results strongly support the view that a single main critical region for DS actually exists, that it appears to be much smaller than previously suspected and that it could contain currently undescribed genes whose identification should become a priority for understanding the fundamental genotype-phenotype relationships in DS and in searching for highly relevant targets for a cure of DS.

P13.20

First report of MEFV duplication in FMF patient

G. Sarabay¹, D. Mechin¹, B. Dumont¹, M. Andre², I. Touitou¹;

¹UMAI laboratoire de génétique, Montpellier, France, ²Médecine Interne CHU Clermont Ferrand, Clermont Ferrand, France.

Familial Mediterranean fever (FMF) is a rare monogenic disease and the prototype of autoinflammatory disorders. It is caused by mutations in the MEFV gene and is autosomal recessively inherited. Most mutations are missense substitutions, small deletions are quite rare, and only three nonsense mutations have been described. Large rearrangements have been searched for in the frame of a collaborative project including 216 patients but were not identified.

We report here a 21 years-old woman who presented with classical FMF phenotype: recurrent fever, arthralgia, and abdominal pain with vomiting. Attacks lasted three days and biological inflammation was documented with elevated C-reactive protein. Her father is Armenian and her mother Malagasy, and both are asymptomatic.

We identified a well-known severe mutation: p.Met694Val, and a controversial variant: p.Glu148Gln. Parental testing confirmed that the variants were non-allelic. Sanger sequencing displayed unbalanced ratio of the mutated and wild type alleles. Mosaicism was excluded because all polymorphisms were found at the same 1:2 ratio. DNA contamination was ruled out through microsatellite analysis. We thus suspected a gene micro-rearrangement. Quantitative polymerase chain reaction and deep-sequencing revealed a heterozygous duplication of the entire wild MEFV gene inherited from the mother. Two close surrounding genes (NAA60 and OR1F1) were not duplicated demonstrating that this rearrangement was confined to the MEFV region.

We report here the first MEFV duplication in a FMF patient who subsequently expressed 1/3 dose of p.Met694Val. Interestingly, the "dilution" of the pathological variants did not moderate the patient's phenotype.

Functional assays and bioinformatics predictions reveal a high contribution of splicing mutations in the most frequent forms of hereditary cancer

O. Soukarieh^{1,2}, P. Gaildrat^{1,2}, G. Castelain^{1,2}, S. Krieger^{1,2,3}, S. Baert-Desurmont^{1,2,4}, D. Di Giacomo^{1,2}, J. Abdat^{1,2}, H. Tubeuf^{1,2}, A. Killian^{1,2}, J. Thery^{1,2}, C. Bonnet^{1,2}, S. Akli^{1,2}, A. Drouet^{1,2}, M. Vezain^{1,2}, M. Hamieh^{1,2}, E. Rouleau⁵, I. Tournier^{1,2}, S. Caputo⁵, C. Houdayer^{5,6}, T. Frébourg^{1,2,4}, M. Tosi^{1,2}, A. Martins^{1,2}, in collaboration with the French Oncogenetics Network;

¹Inserm U1079, University of Rouen, Institute for Research and Innovation in Biomedicine, Rouen, France, ²Normandy Centre for Medical Genomics and Personalized Medicine, Rouen, France, ³Department of Clinical Biology and Oncology, François Baclesse Cancer Centre, Caen, France, ⁴Department of Genetics, University Hospital, Rouen, France, ⁵Genetics Department, Curie Institute, Paris, France, ⁶University Paris Descartes, Paris, France.

The identification of a causal mutation is essential for molecular diagnosis and clinical management of hereditary cancers. However, even if high-throughput DNA sequencing has greatly improved the detection of nucleotide changes, the biological interpretation of most variants remains challenging. Here, we report the development and outcome of minigene assays allowing the identification of splicing mutations in any gene of interest. We analyzed in this system more than 600 variants identified in genes implicated in Lynch syndrome or in hereditary breast and ovarian cancer syndrome, notably MLH1, MSH2, BRCA1 and BRCA2. Patient RNA was also analyzed

when available. Our results indicate that more than 25% of variants of unknown significance in these genes have an impact on RNA splicing, an information that contributed to the clinical classification of several of these variants. Moreover, our targeted studies on "model-exons", including MLH1 exon 10 and BRCA2 exon 7, revealed an unexpected large number of variants altering potential exonic splicing regulatory elements (ESR), an effect that could not be predicted by commonly used bioinformatics approaches. We then evaluated the predictive power of three newly developed ESR-dedicated algorithms. Our results pinpointed the good sensibility and specificity of two of these methods both at identifying ESR mutations and at predicting their severity. This study highlights the potential of in silico approaches as filtering tools for prioritizing variants for functional analyses, a strategy that may help identifying pathogenic variants among the plethora of nucleotide changes detected by exome sequencing. Our findings have implications for all genetic disorders.

P13.22

Detection of genomic alterations using high-throughput technology in Brazilian patients with hearing loss

P. L. Jacob¹, S. M. Da Silva Costa¹, G. O. L. Rodrigues², J. A. Yunes², A. M. Castilho³, E. L. Sartorato¹;

¹Human Molecular Genetics Laboratory, Molecular Biology and Genetic Engineering Center (CBMEG) - University of Campinas, Campinas, Brazil, ²Children's Hematological Investigations Center Dr. Domingos Boldrini, Campinas, Brazil, ³Otorhinolaryngology Department, University of Campinas (UNICAMP), Campinas, Brazil.

Hearing loss is one of the most common sensory disorders in humans. The identification of genetic variants associated with deafness can contribute to a better understanding of the molecular basis and the pathophysiological mechanisms involved in the different phenotypes of hereditary hearing loss. Moreover, it can provide an accurate diagnosis, development of specific treatments and genetic counseling for patients and families. The application of new high-throughput technologies, such as CytoScan HD Array, allows an optimization of genetic diagnosis and a comprehensive investigation of hereditary hearing loss. The main goal of the present study was to elucidate the genetic etiology in a cohort of Brazilian patients heterozygous for GJB2 gene mutation with hearing loss using the CytoScan HD Array Microarray. Genomic DNA from 14 patients with hearing loss was evaluated by CytoScan HD Array (Affymetrix). We found 68 genomic changes. The most significant changes were observed on chromosome 13 (13q12.11), near the GJB6 gene (Connexin 30). It was observed a loss of heterozygosity (LOH) in three regions. The first interval have 419,27kb of size, where are located the genes PSPCI, ZMYMS, ZMYM2, GJA3; in an intronic region there is an interval with 179,84kb of size, and other interval with 348,69kb which includes the genes CRYL1, IFT88, MIR 4499. To date, we are mapping the flanking regions of these intervals in order to study the segregation of these changes in the other family members. These quantitative changes may play a role in the development of hereditary hearing loss.

P13.23

Functional analysis of an $\text{A}\gamma$ -globin gene promoter variant (HBG1: g.-225_-222delAGCA) underlines its role in increasing fetal hemoglobin levels under erythropoietic stress

J. D. Vasiljevic¹, M. M. Ugrin¹, M. M. Stojiljkovic¹, B. Zukic¹, K. Klaassen¹, T. Katsila², L. Dokmanovic³, D. Janic³, G. P. Patrinos³, S. Pavlovic³;

¹Institute of Molecular Genetics and Genetic Engineering, University of Belgrade, Belgrade, Serbia, ²Department of Pharmacy, University of Patras School of Health Sciences, Patras, Greece, ³Department of Hematology and Oncology, University Children's Hospital, School of Medicine, University of Belgrade, Belgrade, Serbia.

Hereditary persistence of fetal hemoglobin is a condition characterized by persistent γ -globin gene expression and synthesis of high levels of fetal hemoglobin (HbF; $\alpha 2\gamma 2$) during adult life. It is usually caused by promoter variants affecting the human fetal globin genes (*HBG1* and *HBG2*). Some of these variants, such as *HBG2*: g.-158C>T, exert their effect only under conditions of erythropoietic stress, typical for β -thalassemia patients. We analyzed a previously reported deletion residing in the promoter region of the *HBG1* gene (*HBG1*: g.-225_-222delAGCA), both in normal conditions and under conditions of erythropoietic stress. Our results indicate that this deletion is responsible for decreased *HBG1* gene expression. Specifically, this deletion was shown to result in drastically reduced reporter gene expression in K562 cells, compared to the wild-type sequence but only under conditions of erythropoietic stress, mimicked by introduction of erythropoietin into the cell culture. Also, electrophoretic mobility shift analysis showed that the *HBG1*: g.-225_-222delAGCA deletion creates additional transcriptional factors' binding sites, which, we propose, bind a transcriptional repressor, thus decreasing the *HBG1* gene promoter activity. These results are consistent

with *in silico* analysis, which indicated that this deletion creates a binding site for GATA1, known to be a repressor of the γ -globin gene expression. These data confirm the regulatory role of the *HBG1*: g.-225_-222 region that exerts its effect under conditions of erythropoietic stress characteristic for β -thalassaemia patients.

Acknowledgments: This study has been funded by the MoESTD, Republic of Serbia (grant no. III 41004) and by a European Commission grant (RD-CONNECT; FP7-305444).

Identification of binding partners of the LPAR6 protein involved in hypotrichosis

M. T. Romano¹, S. M. Pasternack-Ziach¹, B. Basmanav¹, S. Kittanakom², A. M. Oprisoreanu³, N. Ishorst¹, A. Linneborn¹, S. Schoch³, I. Stagljar², R. C. Betz¹;

¹Institute of Human Genetics, University of Bonn, Bonn, Germany, ²Department of Biochemistry, University of Toronto, Toronto, ON, Canada, ³Institute of Neuropathology, University of Bonn, Bonn, Germany.

Introduction: Hypotrichosis simplex (HS) is a genetically heterogeneous hair loss disorder characterized by progressive hair loss. Mutations in more than 10 genes have been identified for HS, including the LPAR6 gene encoding for the human lysophosphatidic acid receptor 6 (LPAR6). This protein belongs to the same signaling network of lipase H (LIPH), which is also a causative gene for HS. Considering the importance of this pathway in the determination of proper hair growth, we speculated that more genes related to the same pathway could be a cause of HS. Therefore, our goal was to identify new interactors of LPAR6.

Materials and methods: Membrane yeast two hybrid (MYTH) assay and bait-dependency test were performed to spot putative binding partners (BPs) of this receptor. The results revealed 72 putative interactors from the skin/hair follicle library. The last step was to further assess the interaction by performing pull-down assay, to discard false positive results and, at the same time, confirm the interaction between LPAR6 and the candidate proteins.

Results: Using this methodology, five true BPs have already been confirmed, including the U11/U12 small nuclear ribonucleoprotein 35 kDa protein (SNRNP35), the 40S ribosomal protein S28 (RPS28), the emopamil-binding protein (EBP), the transcription factor AP-1 (JUN) and the lymphocyte antigen 6 complex locus D (LY6D).

Conclusions: We were able to identify some of the BPs of LPAR6. Many more putative interactors have been already been cloned and await to be studied.

Mechanistic Insight into Formation of Chromosomal Insertions

P. Stankiewicz^{1,2}, S. Gu¹, P. Szafrański¹, Z. H. C. Akdemir¹, B. Yuan¹, M. A. Magrini³, C. A. Bacino^{1,2}, S. L. Lalani^{1,2}, A. M. Breman^{1,2}, J. L. Smith^{1,2}, A. Patel^{1,2}, S. W. Cheung^{1,2}, C. M. B. Carvalho¹, W. Bi^{1,2}, J. R. Lupski^{1,4,5};

¹Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX, United States, ²Baylor Miraca Genetics Laboratories, Houston, TX, United States, ³Instituto Hermes Pardini S.A., Sao Paulo, Brazil, ⁴Department of Pediatrics, Baylor College of Medicine, Houston, TX, United States, ⁵Human Genome Sequencing Center, Baylor College of Medicine, Houston, TX, United States.

Chromosomal insertions are genomic rearrangements with a chromosome segment inserted into a non-homologous chromosome or a different region on the same chromosome. Insertions, usually revealed through G-banded chromosome or FISH analyses, constitute ~2% of nonrecurrent copy-number gains. Very little is known about the molecular mechanisms of their formation. Recently, microhomologies at the insertion sites were found in a few cases, suggesting a replicative mechanism of formation. We identified 16 individuals with complex insertions among 56,000 individuals tested at Baylor Miraca Genetics Laboratories using FISH and clinical array comparative genomic hybridization (aCGH). Custom high-density aCGH was performed on 10 individuals with available DNA, and breakpoint junctions were fine-mapped at nucleotide resolution by long-range PCR and DNA sequencing in six individuals. We observed microhomologies and templated insertions at the breakpoint junctions, resembling the signatures found in CGRs and chromoanaysynthesis involving two or three chromosomes generated through replication-based mechanism(s) such as FoSTeS/MMBIR. In addition, using custom high-density aCGH, we studied 11 families with unbalanced simple insertions in children, inherited from a parent, carrier of an apparently balanced insertion detected by FISH. We found that three parents had additional small CNVs at one or both sides of the inserting fragments. Moreover, in one family, we identified an additional submicroscopic reciprocal insertion. In conclusion, we propose that significant fraction of both complex insertions generated through chromoanaysynthesis involving two or more chromosomes and apparently balanced simple insertions are caused by DNA replication with template switching errors.

Introduction: Aneuploidy can lead to changes in epigenetic landscape and, vice versa, epigenetic errors can cause aneuploidy. In this study, a relationship between the level of DNA methylation and aneuploidy was analyzed in human cells during pre- and postnatal stages of ontogenesis.

Materials and Methods: Retrotransposon LINE-1 methylation was assessed by pyrosequencing in extraembryonic mesoderm and trophoblast of 17 full and 35 mosaic trisomic miscarriages, 21 induced abortions and lymphocytes of 24 healthy individuals. Spontaneous chromosome loss rate (SCLR) was analyzed *in vitro* by micronucleus test with FISH in extraembryonic fibroblasts and adult lymphocytes.

Results: LINE-1 methylation index was similar among pure trisomics (mostly of meiotic origin) and induced abortions (50-53%), but it was higher (55-56%, p=0.003) in miscarriages with mosaicism. Perhaps, this result from incomplete epigenetic genome reprogramming at preimplantation stage and may be accompanied by hypermethylation of checkpoint genes leading to aneuploidy. In adult lymphocytes, significantly higher LINE-1 methylation index (75%) was observed.

SCLR did not differ significantly between groups of embryos with different LINE-1 methylation index. However, SCLR was lower in adult lymphocytes (2.6±1.3‰) than in fibroblasts of trisomic (5.5±5.8‰, p=0.03) and induced (3.7±3.0‰, p=0.09) abortions. One can suggest that this results from centromere conformation abnormalities due to genome hypomethylation in extraembryonic tissues.

Conclusions: LINE-1 hypomethylation in extraembryonic mesoderm is associated with mitotic SCLR in comparison with adult lymphocytes. In contrast, LINE-1 hypermethylation can lead to mosaicism in early embryo development.

P13.29

Systematic investigation of a potential role of microRNAs in the pathogenesis of male pattern baldness

L. M. Hochfeld^{1,2}, T. Anhalt^{1,2}, A. Hofmann³, N. Fricker^{1,2}, M. M. Nöthen^{1,2}, S. Heilmann-Heimbach^{1,2};

¹Institute of Human Genetics, University of Bonn, Bonn, Germany, ²Department of Genomics, Life&Brain Center, University of Bonn, Bonn, Germany, ³Institute of Medical Microbiology, Immunology and Parasitology, University Hospital Bonn, Bonn, Germany.

Male pattern baldness (MPB) is characterised by an androgen-dependent loss of hair from the frontal and vertex area of the scalp which does not affect hair follicles (HFs) of the occipital scalp area. So far, the biological mechanisms that underlie these paradox differences in androgen-sensitivity between HF-subpopulations remain elusive. As microRNAs have been demonstrated to be differentially expressed in androgen-dependent vs. androgen-independent tissues and have already been implicated in hair biology, we hypothesised, that microRNAs may contribute to the differences in androgen-sensitivity between HF-subpopulations during MPB-pathogenesis. We therefore performed microRNA-profiling and differential expression analysis in HFs from the frontal and occipital scalp of 25 healthy male donors. A total of 42 microRNAs showed significant differences in gene-expression between frontal and occipital HFs. To identify potential target genes and biological pathways of these microRNAs, we searched miRWalk2.0 for validated and predicted target genes. Expression of 104 validated and 956 predicted target genes in human HF was confirmed using an in-house data set on HF mRNA expression. The subsequent Ingenuity pathway-based analysis revealed an enrichment of HF-expressed target genes in mTOR- and AKT-signalling, which have been implicated in cell proliferation and HF-homeostasis and androgen- and IL-1-signalling, the latter being described to influence androgen-regulated gene expression in dermal papilla cells. In summary, our data render a role of microRNAs in MPB-development via the control of HF-sensitivity to androgens likely. Additional studies are now warranted to elucidate the exact molecular mechanisms and to evaluate microRNAs as potential new drug targets for MPB therapy.

P13.30

Profound developmental delay, congenital heart disease, epilepsy, hearing impairment and dysmorphisms in a one-year-old girl caused by a novel heterozygous de novo missense variant in MED13L

I. M. Bader¹, C. Rauscher², W. Sper¹, O. Rittinger¹, T. B. Haack^{3,4}, R. Kovács-Nagy³, T. Meitinger^{3,4};

¹Clinical Genetics Unit; Children's Hospital; Paracelsus Medical University, Salzburg, Austria, Salzburg, Austria, ²Children's Hospital; Paracelsus Medical University, Salzburg, Austria, Salzburg, Austria, ³Institute of Human Genetics, Technische Universität München, Munich, Germany, ⁴Institute of Human Genetics, Helmholtz Zentrum München, Neuherberg, Germany.

Heterozygous *MED13L* variants are reported to cause a spectrum of phenotypes ranging from isolated congenital heart disease to a syndromic form of intellectual disability (ID) described recently (Adegbola et al. 2015).

While missense mutations in *MED13L* have early been associated with the cyanotic form of non-syndromic congenital heart diseases including dextro-looped transposition of the great arteries (MIM#608880), a *MED13L* haploinsufficiency syndrome has recently been described in two patients with moderate ID, conotruncal heart defects, facial abnormalities and hypotonia (Asadollahi et al. 2013). Ten further patients with severe syndromic ID, delay in motor and speech development but without cardiac phenotypes have been reported, mainly associated with dosage changes (van Healst et al., 2015, Adegbola et al. 2015). One report exists about a homozygous missense variant in *MED13L* in a patient with mild ID (Najmabadi et al. 2011).

Here we present the phenotype of a one-year-old girl with coarctation of the aorta, profound developmental delay, epilepsy, hearing impairment and with additional dysmorphisms that fit into the syndromic spectrum found in patients with *MED13L* haploinsufficiency.

Whole exome sequencing and molecular karyotyping revealed a novel *de novo* heterozygous missense mutation in *MED13L* as the likely cause of the condition in this girl.

The accumulation of clinical signs and symptoms, dysmorphisms as well as the severity of the profound developmental delay rises the hypothesis that the novel missense mutation in *MED13L* in this girl could exert a dominant negative effect.

P13.31

Identification of genes that escape X-inactivation

M. Rask-Andersen^{1,2}, Å. Johansson²;

¹Uppsala University, Uppsala, Sweden, ²Uppsala University, department of Immunology, genetics and pathology, Uppsala, Sweden.

Introduction: Cells of females contain two copies of the X chromosome. To avoid high expression of X-linked genes, due to gene dosage effects, one of the X-chromosomes are silenced by a mechanism called X-inactivation. This mechanism is associated with specific histone modifications and hypermethylation along the inactivated chromosome. However, a number of genes escape silencing by an unknown mechanism. In this study we utilize epigenome wide DNA methylation data to identify genes that escape X-inactivation and to contrast our findings with available public DNA methylation datasets from different tissues.

Methods: The study included 732 participants (389 female and 341 male). DNA methylation in blood samples was assayed using the Infinium Human-methylation450 BeadChip which includes 11232 probes on the X-chromosome. Escape from X-inactivation was defined as probes with an average methylation below 15% in both males and females; and non-overlapping methylation ranges.

Results: A total of, 579 CpG probes associated with 160 unique genes displayed DNA methylation patterns that were consistent with X-inactivation escape. This pattern was particularly enriched on the short arm of chromosome X, which is consistent with previous publications. The X-chromosome contains 827 genes and escape from X-inactivation was detected for approximately 19% of these genes.

Conclusion: DNA methylation data can be utilized to identify and study regions of the X-chromosome that escape inactivation. Further studies may reveal how X-inactivation and escape is related to complex traits and diseases, as well as X-inactivation dynamics related to age.

P13.32

Missense mutations leading to exon skipping in ATP7A

L. B. Moeller;

Kennedy Center, Rigshospitalet, Glostrup, Denmark.

Menkes disease (MD) is caused by mutations in *ATP7A*, encoding a copper-transporting P-type ATPase. Missense mutations have been widely used to

identify functionally important amino acid residues, but it is necessary to be cautious. By investigation of the molecular effect of 36 *ATP7A* missense mutations identified in phenotypic different MD patients, we found that 7 out of the 36 *ATP7A* missense mutations affect splicing, leading to absence of protein product due to nonsense mediated decay of the *ATP7A* transcript or to truncated forms of the ATPase due to exon skipping. Three of the mutations affects nucleotides located at the 3' end of exon 10, 12 and 15 respectively and lead to skipping of exon 10, 12 and 15 probably as a result of poor 3' donor splice site recognition. Four missense mutations, two located in the middle of exon 8 and two in the middle exon 21 lead to skipping of exon 8 and exon 21 respectively probably due to effects on exonic splicing silencers (ESS) or exonic splicing enhancers (ESE), as these mutations lead to increased ESS/ESE values. The exon skipping lead in some cases to in frame transcript and in other cases to premature termination codon due to frameshift. Normal amount of transcript was observed if the exon skipping preserves the reading frame or if the premature termination codon was located close to the last exon, exon 23.

P13.34

Identification of type-1 NF1 deletion breakpoints mediated by a novel mutational mechanism, palindrome-induced NAHR

A. Summerer¹, M. Hillmer¹, V. Mautner², D. Cooper³, L. Messiaen⁴, H. Kehrer-Sawatzki¹;

¹Institute of Human Genetics, University of Ulm, Ulm, Germany, ²Department of Neurology, University Hospital Hamburg Eppendorf, Hamburg, Germany, ³Institute of Medical Genetics, School of Medicine, Cardiff University, Cardiff, United Kingdom, ⁴Medical Genomics Laboratory, Department of Genetics, University of Alabama at Birmingham, Birmingham, AL, United States.

Neurofibromatosis type 1 (NF1) occurs with an incidence of 1 in 3000. In 5% of all patients with NF1, the cause of the disease is a large deletion encompassing the NF1 gene and its flanking regions. The majority of these large NF1 deletions are type-1, encompassing 1.4-Mb with breakpoints located in the low-copy repeats NF1-REPa and NF1-REPC which exhibit high sequence homology over a 50-kb region. Previous studies have indicated that non-allelic homologous recombination (NAHR) constitutes the major mutational mechanism underlying type-1 NF1 deletions. In the present study, we analysed 118 patients with type-1 deletions by MLPA. In 99 (84%) of the 118 deletions, the breakpoints were located within the NAHR hotspots PRS1 and PRS2, separated by 20-kb. However, 19 deletions did not exhibit breakpoints located within PRS1 or PRS2, and the aim of this study was to identify and characterize these breakpoints. To this end, we performed high-resolution array CGH and analysed overlapping long-range PCR-products using paralog-specific primers. Our results indicate that many of these type-1 deletions not mediated by NAHR within the known NAHR hotspots exhibit breakpoints close to or within long palindromic sequences capable of forming hairpin or cruciform structures. These findings imply a novel mutational mechanism, termed palindrome-induced NAHR, which is triggered by a secondary structure-induced DNA double strand break (DSB). By contrast, type-1 NF1 deletions with breakpoints located within the NAHR hotspots are likely to be regulated by PRDM9 which binds to specific DNA sequence motifs and initiates recombination by recruiting the DSB-machinery.

P13.35

Non-coding variant in a remote and putative enhancer in the cis-regulatory domain of FOXL2 found in a multigenerational Polynesian family with BPES

H. Verdin¹, A. Shelling², D. Markie³, A. L. Vincent^{4,5}, E. De Baere¹;

¹Center for Medical Genetics, Ghent University, Ghent, Belgium, ²Department of Obstetrics and Gynecology, Faculty of Medical and Health Sciences, University of Auckland, Auckland, New Zealand, ³Pathology Department, Dunedin School of Medicine, Otago University, Dunedin, New Zealand, ⁴Department of Ophthalmology, New Zealand National Eye Centre, Faculty of Medical and Health Sciences, The University of Auckland, Auckland, New Zealand, ⁵Eye Department, Greenlane Clinical Centre, Auckland District Health Board, Auckland, New Zealand.

Introduction: Both coding loss-of-function mutations of *FOXL2* and remote *cis*-regulatory deletions of the *FOXL2* region lead to the rare, autosomal dominant disorder blepharophimosis syndrome (BPES), associating an eyelid malformation with premature ovarian insufficiency. Despite extensive genetic studies, the molecular cause remains unexplained in 12% of typical BPES patients.

Patients and Methods: The goal of this study was to unravel the molecular cause in a multigenerational Polynesian family in which linkage to *FOXL2* (LOD of 3.8) was shown. *FOXL2* and its entire *cis*-regulatory domain (chr3:138652808-139067278;GRCh37) was enriched using HaloPlex followed by next-generation sequencing in five individuals. Data-analysis was performed using CLCbio.

Results: We identified a heterozygous non-coding variant, Chr3(GRCh37):g.138954755G>A, in a non-conserved sequence, predicted to function as an enhancer by Epigenome Roadmap and Ensembl. In addition, this predicted enhancer is located in the shortest region of overlap of previously delineated *cis*-regulatory deletions. An interaction of this fragment with the *FOXL2* promoter has been demonstrated using Chromosome Conformation Capture (3C) in human granulosa-like tumor KGN cells (D'haene et al. PLoS Genetics 2009).

Conclusions: This is the first report of a non-coding variant in a putative novel enhancer of *FOXL2* leading to BPES. Our study adds to the increasing number of Mendelian developmental disorders caused by subtle genetic defects of *cis*-regulatory elements, such as the ZRS and SIMO elements in the *SHH* and *PAX6* regions respectively.

Functional analyses of mutations in the mTOR regulator NPRL3 which are responsible for focal epilepsy and cortical dysplasia

M. Eggert, D. Buschmann, S. Müller, O. K. Steinlein;
Institute of Human Genetics, Munich, Germany.

Recently, mutations in the GATOR1 complex subunit gene NPRL3 were described as new genetic cause for focal epilepsy and cortical dysplasia. NPRL3 together with NPRL2 and DEPDC5 constitute the GATOR1 complex, an important inhibitor of the mechanistic target of rapamycin complex 1 (mTORC1). Yet, not much is known about the cellular function of these three GATOR1 proteins. As to mTORC1, it is known that this enzyme complex plays a key role in cellular energy homeostasis, autophagy, as well as in cell growth and cell cycle pathways. Activation of mTORC1 leads to activation of two important translation regulatory enzymes, 4-EPB and S6K.

So far, no functional study has been conducted to investigate the mechanisms underlying NPRL3 mutations in focal epilepsy. Therefore, we performed in vitro mutagenesis experiments to investigate the impact of NPRL3 mutations published by us and others on the mTORC1 pathway. The ELISA results indicate that the protein interaction between NPRL3 harboring a mutation and DEPDC5 is not affected. Our western blot analyses revealed phosphorylated 4-EPB and S6K, even under amino acid deprivation condition, indicating loss of function of the mTORC1 inhibitor GATOR1 due to mutated NPRL3. These results indicate that mutations in NPRL3 lead to loss of mTORC1 inhibition. It is therefore likely that NPRL3 is essential for a functional GATOR1 complex.

Three cases with partial 14q trisomy detected in abnormal karyotype and more precisely identified by SNP array

V. Becvarova¹, V. Curtisova², P. Capkova², V. Hurkova³, M. Magner⁴, R. Mihalova⁴, J. Horacek¹, M. Trkova¹;

¹GNNET, Prague, Czech Republic, ²University Hospital, Olomouc, Czech Republic, ³Prediko, Zlin, Czech Republic, ⁴University Hospital, Prague, Czech Republic.

Introduction: Chromosome 14 is often involved in chromosomal rearrangements. Partial trisomy of the distal segment can come from intrachromosomal or interchromosomal rearrangements in parental karyotypes or de novo formation. Determination of the unidentified extra material is usually performed by array analyses. Until recently, a few 14q duplication cases were reported. Most common clinical features are low birth weight, intellectual disability, hypotonia, microcephaly, dysmorphia, respiration failure, hypertelorism. However, no specific critical genes in this region are known yet. Reporting patients with similar aberrant chromosomes 14 will be helpful in order to characterize typical clinical genotype - phenotype correlation.

Material and Methods: Chromosomal aberrations were detected by standard karyotyping. Array analysis was performed by Illumina HumanCytoSNP 12v2.1; GRCh37/hg19. We report 3 patients of different ages (7 years, 4 months, 22 years) and with different range of duplicated chromosomal segments.

Results: Patient 1 - boy 7 years old; arr[hg19] 14q32.1 1q32.33(91,474,831-107,282,437)x3 dn, patient 2 - girl 4 months; arr[hg19] 14q31.1q32.33(83,208,737-107,282,437)x3 dn, patient 3 - woman, 22 years old; arr 12p13.33p13.32(1-5,168,849)x1,14q31.3q32.33(86,991,381-107,283,504)x3 - comes from paternal balanced translocation. Phenotypes of all 3 patients were similar.

Conclusions: In three detected partial 14q trisomies different number of genes are included: patient 1 - 140 OMIM genes; patient 2 - 153 OMIM genes; patient 3 - 152 OMIM genes (with concurrent partial deletion 12p). All examined patients share the distal 140 OMIM genes region (15.8 Mb).

Common clinical features as a typical craniofacial dysmorphism, respiration failure and intellectual disability are present in all three patients and phenotype-genotype is discussed.

P13.38

Splicing analysis of exonic OCRL mutations causing Lowe syndrome or Dent-2 disease

L. Suarez-Artiles, E. Ramos-Trujillo, E. Cordoba-Lanus, F. Claverie-Martin;
Unidad de Investigacion, Hospital Nuestra Señora de Candelaria, Santa Cruz de Tenerife, Spain.

Mutations in the OCRL gene are associated with both Lowe syndrome and Dent-2 disease. Patients with Lowe syndrome present congenital cataracts, mental disabilities and a renal proximal tubulopathy, whereas patients with Dent-2 disease exhibit similar proximal tubule dysfunction but only mild, or no additional clinical defects. It is not yet understood why some OCRL mutations cause the phenotype of Lowe syndrome, while others develop the milder phenotype of Dent-2 disease. Our goal was to gain new insights into the consequences of OCRL exonic mutations on pre-mRNA splicing.

Thirteen missense mutations and one synonymous mutation located mainly in poorly defined exons and potentially affecting splicing regulatory elements or splice sites were selected. Their effects on splicing were studied using bioinformatics tools and a minigene assay. Specific mutations were introduced by site-directed mutagenesis, and the RNA was analysed by RT-PCR and DNA sequencing.

We found that three presumed missense mutations caused alterations in pre-mRNA splicing. Mutation p.W247C generated a splicing silencer and disrupted a splicing enhancer resulting in skipping of exon 9, while mutations p.A861T and p.A861P abolished a donor splice site and resulted in skipping of exon 23.

In conclusion, these results highlight the importance to evaluate the effects of missense mutations at the mRNA level in Lowe syndrome. Our findings also allowed the detection of previously unpredicted splicing regulatory elements in OCRL exon 9.

Propranolol exerts its effects through cell cycle and proliferation genes on cancer cells

F. I. Sahin¹, O. D. Iseri², Y. K. Terzi¹, F. Sarialioglu²;
¹Baskent University Faculty of Medicine Department of Medical Genetics, Ankara, Turkey, ²Baskent University Institute of Transplantation and Gene Sciences, Ankara, Turkey, ³Baskent University Faculty of Medicine Department of Pediatric Oncology, Ankara, Turkey.

Introduction: Utilization of beta adrenergic receptor antagonists in several cancer types have been reported in the recent years. Mechanisms underlying drug effects are being investigated. In a previous study, we demonstrated that propranolol, atenolol and IC1118,551 inhibited cell growth and migration in vitro in three different cell lines. In the current study, we aimed to investigate the effects of propranolol on metastatic breast carcinoma (MCF7) and colon carcinoma (HT29) cell lines.

Materials and Methods: We detected beta adrenergic receptor expression in the two cell lines and then analyzed RNA expression levels of 86 different genes playing role in cell cycle and proliferation as well as apoptotic pathways.

Results: We noticed that, exposure of both cell lines to propranolol for 24-72 hours resulted in cell death regardless of beta adrenergic receptor expression levels.

Conclusions: Thus, for the first time in the literature, we concluded that propranolol exerts its effect by inhibiting or activating the expression of multiple genes involved in cell proliferation and death.

This study has been approved by Baskent University Institutional Review Board (Project No: DA15/09) and supported by Baskent University Research Fund.

P13.40

Altered pre-mRNA splicing due to missense CLDN16 and CLDN19 mutations associated with familial hypomagnesaemia with hypercalciuria and nephrocalcinosis

A. Perdomo-Ramirez, M. de Armas-Ortiz, E. Ramos-Trujillo, H. Gonzalez-Acosta, F. Claverie-Martin;
Unidad de Investigación, Hospital Nuestra Señora de Candelaria, Santa Cruz de Tenerife, Spain.

Familial hypomagnesaemia with hypercalciuria and nephrocalcinosis (FHHNC) is an autosomal-recessive renal tubular disorder characterized by excessive urinary losses of magnesium and calcium, bilateral nephrocalcinosis and progressive chronic renal failure. This rare disease is caused by mutations in CLDN16 or CLDN19. Patients with mutations in CLDN19 also present severe ocular abnormalities. Most of these mutations are predicted as missense. However, it is known that a large fraction of exonic mutations can alter pre-mRNA splicing. In this study, we tested presumed missense mutations in these genes for their effects on splicing.

Bioinformatics tools were used to select mutations with potential effect on splicing. Variants were experimentally tested using minigene assays. Specific mutations were generated by site-directed mutagenesis. RNA from cultured cells was analyzed by RT-PCR and automatic DNA sequencing.

Seven CLDN16 mutations; p.L145P, p.R149Q, p.R149L, p.L151F, p.L151W, p.G198D and p.G198A and two CLDN19 mutations; p.G130C and p.G130D were analyzed. RT-PCR results showed that p.G198A, p.G198D and p.G130C produced skipping of exons 4 and 2, respectively. We also found that mutations p.R149L and p.L151F resulted in loss of an exon 3 fragment.

Our results indicate that some presumed missense mutations act as splicing mutations. These nucleotide substitutions represent the first exonic mutations that induce aberrant mRNAs in FHHNC. These findings strengthen the significance to evaluate the consequences of missense mutations at the RNA level.

This work was supported by grant PI14/00760, co-financed by Instituto de Salud Carlos III (Spain) and the European Regional Development Fund "A way to build Europe".

Spermatocytic tumour (SpT) is a rare testicular tumour that is clinically distinct from the common classical seminoma. With a median age of onset ~55y, it is the only germ cell tumour of postnatal origin and thus represents a useful model to study human germ cell biology and the characteristics of germline mutations. We performed whole genome sequencing on 4 SpTs (52x coverage) and matched normal tissue (26x). The tumours exhibit extensive aneuploidy (50-99 autosomes/tumour) unusually involving whole chromosomes, with relative gains of chr9 and chr20 common to all tumours. Genome-wide, the acquired single nucleotide variant (SNV) load was extremely low for these adult-onset tumours (~0.2 per Mb). An average of 6 (2-9) non-synonymous variants were called per tumour; no SNVs were shared across tumours and no known oncogenic drivers were identified. Strikingly, in all cases, mutant allelic ratios were low (<50%) and inversely correlated with chromosomal copy-number, suggesting that they represent secondary passenger mutations. Two-thirds of SNVs were transitions, with C>T accounting for 51% of all SNVs, most commonly occurring at CpGs; a bias to specific trinucleotide contexts was observed. This mutational signature, which is distinct from other germ cell tumours, is typical of that observed for de novo germline mutations. We propose that in this unique tissue, gene imbalance caused by chromosomal aneuploidy is the oncogenic mechanism driving tumourigenesis and results in spermatogonia's re-entry into mitosis following failure to complete meiotic divisions. Analyses of splicing mutations in the SFTPC gene: example of the p.Gln145His mutation

C. Delestrain^{1,2}, S. Simon¹, A. Aissat^{1,2}, R. Medina³, X. Decrouy¹, B. Costes¹, R. Epaud^{1,2}, P. Fanen^{1,3};
¹INSERM U955, Creteil, France, ²Centre Hospitalier Intercommunal de Créteil, Service de Pédiatrie Générale, Creteil, France, ³AP-HP, Hôpital Henri Mondor, Département de Génétique, Creteil, France.

Since the first description of interstitial lung disease (ILD) being associated with an alteration of the SFTPC gene in 2001, about 50 different mutations have been reported. All patients are heterozygous carriers of autosomal dominant SFTPC mutations and the lung disease caused by different SFTPC mutations covers a broad range of phenotypes from neonatal respiratory distress syndrome to adult ILD. The wide phenotypic variability is not fully explained by the genotype and we postulated that splicing defect could explain such a discrepancy.

We first study an exonic mutation, c.435 G> C (p.Gln145His) localized in the well conserved BRICHOS domain of the pro-protein SP-C (proSP-C) and associated to a fatal neonatal respiratory distress syndrome. In silico analysis predicted a drastic reduction of the splice donor site at the exon-intron 4 junction's strength score. Using wild-type and mutant minigenes transfected in alveolar type II epithelial cells (A549), we showed a complete exon skipping due to this mutation. When co-transfection of both wildtype and mutant minigenes was performed, a dominant negative effect on the splicing was observed. Exon 4 is in frame and its skipping lead to a truncated protein which is retained in the endoplasmic reticulum as shown by confocal microscopy.

These results indicated that the mutation p.Gln145His (Q145H), previously described as a missense mutation, is actually a splicing mutation which should be referred as c.325_435del (p.Leu109_Gln145del). The absence of alternative splicing leading to the skipping of exon 4 fully explained the severity of the phenotype observed.

P13.44

A comparative analysis of functionality between a recombinant thermostable reverse transcriptase and a commercial mesophilic reverse transcriptase using RT-PCR and Real time PCR

N. Faramarzi Garous, S. Gharavi, Z. Moosavi Nejad, N. Ghorbanmehr, M. Sheikh Hosseini;
Alzahra University, Tehran, Iran, Islamic Republic of.

Reverse Transcriptase, is an important enzyme involved in the synthesis of cDNA from unstable RNA molecules and has applications in transcriptome and RNA expression profiles. The efficiency of this enzyme relies on its molecular characteristics, including those that confer thermostability processivity and error-free reverse transcription capabilities. cDNA production at high temperatures has several advantages like elimination of secondary structures in the RNA molecule and use of RNA with GC-rich regions in templates.

A bacterial intronic gene coding for thermostable reverse transcriptase (*trt*) has been identified and cloned in pET28a vector and subsequently expressed in a suitable host (*E.coli* BL21). Following induction of the bacterial culture and sonication of the cells, the enzyme was purified by Ni+2 columns.

The efficacy of the recombinant enzyme was successfully tested in RT and Nested-PCR reactions at 37, 60, 70, 80 and 90°C for the detection of tr 9:22. The capabilities of this enzyme was also compared to the mesophilic M-MLV RT and proved to be more versatile and robust. Specific activity in optimum conditions compared for Trt and MMLV enzymes by Real time-PCR. The optimum temperature for Trt activity was 70 °C. A significant increase compared to optimal temperature of MMLV activity (37 °C) is shown.

The Trt protein can carry out reverse transcription at very hot temperatures (cDNA synthesis was detectable at 90°C) and is a novel type of RT that may be exploited for applications where synthesis of cDNA at high temperatures is preferable to diagnose CML, ALL, AML diseases.

P13.45

De novo translocation frequency of the recurrent constitutional t(11;22)(q24.13;q11.21) in normal somatic tissues

H. Kurahashi, T. Kato, M. Suzuki, M. Tsutsumi, T. Ohye, H. Inagaki;
Institute for Comprehensive Medical Science, Fujita Health University, Toyoake, Aichi, Japan.

The t(11;22)(q23.3;q11.2) is one of several recurrent constitutional translocations mediated by palindromic AT-rich repeats (PATRRs). Although it is likely that the secondary structure triggers the initiation of the translocati-

on formation, precise underlying mechanism remains enigmatic. In this study, we carried out the t(11;22)-specific PCR for the der(11) or the der(22) using primers flanking the PATRR11 and PATRR22. To analyze the de novo t(11;22) in the genomic DNA from normal individuals, the PCR was carried out to detect the t(11;22) at the single cell sensitivity. No translocation was detected in the DNA from somatic tissues including stomach, small intestine, colon, spleen and bone marrow. When we use DNAs from testis or ovary from fetus and adult, only the testicular tissue from adult showed the t(11;22)-specific PCR products at a lower frequency than that generally observed in normal semen. DNA from eight cancer or leukemia cell lines were also negative for the PCR. Our data suggest the hypothesis that non-replicative mechanism for formation of the recurrent palindrome-mediated translocations.

P13.46

Unbalanced de novo X;13 translocation with skewed X chromosome inactivation

M. Orera¹, C. Rodriguez Hernandez¹, L. Fernandez Garcia Moya², M. Morí², V. Seidel¹; ¹Hospital Gregorio Marañón, Madrid, Spain, ²Hospital La Paz, Madrid, Spain.

Introduction: X chromosome inactivation is meant to provide an equal gene dosage between males and females. X-autosome translocations are rare events. When the translocation yields an unbalanced genomic rearrangement, the derivative X chromosome is generally selectively inactivated, avoiding the effect of the autosomal trisomy. We present a girl with an unbalanced X-13 translocation.

Materials and Methods: 4th child of non-consanguineous parents. The mother was treated with thyroid hormone and hydroxychloroquine during the pregnancy. A C- section was performed for fetal distress at 38 weeks, with birth weight 2580 g, length 49 cm. She presents postaxial polysyndactyly on the left foot, anteriorly placed anus and a sacral dimple. Abdominal USS detected a bicornuate uterus. At age 12 months a mild developmental delay was noted. Her overall growth remains between 3rd and 10th centiles.

Results: Standard karyotype: 46,X,der(X)t(X;13)(p11;q12.1)

Chromosome microarray: 13q12.3-q34 duplication (84 Mb) and Xp22.33-Xp11.23 deletion (46 Mb)

X inactivation studies showed a markedly skewed inactivation pattern.

Parental karyotypes were normal.

Conclusions: The mild clinical phenotype of partial trisomy 13 together with the skewed X inactivation pattern in blood suggests that the derivative X chromosome carrying a large segment of chromosome 13 is preferentially inactivated in most tissues. Mild features of partial Xp monosomy are to be expected as the deletion affects PAR.

To our knowledge, this is the first report of a child with almost complete trisomy 13 originated by a de novo X;13 translocation.

P13.47

Identification of chromosomal translocation breakpoints associated with holoprosencephaly using whole-genome sequencing: Suggestion of a positional effect.

J. Klar^{1,2}, H. Ehrencrona³, N. Dahl^{1,2};

¹Department of Immunology, Genetics and Pathology, Uppsala, Sweden, ²Science for Life Laboratory, Uppsala, Sweden, ³Division of Clinical Genetics, Lund, Sweden.

Introduction: We identified a boy with developmental delay, diplegia and lobar holoprosencephaly (HPE). Karyotyping revealed an apparently balanced reciprocal *de novo* chromosomal translocation t(10;12)(q24;p13). Genome-wide array analysis (Affymetrix Cytoscan HD) and exome sequencing did not detect any pathogenic variants.

Materials and Methods: We performed whole-genome sequencing (WGS) using Illumina TruSeq (insert size of 350 bp) on a HiSeqX (paired-end and 150bp read length). To identify breakpoints we utilized BreakDancerMax, a Perl/C++ package that provides genome-wide detection of structural variants. Anomalously aligned reads at chromosome 10q24 and chromosome 12p13 were visualized using Integrative Genomics Viewer (IGV) and confirmed by Sanger sequencing.

Results: At the breakpoint on the chromosome 10 derivative, we identified a deletion of 7 bp and an insertion of 20 bp of unknown origin. Likewise, at the breakpoint on the chromosome 12 derivative, we identified a deletion of 31 bp followed by an insertion of 14 bp of unknown origin. Both breakpoints are situated in intergenic regions, specifically between the genes *FBXW4* and *FGF8* on chromosome 10q24 and between *EFCA4B* and *PARP11* on chromosome 12p13. According to Decipher database, insertion and deletions spanning both breakpoint regions are associated with intellectual disability and macro/microcephaly. Furthermore, variants in *FGF8* have been reported in autosomal recessive HPE.

Conclusions: Traditional methods to determine translocation breakpoints, such as FISH, Southern blot or long-range PCR, are laborious and with limited resolution. Our results demonstrate the efficacy of WGS for the precise identification of translocation breakpoints in non-coding regions.

When genotype does not account for phenotype: the lesson from isodisomic chromosomes

A. La Barbera¹, A. Provenzano², M. Garonzi³, E. Zago⁴, V. Orlandini², M. Pantaleo¹, G. Traficante², M. Vignoli⁵, G. Bacci⁶, S. Guarducci¹, S. Bargiacchi⁷, E. Gambineri⁸, M. Delledonne^{3,4}, O. Zuffardi⁷, S. Giglio^{1,2};

¹Medical Genetics Unit, Meyer Children's University Hospital, Florence, Italy, ²Medical Genetics Unit, Department of Clinical and Experimental Biomedical Sciences, Mario Serio; University of Florence, Florence, Italy, ³Department of Biotechnology, University of Verona, Verona, Italy, ⁴Personal Genomics srl, Verona, Italy, ⁵Department of „NEUROFARBA,” Section of Children's Health, University of Florence, Anna Meyer Children's Hospital, Florence, Italy, ⁶Ophthalmology Unit, Department of Neuroscience, Meyer Children's Hospital, Florence, Italy, ⁷Department of Molecular Medicine, University of Pavia, Pavia, Italy.

We demonstrated isodisomy for chromosome 1 in two unrelated subjects from non-consanguineous parents, affected by autosomal recessive syndromes associated with two genes on chromosome 1, type 2 nephrotic syndrome (#600995) and campodactyly-arthropathy-coxa vara-pericarditis (#208250). We detected an homozygous mutation in NPHS2 (1q25.2,c.538G>A) in case 1, and in PRG4 (1q31.1,c.2288C>G) in case 2, inherited only by the father. SNP-CGH array analysis showed complete homozygosity for chromosomes 1 in both cases. This finding is in agreement with post-zygotic monosomy rescue of the paternal chromosome 1, as a consequence of maternal non-disjunction of chromosomes 1. To exclude recessive conditions for other genes located on chromosome 1, we performed whole exome sequencing. We identified variants in FUCA1, DPYD, ABCA4, NPHP4, PINK1 (case 1) and DDOST, STIL, ATP7B, CFH genes (case 2), considered disease-causative by HGMD and never reported in dbSNP and Exac. A detailed clinical examination in both patients did not show any signs of the expected diseases, excepted for PINK1 that is associated with a late onset disease. Our observations further demonstrate that low penetrance and extensive phenotype heterogeneity occur even for genomic variants reported as causative in homozygous state. The analysis of entire exome/genome is a major challenge to geneticists in order to provide genotype-phenotype correlations, especially in prenatal setting.

Transcriptome Sequencing and characterization of two Bloom's syndrome patients

M. M. Montenegro, G. M. Novo-Filho, A. M. Nascimento, E. A. Zanardo, A. T. Dias, T. V. M.

M. Moura, C. Milani, F. Madia, D. A. M. Silvestre, C. A. Kim, L. D. Kulikowisk; FMUSP, São Paulo, Brazil.

Introduction: Transcriptome profiling of mRNA could be a powerful approach to identify new transcripts, fusion genes, gene regulation, mutations and networks of genes that play a role in diseases. We investigated relevant genomic markers that could be associated to Bloom's syndrome (BS), a chromosomal instability disorder caused by mutations in BLM gene. **Materials and Methods:** We performed a deep-sequencing RNA-Seq profiling using high throughput sequencing (Illumina HiSeq 2500 platform) of samples derived from two patients with BS and three unaffected controls. The raw data analysis was generated using specialized softwares (CASAVA 1.8.2, Bowtie2, EdgeR, Rsubread and DESeq2). **Results:** The RNA-Seq assay revealed the precise location of transcription limits, with resolution of a single nucleotide and high level of efficiency, showing high genetic complexity. The results disclosed 399 genes differentially expressed : 216 up regulated in the group with Bloom syndrome and 183 up regulated in the control group. Unexpected most of them were immune system-related genes. Also, we detected large number of SNP and IDELS in one of BS patients, highlighting a frameshift in the BLM gene. **Conclusions:** Our results suggested that gene expression network in BS could interfere in the regulation of the pathways associated with the immunological systems regulation probably caused by disturbance of DNA repair mechanisms. Furthermore, the study of the transcriptome using RNA-Seq may help to a breakthrough in the pathogenesis of BS. Grants: FAPESP: 09/53105-9 and FINEP-CT INFRA 0160/12 SP8.

C26-ceramide is a new and sensitive biomarker for Farber's disease

C. Cozma¹, M. I. Iurascu¹, S. Eichler¹, S. Zielke², A. Rolfs², J. Köster¹;

¹Centogene AG, Rostock, Germany, ²Albrecht-Kossel-Institute, University of Rostock, Rostock, Germany.

Farber disease (Farber's lipogranulomatosis, ceramidase deficiency), is an autosomal recessive, extremely rare disease caused and characterized by a deficient acid ceramidase activity encoded by ASA1 gene. Low ceramidase activity is resulting in accumulation of fatty substances, mainly ceramides. At clinical level, Farber disease is manifesting through hallmark symptoms such as: periarticular nodules, lipogranulomas, swollen and painful joints and a hoarse voice or a weak cry; in addition to these, also hepatosplenomegaly, rapid neurological deterioration or developmental delay are reported [1, 5-6]. Seven different Farber types were described, with phenotypes varying from mild cases with a longer life expectancy to very severe cases, where the patients do not survive past their first year of life.

The screening through over 40 different ceramide-like molecule show that only C26 is specifically increased in samples from Farber patients. We present here a new method of diagnosis of Farber disease by determining the concentration of C26 ceramide isoforms using LC/MRM-MS and C25 ceramide as internal standard. Moreover, we found that cis-isomer of the C26 ceramide is a specific biomarker for Farber disease, with pathological values in a range of 39.2-150.0 nmol/L blood (normal range 13.6-23.4 nmol/L blood, N=192, healthy individuals). The new biomarker can be determined directly in the dried blood spot extract with low sample consumption, easy sample preparation, high reproducibility and it presents the possibility of to be used in high throughput screenings.

P14.004

Development of a new biomarker method for the diagnosis of MLD using tandem mass spectrometry

S. Eichler¹, C. Cozma¹, M. I. Iurascu¹, A. Rolfs²;

¹Centogene AG, Rostock, Germany, ²Albrecht-Kossel-Institute, University of Rostock, Rostock, Germany.

Metachromatic leukodystrophy (MLD) is a lysosomal storage disease with an autosomal recessive inheritance pattern. MLD is caused by a deficiency of the enzyme arylsulfatase A (ARSA) and is characterized by enzyme activity in leukocytes that is less than 10% of normal controls. However, assay of the ARSA enzyme activity alone is not sufficient for diagnosis; ARSA pseudodeficiency, which is characterized by enzyme activity that is 5~20% of normal controls does not cause MLD. Without this enzyme, sulfatides build up in many tissues of the body, eventually destroying the myelin sheath of the nervous system with serious consequences manifested in clinical symptoms e.g. weakness, muscle rigidity, developmental delays, convulsions, paralysis, and dementia. A recent study contended sulfatide is not completely responsible for MLD because it is nontoxic. It has been suggested lysosulfatide plays a role because of its cytotoxic properties in vitro. Recently developed enzyme replacement therapy and the steep progression of the disease in ARSA patients make the development of HTS diagnosis of high importance.

Here we report the development of a new biochemical screening method for ARSA patients using a combination of two techniques: (i.) arylsulfatase enzymatic activity and (ii.) quantification of ARSA specific biomarkers (both lyso-sulfatide and selected sulfatides). Both assays are using for the analysis liquid chromatography coupled with high resolution multiple reaction monitoring mass spectrometry (LC/MRM-MS) and the results were confirmed by genetic analysis. This screening method has been validated for dried blood spot (DBS) technology which further simplifies the sample handling, processing and analysis.

P14.005

The use of automated facial analysis in the clinical diagnostic of autism spectrum disorders (ASD)

N. A. Varga, P. Balicza, K. Pentelenyi, H. Piko, M. Szegedi, V. Karcagi, M. Molnar; Institute of Genomic Medicine and Rare Disorders, Budapest, Hungary.

Introduction: Autism can be part of a genetic syndrome associating with dysmorphic features. While there are many studies that described genetic alterations associated with ASD, none have identified facial phenotypes associating to ASD with computer-aided facial analysis. Here we evaluate the geno/phenotype relation in a limited number of autistic individuals.

Methods: An image set of affected individuals divided into two cohorts: presenting facial dysmorphologies (AFD) (n=20) and without dysmorphology (ANFD) by human experts. These cohorts were compared to unaffected controls (n=50) using variables and rankings produced by the Facial Dysmorphology Novel Analysis (FDNA) technology. In both ASD cohorts mutations of 103 genes associated to autism, repeat expansions of FMR1 gene, and in some AFD cases chromosomal abnormalities have been identified.

Results: Clear trends were recognizable in the three groups along facial dysmorphology variables and rankings. Although labeled as not showing facial dysmorphology, the ANFD cohort was automatically ranked separately from the unaffected controls. In addition, two possible clusters of ANFD were recognized by the technology. The AFD cohort was clearly recognized as separate from the other two cohorts. In the AFD group Fragile X, CHARGE, Silver Russell, Cohen, 2q37.3 microdeletion syndrome, and Speech Language Disorder 1 were identified.

Conclusion: The preliminary results show that deep phenotyping provided by a computer-aided facial analysis could be instrumental in the early clinical diagnostic of the syndromic ASD forms and could help in the selection of diagnostic molecular tests. Larger study is needed to assess these trends and to allow cross-validation.

P14.006

A comparison of two NGS novel targeted panel-sequencing assays for patients with autoinflammatory disease

M. Antolín¹, H. Valbuena¹, A. Fernández Rodríguez², A. Outeiral¹, A. M. Cordero¹, E. García-Arumí^{1,2}, E. Tizzano^{1,2};

¹Department of Clinical and Molecular Genetics and Rare Disease Unit, Hospital Vall d'Hebron, Barcelona, Spain, ²Biomedical Network Research Centre on Rare Diseases (CIBERER), Instituto de Salud Carlos III, Madrid, Spain.

The molecular diagnosis of autoinflammatory diseases includes several candidate genes such as *MEFV*, *MVK*, *TNFRSF1A*, *NOD2* and *NLPR3*. NGS offers an improvement in time and costs versus Sanger sequencing. We compared two different NGS approaches for molecular diagnosis of these patients.

Two different library approaches were followed. In the first, 8 different fragments *MEFV* (14.600 kb), *MVK* (23.576 kb), *TNFRSF1A* (13.358 kb), *NOD2* (35.939 kb) and *NLPR3* (31.054 kb) were amplified using Takara *LA Taq* DNA Polymerase and library preparation was performed using NexteraXT. In the second, a Custom GeneRead DNAseq panel of targeted genes was amplified (197 amplicons with a mean size of 203 bp) and libraries were prepared with NEBnext Ultra DNA kit. In both approaches, libraries were pooled and sequenced using paired-end on the MiSeq platform. Sequencing data were analyzed with the Variant Studio and GeneRead Seq Variant Analysis software, respectively. The validation of the potential pathogenic variants was performed by Sanger sequencing.

The Nextera approach requires a high quality of DNA to amplify fragments until 15000 bp. The sequences include the whole intronic regions, but the coverage is very heterogeneous. On the other hand, GeneRead protocol is fast, it predicts the uncovered regions and the coverage is similar and constant between runs. In both procedures, the detected variants were highly similar and false positives have not been observed.

Both approaches are useful in the detection of variants associated with the pathogenesis of autoinflammatory diseases. In our hands, GeneRead appears faster and more reproducible between runs.

A novel mutation in WDR62 gene identified in a Moroccan family with autosomal recessive primary microcephaly using Next - Generation Sequencing

I. Cherkaoui Jaouad^{1,2}, A. Zrhidri¹, W. Jdioui^{1,2}, J. Lyahyai¹, L. Raymond³, M. Taoudi², G. Egea³, S. El Mouatassim³, A. Sefiani^{1,4};

¹Centre de Génétique Humaine, Faculté de médecine et de Pharmacie, Rabat, Morocco,

²Département de Génétique Médicale, Institut National d'Hygiène, Rabat, Morocco,

³Département de Génétique Moléculaire, Laboratoire Biomnis, Lyon, France, ⁴Institut National d'Hygiène, Rabat, Morocco.

Introduction: Autosomal recessive primary microcephaly (MCPH) is a rare genetically heterogeneous disorder of neurogenic brain development characterized by reduced head circumference at birth with no gross anomalies of brain architecture and variable degrees of intellectual impairment. Clinical and genetic heterogeneity in monogenetic disorders represents a major diagnostic challenge.

Here, we used the whole-exome sequencing as a diagnostic approach for establishing a molecular diagnosis in a family with two children with MCPH. Materials and Methods: Two patients, 11 and 9 years old, born from consanguineous parents, were referred to the department of medical genetics. The diagnosis of MCPH was made, based on reduced head circumference without brain architecture abnormalities. Whole-exome sequencing was per-

formed in these patients, their parents and their two healthy sibling. Results: A homozygous mutation c.1027C>T; p.Gln343Ter in exon 8 of WDR62, a gene already known to be related to MCPH, was identified. Sanger sequencing confirmed this mutation in the affected children. This mutation was not found in HGMD and 1,000 Genome database.

Conclusions: Our data expanded the spectrum of mutations in WDR62 gene, and give more arguments of the powerful and cost-effective tool of whole exome sequencing for the molecular diagnosis of genetically heterogeneous disorders such MCPH. Exome sequencing allows us to have faster molecular results especially when specific diagnosis needs a longer time to sequence many genes.

P14.008

Development of a next generation sequencing panel for diagnostic and investigation of bleeding disorders

N. Borràs^{1,2}, L. Ramírez^{1,2}, N. Comes^{1,2}, C. Altisent³, R. Parra^{1,3}, F. Vidal^{1,2}, I. Corrales^{1,2};
¹Blood and Tissue Bank, Barcelona, Spain, ²Vall d'Hebron Research Institute, Barcelona, Spain, ³Vall d'Hebron University Hospital, Barcelona, Spain.

The advent of NGS has opened the possibility to design custom protocols for molecular analysis of several genes in parallel. This approach is particularly valuable in the diagnosis of diseases with similar phenotype although caused by a heterogeneous molecular basis. Taking advantage of this novel opportunity, we designed and validated a NGS custom panel to simultaneously analyze the 23 essential genes involved in inherited bleeding disorders.

The targeted exon enrichment GeneRead panel (QIAGEN) designed comprises a total of 1,285 amplicons (size average 169 bp) covering the 98.7% of the target genomic regions. Construction of libraries, including patient-specific indexation, was performed with NEBNext Ultra DNA Library Prep Kit. Between 24 and 48 libraries were sequenced together in every MiSeq (Illumina) run. To date, we have been diagnosed in this way more than 250 patients, suffering both frequent and minor coagulopathies. Putative mutations were identified by GeneRead Variant Calling software and further validated by Sanger methodology, reaching 100% sensitivity. This versatile protocol allows to process together samples from different pathologies, with the consequent simplification of routine procedure and cost reduction. Likewise, it has been especially advantageous when clinical diagnosis was unclear or controversial due to a borderline phenotype with various candidate genes. Importantly, this methodology offers invaluable genetic information of all the variants, polymorphisms and causative mutations, from several hemostatic genes. Analysis and integration of this data could refine the knowledge of genotype-phenotype correlation and improve the forecasting of hemorrhagic risk.

P14.009

Novel thermal cycler amplifies the entire BRCA1 gene within 10 minutes

R. Cammaert¹, M. Kribbe², W. H. Deelen², R. Hofstra², G. de Vos¹;
¹Molecular Biology Systems, Goes, Netherlands, ²Erasmus Medical Center, Rotterdam, Netherlands.

Background: The most commonly used technique in clinical genetics is PCR. PCR is reasonably time consuming. Most labs perform maximal 4 PCR's per day (including one overnight). Making PCR faster has been accomplished by introducing faster Peltier based equipment and using faster chemistry. Here we report a novel thermal cycler, which can amplify the complete BRCA1 gene under 10 minutes, reducing the amplification time from 150 minutes to less than 10 minutes.

Methods: Amplification is performed in ultra thin wells (<50 micron) in a 96-well microplate format. The PCR machine consists of three temperature zones for denaturation, annealing and extension. Each zone consists of two opposite heated blocks. When the tray enters a temperature zone, the heated blocks are brought together, thus squeezing the wells. The reaction mix reaches the desired temperature instantaneously.

Results: 29 fragments, covering all the exons of the BRCA1-gene were amplified in under 10 minutes, employing 30 cycles over 3 temperatures. Results were confirmed by Sanger sequencing. Moreover, a 102 basepair fragment was amplified in less than 2 minutes, employing 30 cycles over 3 temperatures.

Discussion and conclusion: This technology introduces a microplate compatible PCR format, which can perform most PCR's in less than 10 minutes. It will allow laboratories to change their logistics (a machine is always available shortly), increase their throughput or speed up their process. With this technology one machine comfortably performs over 40 PCR's in an 8-hour working day.

Clinical validity, reproducibility, and utility of NGS panel tests for hereditary breast and ovarian cancer: challenges and solutions

S. Lincoln¹, A. Desmond², A. Kurian³, D. Haussler⁴, S. Yang¹, M. Cline⁵, S. Aradhya¹, J. Ford², L. Ellisen², B. Paten⁴, R. Nussbaum¹;
¹Invitae, San Francisco, CA, United States, ²Massachusetts General Hospital, Boston, MA, United States, ³Stanford University Medical Center, Palo Alto, CA, United States, ⁴University of California, Santa Cruz, CA, United States.

Background: In studies of over 1000 patients [1,2] we recently demonstrated that multigene testing can produce clinically valid results, comparable to traditional tests while expanding patient management impact. Other findings included (a) that pathogenicity classifications produced using publicly available resources under recent guidelines [3] were 99.8% similar to those produced by others using a large proprietary database. Also (b) many pathogenic variants were technically challenging for NGS. Here, we further explore these topics in a substantially larger data set.

Methods: De-identified panel test results for roughly 20,000 individuals were examined. In addition, data from the ClinVar database, representing another approximately 20,000 patients, were used.

Results: Consistent with our prior results, about 4-5% of patients harbor mutations in genes other than BRCA1/2. Most of these findings are consistent with the patient's personal/family history and are not incidental. About 10% of these mutations are of types known to be challenging for NGS (e.g. single exon CNVs, large indels, complex events, etc.). These require specialised algorithms or NGS biochemistries to accurately report.

Considering BRCA1/2 variants, interpretations are highly concordant (98.5%) between established diagnostic labs in terms of clinical management impact. Moreover all of the discordances are in rare variants that appear in few patients. Thus, 99.8% of patients are expected to be concordant, as we observed previously.

Conclusions: When using appropriate NGS and variant interpretation methods, validity and utility of panels tests can be established.

Cell-free DNA as a tool for non-invasive cancer detection

A. Montaner^{1,2}, J. González², L. Armengol¹, J. Rodríguez²;
¹qGenomics Laboratories, Esplugues de Llobregat, Spain, ²Bioinformatic Research Group in Epidemiology, Centre de Recerca en Epidemiologia Ambiental (CREAL), Barcelona, Spain.

Introduction: Early detection is key for increasing survival in cancer patients but it is limited by the sensitivity of current detection methods. In this context, cell-free DNA (cfDNA), currently used as a non-invasive tool for aneuploidy detection in prenatal screening and graft rejection monitoring, promises to improve early cancer detection. Because cfDNA levels in blood are very low, sample preparation must be optimized. Here we set up a workflow for generating high quality libraries from low cfDNA inputs that can be sequenced using next generation sequencing (NGS) platforms.

Materials and methods: Blood samples from healthy individuals, pregnant women and cancer patients were collected in Streck tubes to avoid genomic DNA contamination from white blood cells. Plasma was separated by centrifugation prior to cfDNA extraction. Multiple cfDNA extraction methods were tested. Library construction was optimized for low cfDNA inputs and samples were analyzed by qPCR and targeted NGS.

Results: Bead and column-based methods produced similar yields (2.5 - 10 ng/mL) but the bead-based methods were preferred for being faster and not requiring the addition of carrier molecules. Using this workflow we were able to detect fetal cfDNA by qPCR, and to successfully sequence libraries constructed from 1ng input DNA.

Conclusions: We have set up a workflow that allows the analysis of limiting amounts of cfDNA through NGS, which can be applied to the detection of biomarkers present in cfDNA in samples from multiple biological origins, including cancer.

Molecular genetic testing and the future of Clinical Genomics

A. Nuzzo¹, D. Katic¹, M. Dulovits¹, G. Rosenauer¹, P. Miglinci¹, M. Uendemir², S. Pabinger², E. Heitzer³, C. Bock⁴, G. Hoermann⁵, M. Speicher³, A. Kriegner¹;
¹Platomics GmbH, Vienna, Austria, ²Health and Environment Department, Molecular Diagnostics, AIT Austrian Institute of Technology, Vienna, Austria, ³Institute of Human Genetics, Medical University of Graz, Vienna, Austria, ⁴CeMM Research Centre for Molecular Medicine of the Austrian Academy of Sciences, Vienna, Austria, ⁵Department of Laboratory Medicine, Medical University of Vienna, Vienna, Austria.

Introduction: Deep sequencing technologies significantly affect the way modern genetic tests are performed. The availability of genome-wide screening technologies shifted the paradigm from few gene investigation strategies to a multi genes / complete genome analysis. Nevertheless, clinical application are often still focused on the analysis of specific target regions. As a result, a new trend is emerging that exploits the genome-scale approach by “sequencing everything”, but analyzing only the regions of interest of specific diagnostic cases (e.g., diseases). As a consequence, sequencing data that is available, but has not been analyzed, will be reused in the future to answer different questions over time. Moreover, an increasing need for decision support in routine diagnostics with multiple applications will be noticed.

Methods: Following this trend, Platomics proposes an analogue approach to software solutions designed for genetic data analysis. The computational approach can be summarized as: one specific software app for each diagnostic use case. This also marks a paradigmatic shift in software development, as it is focused on atomic validated reproducible applications rather than omni-comprehensive highly configurable solutions. Therefore, each application needs to be in line with the specific genetic screening requirements, in terms of ethics, benefits for the patient, and effects on health care costs.

Conclusions: Genetic-test manufacturers will be enabled to bring their new products faster to the market and lowering the barrier-to-entry by shortening the time-to-market path. Furthermore, the new Platomics approach will provide a streamlined way to drive the adoption of new genetic tests in routine diagnostics.

P14.013
Carrier risk estimation using SNP-based measures of relatedness

R. Shraga, M. Gold, A. Manoharan, S. Yarnall;
Recombine, New York, NY, United States.

Background: Our goal was to evaluate localized genetic relatedness in clinically-relevant regions. We focused on DNA surrounding genes related to Cystic Fibrosis, Sickle-Cell Anemia, and Smith-Lemli-Opitz Syndrome.

Methods: We created three cohorts by selecting carriers of the disorders and adding randomized control patients (non-carriers) of the same ethnicity. To study the relatedness of each group, we selected single nucleotide polymorphisms (SNPs) in the region of the genes implicated in each disease. We created genetic similarity matrices for each cohort using six SNP-based measures of relatedness. We compared average relatedness within the case groups, within the control groups, and between the two groups. This led to development of an initial carrier risk classifier for Cystic Fibrosis mutation DeltaF508, which modifies the k-Nearest Neighbor (KNN) algorithm to use our SNP-based relatedness measure instead of Euclidean distance. We tested the performance of our classifier using repeated random sub-sampling cross-validation.

Results: Carriers of all 3 disorders appeared more similar to each other than to controls. We found that inter-group relatedness between sets of patients that are carriers of different mutations for the same disease varied widely. Using the modified KNN classifier, we randomly sub-sampled our cohort into training and testing sets, and found 98% of cases get classified as at risk compared to 20% of controls.

Conclusion: These results indicate it may be feasible to classify carrier risk when direct observation of a mutation is not possible. This may be useful for improving sensitivity where direct testing is difficult or error prone.

P14.014
Variability in apoptosis patterns in cfDNA in body fluids in healthy individuals

B. Gudmundsson^{1,2,3}, H. G. Thormar^{1,3}, O. Hammarlund¹, J. Lindblad¹, M. L. Sigurdardottir^{1,3}, S. Rafnsdottir^{1,3}, A. Sigurdsson¹, B. Thorsteinsdottir^{1,2}, **J. J. Jonsson**^{1,2};
¹Univ. of Iceland, Reykjavik, Iceland, ²Landsþítali - National University Hospital of Iceland, Reyjavik, Iceland, ³Lifeind ehf., Reykjavik, Iceland.

Introduction: Cell-free DNA (cfDNA) in plasma is used for fetal sexing, NIPT and Rhesus genotyping. cfDNA also holds promise in detecting acquired somatic changes in cancer. We used a new technique, Northern Lights Assay (NLA), to further investigate structure of cfDNA in body fluids in healthy subjects.

Materials and Methods: NLA is based on Two-Dimensional Strandness-Dependent Electrophoresis (2D-SDE), a technique of nucleic acid separation based on size, standness, and conformation changes induced by damage. Each specimen is analyzed in sample pairs of non-digested DNA to detect single- and double-stranded breaks and MboI-digested DNA to detect various other lesions. NLA is run in microgel to improve sensitivity. We tested NLA on cfDNA isolated with gentle methods from whole blood, plasma, saliva, urine sediment and cell-free urine in healthy controls (7 males and 13

females) age 21 to 80.

Results: Yield from clinical volume samples was sufficient for sensitive analysis with NLA. Variable but generally extensive damage was detected in cfDNA from various body fluids. cfDNA in plasma ranged from essentially at least 3 kb long fragments only to a substantial fraction comprising apoptosis DNA fragments.

Conclusions: The findings have implications for cfDNA assays. Consistent differences in rates of apoptosis in healthy subjects seem unlikely. A more plausible explanation is time-coordinated pulse release of cfDNA fragments from apoptotic cells. This pulse would have previously gone undetected using protein markers of cell death with half life of hours in plasma instead of minutes for cfDNA.

P14.015
Detecting EGFR and related mutations in the cfDNA of lung cancer patients

M. Tamm¹, K. Oselin², P. A. Kivistik¹, K. Keerma¹, R. Roosipuu³, M. Saare¹, H. Roomere⁴, A. Metspalu^{1,5}, N. Tõnisson^{1,4};
¹Estonian Genome Center, University of Tartu, Tartu, Estonia, ²North Estonia Medical Centre, Tallinn, Estonia, ³Dept. of Pathology, Tartu University Hospital, Tartu, Estonia, ⁴Dept. of Genetics, Tartu University Hospital, Tartu, Estonia, ⁵Institute of Molecular and Cell Biology, University of Tartu, Tartu, Estonia.

Introduction: According to WHO, lung cancer is the leading cause of cancer deaths worldwide. Besides invasive tumor biopsy, molecular diagnostic analysis of tumor cell-free DNA is becoming increasingly popular as a method enabling to capture the whole tumour heterogeneity in almost real-time setting. This may have applications in both early diagnostics, as well as therapeutic monitoring of alterations predictive for drug response.

Objectives, materials, methods: Our primary objective was to set up a straightforward platform for the analysis of clinically relevant mutations. Our study cohort currently comprises of 58 lung adenocarcinoma patients who have donated blood plasma samples prior to initiation of chemo- or targeted therapy. The cohort will be longitudinally monitored and repeated blood samples collected upon progression. FFPE tumor samples have been available for approximately 50% of the study subjects. We have currently set up allele-specific fragment analysis workflow for EGFR gene common mutations and amplicon-based multiplex next-generation sequencing (NGS) in 5 lung cancer-related genes (EGFR, BRAF, HER2, KRAS, PIK3CA).

Results: Our preliminary results show that both approaches detect <1% mutant allele content. The methods will be compared in both cfDNA and FFPE analysis, as well as with the available clinical DNA data.

Perspectives: Our further aim is to collect longitudinal samples and perform a larger screen of drug susceptibility and resistance mutations in our study cohort, involving detection of point mutations, copy number analyses and DNA methylation changes. We strongly believe that cfDNA analysis will become a clinical routine in various cancers in the near future.

P14.016
A low cost, comprehensive, ctDNA assay based on targeted enrichment of rare alleles and error-reduced sequencing

D. Broemeling¹, J. Pel¹, M. Wiggan¹, A. Marziali^{1,2};
¹Boreal Genomics, Vancouver, BC, Canada, ²University of British Columbia, Vancouver, BC, Canada.

Identification of circulating tumour DNA in a blood sample (liquid biopsy) can be used to detect and genetically profile tumours in a routine and minimally invasive assay. As certain somatic mutations are specifically associated with cancer, liquid biopsy has the potential to be an exceptionally specific and low-risk screening tool that could stage-shift cancer detection to earlier, more curable stages.

We present two complementary methods to optimize sensitivity over broad gene regions at low cost. We combine a highly selective enrichment technology to screen hotspot mutations at very high sensitivity, with a high accuracy sequencing technology that can scan large regions of the genome at low cost, albeit with reduced sensitivity. Using the commercially available OnTarget enrichment technology, activating mutations consisting of SNVs and short indels can be preferentially selected for sequencing over wild-type sequence. This approach enables highly sensitive detection to 0.01%, or below, for up to 1,000 unique variants.

Broader coverage of regions without hotspot mutations, as well as detection of copy number variants and translocations, can then be addressed with a novel library construction process for NGS sequencing that increases the accuracy of the workflow by an order of magnitude. Named Proximity-Sequencing (Pro-Seq), the method duplicates sequence information in each original DNA strand, achieving sensitivity in the 0.1-0.01% range depending

on read depth.

The addition of Pro-Seq library construction to OnTarget enrichment enables low cost, high sensitivity, liquid biopsy tests to be developed, enabling commercialization in applications with limited reimbursement, potentially including early cancer detection.

P14.017

The difficult interpretation of blood mosaicism in routine diagnostic specimens: discordant results between conventional cytogenetic/FISH and CGH array

A. Plaja, 08035, T. Vendrell, N. Castells, A. Cueto-González, M. Borregan, F. López-Grondona, L. Martínez-Ribot, Q. Ferrer-i-Carbonell, E. Tizzano; Dept. Clinical and Molecular Genetics. H. Vall d'Hebron, Barcelona, Spain.

Introduction: Low-level somatic mosaics can be associated with severe birth defects, but reliable detection remains challenging. We describe three cases with discordant cytogenetic/FISH and CGH array results in blood samples.

Material and methods:

Patient 1: aged 14 years, shows epileptic encephalopathy and a normal 46,XY[15] karyotype.

Patient 2: aged 32 years, shows Fallot tetralogy and leukopenia.

Patient 3: aged 4 years, shows global developmental delay and karyotype result of 46,XY,del(18)(q21.3)[13]/46,XY[17]

All patients were studied with array CGH (Agilent, USA, G4827A CGH ISCA v2, 8x60K) and Cytogenomics CNV detection software (Agilent, USA). Cytogenetic techniques involved G banding and FISH with BACs RP11-81j7 (1p36.22) and RP11-81h19 (1q24).

Results: Patient 1: CGH-array Cytogenomic software (CS) showed a 1q21.1q32.1 mosaic duplication (hg19: 145415190-206794531). A new chromosomal study revealed a 46,XY,dup(1)(q21q32.1)[4]/46,XY[331] and FISH analysis revealed two nucleus and one metaphase of 300 showing 3 signals.

Patient 2: CGH-array CS showed a 1p36.32p36.13 mosaic deletion (hg19: 5159991-17753699) and FISH analysis revealed 23 nucleus of 233 showing only one signal.

Patient 3: CGH-array CS did not reveal CNVs in chromosome 18. Visual inspection of CS plots revealed an 18q21.31q22.2 mosaic deletion (54370433-68956470).

Conclusions: CGH-array analysis was able to detect mosaic CNVs of 1.2% (1q21dup) and 9.9% (1p36del), but failed to detect the presence of a 43% 18q21.31q22.2 mosaic deletion.

CGH-array analyzes DNA from all nucleated blood cells while cytogenetic/FISH on cultured samples analyzes only T-lymphocytes. Our results highlight the importance of applying combined molecular and cytogenetic techniques when there is suspicion of mosaic anomalies.

four cases of CNVs identification using an exome sequencing approach

P. Maietta¹, J. Botet¹, M. Peña-Vilabelda¹, M. Martínez-García¹, D. Martínez Fernández-Mayoralas², L. Martorell Sampo¹, A. Fernández-Perrone², S. Álvarez de Andrés¹;

¹NIMGenetics, Madrid, Spain, ²Universitary hospital Quirónsalud, Madrid, Spain,

³Universitary children's hospital Sant Joan de Deu, Barcelona, Spain.

Introduction: For the identification of molecular defects in patients with suspected genetic disorders, whole exome sequencing (WES) has now entered in medical practice as a diagnostic approach. Unfortunately, it presents some limitations for CNVs detection, principally due to the unbalanced distribution of the exons through the different chromosomes.

Material and Methods: We performed exome sequencing using the Ion AmpliSeq™ exome technology (Life Technologies) with Ion Proton™ and IonS5-XL™. Sequencing reads were analysed using Ion Reporter™ Software, where the overall distribution and depth has been normalized against a baseline generated with data coming from 10 unrelated males.

Results: Here we present 4 cases with phenotypes associated to 4 different disorders, such as epilepsy, spastic paraplegia, psychomotor retardation and intellectual disability. Using the score generated by the automatic software, in combination with the clinical information, we were able to prioritize deletions of different sizes ranging from 5kb on PLP1 gene to 5Mb on the long arm of chromosome 2. These alterations were posteriorly validated using array CGH technology or MLPA. The criteria used for the identification on those cases will be presented.

Conclusions: WES presents different limitations for the detection of CNV, but for some regions the data can be used to suggest the presence of regions with aberrant copy changes. The systematic evaluation of this information could help to accelerate the patient's diagnosis.

P14.019

Application of CNV Sequencing for whole genome copy number variant detection over a two year period

P. Roberts¹, S. V. Hewitt¹, A. Coates¹, C. M. Watson^{1,2}, L. Crinnion^{1,2}, D. T. Bonthron²;

¹Leeds Genetics Lab, St James's Hospital, Leeds, United Kingdom, ²School of Medicine, St James's Hospital, Leeds, United Kingdom.

Introduction: Since January 2014 we have applied CNV Sequencing, a next generation sequencing technology, to assess DNA dosage status either to validate array CGH findings, or for poor quality/low volume samples that fail the QC status for array CGH.

Materials and Methods: The technique uses the Illumina HiSeq 2500 Sequencing platform for whole genome copy number variant detection and relies on a custom-designed computational pipeline for copy number variant calling. Ten samples are run in a multiplex, each analysis being based on 20-25 million single-end 50-nt reads.

Results: From 2014-2016, we have sequenced over 220 diagnostic samples from difference sources, i.e. blood, tissue from products of conception, amniotic fluid, saliva. A successful result was obtained for 206/224 samples, with an average resolution per patient of 40 kb, and an analytical sensitivity of ~98% for imbalances ≥40 kb. Higher resolution can be achieved by sequencing the libraries at higher coverage with relatively minimal cost implications.

Conclusions: CNV Sequencing leads to improved success rates on low volume/poor quality DNA samples, and presents additional advantages over array CGH via its digital approach to evaluating DNA dosage changes. We are presently evaluating the potential for its introduction in prenatal diagnosis where suboptimal DNA quality for array CGH is especially problematic. We believe that our method is cost effective, reliable and accurate and that it potentially overcomes the technical challenges of calling dosage changes by whole exome sequencing.

P14.020

Detecting copy number variation by limiting dNTP PCR and high-resolution melting

L. Zhou¹, R. Palais², C. Wittwer¹;

¹Department of Pathology, University of Utah School of Medicine, Salt lake City, UT, United States, ²Department of Mathematics, Utah Valley University, Orem, UT, United States.

Introduction: About 13% of genes in the human genome have variation in copy number. Copy number alterations (CNAs), somatic changes to chromosome structure that result in gain or loss in copies of sections of DNA, are very common in cancer and associated with particular cancer types.

Materials and Methods: Ratios of reference and copy number variants were maintained by limiting quantities of dNTPs and allowing PCR to plateau. Suitable fragments having single melting domains, well-separated Tms, and no common homologs were designed using uMelt melting curve prediction software. MeltWizard 6 software was used to remove background, equalize negative derivative melting peaks corresponding to the reference segment, and identify and quantify samples with different CNV ratios from the amplitude of their target melting peaks.

Results: CNV ratios far beyond this range, as small as 2: 2.125 (5.88%), were detectable using the most robust, simplest, and highest resolution method of limiting dNTPs at an optimal 3.25 uM. Duplex PCR of reference and a target was used to detect copy number variation in SMN1, SMN2, EGFR, chromosome X, Y, 13, 18, and 21. Blinded test of 50 potential trisomic samples were concordant to karyotyping. In 7 out of 8 of lung cancer, the copy number of EGFR is higher than normal copy 2.

Conclusion: The simple closed-tube method is fast, economical, more accurate and less susceptible to contamination than other methods. Assays are easy to design, limiting dNTPs is simple, and the results are stable and reliable.

P14.021

CoNVaDING: single exon variation detection in targeted NGS data

F. van Dijk, L. F. Johansson, E. N. de Boer, K. K. van Dijk-Bos, J. D. Jongbloed, A. H. van der Hout, H. Westers, R. J. Sinke, M. A. Swertz, B. Sikkema-Raddatz;

Department of Genetics, University Medical Center Groningen, Groningen, Netherlands.

We have developed a tool for detecting single exon copy number variations (CNVs) in targeted next-generation sequencing data: CoNVaDING (Copy Number Variation Detection In Next-generation sequencing Gene panels). Existing methods consider all control samples equally informative even though there are sample to sample variations caused by differences in PCR and capturing efficiency. CoNVaDING selects the control samples showing a coverage pattern most similar to that of the sample analysed. Data is

then normalized, using within the sample all autosomal targets or all targets within the same gene. Based on the normalized data, for each target the ratio of the normalized average read depth of the sample to that of the controls and a distribution analysis using a Z-score are calculated. Based on the calculated ratio and distributions a prediction is made for each target to determine whether a CNV is present or not, providing additional sample quality metrics during several stages of the analysis.

We compared the performance of CoNVaDING with XHMM and CoNIFER in 320 samples captured with two different targeted gene-panels containing in total 308,574 exons. For all CNV calls made by one of the three methods MLPA was performed. CoNVaDING detected all known CNVs in high quality targets, giving 100% sensitivity, at a 99.998% specificity. Thereby outperforming XHMM and CoNIFER by exhibiting a higher sensitivity and specificity and by precisely identifying low-quality samples and regions. These improved quality control metrics enable use in both research and clinical diagnostics setting.

P14.022

Evaluation of CNV detection from targeted next-generation panel sequencing data in routine diagnostics

A. M. Nissen, M. Locher, C. Rapp, A. Laner, A. Benet-Pages, E. Holinski-Feder, MGZ Medical Genetics Center, Munich, Germany.

Copy number variation (CNV) detection from exon-capture NGS data is challenging because of non-uniform capture efficiency of targeted exons or short read lengths. Often CNV detection in routine diagnostics is still performed by additional techniques (MLPA, microarray) instead of using NGS data for both SNV and CNV. We used a bioinformatics pipeline comprised of ExomeDepth, XHMM and in-house methods to detect exonic CNVs using read depth data derived from a targeted NGS Panel (Illumina TruSight Cancer). Capture efficiency per exon was assessed with a set of CNV negative patients to identify reliable regions. Additionally, genes with pseudogenes, paralogues and repeat regions were excluded from the study design. We present a first evaluation with a set of 86 patients previously tested for SNVs (NGS) and CNVs (MLPA). 51 patients presented pathogenic SNVs and 35 patients pathogenic CNVs. We confirmed 15 deletions and two duplications with high significance. Another nine deletions and two duplications were correctly detected with lower confidence, which affected a smaller number of exons compared to the high confidence results. In addition, five inconspicuous cases showed contradictory results due to SNVs affecting MLPA-probe binding site. In two cases deletion events of one exon could not be detected. No additional CNVs were found in patients with pathogenic single mutations. This proof-of-concept study demonstrates the feasibility of using a single testing strategy to detect simultaneously SNVs and CNVs for clinical diagnosis. However, this method is only applicable for selected genes and consistent workflow conditions.

P14.023

Whole-gene CFTR sequencing combined with digital RT-PCR improves genetic diagnosis of cystic fibrosis

L. Straniero^{1,2}, G. Soldà^{3,2}, L. Costantino⁴, M. Seia⁴, P. Melotti⁵, C. Colombo⁶, R. Asselta^{3,2}, S. Duga^{3,2};

¹Department of Medical Biotechnology and Translational Medicine, University of Milan, Milan, Italy, ²Humanitas Clinical and Research Center, Rozzano-Milano, Italy, ³Department of Biomedical Sciences, Humanitas University, Rozzano-Milano, Italy, ⁴Medical Genetics Laboratory, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy, ⁵Cystic Fibrosis Center, Azienda Ospedaliera Universitaria Integrata di Verona, Verona, Italy, ⁶Cystic Fibrosis Center of Milan, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy.

Introduction: Cystic fibrosis (CF) is a common recessive disorder caused by >1,900 mutations in the CFTR gene. Despite extensive screening, 1-5% of patients lack a definite molecular diagnosis. Here, we propose an efficient, sensitive, and cost-effective whole-gene NGS protocol applied to the molecular screening of CF patients.

Methods: We designed a custom Nimblegen SeqCap EZ capture kit targeting the entire 189-kb-long CFTR gene and the coding portions of the SCNN1A, SCNN1B, and SCNN1G genes, encoding the subunits of the sodium channel ENaC, reported to be mutated in CF-like patients. Sequencing was performed on a HiSeq2000 platform, multiplexing up to 18 samples in a sequencing lane.

Results: We analyzed 23 CF patients and one carrier: 4 previously-characterized patients served as controls; 17 were lacking a complete diagnosis after conventional CFTR screening; 3 were not previously genetically screened. We obtained a mean depth >1,150X and 98% coverage of the target region. Our approach allowed the identification of 22 previously-known CFTR mu-

tations, including 2 large deletions. For 2 patients, compound heterozygous for a CFTR mutation and the intron-9 c.1210-34TG[11-12]T5 allele - associated with decreased CFTR mRNA levels - the molecular diagnosis was implemented by measuring the residual level of wild-type transcript by digital RT-PCR on RNA extracted from nasal brushing.

Conclusions: We demonstrated that whole-gene resequencing combined with digital RT-PCR is a cost-effective and accurate approach for the genetic testing of CF and CF-related disorders.

Funding: This work was supported by the Italian Cystic Fibrosis Foundation, grant FFC#6/2011 and FFC#5/2015.

P14.024

Compiling a default list for intellectual disability in different laboratories in the Netherlands.

M. Kriek¹, C. A. L. Ruivenkamp², K. L. I. van Gassen³, M. A. van Slegtenhorst⁴, A. P. A. Stegmann⁵, R. P. Pfundt⁶, T. Dijkhuizen⁷, M. Alders⁸, M. M. Weiss⁹;

¹Department of Human and Clinical genetics, Leiden University Medical Center, Leiden, Netherlands, ²Department of Clinical genetics, Leiden University Medical Center, Leiden, Netherlands, ³Department of Medical Genetics, University Medical Center, Utrecht, Netherlands, ⁴Department of Clinical Genetics, Erasmus MC, Rotterdam, Netherlands, ⁵Department of Clinical Genetics, Maastricht UMC, Maastricht, Netherlands, ⁶Department of Human Genetics, Radboud University Medical Center, Nijmegen, Netherlands, ⁷Department of Clinical Genetics, University Medical Center, Groningen, Netherlands, ⁸Department of Clinical Genetics, Academic Medical Center, Amsterdam, Netherlands, ⁹Department of Clinical Genetics, VU Medical Center, Amsterdam, Netherlands.

Using exome sequencing, the coding genetic material (exons) is examined for genetic variants. In accordance with recent guidelines abnormalities will initially be sought in a dedicated list of genes (default list) with a known relationship to the patient's disease (targeted analysis). Our goal was to get an insight of what choices were made regarding the content of the list with dedicated genes in different laboratories in the Netherlands. A questionnaire was sent out in 2015 to all (n=7) clinical genetic laboratories in the Netherlands after one contact person per laboratory had agreed to participate in this study. Six laboratories returned the questionnaire. It contained 10 questions regarding the selection of genes for the default list of intellectual disability.

The process of compiling the list is dissimilar on a quite a number of items; there were discrepancies in both the experts involved as the sources used between the laboratories. In addition, the level of evidence for causality e.g. selection criteria for genes, differed slightly between laboratories. Points of internal discussion included the application of genes present in the heel prick and whether the DMD- and TTN gene should be added to the list. The agreements included the frequency of updating the list and the willingness of sharing its content. The combined questionnaire results will help to set standards to the selection process of genes for default lists and may lead to a national agreement on a minimal list of core genes (e.g. genes that are covered completely) for intellectual disability.

P14.025

The 100,000 Genomes Project: Improving DNA quality, it's in our blood

N. Iley¹, V. Davison^{2,3}, Z. Deans¹, S. Hill^{2,3};

¹UK NEQAS for Molecular Genetics, Edinburgh, United Kingdom, ²NHS England, London, United Kingdom, ³Health Education England, London, United Kingdom.

Whole genome sequencing (WGS) requires the input of genomic DNA of sufficient quantity and quality to ensure a high quality sequencing output. To ensure samples submitted into England's 100,000 Genomes Project are of appropriate quality to enable accurate WGS, NHS England with UK NEQAS for Molecular Genetics have developed an external quality assessment (EQA) scheme for the extraction of high quality genomic DNA from fresh whole-blood samples. All laboratories providing DNA samples for inclusion in the project are required to participate in this EQA scheme.

Since December 2014, laboratories have participated in three practical EQA runs. In each run, three homogenised donor whole-blood samples of varying volumes were provided and laboratories instructed to extract DNA from the whole sample and return it to UK NEQAS for analysis. The quality metrics assessed and scored include DNA sample volume, total DNA mass, 260/280 ratio, Illumina Delta Cq assay, Library Preparation and Bioanalyser trace using the TruSight Cancer Panel and agarose gel electrophoresis. An overall combined score for genomic DNA quality was generated and laboratories bench-marked against each other.

Initial results showed a broad range of DNA extraction methodologies and a high variation in DNA quality. Continued participation in EQA runs showed marked improvement in the quality of DNA extracted.

Participation in DNA extraction EQAs highlighted extraction methodologies used for routine molecular genetics applications were not entirely suitable for WGS. Application of quality metrics, inter-laboratory bench-marking and continued participation allowed laboratories to identify areas of concern promptly and address them efficiently and effectively.

P14.027

PepPipe and MethPipe: pipelines for discovery and validation of DNA-methylation and antibody profiles to improve hereditary autoinflammatory disease diagnosis

A. Weinhaeuser, Manuela Hofner, Walter Pulverer, Stephan Pabinger, Regina Soldo, Peter Hettegger, Ram Vinay Pandev, Lisa Milchram, Ronald Kulovics, Silvia Schönthaler, Gabriel Beikircher, Christa Noehammer, Klemens Vierlinger; AIT, Vienna, Austria.

Systemic autoinflammatory diseases (SAID) are highly heterogeneous monogenic or multifactorial conditions secondary to deregulation of mechanisms controlling the innate immune response. Best known examples are the hereditary periodic fever-syndromes; however molecular analysis is inconclusive in 70-80% of "undefined SAID" patients. Thus there is a great need to improve correct diagnosis. Within the recently started E-Rare-3 project "INSAID", the AIT Molecular Diagnostics group will use their analysis pipelines MethPipe and PepPipe to perform highly paralleled epigenetic and immunomic profiling of Familial Mediterranean Fever (FMF) as a model. Here we will present our two pipelines:

PepPipe: Protein-microarrays presenting about 7400 different human proteins from 15284 expression clones and high density peptide arrays are used for highly efficient auto-antibody profiling. For validation we have established Luminex-assays enabling high-multiplexed targeted analyses of antigenic markers. In parallel immune-qPCRs will be performed for 92 inflammation markers from 1µl serum using Proseek® Multiplex assays.

MethPipe: Genome-wide methylation screening is performed via Illumina's 850k arrays which can be combined with targeted bisulfite sequencing for targeted analysis. Highly paralleled marker validation is then carried out via methylation-sensitive restriction enzyme coupled MSRE-qPCR using Fluidigm's Biomark system, enabling testing up to 96 samples and 96 assays in a single qPCR run.

The findings of these experiments will be used to characterize undefined SAID on the epigenetic-, immunomics-, and inflammatory- level of molecular disease pathology and to identify new biomarkers to improve correct disease diagnosis.

Funding: EraNet „E-Rare-3 JTC 2015" project "INSAID"(FWF grant number I 2742-B26)

P14.028

Novel PCA-based normalization technique for inferring exon level copy number

M. Gold, R. Shraga, S. Yarnall; Recombine, New York, NY, United States.

Background: Most microarray-based CNV-detection algorithms infer copy number by comparing a bead's intensity for a given sample to a control intensity (called an r-ratio). We have developed a novel normalization technique to improve exon-level CNV-calling and tested it on the DMD gene.

Methods: We used the Illumina Infinium Assay with custom content and designed unique beads to cover the DMD exons and the fifty nucleotides surrounding each exon. We applied Principal Component Analysis (PCA) to the r-ratio for 2671 beads with low minor allele frequency outside of the DMD gene in an attempt to capture intensity variability due only to technical noise. Copy number was determined by comparing a sample's observed r-ratio per exon to the r-ratio predicted for that exon by a regularized linear regression model trained on the principal components of the outside beads. **Results:** We ran the algorithms on 1715 female research-consented samples, using a null-call threshold based on the smoothness of the r-ratio values across exons. We observed 733 normal, 976 NC, and 6 CNV calls for the standard r-ratio algorithm and 1698 normal, 15 NC, and 2 CNV calls for the novel algorithm.

Discussion: We validated the two PCA-normalized CNV calls using an outside lab. Patterns in the four CNV calls made by the un-normalized algorithm indicate false positive calls, but this was not confirmed. This novel technique further normalizes r-ratio data by removing non-biological noise and can be used to improve exon-level copy number detection for screening and diagnostic microarray assays.

P14.029

Multiplex TaqMan Assays for Rare Mutation Analysis Using Digital PCR

M. Laig, F. Chan, L. Lac, B. Moy, T. Straub, K. Varma, D. Keys; Thermo Fisher Scientific, South San Francisco, CA, United States.

Introduction: Detection of rare mutations for research purposes in tumor tissue and cell free DNA (cfDNA) allows for monitoring of tumor progression and regression. cfDNA isolated from plasma combined with a sensitive detection method like digital PCR is non-invasive and enables earlier detection compared to conventional imaging techniques.

Building on the TaqMan based Rare Mutation assay set for detection of rare mutations using digital PCR on the QuantStudio 3D Digital PCR System, we are now developing multiplex assays for simultaneous detection of several mutations. We selected relevant mutations in the EGFR and KRAS genes for our initial multiplex application: EGFR G719, EGFR exon 19 deletions, and KRAS G12/G13. These mutations may have implications for potential future targeted therapy.

Methods: Primers and probes of singleplex Rare Mutation Assays were reformulated to generate multiplex assays detecting the EGFR and KRAS mutations. All multiplex assays were tested on template composed of wild-type genomic DNA background mixed with mutant plasmid reflecting each of the mutations detected by the multiplex assays.

Summary: Initial experimental results were successful and showed excellent signal intensity and clear cluster separation when analyzed with the QuantStudio 3D AnalysisSuite™ Cloud Software. The EGFR G719 mutations (COSM6239, COSM6253, COSM6252) were detected using a 3plex assay, EGFR exon 19 deletions (COSM12383, COSM12422, COSM12678, COSM6223, COSM6254, COSM6255) were detected using a 6plex assay, and KRAS G12/G13 mutations are underway.

Conclusion: Multiplexing assays for three relevant mutation loci proved feasible and presents an efficient way to assess the presence and the percentage of mutations.

P14.030

Phenotyping Emanuel Syndrome using computer-aided facial dysmorphism analysis of 2D photos

A. B. Hamid Al-Rikabi¹, N. Fleischer², M. Rinholm³, S. St-Pierre³, I. Schreyer^{1,4}, T. Liehr¹; ¹Jena University Hospital, Friedrich Schiller University, Institute of Human Genetics, Jena, Germany, ²FDNA, Herzliya, Israel, ³Chromosome 22 Central, Fuquay-Varina, NC, United States, ⁴Center for Ambulant Medicine, Human Genetics, Jena, Germany.

While sequencing technology and variant interpretation are continuously progressing, the critical process of phenotyping and gathering clinical information has not changed much. Here the facial dysmorphism novel analysis (FDNA) technology was used to automatically identify facial phenotypes associated with Emanuel Syndrome (ES; OMIM 609029) based on 2D facial photos. ES, also denominated supernumerary der(22)t(11;22) syndrome is characterized cytogenetically by a small supernumerary marker chromosome (sSMC). Clinical signs include severe mental development delay, microcephaly and dysmorphic features. Besides heart defects, cleft lip and palate, kidney malformations and anal atresia, etc., can complicate the clinical problems. Here 65 facial photos of molecularly diagnosed ES patients were compared to unaffected controls (n=1000) and to a second control group (n=1000) of individuals affected with one of 100 other syndromes with facial phenotypes. The mean area under the curve (AUC) comparison between ES and normal individuals (0.99, STD 0.001) expresses an almost full separation between these two cohorts. A slightly lower mean AUC (0.985, STD 0.046) was obtained when comparing between ES and individuals affected with other syndromes. Our preliminary results show that computer aided facial recognition is able to help in the clinic and could possibly reduce the time patients spent in the diagnostic odyssey. Also it may help to differentiate ES from other patients with sSMC, especially in countries with no access to more sophisticated genetic approaches apart from banding cytogenetics. Inclusion of more facial pictures of ES-patient is welcome and may also contribute to a higher detection rate.

P14.031

Detection method for the 3'EPCAM genomic deletion and its frequency in Polish HNPCC patients

P. Borun¹, J. Szczepinska¹, M. Siolek², B. Kozak-Klonowska², A. Plawski¹; ¹Institute of Human Genetics, Poznan, Poland, ²Department of Genetics, Holycross Cancer Centre, Kielce, Poland.

Lynch syndrome is a frequent, autosomal, dominantly-inherited cancer predisposition caused by various germline alterations that affect DNA mismatch repair genes, mainly MLH1, MSH2, MSH6 and PMS2. Large rearrangements of the EPCAM (Epithelial Cell Adhesion Molecule) gene, which is localized

on chromosome 2 upstream of the MSH2 gene, have been recently described as a genetic cause of the Lynch syndrome occurrence. The rearrangements, encompassing mainly 3' end of the EPCAM gene, lead to mismatch repair deficiency in some Lynch syndrome families.

The aim of the study was to develop cost-effective screening tool for the rapid detection of 3'EPCAM genomic rearrangements, along with its validation, and determination of the 3'EPCAM mutation status in our group of polish HNPCC patients. We applied C-HRM, a method enabling the detection of 3'EPCAM rearrangements and simultaneously screening for small mutation in two exons of the MLH1 gene containing small mutation hot-spots. With the developed assay, in our group of 250 Lynch syndrome probands, we detected 2 cases of 3'EPCAM genomic rearrangement and 4 small mutations within the studied exons of the MLH1 gene.

P14.032

An exome routine genetic diagnoses assay

B. Cogne, P. Boisseau, S. Schmitt, S. Kury, X. Latypova, W. Deb, J. Le Gall, M. Nizon, M. Vincent, T. Besnard, S. Mercier, B. Isidor, S. Bezieau; CHU Hotel Dieu, Nantes, France.

Background and aims: As shown by the abundance of publications, exome may be a promising technique to discover genes causing diseases. But, could exome be an efficient routine strategy to perform genetic diagnoses? We wanted to ask this question in current convergence of some difficult pathology presentations and an easy access to exome technology.

Method: We selected 20 patients affected with greatly heterogeneous genetic pathologies without any obvious gene causing disease or previous unsuccessful targeted genes analyses. Exome sequencing was done for each of them. We analysed raw data with an in-house bioinformatic pipeline "phenotype guided" designed (it uses HP terms for the pathology description which fit or not with Human Phenotype Ontology database), the filter used was 1000g database. This pipeline generated a set of sequence variations according to possible mode of inheritance and MIM data. Candidate sequence variations were confirmed by Sanger sequencing and family segregations.

Results: The first results were encouraging: 11 genes were very likely pathogenic (55% of the patients) and 4 others were possibly deleterious (20%).
Discussion and conclusions: These first results allow us to continue this assay to confirm or not these promising test performances. Nevertheless, improvements have to be implemented to this strategy to avoid missdetection of sequence variations, like the use of a SNP local database, a bioinformatic splice testing for silencing SNP and exon-intron junction nucleotides and an analysis of copy number variations.

P14.034

MedExome: An optimized whole exome design for identification of medically relevant genetic variants

M. Brockman, H. Rosenbaum, L. Lincoln, D. Burgess, T. Richmond, J. Wendt; Roche NimbleGen, Madison, WI, United States.

Introduction: Whole exome sequencing provides a comprehensive view of protein coding regions, but the typical depth of sequencing can result in regions of low or missing coverage throughout the exome. Mitochondrial variant calling is also of increasing interest but has been difficult to combine with exome enrichment. Here we present performance of MedExome, an optimized whole exome sequencing design with the option for including mitochondrial target enrichment in a streamlined workflow.

Materials and Methods: 100ng of DNA from samples of varying populations (Coriell Institute; BioServe) was used in library prep from Kapa BioSystems. Sequence capture with multiple iterations of Roche NimbleGen SeqCap EZ MedExome with overnight hybridization was used to gather empirical data and optimize capture design performance. Sequencing at 2x101bp was performed on Illumina HiSeq 2500 instruments.

Results: We used empirical data at multiple stages of development to optimize performance resulting in high uniformity (fold 80 base penalty 1.90-2.03) and an average of 95.7% of bases with 20X coverage or higher given 6Gb of raw sequencing. We developed a companion protocol for optional enrichment of the mitochondrial genome without sacrificing whole exome coverage.

Conclusions: We have developed MedExome, a new whole exome sequencing design with application for the identification of known and novel medically relevant variants with the option of combining mitochondrial and whole exome sequencing.

For Life Science Research Use Only. Not for use in diagnostic procedures. This study was supported by Roche NimbleGen, a part of Roche Sequencing. All authors are employees of Roche NimbleGen.

Clinical whole-exome sequencing for the diagnosis of rare disorders with multiple congenital anomalies: feedback on 400 consecutive tests

J. Thevenon¹, S. Nambot¹, P. Kuentz¹, Y. Duffourd¹, S. El Chehadah-Djebbar², D. Lehalle¹, N. Jean-Marçais¹, A. Masurel-Paulet¹, P. Callier¹, N. Marle¹, A. Mosca-Boidron¹, C. Poé¹, T. Jouan¹, M. Chevarin¹, N. Gigot¹, A. Bruel¹, M. Lefebvre¹, J. Saint-Onge¹, E. Tisserant¹, J. Deleuze³, J. Rivière¹, L. Faivre¹, C. Chauvin-Robinet¹;

¹Centre Hospitalier Universitaire, Dijon, France, ²Centre Hospitalier Universitaire, Strasbourg, France, ³Centre national de génotypage, Evry, France.

The World Health Organization estimates the existence of more than 8.000 rare disorders. Each of these disorders is individually rare and affect by definition less than 5/10.000 individual, but are collectively frequent with 8% of the overall population affected. The prevalence of most of rare disorders cannot even be estimated and are ascertained through several publication or case reports. Most of the rare disorders are suspected to be Mendelian diseases with high genetic and clinical heterogeneity. To enhance the diagnostic yield of our generalist consulting genetic center, we have developed a clinical proband whole-exome sequencing strategy. This study reports on the clinical and molecular characterization of a cohort of 400 consecutive proband with multiple congenital anomalies who have had exome sequencing.

Whole-exome sequencing was performed in collaboration with the Centre National de Génotypage. Raw data were analysed on the Computing centre of the University of Burgundy. Overall, the mean depth of coverage was 90x, with 93% of coding regions referenced in RefSeq and sequenced by at least 10 reads. Actually, 297 results were returned to the clinician with a diagnostic yield of 30% for positive results, 15% of non-conclusive results, based on current scientific knowledge. In the first 300 individuals, 2 secondary findings were reported. Twelve months after returning the results, a prospective re-analysis of 130 exomes identified eight additional diagnoses (6%). Pro-active international data-sharing through the Match-Maker exchange initiative allowed the identification of recurrent implication of several new disease-causing genes.

P14.036

A comparative evaluation of two DNA exome library preparation methods for ion torrent Proton.

P. Gampawar¹, Y. Saba¹, M. Bemelmans², J. Semmler-Bruckner¹, H. Schmidt¹; ¹Medical University of Graz, Graz, Austria, ²University of Applied Sciences. Biomedical Sciences, Graz, Austria.

Aims:

Whole exome sequencing is a cost effective way to detect common and rare variants. While several studies on library preparation methods for Illumina platforms are available, data for the Ion Proton™ sequencer are sparse. Here we compare the performance of AmpliSeq™ Exome RDY IC and SureSelect Human All Exon V6 library preparation kits.

Methods:

Genomic DNA was extracted from 4 human blood samples. In total 100 ng of DNA was used for AmpliSeq and 1µg for SureSelect libraries. Template preparation and loading of the chip was done on Ion Chef Instrument. The Ion Reporter™ software was used for data analyses. Validation of variants against microarray data (Affymetrix Human_SNPArray6.0 and Illumina HumanExome_v1.1) is in progress.

Results:

Parameters	AmpliSeq	SureSelect
DNA input	100ng	1µg
Library preparation time	6 hour	2.5 days
Reference BED file	AmpliSeqExome_20141113 (60.5Mb)	V6-BED_Test.4 (58.72Mb)
Total bases sequenced/sample	7.2Gb	4.4Gb
Number of reads/sample	40278595	40164626
Mean Read length	179bp	130bp
Reads on target	>95%	>80%
Mean coverage	130X	55X
Number of variants/sample	37694.5	45840.25

Conclusion:

Both methods showed high level of target enrichment and covered large part of targeted region. AmpliSeq needed lower input DNA and shorter library preparation times. It also showed longer read length and higher mean coverage. SureSelect identified more variants. Validation of variants against GWAs and exome chip data is important to identify false positive and negative calls.

P14.037

Validation of a ten-gene panel for improved diagnosis of familial MDS/AML

G. Ryan¹, P. Page¹, S. Akiki¹, S. R. C. Cardoso², T. Vulliamy², I. Doka¹, F. J. Fitzgibbon², Y. Wallis¹;

¹West Midlands Regional Genetics Laboratory, Birmingham Women's Hospital, Birmingham, United Kingdom, ²Blizard Institute, Barts and The London School of Medicine and Dentistry, Queen Mary, University of London, London, United Kingdom.

Cases of familial Myelodysplastic Syndrome (MDS)/Acute Myeloid Leukemia (AML) are rare, although the true prevalence is likely to be underestimated. The clinical utility of genetic testing is extensive as it aids prognosis, patient management and identifying at-risk relatives. At least ten genes are linked to familial MDS/AML, involved in transcription regulation, telomere maintenance and splicing. Our laboratory currently offers Sanger sequencing for RUNX1 for familial platelet disorder with propensity to AML, and familial AML with mutated CEBPA. As part of a collaborative LLR funded project with the Barts Cancer Institute to improve testing, diagnosis and management of these patients, we have designed and validated a ten-gene familial MDS/AML NGS panel. The panel was designed using Agilent Sure-Design software and samples enriched using Agilent SureSelect QXT chemistry. Libraries were sequenced using the MiSeq and data analysed using Agilent SureCall software. There was >99% coverage for each gene with at least 100x read depth over two runs for each target region. We have detected known variants in all ten genes, as well as two novel likely pathogenic mutations in the DDX41 gene, a newly associated familial MDS/AML gene. This panel will subsequently be utilised for characterisation of both retrospective and prospective cases from Barts and will be available as a new UK wide and international service for suspected familial MDS/AML patients to increase diagnoses and aid improved patient management.

P14.038

Clinical utility of MEFV gene analysis in patients with a clinical suspicion of Familial Mediterranean Fever

V. Procopio, I. Loddo, A. Romeo, G. Bianco, C. Liuzzo, G. Conti, L. Rigoli, C. Salpietro; UOC Genetics and Pediatric Immunology, University of Messina, Messina, Italy.

Introduction: Familial Mediterranean Fever (FMF) is an auto-inflammatory disease characterized by brief recurrent episodes of fever and serositis that result in abdominal, chest, joint and muscular pain.

Materials and methods

We tested 31 patients and their family members by Reverse Dot Blot analysis.

Results: All patients with FMF showed both homozygous or heterozygous MEFV mutations. Analysis performed on family members allowed us to identify 36 individuals with heterozygous MEFV mutations. Only 53.8% of them presented some clinical manifestations attributable to a mild FMF.

Conclusions: Mutations identified by Reverse Dot Blot analysis covered about 90% of the mutations, as well as that identified by Sanger sequencing. According to the literature, a significant subset of person with FMF (25%) have a heterozygous MEFV pathogenic variant, then the sequencing detection rate of cases not diagnosable by Reverse Dot Blot drops to 67.5%.

The reason may be due to:

- 1) Mutation in another gene;
- 2) Overlapping manifestations with other autoinflammatory diseases that make difficult differential diagnosis.

In literature, rare mutations in other genes have been reported in patients carrying only a heterozygous mutation in MEFV gene.

In heterozygous patients, we consider most useful to perform a six-month trial of colchicine therapy to confirm the diagnosis of FMF and, if no benefit, to analyse other genes responsible for autoinflammatory disease in differential diagnosis with FMF.

We propose a flow chart for genetic testing in FMF, which has an inheritance not well clarified.

P14.039

Enabling exome sequencing in non-genetic clinical practice: fast-WES as a routine diagnostic test

C. A. L. Ruivenkamp¹, A. C. J. Gijbbers¹, A. H. B. Bollen¹, J. K. Vis¹, I. F. A. C. Fokkema¹, A. van Haeringen¹, N. den Hollander¹, L. Hoefsloot^{1,2}, C. van Asperen¹, M. J. V. Hoffer¹, G. W. E. Santen¹;

¹Leiden University Medical Center, Leiden, Netherlands, ²Erasmus MC, Rotterdam, Netherlands.

Although whole exome sequencing (WES) is increasingly applied in clinical genetics, it is mostly used to replace the gene-by-gene sequencing paradigm that we were used to. However, several studies have shown that the possible applications of WES stretch beyond clinical genetics: in other clinical situations,

particularly in the neonatal intensive care unit (NICU), an unbiased tool to make a diagnosis can be extremely useful.

Several hurdles, such as proven soundness and cost-efficacy, need to be taken before a test can be implemented in a routine clinical setting. To our opinion the long turnaround time for WES has been the major barrier. The full standard WES procedure sometimes takes over six months in diagnostic labs. We managed to reduce the waiting period from several months to one week through developing a protocol that combines Agilent's SureSelectXT workflow with rapid Illumina NextSeq sequencing. The sequencing workflow is seamlessly integrated with our bio-informatics pipeline and in-house analysis software, enabling delivery of WES reports based on high quality exome data within two weeks. We will present our workflow, as well as examples underscoring the utility of fast-WES for physicians and parents in the context of NICU. We believe that fast-WES opens many new possibilities for the introduction of WES in routine clinical practice.

P14.041

Improving access to genetic diagnostic tests

S. Abbs¹, R. Stojnic², I. Johnson¹, J. Aleksic²;

¹East Anglian Medical Genetics Service, Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom, ²GeneAdviser, Cambridge, United Kingdom.

The Regional Genetics Laboratory at Cambridge University Hospitals, UK, has partnered with GeneAdviser to develop an online platform to streamline searching, ordering, and paying for clinical exome sequencing and other genetic tests.

Tests can be searched for by gene, by disease, or by test, at www.geneadviser.com. The methodology, sequencing coverage by gene, cost, reporting time, and the Laboratory's experience with each test are displayed. A "related tests" feature is useful to help clinicians identify additional gene sequencing panels that may be appropriate for patients with heterogeneous phenotypes, searching over 250 gene panels and almost 5000 genes available via our GEMINI clinical exome sequencing. Through an API interface, whenever new tests are added to the Laboratory's database they are almost instantly visible online, ensuring that clinicians have access to tests as soon as they are available.

Electronic ordering of tests through the GeneAdviser secure platform will allow seamless integration with the testing Laboratory's LIMS, improving efficiency in the laboratory and reducing the likelihood of transcription errors. All invoicing and payment for tests are handled centrally through GeneAdviser, meaning that the Laboratory only has to arrange a single periodic invoice and payment for all transactions, avoiding numerous financial transactions and transmissions of supporting documentation with individual clinicians and institutions.

By making it easier for clinicians to find and order genetic diagnostic tests for their patients, and by improving efficiency in the laboratory, this platform will help more patients gain access to the most appropriate and latest tests available.

P14.042

GOSHG2P: web-app and database for diagnostic clinical exome analysis

R. M. Nyanhete, C. Boustred, T. Cullup, L. Jenkins;

North East Thames Regional Genetics Laboratory, London, United Kingdom.

Next-generation sequencing (NGS) technologies have enabled diagnostic genetic laboratories to move from single gene tests to targeted gene panels and clinical exomes. The result has been a rapid increase in the number of genetic variants identified. Legacy approaches to storing and interpreting variants are not scalable and have traditionally used different systems to store variants. To address this problem we have developed a database and web application for variant storage and interpretation.

Great Ormond Street Hospital Genotype to Phenotype (GOSHG2P) is an application that provides clinical scientists with an interface for variant interpretation. All variants identified through our NGS pipeline are stored in a standard format, with annotations of all refseq transcripts consisting of conservation, variation database frequencies and *in silico* tools for pathogenicity prediction. Variant frequencies across sequencing runs are calculated based on virtual gene panels tested. Virtual gene panels can be created and curated within the application. Run quality metrics and a database of PCR primers for variant confirmation are available. GOSHG2P has the capacity to store patient phenotypes, which will aid the interpretation of sequence variants.

GOSHG2P enables clinical scientists to analyse virtual gene panels on our clinical exome that are relevant to the phenotype of a patient or reason for referral without the discovery of incidental findings. Standardisation of va-

riant storage enables variants and their interpretation to be exported using VCF format. This provides a good platform for variant sharing with other clinical laboratories and the wider genetics community for better research into rare disorders.

P14.043

Comparing Immunohistochemistry (IHC) and Fluorescence In Situ Hybridization (FISH) assays in two different invasive breast cancer cohorts using 2007 and 2013 American Society of Clinical Oncology/ College of American Pathologists (ASCO/CAP) Human Epidermal Growth Factor Receptor 2 (HER2) gene testing guidelines

T. H. Lim, A. S. T. Lim, Y. Y. S. Yeap, J. K. K. Ho, K. C. H. What, S. L. Tien, P. H. Tan; Pathology Department, Singapore General Hospital, Singapore, Singapore.

Introduction: HER2 amplification in breast carcinomas is used as a predictive marker for trastuzumab treatment. IHC and FISH testing algorithms have been based on 2007 ASCO/CAP guidelines with new scoring criteria updated in 2013. This study assessed the impact of the new guidelines on HER2 testing.

Materials and Methods: Retrospective review of 590 invasive carcinomas with concurrent IHC and FISH results based on 2007 ASCO/CAP guidelines was performed from July 2011-June 2013. Ratio of HER2 FISH to centromeric 17 signals of <1.8 was negative, 1.8 to 2.2 equivocal, and >2.2 amplified. Another subset of 486 carcinomas from January 2014-August 2015 was evaluated using the updated guidelines, which defined negative as ratio <2.0 with average <4.0 HER2 copies, ratio <2.0 with ≥4.0 to <6.0 HER2 copies equivocal, ratio ≥2.0 or ratio <2.0 with ≥6.0 HER2 copies amplified. IHC 3+ was revised from uniform intense membrane staining >30% invasive tumour cells to >10%. Concordance rates between the assays were compared in both sets of data.

Results: Overall concordance rate for FISH and IHC was increased from 94.9% to 95.5% with 2013 classifications. Positive IHC concordance increased from 93.1% to 100% but negative IHC concordance declined from 95.8% to 93.8%. Negative FISH cases decreased from 79.2% to 63.8% while FISH positive cases significantly increased from 20.2% to 34.4%. Equivocal cases also increased from 0.68% to 1.85%.

Conclusions: Improvement in overall concordance rate and positive IHC concordance with updated 2013 ASCO/CAP criteria were observed with more patients being classified as HER2 positive.

P14.044

Comprehensive genetic testing for hereditary cancer with I2HCP: custom design to preserve understanding and control over the whole diagnostics workflow

E. Castellanos¹, B. Gel¹, I. Rosas¹, E. Tornero², S. Santín¹, L. Sumoy¹, M. Perucho¹, I. Blanco³, M. Pineda³, L. Feliubadaló², J. Brunet², G. Capellá², C. Lázaro², E. Serra¹;

¹Institute of Predictive and Personalized Medicine of Cancer (IMPPC), Badalona (Barcelona), Spain, ²Catalan Institute of Oncology, Barcelona, Spain, ³Germans Trias i Pujol Hospital, Badalona (Barcelona), Spain.

Introduction: We wanted to implement an NGS-based strategy to analyze 122 hereditary cancer genes with diagnostics quality. The challenge was to retain in the diagnostics lab the same understanding and control over all workflow steps reached by pre-NGS strategies.

Materials and Methods: We developed the I2HCP panel, a custom bait library improved by bait behavior monitoring. We customized sample preparation, tested different NGS platforms and created a clinically-driven custom data analysis pipeline.

Results: Training (n=24) and validation (n=40) sets focused on hereditary colorectal cancer, hereditary breast and ovarian cancer and Neurofibromatosis, for which tested gene sets were established by a multidisciplinary team based on clinical utility. Yield and QC parameters reached diagnostics quality and were maintained after the first 150 samples tested in the routine diagnostics. I2HCP strategy achieved an accuracy, analytical sensitivity and specificity greater than 99%, matching Eurogentest recommendations. We provide examples of how the new workflow improved diagnostic sensitivity, solved uncertain clinical diagnoses and allowed the identification of mutations in candidate cancer predisposition genes.

Conclusions: We developed, validated and implemented an NGS-based diagnostics strategy for hereditary cancer preserving understanding and control over the whole process. A global analysis of hereditary cancer genes revealed a complex variation landscape cohabiting with the disease-causing mutation.

OncoVirSeq: Targeted sequencing of viral integration in human tumours

S. Leonard¹, A. Skowronska², N. Dyer³, S. Ott³, S. Clokie², C. Woodman¹, C. Tan², A. Rettino², M. Griffiths²;

¹Institute of Cancer and Genomic Sciences, College of Medical and Dental Sciences, University of Birmingham, Birmingham, United Kingdom, ²West Midlands Regional Genetics Laboratories, Birmingham Women's NHS Foundation Trust, Birmingham, United Kingdom, ³Warwick Systems Biology Centre, University of Warwick, Coventry, United Kingdom.

High risk human papillomaviruses (HR-HPV) are associated with nearly 100% of cervical cancers, as well as with vulval, anal, penile and oropharyngeal cancers. Integration of HR-HPV into the human genome is an early event following HPV infection in vivo, however whether integration of the virus is capable of driving tumorigenesis remains unclear.

To understand the relationship between HR-HPV integration and tumorigenesis, we have developed OncoVirSeq, a highly sensitive sequencing approach and analysis pipeline, which specifically identifies viral-human integrant boundaries. We have used Next Generation Sequencing coupled with sonication and a hybridization-based enrichment method.

To date, we have successfully used this methodology to confirm the already known HPV integration sites in the HPV positive cell lines SiHa, HeLa and Caski. Furthermore, using a longitudinal model of replication, we have identified both the early and late integration events which follow transfection of primary keratinocytes with episomal forms of HPV 16 and 18. From this analysis, we have mapped the most common breakpoints in both HPV 16 and 18, as well as those in the human genome. We have also identified those integration sites which may be important in driving clonal expansion. Importantly, we show that some of these HPV integration sites are the same as those found in HPV associated tumours. We are currently developing this technology for its use with HPV positive tumours, as we believe it will be a useful tool for identifying those viral integration sites important for tumour initiation and progression.

Massively parallel next generation sequencing to investigate the cis-acting genetic modifiers of instability in Huntington disease

A. M. Alshammari¹, M. Ciosi¹, S. Cumming¹, G. Hamilton², K. Nasser¹, A. Maxwell¹, D. G. Monckton¹, The US-Venezuela Collaborative Research Project;

¹Institute of Molecular, cell and system biology, University of Glasgow, Glasgow, United Kingdom, ²Glasgow Polyomics, Research Institute of Molecular, Cell & Systems Biology, University of Glasgow, Glasgow, United Kingdom.

Introduction: Huntington disease (HD) is an extremely variable inherited neurodegenerative disorder caused by an unstable expansion of a CAG trinucleotide repeat in the huntingtin gene (*HTT*). The traditional method of diagnosis is limited due to the assumption that the length of the fragment is equal to the repeat number. This may not always be true because there is a variable CCG repeat downstream of the CAGs and also atypical intervening sequences. Moreover, the traditional approaches cannot measure somatic mosaicism of the expanded CAG repeat, or detect variants within or flanking the repeats. We have used Next Generation Sequencing (NGS) to quantify germline and somatic variants in the HD allele.

Materials and Methods: The HD CAG and CCG repeats were amplified from genomic DNA using locus specific primers combined with barcoded Illumina adapters. The PCR products were sequenced using the MiSeq platform and genotyped by alignment of reads against custom reference sequences.

Results and Discussion: We used the MiSeq platform to sequence and genotype HD alleles and the adjacent CCG repeats from more than 490 DNA samples from both HD patients and unaffected individuals. Our data have revealed three atypical allele structures represented in 56 alleles. However, it must be noted that no atypical haplotypes were detected in intermediate or expanded alleles. We observed the degree of somatic mosaicism for patients with HD is correlated with CAG repeat size and age at sampling. NGS is promising diagnostic tool for genotyping HD and potentially replacing existing methods.

P14.047

Study of in-silico predictors to assess the pathogenicity of variants in clinical diagnosis

A. del Pozo^{1,2}, K. Ibañez¹, J. Silla-Castro¹, E. Vallespín^{3,2}, P. Lapunzina^{4,2};

¹Bioinformatics Section, Institute of Medical and Molecular Genetics (INGEMM), Madrid, Spain, ²Centro de Investigaciones Biomédicas en Red de Enfermedades Raras (CIBERER), Madrid, Spain, ³Structural and Functional Genomics Section, Institute of Medical and Molecular Genetics (INGEMM), Madrid, Spain, ⁴Institute of Medical and Molecular Genetics (INGEMM), Madrid, Spain.

Introduction: Next Generation Sequencing (NGS) allows full and simultaneous study of all mutations present in a set of genes. This advantageous feature becomes a difficult issue if it is unable to select those variants that may be causally associated with the phenotype under study.

As first-phase of variant filtering, it is usually carried out the analysis of the deleterious effect of the variants based on phylogenetic conservation, allele frequency and in-silico predictions. However, the extensive use of prediction tools should be accompanied of criteria that allow for general and good practice recommendations to interpret the numerical results in context of clinical suspicion of the patient.

Results: In this study we have performed a comparative analysis of a suite of prediction tools aiming to:

a) establish a unified criteria that enables the assignment of cutoffs to each program and their labelling into some predefined functional categories b) based on these values, assess their predictive value using a benchmark set of variants c) finally, discuss the more suitable strategy of use of in-silico prediction programs in terms of the pattern of inheritance of the disease or the haploinsufficiency status of the gene under study.

Materials and Methods: It had selected a set of 11 prediction tools and it had obtained prediction values in a benchmark set of more than 20,000 variants (missense, nonsense, splicing, small insertions and deletions) extracted from literature, a filtered version of humpvar from SWISS-PROT and in-house set of mutations.

P14.048

Variants effecting inflammatory expression profiles identified by a novel biological pathway approach

R. Attard¹, K. Cassar¹, R. Farrugia¹, S. Bezzina Wettinger¹; University of Malta, Msida, Malta.

Introduction: The genes involved in the generation of an inflammatory immune response are many. Approaches used to date have not yet unveiled the variants responsible for the generation of different inflammatory expression profiles.

Methods: In this family-based candidate gene approach, families were selected from the extreme ends of the phenotype distribution of inflammatory expression profiles, as assessed by multiplex ligation-dependent probe amplification assays on whole blood. Exome sequencing of inflammation-related genes was carried out on an Illumina HiSeq4000. SNPs and indels were compared between families with low and high expression profiles. Variants in genes coding for proteins which physically interact, carry out similar/overlapping functions and which participate in the same biological pathway were analysed per family.

Results: Patterns of TLR and inflammatory expression profiles tended to be similar in members of the same family. First-degree relatives share a considerable number of variants in inflammation-related genes, while very few differences were observed between families with low and high inflammatory expression profiles. While an accumulation of variants were identified in some TLRs, IRAK and MAPK genes, fewer or no variants were observed in molecules having a more critical role in the TLR signaling pathway including MyD88, and transcription factors.

Conclusions: The similar pattern of inflammatory expression profiles in families is possibly due to the presence of inherited factors. Genetic variation influences the fine-tuning of the inflammatory response, where the overall effect on a pathway is an accumulation of the effects of the variants within that pathway.

P14.049

A "sequencing artifact" in LEPRE1 causes osteogenesis imperfecta

K. Tveten¹, Ø. L. Holla¹, E. Bryne², Ø. L. Busk¹;

¹Telemark Hospital Trust, Skien, Norway, ²Vestfold Hospital Trust, Tønsberg, Norway.

Introduction: A child with clinical osteogenesis imperfecta (OI) was referred to genetic testing. Recessive inheritance was presumed. Previous genetic testing of COL1A1 and COL1A2 was negative.

Materials and Methods

Exome sequencing was performed and variants were called in all known OI

genes.

Results: At first, no obvious causative variants were found. However, a homozygote variant in LEPRE1 caught our attention. It had a high allele frequency in ESP (92.44%), but no entries in 1000G nor ExAC. Because of the big difference in allele frequencies, ESP was contacted. They confirmed the allele frequency, but regarded it as a sequencing artifact. The variant was a frameshift deletion in the last exon of LEPRE1 and had not been detected in our lab previously. The variant passed all quality criteria and was confirmed by Sanger sequencing.

LEPRE1 encodes prolyl 3-hydroxylase 1 (P3H1) which belongs to a family of collagen prolyl hydroxylases required for proper collagen biosynthesis, folding, and assembly. The variant changes the reading frame for the last 18 amino acids and elongates the protein by 10 amino acids. This region harbors a KDEL sequence which retains P3H1 in the endoplasmic reticulum. P3H1 will probably not be able to retain its function when this sequence is altered.

Conclusion: This sequence variant is the probable cause of OI in this patient. Caution must be taken when filtering sequence variants where there is big discrepancy between reported allele frequencies.

P14.050

A network-based computational approach for the diagnosis and novel gene identification of leukodystrophies and hereditary spastic paraplegias

A. Schlüter^{1,2}, M. Ruiz^{1,2}, A. Rodríguez-Palmero³, J. Martínez^{1,2}, C. Redin⁴, J. Mandel^{4,5,6}, A. Macaya⁷, A. López de Munain^{8,9,10}, C. Casanovas^{1,11}, A. Pujol^{1,2,12};

C/ Faraday 7-28049, Madrid, Spain, ¹¹Neuromuscular Unit, Neurology Department, Hospital Universitari de Bellvitge, Hospitalet del Llobregat, Spain, ¹²Catalan Institution of Research and Advanced Studies (ICREA), Barcelona, Spain.

Leukodystrophies and Hereditary spastic paraplegias (HSPs) are neurodegenerative diseases manifesting frequently with similar clinical pictures, i.e. chronic progressive spasticity, due to common underlying causes and physiopathological mechanisms. Although the genetic basis is partly understood, only a small fraction of cases receives a definitive genetic diagnosis using targeted approaches nowadays. Whole exome sequencing (WES) may improve diagnostic yield and identify novel causative genes. To analyze the derived data, we have developed a global, network-based computational method designed to prioritize disease genes based on the observation that genes causing similar diseases tend to lie close to one another in a network of protein-protein interactions. This information is integrated with a phenotypic disease metric based on Human Phenotype Ontologies (HPO), to score the strength-of-association of proteins with leukodystrophy and HSP phenotypes. Our diagnostic yield from 41 cases analyzed by WES is as follows: i) Positive diagnosis in 17 cases (pathogenic or likely pathogenic variants); ii) Possible diagnosis in seven cases with variants of unknown significance, of which four are non-previously related to HSP or leukodystrophies; iii) Three novel candidate genes; iv) 14 Inconclusive cases. Our analysis links HSP and leukodystrophy to other neurodegenerative disorders and may facilitate gene discovery and mechanistic understanding of white matter and cortical motor neuron diseases.

P14.051

Diagnostic workup, outcome and cost for patients with suspected Lynch syndrome

S. Gebre-Medhin, K. Henriksson, H. Ehrencrona, I. M. Holm; Department of clinical genetics, Lund, Sweden.

Background and aim: We have performed a retrospective analysis of the family history of cancer, laboratory results and costs for 372 probands with suspected Lynch syndrome (LS), the most common known hereditary CRC condition. The cluster of affected first degree relatives (CFDR) with the largest number of LS-associated cancers was identified in each proband's pe-

digree. Lowest age at cancer diagnosis (LAD) in each CFDR, including also any affected second degree relatives, was determined. Results: 368 patients were investigated with DNA mismatch repair (MMR) functional analyses of which 92 patients (25 %) were considered to have an MMR deficient tumor. Compared to CFDRs with normal MMR function, CFDRs with MMR deficiency had significantly larger numbers of LS tumors as well as lower LAD. A total of 114 patients were subjected to MMR gene mutation screening of which 92 had an MMR deficient tumor, 10 had a MMR proficient tumor, the remaining 12 having unknown MMR function. Among mutation screened patients, 48 (42 %; i.e. 13 % of the entire cohort) had an LS-associated mutation. Mutations were found in MSH2 (46 %), followed by MLH1 (31 %), MSH6 (21 %) and PMS2 (2 %). Total laboratory costs were 248 482 €. Conclusion: Our data indicate that, in selected patients, the application of a multigene panel covering all major hereditary CRC syndromes as a first line investigation would probably be a more rapid and cost effective strategy to identify individuals in benefit of targeted cancer surveillance and treatment.

P14.052 Characterizing male idiopathic infertile phenotypes based on a panel of 228 genes using Targeted Next Generation Sequencing

R. Cocos^{1,2}, F. Raicu^{1,2};
¹Carol Davila University of Medicine and Pharmacy, Bucharest, Romania, ²Genome Life Research Center, Bucharest, Romania, ³Francisc I. Rainer Anthropological Research Institute, Romanian Academy, Bucharest, Romania.

Innumerable combinations of genetic, epigenetic and environmental factors could explain the causes of male infertility. Recent studies have shown that mutations or polymorphisms in new candidate genes are responsible for the majority of idiopathic forms of spermatogenic failure.

Given the recent evolution in the development of Next Generation Sequencing techniques and the growing number of known and candidate genes we designed and developed a targeted sequencing protocol onto Ion Torrent PGM platform that captures the exons of 228 genes AmpliSeq panel to further increase our knowledge on the molecular base of male infertility.

In our pilot study we tested this panel on DNA samples of 15 out of 100 patients with idiopathic infertility that presented no Y chromosome microdeletions. All samples had 97.85% average of target regions with coverage by at least 30 folds. Data were analyzed using a bioinformatics in house pipeline based on GATK, Picard and Anovar software for reading alignments, variant calling, filtering and annotation.

Up to date, all analysed patients had a total of 48 possible causative variants in 37 different genes, excluding common polymorphisms, but increasing the number of samples we probably be able to detect more associated variants or mutations.

Our approach provide a robust and sensitive method to detect novel genetic variants and can represent a powerful method for investigating affected male in order to discover new key molecules that could represent in the future the target for personalized drug or gene therapy. This work was supported by the CNCS-UEFISCDI grant PN-II-RU-TE-2014-4-0527.

P14.053 RNA sequencing analysis of human sperm samples

L. Ramos¹, S. Santin¹, G. Rech¹, L. Bassas², A. Mata², L. Sumoy¹, S. Larrriba²;
¹IMPPC, Badalona, Barcelona, Spain, ²Fundació Puigvert, Barcelona, Spain, ³IDIBELL, L'Hospitalet de Llobregat, Barcelona, Spain.

Introduction: Spermatozoa contain, besides the haploid genetic material, functionally viable transcripts that are delivered into the oocyte during fertilization. The sperm gene expression profile could reflect the fertilizing potential of spermatozoa. However, the assessment of human sperm-RNAs, generally characterized by low quantity and high fragmentation, is complex. We aimed to develop a strategy to characterize the human sperm-RNAs by RNA-seq technology.

Materials and Methods: Two different methods were used to isolate spermatozoa from semen (discontinuous density-based centrifugation and swim-up) and three different methods of RNA extraction (Trizol_Thermo Fisher, NucleoSpin RNA_Macherey Nagel and miRCURY_Exiqon) were compared. RNA samples were DNase treated and removed from contaminants with Nucleospin RNA Clean-up XS_Macherey Nagel. SMARTer Stranded RNA-Seq Kit_Clontech was used for library preparation, preceded by a ribosomal RNA (rRNA) depletion step, for which two different procedures (RiboGone_Clontech and Ribo-Zero Gold_Illumina) were compared. Libraries were sequenced in a HiSeq-2500 (2x50 PE).

Results: All sperm isolation and RNA extraction methods provided comparable results in terms of library RNA class representation. However, exploratory analysis pointed to a list of 56 protein-coding genes differentially ex-

pressed between gradient purification and swim-up sperm isolation. Regarding the rRNA depletion step, RiboGone provided better cytoplasmic rRNA removal efficiency than Ribo-Zero Gold (0.48% vs. 13.1% reads mapping to rRNA), resulting in higher percentage of reads mapping to protein-coding genes (75.53% vs. 61.1%).

Conclusions: The application of an optimized low input RNA-seq procedure to sperm-RNA comparative studies may contribute to a better understanding of the molecular mechanisms underlying male infertility.

P14.054 The role of massively parallel sequencing in the molecular diagnostics of repeat expansion disorders

J. Radvanszky^{1,2}, J. Budis³, F. Duris², J. Gazdarica⁴, M. Gabriel^{4,2}, L. Kadasi^{1,4}, T. Szemes^{4,2};
¹Institute for Clinical and Translational Research, Biomedical Research Centre, Bratislava, Slovakia, ²Geneton Ltd., Bratislava, Slovakia, ³Department of Computer Science, Faculty of Mathematics, Physics and Informatics, Comenius University, Bratislava, Slovakia, ⁴Department of Molecular Biology, Faculty of Natural Sciences, Comenius University, Bratislava, Slovakia.

Introduction: In repeat-expansion disorders (REDs) both normal, as well as permutation and mutation range repeat numbers are highly variable, posing a challenge for molecular diagnostics. In the majority of REDs there is still no single method that would allow identification and sizing of the entire allele range. Therefore, at least two complementing methods are generally required, while sequencing has no special place among them. Using myotonic dystrophy (DM) as a model, we developed an STR genotyping algorithm that allows massively parallel sequencing (MPS) to be applied, as a first tier test, for the exclusion of the presence of REDs associated expansions.

Materials and methods: Following a custom HaloPlex based enrichment, sequencing was performed on Ion Torrent PGM. Repeat number estimations from FASTQ data were performed as follows: motif filtering, annotation of the remaining reads with profile Hidden Markov model and final clustering the annotated reads into groups corresponding to individual alleles.

Results: As second generation sequencing (SGS) has standard amplification derived limitations, expanded alleles remained un-amplified and un-detected, making SGS-based testing un-useful for REDs diagnosis confirmation. Assessed genotypes of healthy-range alleles were, however, highly concordant with those generated by conventional methods, suggesting that even SGS allows diagnosis exclusion if two healthy-range alleles are identified.

Conclusions: If reliable STR genotyping/annotation tools are exploited in the sequence variant annotation process, inclusion of disease-associated repeat regions into targeted sequencing panels may, at least partially, extend the possibilities of MPS based diagnostics into the field of microsatellite expansion disorders (financial support: VEGA_2/0115/15).

P14.055 Next generation sequencing for the identification of mutations in MDS patients - A comparison between peripheral blood, CD34+ blood cells and bone marrow aspirate

R. Martin, C. Ganster, D. Haase;
University Medical Center Göttingen, Clinics of Haematology and Medical Oncology, Göttingen, Germany.

Myelodysplastic syndromes (MDS) are clonal stem cell diseases of the bone marrow (BM). Acquired somatic mutations account for MDS formation and constitute important markers for diagnosis in up to 90% of MDS cases. Currently BM aspirates are used for molecular genetic analysis of MDS patients. The aim of this study was to investigate if the high sensitivity of next generation sequencing (NGS) allows reliable genetic diagnostics using peripheral blood (PB).

Six patients (3xRCMD, 3xRAEB-2) were included in our pilot study. For all patients genomic DNA was extracted from mononuclear bone marrow (BMMC), peripheral blood (PBMC) and immunomagnetically enriched CD34+ peripheral blood cells (CD34+). Sequencing was performed using the TruSight Myeloid Sequencing-Panel and a MiSeq instrument (Illumina). Reads were aligned with BWA (hg19) and further processed using the software packages Picard, GATK and Anovar. Mutations with an allele frequency $\geq 5\%$ were included in the analysis. T-cells were used to prove somatic origin.

We identified somatic mutations in all patients. Overall we found 13 aberrations in our cohort (3xRUNX1, 3xSRSF1, 2xU2AF1, 1xASXL1, 1xETV6, 1xIKZF1, 1xTET2, 1xTP53). All mutations were detectable in PB (12xCD34+, 11xPBMC). Eight mutations were present in all tested sample types (BMMC, CD34+ and PBMC). Further details including clone sizes and comparisons between different materials will be demonstrated. Our findings indicate that

NGS enables adequate detection of somatic mutations also from PB preparations. We conclude that NGS will improve diagnostics and disease monitoring. Genetic analysis of PB would significantly reduce invasive clinical interventions.

P14.056

Gene-based variant classifier to assist medical sequencing

K. J. van der Velde, E. N. de Boer, C. C. van Diemen, B. Sikkema, K. M. Abbott, L. Franke, R. H. Sijmons, T. J. de Koning, C. Wijmenga, R. Sinke, M. A. Swertz; UMC Groningen, Groningen, Netherlands.

The widespread application of medical sequencing is seriously hampered by the lack of vast, accurate and fully automated interpretation tools. Existing variant pathogenicity predictors do not include knowledge from the (public) clinical domain such as known genomic variation and its relationship to human health. They cannot reliably perform automated interpretation for clinical DNA/molecular diagnostics. Here, we address this challenge and present a novel method that delivers accurate computational variant classification. We evaluated allele frequencies, putative protein impact and estimated deleteriousness for >100,000 variants from ClinVar and ExAC in >3,000 genes, resulting in gene-specific calibrations of benign versus pathogenic variants. Next, we developed an algorithm that utilizes these data to classify any new variant that may be found within these genes, and ran successful validation on test sets from VariBench and MutationTaster2. The method's power emerged in a clinical setting, where we found an overall yield of 79% (correlation * coverage) compared to 30-67% of existing tools when applied to 2,359 pre-assessed variants in patients in five different diseases. This high yield is achieved by a large proportion of variants being located in calibrated genes, demonstrating that human clinical expertise implicitly stored in existing interpreted variant lists can be leveraged to accurately and computationally classify new variants in their gene context. This method can also be used in automated whole-genome interpretation. We provide an online service to annotate VCF files, and an executable including source code is downloadable as open source for use in bioinformatic pipelines.

P14.057

Verification of miRNA expression using nuclease protection and targeted next generation sequencing

M. M. Reinholz, Q. Liu, M. Schwartz, P. Roche, B. LaFleur; HTG Molecular Diagnostics, Tucson, AZ, United States.

Introduction: miRNAs are short, ~22nt RNA sequences that modulate gene transcription and downstream cell behavior. The HTG EdgeSeq miRNA Whole Transcriptome Assay (WTA) enables users to measure the expression of 2,083 human miRNA transcripts using next generation sequencing. HTG EdgeSeq extraction-free sample preparation chemistry is compatible with FFPE, cell lines, extracted RNA, and plasma.

Materials and Methods: Two studies were conducted to characterize the performance of the HTG EdgeSeq WTA assay in FFPE and plasma sample types. The sample input studies evaluated a range of sample input amounts for both plasma and FFPE sample types. Optimal input range was established based on sample quality (using process controls) and performance (technical correlation and detection of low expression). Reproducibility studies across technical replicates were also performed for both sample types. **Results:** Read depth, defined as the total aligned counts at the sample level, for FFPE ranged from 524K at the lowest sample input (1.56 mm²/well) to 5 million at the highest sample input (12.5 mm²/well) with no loss of sample quality or expression sensitivity. Thus, for FFPE samples any input volume over the entire range is acceptable. The recommended sample input for plasma was established as 12.5 µL/well, this volume resulted in a minimum of 642K reads. Pairwise Pearson correlation coefficients on technical replicates ranged from 0.93 to 0.98 for FFPE samples and from 0.82 to 0.98 for plasma.

Conclusions: The HTG miRNA WTA assay allows for highly reproducible expression with low sample input volumes for both plasma and FFPE samples.

P14.058

Highly sensitive TaqMan®-based microRNA detection for translational research

L. Wong, C. Liu, F. Hu, T. Gulham, S. Dong; Thermo Fisher Scientific, South San Francisco, CA, United States.

MicroRNAs (miRNAs) are small non-coding RNA molecules that have been identified as efficacious biomarkers for the classification of tumors and prediction of outcome for many diseases because of their evolutionary con-

servation, unique expression signatures, relative stability, and abundance. Detection of circulating microRNAs in serum, plasma, and other body fluids holds great promise for a non-invasive approach to molecular diagnostic and therapeutics. However, detection of miRNAs in these clinically relevant samples has been difficult, often requiring greater sensitivity. A typical study workflow in translational research involves first identifying differentially expressed miRNAs in normal and diseased sample types by profiling many miRNAs, then screening or validation of a smaller set of relevant miRNAs. We have developed a new method for the detection and quantification of miRNAs that is highly specific and sensitive. The upstream chemistry allows synthesis of miRNA template library that is used in the downstream real-time TaqMan qPCR for miRNA-specific detection. The universality of template synthesis simplifies the workflow and provides the flexibility for scalable content (miRNA coverage). Whether applied to basic or translational research, profiling, screening, or validation, this new and robust method allows detection and quantification of miRNAs to address the unmet needs in workflow and sensitivity that exists today with next generation sequencing and other qPCR technologies, especially with clinical samples. Results show miRNA-specific detection down to a single cell level providing greater confidence for low copy detection to meet the needs of translational research. Data from plasma and serum will be presented.

P14.059

Suitability of various tissues for mitochondrial genome testing

S. L. Hume, S. Taylor, L. Vican, K. Siriwardena, K. Baptista, L. Podemski, P. Lisa, K. Sprysak, M. Somerville; University of Alberta, Edmonton, AB, Canada.

As next generation sequencing is able to detect low amounts of mitochondrial heteroplasmy, we sought to investigate tissue sources that would be amenable to full mitochondrial genome testing including sequencing and deletion analysis. Our results demonstrate that either first morning urine or buccal swab samples provide high quality DNA suitable for next generation sequencing. We tested multiple samples from a patient and her mother with a complex I deficiency, m.13513G>A (p.Asp393Asn, NADH dehydrogenase). Although this mutation was present at higher levels in urine and buccal samples than in blood, it was detectable by NGS in all specimens. Of note, this mutation was not detectable in either a urine or buccal sample from the mother. In contrast, deletion analysis by Southern blot is generally not possible on urine or buccal samples as the DNA obtained is insufficient. Additionally, long-range PCR testing of the Kearns-Sayre region revealed that urine has low specificity as deletions are frequently detected in normal unaffected control samples. Southern blot analysis using DNA derived from a muscle sample remains the gold standard for mitochondrial testing. We estimate that the sensitivity of Southern blot analysis is 5% for heteroplasmy while the long-range PCR detects below 5%. In our experience, a long-range PCR of the Kearns-Sayre region must be interpreted with other clinical information (such as CN or BN-PAGE or respiratory enzyme studies) and should not be used in isolation. Therefore, our current mitochondrial genome test algorithm involves NGS on urine followed by Southern blot analysis using a muscle sample.

P14.060

Functional analysis of variants of uncertain clinical significance in components of the TORC1 signaling pathway

M. Hoogeveen-Westerveld¹, M. Hosseinzadeh¹, R. Swenker¹, R. Ekong², S. Povey², N. Migone², G. Mancini¹, L. Hoefsloot¹, F. Verheijen¹, M. Nellist¹; ¹Erasmus MC, Rotterdam, Netherlands, ²University College London, London, United Kingdom, ³University of Turin, Turin, Italy.

The mechanistic target of rapamycin (mTOR) complex 1 (TORC1) is an essential protein kinase complex that controls cell growth and metabolism. Mutations in different components of the TORC1 signaling pathway are associated with a broad spectrum of inherited and somatic diseases. We have investigated the effects of >300 variants of uncertain clinical significance (VUS) identified in genes encoding components of the TORC1 signaling pathway, on TORC1 activity. Our work has provided insight into the likely pathogenicity of the tested VUS, the genetic risks in the families segregating the tested variants, genotype-phenotype correlations and structure-function relationships. Investigating the effects of VUS on TORC1 signaling is a useful adjunct to standard genetic testing and can provide essential information for appropriate clinical management. The tests have been validated for use in our diagnostic laboratory. We will present an overview of our work.

P14.061

Transition to massively parallel sequencing using a multi-disciplinary team approach - the South Australian experience

L. H. Rawlings¹, K. Kassahn¹, P. Kaub¹, K. Friend¹, A. Tirimacco¹, K. Brion¹, E. Douglas¹, L. McIntyre¹, D. Lawrence¹, J. Geoghegan^{1,2}, H. Scott^{1,2}, C. Barnett³, J. Liebelt⁴, L. McGregor⁵, E. Thompson³, E. Haan⁴, S. Bain¹, J. M. Fletcher¹;

¹SA Pathology, Adelaide, South Australia, Australia, ²Centre for Cancer Biology, Adelaide, South Australia, Australia, ³Paediatric and Reproductive Genetics SA Clinical Genetics Service Women's and Children's Hospital, Adelaide, South Australia, Australia, ⁴Adult Genetics Unit SA Clinical Genetics Service Women's and Children's Hospital, Adelaide, South Australia, Australia.

Globally, the implementation of Massively Parallel Sequencing (MPS) has expanded genetic diagnoses by delivering exponential amounts of data at reduced labour costs. The Genetics and Molecular Pathology (GMP) Directorate of SA Pathology (South Australia) comprises four laboratories across three tertiary hospitals testing both constitutional and somatic variants for a large number of genetic disorders. Traditionally, genetic diagnoses were siloed to specific laboratories, based on clinical condition. MPS applications are relevant to every laboratory across the directorate, therefore its implementation has required a cooperative and consolidating approach. Multi-gene panels, whole exomes and genome testing present opportunities to explore causative sequence variants for genetic disorders, once achieved by time-consuming Sanger sequencing. The rapid expansion of complex test requests has required a complementary increase of knowledge in large data management, quality control and complex analyses, and a change in process for accepting requests for testing and reporting.

To facilitate the transition to MPS, a broad, consultative, multi-disciplinary team (MDT) approach was taken, whereby medical and research scientists, bioinformaticians and specialist clinicians contributed to the evaluation and validation of analytical platforms, clinical utility and best reporting practice. Eighteen months post-implementation, this MDT approach continues to sustain the ongoing function and development of the molecular genetic service through regular meetings with three main foci: service development, intake of MPS requests and complex reporting. Clinical-based input and demand is imperative in all.

This presentation will outline key success factors in the transition process from method validation to clinical implementation of MPS testing in South Australia.

P14.062

Functional analysis of variants of uncertain clinical significance in *NF1*

M. Kroos-de Haan, M. Hoogeveen-Westerveld, R. van Minkelen, Y. van Bever, L. Hoefsloot, F. Verheijen, M. Nellist; Erasmus MC, Rotterdam, Netherlands.

Inactivating mutations in *NF1* cause neurofibromatosis type 1 (NF1), an autosomal dominant disorder that affects approximately 1 in 3500 individuals. *NF1* encodes neurofibromin, a GTPase activating protein (GAP) for RAS. Loss or inactivation of *NF1* results in increased levels of active RAS-GTP and increased signaling through the RAS-mitogen activated protein kinase (MAPK) pathway. We have performed RAS-GTP pull-down assays to assess the RAS-GAP activity of *NF1* variants of uncertain clinical significance (VUS) identified in our NF1 patient population. Our preliminary analysis indicates that functional assessment of *NF1* VUS could be a useful adjunct to standard genetic testing to improve molecular diagnostics for individuals suspected of NF1, and could help provide essential information for appropriate clinical management. Functional assessment of *NF1* VUS is currently being validated for use in our diagnostic laboratory. We will present an overview of our work.

P14.063

Next generation sequencing as second-tier test in newborn screening programs

J. Rodríguez¹, M. Segura-Puimedon², B. Rodríguez-Santiago¹, M. A. Bueno-Delgado³, A. González-Meneses³, I. Fernández-Carvajal⁴, M. J. Alonso⁵, Y. González-Irazabal⁶, M. Espada⁶, R. Yahyaoui⁷, L. Armengol⁸, L. A. Pérez-Jurado⁹;

¹R&D, Department, Quantitative Genomic Medicine Laboratories (qGenomics), Barcelona, Spain, ²Departament de Ciències Experimentals i de la Salut, Universitat Pompeu Fabra, Barcelona, Spain, ³Department of Pediatrics, University Hospital Virgen del Rocío, Sevilla, Spain, ⁴Laboratorio de Enfermedades genéticas y cribado neonatal, Departamento de Genética Molecular de la Enfermedad, Instituto de Biología y Genética Molecular Universidad de Valladolid-CSIC, Valladolid, Spain, ⁵Servicio de Bioquímica Clínica, Hospital Universitario Miguel Servet, Zaragoza, Spain, ⁶Public Health Laboratory Standards, Basque Government Department of Health, Bilbao, Spain, ⁷Newborn Screening and Clinical Laboratory, Málaga Regional Hospital, Málaga, Spain, ⁸Departament de Ciències Experimentals i de la Salut, Universitat Pompeu Fabra, Centre de Investigació Biomèdica en Red de Enfermedades Raras (CIBERER), Barcelona, Spain.

Introduction: Newborn screening is a publicly-funded health program for

the diagnosis and intervention of genetic disorders that may otherwise have serious clinical consequences. In order to reduce false positives and negatives, shorten diagnosis time and provide genetic counseling, we are evaluating next generation sequencing (NGS) as a second-tier test.

Methods: We use dried blood spot samples from positively-identified newborns to prepare NGS libraries. We have developed a panel of 71 genes commonly affected in the disorders detected by these programs. A bioinformatics pipeline identifies rare genetic variants that may be disease causing. Following technical validation, we have retrospectively analyzed 109 samples to establish the sensitivity and specificity and are prospectively analyzing positive hits in real time to assess clinical utility and cost-effectiveness. Results: Retrospectively, biallelic mutations were identified in 85.3% of the samples and single allele mutations in 7.3%. Samples in which no mutations were detected (7.3%) corresponded to hypothyroidism in half of the cases. In samples with previous genetic diagnosis (n=33), 100% concordance was found and a second mutation was identified in two samples. In the prospective phase, current turnaround time is 9 days. Among 15 cystic fibrosis (CF) samples analyzed we have found biallelic mutations in 13% cases, single mutations in 53.3% and no mutations in 33.3%. These data are compatible with the high rate of false positives for CF.

Conclusion: We have successfully developed an NGS panel that may allow to bypass or redirect confirmatory tests and provide earlier genetic counseling in newborn screening programs.

Grant support: RETOS2014/5938/1

P14.064

Beyond the Human Exome: finding solutions for clinical research NGS-based applications

M. Corioni, E. Lin, K. Jeong, A. Vadapalli, F. Useche, M. Visitacion, G. Amparo, M. Ramaiah, C. Pabon, M. Isaksson, D. Roberts; Agilent Technologies, Santa Clara, CA, United States.

Protein coding genes constitute approximately 1% of the human genome but harbor most of the disease-associated variants. Targeted re-sequencing enables highly sensitive and comprehensive detection of variants and provides insights into the biology behind a given phenotype. With recent major advances in this technology, combined with a better understanding of biological pathways, NGS is now extensively considered for use in clinical research. A comprehensive Exome is a good solution to catalogue variants and provide deep coverage of genomic content from highly curated databases such as CCDS, RefSeq, GENCODE, Vega, MirBase, UCSC known genes, and Human Gene Mutation Database (HGMD®). We describe here several NGS-based solutions to add value to a comprehensive Exome for specific applications. The first is an augmented Exome for clinical research that focuses on improved coverage of disease-related content, especially that relevant to constitutional disease research. We also describe the combination of Exome with OneSeq probes to extend target enrichment applications to the detection of genome-wide copy-number-changes (CNCs), and copy-neutral loss-of-heterozygosity (cnLOH). Finally, we demonstrate a phased Exome coupled to 10x Genomics' linked read technology. The addition of "phasing" probes allows determination of long haplotype blocks. The separation of exonic reads into haplotypes further aids in structural variant and translocation determination, especially for disease causality in complex genotypes. We describe data analysis and performance attributes for each of these platforms, including SNP/INDEL, loss of heterozygosity, copy number variation, phasing, translocation, and resolution of complex compound heterozygote samples.

P14.065

Using the wrong approach to solve the wrong problem: Sanger validation of single nucleotide variants from next-gen sequencing

L. G. Biesecker, T. Beck, J. Mullikin; NIH - NHGRI, Bethesda, MD, United States.

Many next generation sequencing (NGS) clinical laboratories validate NGS variants using Sanger sequencing, which is costly. To evaluate the utility of this, we performed a large-scale evaluation of Sanger validation of single nucleotide variant (SNV) NGS variants using ClinSeq® data. We used NGS data from 19 genes in five participants, comparing them to Sanger data on the same samples, and found 0/234 discrepancies. We then compared NGS variants in five genes from 684 participants against Sanger data. Of >5,800 NGS-derived SNVs, 19 were not validated by Sanger. Using new primers, Sanger sequencing confirmed 17 of the NGS variants. We conclude that a single round of Sanger sequencing is more likely to incorrectly refute a true positive variant from NGS than to correctly identify a false positive NGS variant. Our validation rate was 99.965%, higher than many medical tests that don't

necessitate orthogonal validation. Validation of NGS-derived variants using Sanger has limited utility. We suggest moving to a model where NGS variants with good quality scores are reported to clinicians, without Sanger validation, and with an estimate of the error rate. Then, clinicians should make a clinical determination as to which patients should undergo post-hoc Sanger validation, based on the testing scenario and the potential downstream clinical utilization of the variant. The overwhelmingly important challenge for our field is the clinical validity and utility of NGS data, not analytic validity. By focusing on analytic validity, we detract from the central issues that need to be overcome to make genomics clinically useful.

P14.066

Is the \$1,000 genome as near as we think? A cost analysis of next-generation sequencing technologies

K. J. M. van Nimwegen;

Radboud umc, Nijmegen, Netherlands.

Introduction: Substantial technological advancements in next-generation sequencing (NGS) have been made, while sequencing costs have rapidly decreased. This contributes to a swift diffusion of NGS technologies into clinical settings. However, since costs of equipment, personnel, and data management, are generally not considered, the real costs of NGS are currently considerably underestimated. This study aims to provide a comprehensive, transparent, and up-to-date overview of the total costs of NGS.

Methods: Cost calculations for targeted gene panels (TGP), whole exome sequencing (WES) and whole genome sequencing (WGS) are based on the Illumina NextSeq500, HiSeq4000, and HiSeqX5 platforms, respectively. Five-year lifecycles, 100x (TGP), 70x (WES), and 30x (WGS) coverage, and 15% (TGP), or 75% (WES, WGS) utilization are assumed in the base case calculations. To anticipate future developments, sensitivity analyses are performed in which these factors, as well as capital and operational costs, are varied.

Results: Per-sample costs were €1,669 for WGS, €587 for WES and €333 for TGP. Sensitivity analyses showed that very efficient, long-term use of the sequencing equipment, large reductions in both capital and consumable costs, combined with lowering sequencing depth decrease these costs to €1,006 (WGS), €298 (WES) and €205 (TGP).

Discussion: Costs for TGP and WES are considerably lower than for WGS. However, this does not imply that these techniques should be preferred in clinical practice, as the choice of NGS approach should be based on a careful trade-off between per-sample costs, sequencing quality, and diagnostic yield. The results of the present study contribute to making such trade-offs.

P14.067

Next Generation Sequencing, a powerful technique for diagnosis. A large gene experience

M. Roca-Cervera, A. Romera-López, D. Cantalapiedra, D. Diego-Álvarez, L. Pérez-Cabornero, A. Andújar, R. Pérez-De la Fuente, S. Valverde, L. Cano-Bermúdez, M. D. Arocas-Castillo, C. Collado-Micó, Á. Arilla-Codoñer, G. Marco, G. Legarda, D. Valero-Hervás, S. Santillán;

Sistemas Genómicos, Paterna, Spain.

Analysis of large genes is one of the main challenges that genetic tests face. NGS technology has helped overcome this situation but in many laboratories, Sanger sequencing still remains the technique of choice for genetic diagnosis. The aim of the present work is to compare both techniques' experience analyzing different large genes and to present the diagnostic results of a Marfan syndrome cohort of patients (*FBN1*). We review 492 samples analyzed with our GeneProfile-NGS panels or with Sanger sequencing to evaluate their performances using parameters such as time-consumed, coverage or amount of DNA used. The cases reviewed included analysis of genes *TTN*, *FBN1*, *DMD*, *COL1A1* and *COL1A2* (ranging 51-363 exons). NGS was performed using SureSelect (Agilent) and SOLiD5500 (Life Technologies) or MiSeq (Illumina) platforms. Clinically significant variants identified were confirmed by Sanger. Sanger was performed using BigDye-Terminator-Kit in an ABIPrism3730xl (Applied Biosystems). Genes initially unaffordable to be analyzed by Sanger (*TTN*) can now be sequenced by NGS in a moderate period of time, resulting cost-effective. Gene coverage by NGS and Sanger was similar, around 99-100%. *FBN1* gene was analyzed in 218 Marfan syndrome patients, of whom 23.7% (2-3weeks/patient) were diagnosed by NGS while 27.8% (2-3weeks/patient) by means of Sanger sequencing. However, the time to complete a Sanger sequencing increases proportionally to the number of samples analyzed, while for NGS remains constant. This confirms that NGS is an effective and accurate technology that allows the analysis of large genes in an affordable time.

P14.068

Evaluation of a custom mendeliome for diagnostic genetic testing

E. Souche, V. Race, A. Corveleyn, L. Dehaspe, J. Vermeesch, J. Van Houdt, G. Matthijs;
KULeuven, Leuven, Belgium.

Next Generation Sequencing (NGS) has become routinely used for the diagnosis of various conditions. Although the most comprehensive NGS test for the diagnosis of heterogeneous conditions would be Whole Genome Sequencing (WGS), this test cannot be implemented in a diagnostic setting yet. In order to reduce sequencing costs, laboratories focus on the sequencing of either all genes by Whole Exome Sequencing (WES) or all genes known to be associated to diseases, generally referred to as clinical exome or mendeliome. Several mendeliomes are commercially available but the size of the region they target differs and some genes listed in the Clinical Genomic Database are not included in any test. We thus developed our own mendeliome by selecting the genes offered in commercial panels, those listed in the Clinical Genomic Database as well as a few more recently published genes. In addition, we included targets for 31 SNPs used for sample tracking. The custom mendeliome protocol is based on Nimblegen SeqCap target enrichment technology. It targets the exonic regions of 5,811 genes, representing a target size of 16.5 Mb and a clinical target (coding bases +/- 2 bp) of 12.8 Mb. The performance of our custom mendeliome and analysis pipeline was evaluated by sequencing well characterized cell lines. The results of the target genes were compared to the full genome information from the platinum genomes project. About 96% of the clinical target could be reliably genotyped. The sensitivity and specificity of genotyping single nucleotides was assessed prior to transfer to clinical diagnostics.

P14.070

niPy - Reproducible and scalable NGS workflows for pathology: Raw data to validated report

D. Brawand¹, C. Wall¹, P. Rushton¹, L. Steedman¹, M. Oakley¹, F. Smith^{1,2};

¹Viapath at King's College Hospital, London, United Kingdom, ²King's College London, Molecular Haematology, Division of Cancer Studies, London, United Kingdom.

Next-generation sequencing (NGS) has been widely adopted in diagnostics, and is set to replace Sanger sequencing as the Gold Standard for clinical applications. The complexity of the analysis process, breadth and quantity of data and the necessity for a complete audit trail, with a highly reproducible analytical process presents an operational challenge to laboratories wishing to transition to NGS.

Here we present an open source, clinically validated diagnostic framework which integrates four main components of a genetic testing workflow: A) NGS data processing, B) trend monitoring of quality control metrics, C) variant classification, and D) automated variant validation. Reporting is possible via a standard pathology LIMS using database outputs to reduce transcription errors. A simple web frontend with PDF reports and worksheets enable clinical and laboratory staff to analyse patient data, calculating variant observation frequencies and reviewing pathogenicity scores. Filtering of benign sequence variants, confirmation primer design and SNP check are fully automated.

niPy is version controlled and packaged in cloud-ready application containers allowing rapid replication on commodity hardware, computational clusters or cloud platforms with limited revalidation.

We have successfully integrated niPy into our diagnostic workup of rare anaemia cases and have successfully analysed data from 240 cases, with 15 having novel pathogenic variants including deletions >50bp in size. The turnaround time from raw data to validated variants for a batch of 16 samples is less than 4 weeks. niPy is a validated structured framework for analysis, confirmation and reporting of NGS data in a clinical laboratory.

P14.071

False-negative in Sanger confirmation of a deletion in BRCA2 found by Next Generation Sequencing (NGS)

R. Muguerza, J. S. Crettaz, L. Otaolea, R. Sáez, Y. Ramírez;

Genetics Department, Donostia University Hospital, San Sebastian, Spain.

Introduction: NGS techniques have increased the possibilities of genome analysis but there is still some reluctance to reporting results without Sanger sequencing (SS) confirmation. We present a case where SS failed to confirm a deletion in BRCA2 found by NGS.

Materials and methods: Amplicon library of coding exonic and flanking intronic regions of BRCA1/BRCA2 was performed and sequenced by NGS (MiSeq, Illumina). Pathogenic, likely pathogenic or unknown variants and regions with depth <100x were confirmed by SS.

Results: A heterozygous deletion was found by NGS in BRCA2: NM_000059.3:c.4000_4001del (depth=4996x, allele frequency=44.5%).

Amplification with M13-tailed PCR primers usually used in our laboratory and SS showed absence of the deletion, making us suspect a NGS false-positive or a sample swap error. PCR amplification and SS of a new DNA extraction showed in the electropherogram very slight peaks consistent with the deletion. New primers were designed targeting a larger template that included primer-binding sites, and SS confirmed the deletion this time. Searching for possible causes for the false-negative in SS, we found by NGS a variant (c.4068G>A) in the reverse M13-tailed primer binding site. This variant was absent in the first SS but was confirmed with the new primers. The segregation study supported the hypothesis that the variant was in *cis* with the deletion and caused an allele drop-out. Conclusion: Although SS is the gold standard sequencing method, false-negatives can occur because allele drop-out, which did not occur in NGS, that was able to detect both the deletion and the variant.

P14.072

Impact of high plasma cell-free DNA linked to hemostasis abnormalities on non-invasive prenatal testing results

D. S. C. Han¹, P. Jiang¹, D. Y. M. Lam², W. B. Liu², R. W. K. Chiu¹, Y. M. D. Lo¹;

¹Li Ka Shing Institute of Health Sciences, Department of Chemical Pathology, The Chinese University of Hong Kong, Prince of Wales Hospital, Shatin, New Territories, Hong Kong, ²Xcelom Ltd, Tai Po, New Territories, Hong Kong.

Introduction: Abnormal clinical non-invasive prenatal testing (NIPT) results have been linked to fetal and maternal chromosomal factors such as fetal mosaicism and maternal cancer. Few studies have investigated other biological confounding factors in NIPT analysis. Identifying factors that can affect NIPT analyses can improve future maternal clinical care.

Methods: Total plasma cell-free DNA (cfDNA) concentrations are monitored for samples undergoing NIPT at a Hong Kong testing service. Plasma cfDNA levels were quantified as genomic equivalent per mL by PCR or fluorometry. Samples with total plasma cfDNA concentrations more than +5 SDs from the mean were investigated. Further analyses of plasma cfDNA were conducted via massively parallel sequencing +/- targeted sequencing to obtain fetal fraction and cfDNA size.

Results: Five cases were identified. Four of these five cases had shorter maternal and fetal plasma cfDNA fragments compared with corresponding reference groups. Three of these five cases had fetal DNA fractions lower than the minimum requirement for NIPT service, necessitating a redraw. A scrutiny into clinical history revealed that each case was associated with an abnormality in the hemostasis system.

Conclusions: These cases show that the ability to report NIPT results are affected by high plasma cfDNA, the levels of which may be linked with the hemostasis system. Further research is necessary to elucidate this link. Meanwhile, these cases attest to the importance of including clinical history in NIPT forms and suggest that patients with hemostasis abnormalities should be pre-counselled of their higher chance of non-reportable result.

P14.073

Benefit of repeated sequencing of old next-generation sequencing libraries with novel sequencing chemistry on IonTorrent PGM

K. Soltys, E. Nagyova, D. Dvorska, M. Sekelska, G. Minarik;

Faculty of Natural Sciences, Comenius University in Bratislava, Bratislava, Slovakia.

As next-generation sequencing (NGS) methods are continuously developing novel version of sequencing chemistries come to the market. In case of NGS analysis on IonTorrent PGM recently HiQ version of emulsion PCR and sequencing kits became available. In our study direct comparison of performance of previously used and recently available sequencing chemistries was performed.

NGS libraries prepared with Haloplex method were amplified by emulsion PCR with use of Ion PGM OT2 and Ion PGM HiQ OT2 kits with subsequent sequencing analysis of amplified libraries with Ion PGM sequencing 200 kit v2 and Ion PGM HiQ sequencing kit. Standard bioinformatic analysis on Torrent server was performed for coverage analysis and variant calling. Hundred of SNP and hundred of InDel variants were used in comparison between the kit performance.

The utilization of new and improved emulsion PCR and sequencing kits led to gain of sequencing data with significantly increased sequencing accuracy and more uniform coverage of gene targets. The homopolymer associated errors were completely disappeared in more than third of previously identified positions and gone to nondetectable in another third. From the point of view of coverage uniformity, standard deviation of coverage decreased from 180 to 156.

Reanalysis of archival NGS libraries with new version of library amplification and sequencing could lead to improved results with more accurate vari-

ant calling and higher uniformity of target coverage. Study was supported with grant VEGA-1/0048/14.

Lyso-SM-509 is an easy-measurable and sensitive biomarker for NP-C: a one-year study

A. Rolfs, C. Cozma, G. Kramp, S. Eichler; Centogene AG, Rostock, Germany.

Niemann Pick Type C (NPC) disease is an autosomal recessive disease caused by mutations in NPC1 /NPC2 genes translated in defects of the lysosomes transport system (cholesterol transporters) leading to abnormal accumulation of cholesterol and glycolipids in the lysosome. Although other organs may be affected (e.g. hepatosplenomegaly), NPC is characterized mainly by progressive neurological deterioration. Recently developed treatment renders the NPC diagnosis of high importance.

The levels of lyso-SM-509 in blood reflect the burden of the NP disease and it can be used for the easy diagnosis of NP patients and for monitoring of the disease progression. Determination of lyso-SM-509 is performed by LC/MRM-MS, an analytical method proven to be reliable and reproducible both in plasma, serum, EDTA blood and dried blood spots (DBS). Moreover, by combining the results with the levels of lyso-SM-465 the type A/B and type C patients can clearly be distinguished.

We identified 152 NPC patients using lyso-SM-509 and the diagnosis was directly confirmed by sequencing of the NPC1 and/or NPC2 gene. Lyso-SM-509 has a sensitivity of 100% and specificity of 96.5% for the diagnosis of NP. We have identified a total of 300 pathological alleles in the different NPC cases. 63 unique variants (54.4% of total found) are described in CentoMD exclusively. Conclusion: All cases identified lyso-SM-509 biomarker were genetically confirmed proving its high specificity. The ease of DBS based lyso-SM-509 makes the marker an ideal parameter for the simple and confident diagnosis of NP as well as the monitoring of the diagnosed NP patients.

P14.075

Supplemental CNV analysis in NGS genepanel data in a diagnostic setting

J. J. Saris, R. van Minkelen, M. A. van Slegtenhorst, H. T. Brüggewirth, L. H. Hoefsloot; ERASMUS_MC, Rotterdam, Netherlands.

Standard diagnostic laboratory flows based on PCR and Sanger sequencing often include MLPA analysis when available and relevant. Introducing NGS genepanels in a clinical setting promises a higher diagnostic yield, but is usually used only for sequence variant detection. Normalized Depth-of-Coverage (DOC) calculation can indicate exon copy number variation (CNV) and might replace MLPA. Our lab has established a NGS sequencing flow using JSI SeqNext software. Recently we validated the effectiveness and usability of a DOC-CNV submodule using data from genes located on chromosome X and positive controls. Type and number of reference files (1-on-1 and n=12), signal-to-noise ratio and detection cut-off were evaluated in SeqNext and independent via Z-score analysis.

Aim: Retrospective analysis of genepanel experiments (232 samples, half cardiomyopathy), comparison to validation results and prospective analysis of future experiments (± 12) for exon-CNV and wetlab confirmation of calls ≥ 2 exons and $< 5\%$ frequency, using an internal database, including a filter of "noisy" ROI.

Results: In 232 samples (19 experiments) DOC based gender determination using chromosome X located genes, calling was concordant with the recorded clinical gender. Six multi-exon (a.o. RFN170 & SLC20A2) and 10 whole gene CNV (a.o. NPHP1, ACTB) were detected, eight confirmed and eight ongoing. Manual curation of single exon CNV indicates deep intronic InDels influencing DOC results on capturing and/or mapping level, e.g. 5' ANKRD1-exon4 (MAF $\pm 30\%$).

Conclusion: CNV detection using DOC-analysis in SeqNext promises to be an possible replacement of MLPA in diagnostics. Validation, update on results and lessons learned will be presented.

P14.076

NGS-based measurement of gene expression of 2532 oncology-related biomarkers in formalin-fixed, paraffin-embedded (FFPE) tissues

D. M. Thompson, M. Reinholz, I. Botros, M. Rounseville, P. Roche; HTG Molecular Diagnostics, Tucson, AZ, United States.

Introduction: The HTG EdgeSeq Oncology Biomarker Panel Assay (OBP) combines our proprietary quantitative nuclease protection chemistry with

Next Generation Sequencing (NGS) to enable extraction-free detection of 2,568 mRNA transcripts (2,532 oncology-related) from different sample types including formalin-fixed, paraffin embedded (FFPE) tissue. We established linearity and reproducibility assay performance characteristics.

Methods: Lung, breast, prostate, and colon carcinomas and melanoma FFPE tissue lysates, THP-1 and HCC78 cell lines, and Universal RNA (URNA) were used for linearity and sample input studies. URNA was used to demonstrate reproducibility of the assay across multiple days and processors. Linear regression R2 and Pearson correlation coefficients (r) were used to assess linearity and reproducibility of the assay.

Results: The R2 for linearity across four concentration points for lung FFPE tissue (6.25-0.78mm2), cell lines (1875-234 cells), and URNA (12.5-1.56ng) were >0.97, 0.99, and 0.99, respectively. The r between low (1.56mm2) and high (12.5mm2) sample inputs for each FFPE tissue type was > 0.98. The r's for intra-run, inter-day, and inter-run reproducibility were >0.95, >0.98, and >0.98. Differential expression of tissue-specific genes was identified in the respective FFPE tissues, including NKX2 and MUC1 in lung, ERBB2 in breast, NKX3, KLK2, and KLK3 in prostate, and SPP1 and PRAME in melanoma.

Conclusions: The HTG EdgeSeq Oncology Biomarker Panel Assay is linear over a wide range of sample inputs, can comprehensively analyze small, clinically relevant tissues, and is highly reproducible. The demonstrated performance of the assay in several FFPE tumor samples enables multiplex oncology biomarker profiling of malignant neoplasms.

P14.077

PCR based target enrichment for NGS panels and Sanger variant confirmation

S. Lefever^{1,2}, J. Vandesompele^{1,2}, F. Coppeters^{1,2};

¹Ghent University, Ghent, Belgium, ²pxlence, Dendermonde, Belgium.

Targeted resequencing is an important application in clinical diagnostics. Due to its flexibility in design, high sensitivity and specificity, the polymerase chain reaction (PCR) is ideally suited as enrichment strategy.

Using our in-house primer design tool primerXL, we have generated almost one million PCR assays for both fresh frozen and formalin-fixed paraffin-embedded samples, covering over 98.7% of the human exome. Assays were designed to limit single nucleotide polymorphisms in primer annealing sites and minimize off-target amplification. We have validated 2200 assays from 200 disease causing genes. Wet-lab success-rate was over 96.5 % upon quantitative PCR testing using uniform conditions. Subsequent next-generation sequencing (MiSeq, Illumina) showed equimolar coverage across the different amplicons with almost 90% of the amplicons having a coverage within 5-fold of the mean. Specificity was very high with almost 95% of the assays having <2% of off-target mapping.

Using our assays, NGS gene panels have already been developed for congenital blindness, deafness and various cancer types using different library preparation methods and sequencing instruments. To date, the Center for Medical Genetics in Ghent incorporates our assays to replace Sanger sequencing-based diagnostic tests with NGS (ISO15189 accreditation). In addition, these assays are used for variant validation of various NGS techniques.

Due to the excellent performance the assays, a spin-off called "pxlence" was recently founded (www.pxlence.com). Its goal is to provide customers easy access to the predesigned assays, enabling them to enrich any exonic region or confirm any variant of interest through either NGS or Sanger sequencing.

Confined placental mosaicism and DNA based prenatal tests aCGH and NIPT: report of two cases

L. Barranco, E. Lloveras, V. Cirigliano, A. Canellas, M. Costa, C. de la Iglesia, D. Fernandez, M. Herrero, B. Méndez, N. Palau, M. Piqué, D. Yeste, E. Ordóñez, L. Rueda, A. Plaja;

Departaments de Genètica i Genètica Molecular. LABCO Iberia. Barcelona, Esplugues de Llobregat, Spain.

Introduction: As new DNA tests such as aCGH on whole uncultured chorionic villus samples (CVS) and cfDNA aneuploidy screening in maternal blood (NIPT) mainly rely on DNA from cytotrophoblastic cells, discrepancies with true fetal constitution due to confined placenta mosaicism should be expected, as observed in short-term cytogenetic cultures. We report two cases involving both assays.

Material and methods: Case 1. aCGH on uncultured CVS was performed because of maternal anxiety using a targeted BAC array (Cytochip Focus, Bluegnome, Illumina) and followed by cytogenetic analysis on long term CVS culture. Follow-up cytogenetic and FISH analysis using LSI D5S23 and D5S721 probes (Vysis/Abbot, USA) were performed on amniotic fluid cells. Case 2. NIPT (NeoBona plus, Labco/Illumina) was performed for ultrasound

abnormalities and result confirmation by aCGH on uncultured amniotic fluid using ISCA 8x60K array (Bluegnome, Illumina).

Results: Case 1. A 5p15.2 deletion was detected by aCGH in uncultured CVS. Both deleted and normal cells were observed by cytogenetic analysis of cultured cells. FISH and cytogenetic analyses on amniotic fluid showed normal results and 5p15.2 deletion was considered a confined placental mosaicism. Case 2. A 1p36 microdeletion was detected by NIPT. aCGH confirmation on uncultured amniotic fluid resulted in 1p36 microduplication, suggesting a possible confined placental mosaicism for the deletion or a low mosaicism of deleted and duplicated cells not detectable by aCGH and NIPT.

Conclusions: aCGH on non-cultured CVS and NIPT share the same biological limitations of direct analysis of CVS thus occasionally failing to reflect the true fetal chromosome constitution.

P14.079

Cytogenetics for ploidy

L. Sunde^{1,2}, D. Lildballe¹, I. Niemann¹, L. Bolund^{2,3}, N. B. Scholz², I. Vogel^{1,2};

¹Aarhus University Hospital, Aarhus N, Denmark, ²Aarhus University, Aarhus, Denmark, ³Beijing Genomics Institute/HuaDa, Shenzhen, China.

Introduction: Until recently, the standard method for screening for gross genetic aberrations was cytogenetic analyses such as karyotyping. Analysis of DNA, such as aneuploidy screening by multiplexed analysis of DNA markers has advantages, like, speed, price and representativeness as more cells are analysed. However, as pooled DNA is analysed, specificity may be hampered. In hydatidiform mole (HM) genetic analyses are performed to discriminate between diploid HMs that impose a high risk of trophoblastic neoplasia and triploid HMs that have a benign course. Diploid HMs exist in various forms: Both genome sets originating in the father (PP), one genome set from each parent (PM), and mosaics (PP/PM).

Materials and methods: In 270 HMs known to be diploid and 154 known to be triploid by karyotyping and/or flow cytometry, DNA markers were analysed.

Results: 259/270 diploid HMs showed markers indicating paternal genome exclusively and 3 showed markers indicating a balanced biparental genome. These would have been classified as having the parental types PP and PM, respectively, without knowing the ploidy.

8/270 diploid HMs and 154/154 triploid HMs showed maternal and paternal markers with indication of a higher fraction of paternal genome, either because two paternal markers were observed in one locus, or because signals from paternal alleles were higher than the signal from the maternal allele. These observations could either be caused by triploidy with the parental type PPM or by mosaicism PP/PM.

Conclusion: In HMs, cytogenetic analyses are superior to DNA analyses for determination of ploidy.

P14.081

Detection of TMPRSS2/ERG Fusion Transcript Using TaqMan Assays and the QuantStudio 3D Digital PCR System

A. Rödel^{1,2}, M. Laig³, A. Schmitz¹;

¹Bayer Pharma AG, Berlin, Germany, ²Beuth University of Applied Sciences, Berlin, Germany, ³Thermo Fisher Scientific, South San Francisco, CA, United States.

Current biomedical research aims at personalized cancer therapeutics, for example in prostate cancer. Due to the high prevalence of the TMPRSS2:ERG fusion which occurs in more than 50% of cases, it seems to be a suitable biomarker for monitoring prostate cancer which can be detected in less invasive sample material such as blood and urine. Use of digital PCR is currently being demonstrated to be a highly sensitive method for reproducible and robust measurements without the use of standard curves. Especially the QuantStudio 3D Digital PCR System from Applied Biosystems has a high point-of-care potential due to the closed, compact and easy to handle system. Aim of this project was to establish a system for the detection of TMPRSS2:ERG fusion on this Digital PCR platform, which can be deployed as a future-oriented method. A TaqMan Fusion and a Gene Expression Assay were used to detect mutant and wildtype alleles, and their performance was optimized by changing the temperature-time profile. RNA isolated from fusion positive VCaP and fusion negative LNCaP cell lines were used as reference material. In wet-lab experiments it was possible to detect TMPRSS2:ERG transcripts with a detection limit of 0.05% fusion portion in a correspondingly high wildtype background. Spike-in experiments allowed the confirmation of an easy workflow. This is a first step forward to apply the assay to prostate cancer samples for monitoring disease and to further validate the significance of the TMPRSS2:ERG fusion as a suitable biomarker. For Research Use Only. Not for use in diagnostic procedures.

P14.082

Achieving an equitable cross border referral service for genetic testing; findings from a quality & patient care perspective

C. Brady, E. Ryan, S. A. Lynch, A. Butler, D. Barton;

Department of Clinical Genetics, Our Lady's Children's Hospital, Dublin, Ireland.

Introduction: Our Department is pursuing accreditation under ISO 15189:2012. Clause 4.5 states 'the referring laboratory shall be responsible for ensuring that examination results of the referral laboratory are provided to the person making the request'. Approximately 50% of our samples are referred externally for testing. We request a copy of the report with the sample, which we don't always receive. We have been unable to proactively monitor the return of external reports. A risk assessment was performed to identify clinical risks.

Materials and methods: Database query written to identify outstanding reports January 2012-July 2015. List of cases emailed to external laboratories. **Results:** 1084 reports identified as outstanding; 863 reports had been reported to clinician no copy to us; 120 analyses ongoing. No notification when reporting targets exceeded. Errors in external laboratory led to failure to report in 3 cases & 36 cases were highlighted as potential errors requiring further investigation.

Conclusions: Audit demonstrated inadequacies in our current system and deficiencies in cross border referral service for genetic testing. Improvements made to our systems to monitor the receipt of outstanding reports & improve patient care. Many laboratories have no system in place for follow of external reports. Directive 2011/24/EU on the application of patients' rights in cross-border healthcare emphasises the potential for European Reference Networks (ERNs) "to facilitate improvements in diagnosis". Our data suggest that ERNs will need to tackle the issue of diverse laboratory practices to ensure patient safety, quality & compliance with cross border referral service for genetic testing.

P14.083

HaloPlex Targeted Resequencing : an interesting approach for rapid molecular diagnosis of RASopathies in Tunisian Patients

N. A. Ghedira¹, L. Kraoua², A. Lagrade³, E. Kerkeni^{1,4}, R. Sakka^{1,4}, K. Ben Ameer^{4,1}, S. Sfar¹, F. Chioukh^{4,1}, S. Olschwang⁵, J. Desvignes⁵, C. Ktaifi⁶, S. Abdelhak⁶, R. Mrad², K. Monastiri^{1,1}, N. Lévy⁵, A. De Sandre-Giovannoli⁵;

¹Research Unit 01/UR/08-14, Faculty of medicine of Monastir, University of Monastir, Monastir, Tunisia, ²Genetic Department, Charles Nicolle Hospital, TunisEl Manar University, Tunis, Tunisia, ³Aix Marseille University, INSERM, GMGF UMR_S 910, Marseille, France, ⁴Department of intensive care and neonatal medicine, CHU Fattouma Bourguiba, Monastir, Tunisia, ⁵Aix Marseille University, INSERM, GMGF UMR_S 910, Marseille, France, ⁶Laboratory of biomedical genomics and oncogenetics- Pasteur Institute, Tunis, Tunisia.

Background: Noonan syndrome and related disorders are autosomal dominant traits resulting from germline mutations in genes evolving the RAS-MAPKinase signaling pathway. Thus, these traits are collectively called the RASopathies. The phenotype of RASopathies associate typical facial dysmorphism, cardiomyopathies, developmental and intellectual delay, skeletal and cutaneous abnormalities and a higher tumorigenesis risk.

Recent advances in genome sequencing have greatly facilitated the genotyping and identification of causal mutations. In this study, we report our personal experience in using Targeted Sequencing for the molecular diagnosis of a cohort of Tunisian patients.

Methods: We performed HaloPlex custom target enrichment and NGS to screen 29 genes commonly mutated in RASopathies or in other overlapping diseases in 30 cases of Tunisian patients with clinical suspect of RASopathies. All pathogenic variants were validated by Sanger Sequencing in patients and available parents.

Results: 27 pathogenic or probably pathogenic mutations were found in 70% of analyzed patients (21/30). 14 variations were already reported in literature. Molecular findings were consistent with the phenotype in the majority of cases. Only in 4 cases, identified variations lead us to review the clinical traits and the initial diagnosis of these patients.

Conclusion: The results demonstrate that this approach captures areas of interest with high specificity and uniformity and detects variants with great accuracy and sensitivity. Targeted sequencing will therefore remain the key to determinate the mutational status in RASopathies with a rapid and cost-efficient manner, and thus, can strongly improve genetic counselling and clinical management of patients.

P14.084

How reference sequences can lead you astray

F. Khawaja¹, P. Lombardi², J. A. Fairley¹, Z. Deans¹;

¹UK NEQAS for Molecular Genetics, Royal Infirmary of Edinburgh, Edinburgh, United Kingdom, ²Department of Clinical Genetics, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands.

For molecular test results to be interpreted appropriately within a clinical setting, the use of universal mutation nomenclature e.g. HGVS, and associated reference sequences is crucial.

Locus reference genomic sequences (LRGs) provide a stable genomic DNA framework for reporting mutations and are independent of any changes in transcript numbering, therefore enable accurate location of sequence variants.

The UK NEQAS for Molecular Genetics 2015 external quality assessment (EQA) schemes demonstrate the clinical impact of misinterpreted reference sequences. Three examples from the molecular genetics/pathology schemes are discussed, where despite the provision of accurate reference information, laboratories reported genotyping errors due to inappropriate testing.

Long QT syndrome scheme participants were required to test for specific gene mutations and were provided LRGs, however, these were misinterpreted and one laboratory tested the incorrect exons for two EQA cases, resulting in critical genotyping errors being reported and the EQA patient being issued with an erroneous result.

In the familial hypercholesterolaemia scheme, one laboratory misinterpreted the LRG provided and reported a false negative result due to incomplete testing. They failed to identify a mutation as only bases 1 to 67 for exon one of the *LDLR* gene were sequenced. However, LRG_274t1 describes exon 1 as a 284 base pair (bp) transcript that includes 187bp untranslated region. Errors were seen not only in inherited diseases, but several laboratories reported incorrect exon locations for hotspot regions of *PK3CA* in the colorectal and lung cancer schemes also, highlighting the confusion experienced by a significant number of laboratories across different disciplines.

P14.085

title: SunScript™ Reverse Transcriptase: a novel high temperature RT engineered from the HIV-1 group O RT

R. Juárez¹, L. Menéndez-Arias², D. Weber³, A. Schneider³;

¹Sygnis Biotech SLU, Madrid, Spain, ²Centro de Biología Molecular Severo Ochoa (CSIC-UAM), Madrid, Spain, ³SYGNIS Bioscience GmbH & Co KG, Heidelberg, Germany.

SunScript™ is the name of a new product line based on a novel, highly thermostable reverse transcriptase, engineered from HIV-1 group O RT. It allows reaction temperatures up to 85°C and offers improved efficiency and speed of cDNA synthesis. It performs complete reverse transcription of very long mRNA molecules (at least up to 16 kb) and is the best option to transcribe difficult RNA molecules with high GC content or high degree of secondary structures. Available are RNaseH+ and RNaseH- versions of the enzyme. Here we show basic features of the stand-alone enzyme as well as performance in one-step RT-PCR and RT-qPCR (SYBR Green™) mixes.

We find that the one step reactions also allow for high temperature RT reaction steps, and outperform similar one step kits on the market in terms of sensitivity and temperature range.

Leveraging network analytics to infer patient syndrome and identify causal mutations using patient DNA sequence and phenotype data

S. Shah¹, A. Krämer¹, K. Boycott², J. Devaney³, G. Eley⁴, R. Felciano¹, S. E. Hofferr³, A. Joecker¹, K. Kernohan², B. W. Meltzer⁵, A. Muthiah¹, K. Patel¹, M. B. Seprish³, B. Solomon¹, J. G. Vockley⁴, D. Richards¹;

¹QIAGEN, Redwood City, CA, United States, ²Children's Hospital of Eastern Ontario (CHEO), Ottawa, ON, Canada, ³Children's National Medical Center, Washington, DC, United States, ⁴Inova Translational Medicine Institute, Falls Church, VA, United States.

A current challenge for identifying genetic variants underlying rare inherited diseases from next generation sequencing data lies in picking out the true disease causing mutation from the list of hundreds and sometimes thousands of deleterious variants. Ingenuity Variant Analysis is a cloud-based application that provides a suite of algorithms and tools to extract valuable insights from such large amount of genetic variation data by leveraging the large-scale causal network derived from the Ingenuity Knowledge Base. The Knowledge Base is a large structured collection of observations in various experimental contexts with over 11 million findings manually curated from the biomedical literature or integrated from third-party databases. Curated findings include mutations, biological interactions, and functional annotations created from individually modeled relationships between proteins, genes, complexes, drugs, and diseases, along with contextual details such as site and type of mutation, cell and/or tissue specific gene expression, mole-

cular interaction, post-translational modifications, details of the experimental design and methods used, and more. To further improve the platform and improve causal variant detection, we also designed preset filter cascades, implementing best practices for rare Mendelian disease genetic data analysis. To assess case solve rate, we analyzed sequence data from 80 patients, afflicted with severe congenital abnormalities, for which the causal variant was previously known. For each sample, we applied the predefined filters, along with the observed clinical signs and symptoms in the patient. By leveraging analytical tools and the Ingenuity Knowledge Base, we achieved over 30x enrichment in the biologically relevant variants.

P14.087

Expanding the spectrum of SHOX mutations in Idiopathic Short Stature patients through a custom array CGH.

D. Babu¹, I. Fusco¹, A. Fanelli¹, R. Muniswamy¹, A. Kozel¹, S. Mellone¹, S. Vannelli², M. Giordano¹;

¹University of Eastern Piedmont, Novara, Italy, ²Ospedale Regina Margherita, Turin, Italy.

Mutations and deletions within the pseudo-autosomal Short Stature Homeobox gene (SHOX, Xp22.33/ Yp11.3) and its enhancer are reported in 2-15% of children diagnosed as Idiopathic Short Stature. Currently molecular diagnosis for SHOX deficiency is carried out by sequencing the coding regions of SHOX and targeted copy number detection assays for the identification of deletions/duplications.

In this study, we screened about 350 ISS patients through sequencing and Multiplex Ligation-dependent Probe Amplification (MLPA) assay. Thirty patients (8.5%) were identified with mutations involving SHOX or its enhancers. In order to see whether there were some patients with alterations not detected through these standard procedures we designed a CGH array (Agilent 8x60K) with a coverage of 8000 probes within the PAR1 region (compared to the 26 probes of MLPA) and additional widely spaced backbone probes.

Nineteen ISS patients tested negative with standard methods were analysed with the custom aCGH. Three patients were identified with deletions or duplications in the SHOX area that are likely contribute to ISS. Two deletions of 12.3 kb and 7kb downstream of SHOX, and an amplification including an intron-exon boundary within SHOX were identified. These variations were not reported in the general population. A specifically designed PCR screening on 150 patients identified other 2 patients carrying the 12.3kb deletion. This deletion was not present in 300 controls analysed. This study reveals the importance of custom-designed aCGH in the molecular analysis of ISS that allowed to detect alterations in a further 15% of patients that would have remained undetected.

P14.088

Stable and predictable TATs: usage of single molecule tags, double tiling, and duplicate smMIP - sequencing

K. Neveling¹, B. van Lier¹, S. Bertens², R. Derks¹, E. Bosgoed¹, A. Rikken¹, M. Tychon¹, A. Mensenkamp¹, D. Zafeiropoulou¹, S. Castelein¹, A. Eijkelenboom³, A. Hoischen¹, M. Nelen¹;

¹Department of Human Genetics, Radboud University Medical Centre, Nijmegen, Netherlands, ²Department of Mechanical Engineering, Eindhoven University of Technology, Eindhoven, Netherlands, ³Department of Pathology, Radboud University Medical Centre, Nijmegen, Netherlands.

Background: Molecular Inversion Probes (MIPs) can be used for enrichment preceding sequencing, and have been shown to result in high quality sequencing data. Usage of single molecule (sm) tags improves data quality, by removal of duplicate reads constructing consensus sequences free of experimental artifacts.

Methods: We have created a fully automated workflow to perform smMIP-based enrichment. Sequencing is performed using a NextSeq500 (Illumina). Pre- and post-PCR Hamilton robots are trained to perform pre- and post-hybridization pipetting. Automated file handling, data transfer and SeqNext analysis (JSI) delivers high quality sequencing data. Both single genes smMIP setup and gene panel strategies were tested in the optimized workflow. The small insert size of smMIPs allows usage of FFPE-derived DNA.

Results: We managed to implement one single protocol for both gDNA and FFPE-derived DNA. By advanced automation, time from DNA isolation to interpretable data is only 4,5 days. Sequencing twice a week is sufficient to handle several hundred samples per week, and sequencing more often only reduces TAT when weekend shifts are included. Single molecules, double tiling and duplicate sequencing deliver very robust data, with Sanger+ sensitivity and specificity.

Conclusions: The newly developed workflow is exceptionally stable and predictable in terms of test completeness and outcome. It is functional for gDNA as well as FFPE-derived DNA. To our knowledge this is the first time that

FFPE DNA can be handled using identical automated enrichment protocols. Based on these results, additional panels are currently implemented. Also CNV analysis based on smMIP data is likely feasible.

P14.089

Minor Variant Finder: a new software for detecting somatic mutations at low level in Sanger sequencing traces

E. Schreiber, H. Leong, S. Berosik, J. Marks, S. Schneider, W. George, H. Sangha, A. Gerstner;

Thermo Fisher Scientific, South San Francisco, CA, United States.

We have developed software that detects and reports 5% minor variants in Sanger Sequencing traces at 95.3% sensitivity and 99.83% specificity. The software calls variants without prior knowledge of location and affords the advantages of Sanger sequencing, of robustness, low error rate, ease of use, human interpretable visual displays of the data, and low cost per sample and target. The software can confirm somatic variants found by NGS. Noise minimization and peak detection algorithms subtract the baseline noise in a control sample from a test sample, detect candidate minor variants, and confirm them in the complementary strand. To test the new algorithms, synthetic mixtures of minor alleles were prepared by combining DNAs containing mutations in known ratios. 25 different amplicons and nine different genes, including TP53, KRAS, BRAF, EGFR, FLT3, RB1, CDH1, ERBB2, and XYLT1 from cell line and FFPE DNA were sequenced on 3500, 3730, and 3130 Applied Biosystems Genetic Analyzers. 632,452 base positions and 2334 total variant positions, spanning variants at 2.5% to 50% were interrogated. The software achieved 95.3% sensitivity and 99.83% specificity for automated detection of 885 variants present at the 5% level in 238,179 high quality base positions. Sensitivity was 98.8% for variants between 7.5-10%, 98.7% for variants between 12.5-25%, and 100% for variants \geq 25%. The software displays a noise-minimized trace view to facilitate visual inspection to confirm candidate variants. Further, reference sequences with hg19 chromosomal locations and NGS vcf files can be imported and aligned with the Sanger sequencing data for orthogonal verification.

P14.090

Low-frequency and rare variants in type 2 diabetes mellitus by exome-sequencing

I. Galan-Chilet, D. Pérez-Gil, V. Martínez-Barquero, P. Cristina, P. Marín-García, A. García-García, F. Chaves;

Biomedical Research Institute Hospital Clinic of Valencia- INCLIVA, Valencia, Spain.

Introduction: Type 2 diabetes mellitus (T2DM) is the result from the interaction of environmental, genetic and acquired factors. Low-frequency and rare variants could explain an important fraction of the estimated genetic component of the disease which could be found in the exome. This study has the aim to identify genetic variants in the exome in relation to T2DM in Spanish population.

Materials and Methods: Exome sequencing in 200 patients with T2DM and 200 Spanish healthy controls; all subjects had a BMI between 25-34.9 kg/m² and were 40 to 65 years old. Exome regions were captured and sequenced by NGS using Illumina systems. A bioinformatic analysis pipeline was used to perform quality controls, to align the reads to a reference genome and identify genetic variants.

Results: It was identified 21,822 SNPs in controls and 17,238 in cases with functional effect, present only in controls or cases that meet quality criteria. In particular, 160 and 132 SNPs were splicing variants, 1,817 and 1,614 SNPs were missense variants and 102 SNPs and 50 SNPs were stop variants in controls and cases, respectively.

Conclusions: We have identified a large number of genetic variants which may be involved in the development of T2DM or in the protection from it. In order to establish the true genetic variants involved in the disease we will need to validate them by different strategies, replication in a large sample of controls and diabetics as well as carrying out functional studies

Multiplex PCR and NGS in detection mutations of target genes associated with hearing loss

V. Mikstiene¹, I. Veibraite², G. Alzbutas², T. Rancelis¹, A. Utkus¹, V. Popendikyte²;

¹Department of Human and Medical Genetics, Faculty of Medicine, Vilnius University, Vilnius, Lithuania, ²Thermo Fisher Scientific Baltics, UAB, Vilnius, Lithuania.

Background. The aim of our project was to prepare a versatile pipeline for DNA library preparation suitable for multigene testing. Eleven genes set associated with the sensorineural hearing loss (SLC26A4, MYO15A, OTOF,

CDH23, Tmprss3, TMC1,TECTA, TRIOBP, TMIE, DFNB59, GJB6) was chosen to assess the clinical utility and feasibility of our method in routine genetic testing.

Methods: We employed multiplex PCR and enzymatic fragmentation of amplicons based preparation of DNA libraries followed by the NGS. Forty eight DNA samples of study participants affected with hearing loss were used to test the pipeline.

Results: 48 DNA libraries of coding sequences of the 11 genes implicated in development of hereditary hearing loss were constructed. Thermo Scientific Phusion U Multiplex PCR Master Mix was used to amplify 63 amplicons in one tube. 126 primers were combined into a single reaction for highly specific and efficient DNA samples multiplexing. Sequences of 126 amplicons with a length range from 300 bp up to 5 kb were prepared, fragmentation was performed and NGS data were generated.

We identified five previously published pathogenic SLC26A4 gene point mutations and eight novel missense/splicing variants of SLC26A4, CDH23, MYO15A, TRIOBP genes in our study group, and classified four of them as likely pathogenic.

Conclusions: The results of our analysis make this approach promising for wide-scale application. Our pipeline is adjustable for the development of the custom gene panels for targeted gene sequencing applications.

P14.092

Coverage profile variability, and gene prioritization inferred from comprehensive statistical analysis of targeted NGS diagnostic panels data

I. Roca¹, S. Gouveia¹, J. Maynou², M. Couce¹, L. Palacios², A. Fernández-Marmiesse¹,
¹Unit of Diagnosis and Treatment of Congenital Metabolic Diseases. Department of Pediatrics. Hospital Clínico Universitario de Santiago, Santiago de Compostela, Spain,
²Progenika Biopharma, a Grifols company, Derio, Spain, Santiago de Compostela, Spain.

Introduction: Sufficient base-pair coverage is the foremost requirement for the reliable detection of genomic variants using Next Generation Sequencing (NGS) technology, being the uniformity of coverage profiles essential for applications such as copy-number variants (CNVs) detection. Due to the imperfect performance of whole exome captures (WES), genetic laboratories have developed custom gene panels to increase coverage of relevant disease genes.

Material and methods: This work comprised the data from 90, 80 and 100 DNA samples analyzed with targeted-NGS panels (in-solution hybridization method and subsequent sequencing in Miseq platform) for mitochondrial diseases, epilepsy and myopathy respectively.

Results: We present a comprehensive coverage and variant pattern analysis from data generated through the routine clinical use of such NGS panels. It shows the influence of GC content, DNA integrity, enrichment kit design, sample processing and mean sample coverage in the coverage profile uniformity and stands for the best conditions to perform a more effective CNV analysis. It also depicts the development of a gene specific score which informs about its specific conservation along evolution and mutational rate, and the subsequent implications on the pathogenicity prioritization of novel mutations found. The higher efficiency of panels with respect to WES and the importance of developing a powerful population variant database are also shown.

Conclusions: Detailed knowledge of coverage and variant pattern can be used to achieve a more efficient evaluation of future patient's dataset in order to 1) develop effective algorithms for detection of CNVs and 2) to assess the possible pathogenicity of new variants detected.

P14.093

Telomeric sequences in cell-free DNA are more abundant in plasma than in serum samples in healthy volunteers

A. Zinkova, A. Svacina, A. Horinek, E. Pazourkova, M. Korabecna;
 Institute of Biology and Medical Genetics of the First Faculty of Medicine and General University Hospital, Prague, Czech Republic.

Introduction: Telomere lengths in leucocytes and plasma samples are analysed with regard to their correlations with various pathological states. Circulating cell-free DNA (cfDNA) represents a biomarker of growing interest in numerous fields of medicine, especially in prenatal diagnosis and oncology. We studied the variations in relative telomere lengths in plasma and serum in young healthy volunteers with regard to clinical utility of both types of samples.

Materials and Methods: We performed quantitative real-time PCR (qPCR) to determine relative telomere lengths (telomere/single copy gene - T/S ratio) in plasma and serum of 26 healthy volunteers aged 20-25 years. The DNA was extracted by QIAamp Circulating Nucleic Acid Kit.

Results: We found significant differences in the relative T/S ratios between paired plasma and serum samples. These ratios were significantly higher in plasma samples (Wilcoxon test, $p < 0.0001$) than in serum samples. Each sample was rendered by relative telomere length of a control sample. The total amount of cfDNA measured using qPCR on single copy gene was significantly higher in serum in comparison with plasma ($p < 0.0001$).

Conclusions: We detected higher abundance of telomeric sequences in plasma than in serum but higher levels of total cfDNA in serum samples. Our results suggest the existence of different mechanisms involved in cfDNA release and clearance in plasma and serum.

P14.094

Transdifferentiation of human fibroblasts to osteoblast-like cells as a novel in vitro model for the study of inherited bone diseases

F. K. Cayami^{1,2}, D. Micha¹, I. E. Kooi¹, B. Zandieh Doulabi³, G. Pals¹,
¹Department of Clinical Genetics, VU medical center, Amsterdam, Netherlands, ²Center of Biomedical Science, Diponegoro University, Semarang, Indonesia, ³Department of Oral Cell Biology ACTA, University of Amsterdam and VU-University of Amsterdam, Research Institute MOVE, Amsterdam, Netherlands.

Background: Inherited bone diseases such as osteogenesis imperfecta and skeletal dysplasia are responsible for 10% of documented Mendelian disorders. The effect of genetic variants can only be studied in bone-related cells such as osteoblasts but bone biopsies are invasive. On the other hand, dermal fibroblasts are easily obtained. We hereby demonstrate a novel method to efficiently derive osteoblasts from dermal fibroblasts, which can be utilized as an in vitro model for the study of osteoblast-dependent inherited disorders.

Methods: We developed a novel transdifferentiation method to differentiate fibroblasts directly to osteoblast-like cells without undergoing the intermediate pluripotent state. After culturing fibroblasts in osteogenic medium supplemented with platelet lysate for 21 days, qPCR analysis of osteoblast-specific marker expression was performed at various time points. Alizarin red staining was done to demonstrate the mineralization capability of trans-differentiated cells. RNA sequencing was performed to characterize gene expression during the transdifferentiation process.

Results: Transdifferentiated osteoblast-like cells showed higher expression of the early osteoblast marker, Runx2 compared to fibroblasts on day 7 which decreased thereafter. The expression of other markers such as alkaline phosphatase, osteopontin and osteonectin increased after day 14. Nodule formation by alizarin red staining indicated the mineralization properties of transdifferentiated osteoblast-like cells. RNA sequencing confirmed the trajectory to osteoblasts-like cells by the expression of components in the BMP, WNT and insulin pathways.

Conclusions: Human fibroblasts can be directly transdifferentiated to osteoblast-like cells by using a novel platelet lysate-based protocol. This opens numerous possibilities for the study of unclassified variants in inherited bone disorders.

P14.095

In silico validation of small CNVs from a dense SNP array

N. Cosemans^{1,2}, N. Brison^{1,2}, P. Claes³, I. Noens^{2,4}, J. Vermeesch¹, K. Devriendt^{1,2}, H. Peeters^{1,2};

¹Center for Human Genetics, University Hospital Leuven, KU Leuven, Leuven, Belgium, ²Leuven Autism Research (LAuRes), Leuven, Belgium, ³Medical Image Computing, ESAT/PSI, Department of Electrical Engineering, KU Leuven, Medical Imaging Research Center, iMinds, Medical IT Department, UZ Leuven, Leuven, Belgium, ⁴Parenting and Special Education Research Unit, University of Leuven, Leuven, Belgium.

Introduction: Arrays based on single nucleotide polymorphisms (SNPs) have been successful for the large-scale discovery of copy number variants (CNVs). However, current CNV calling algorithms have a high false positive rate for small CNVs and experimental validation using qPCR or custom arrays is labor intensive and expensive. Therefore, this study looks at the possibilities of an *in silico* validation approach to distinguish between true and false positive CNV calls smaller than 100 kb resulting from existing CNV calling algorithms.

Materials and Methods: The study sample contains 646 individuals (159 fathers, 157 mothers and 330 children) from 159 families with non-syndromic autism spectrum disorders. All family members were genotyped using the Illumina Human Omni2.5-8v1 SNP array and CNV calls were made using CNV-WebStore. The resulting 42,464 CNVs (1-100 kb) were validated *in silico* by comparing the intensities of the underlying SNPs to the distribution of those intensities over all individuals.

Results: Almost half of the CNVs was classified as random noise based on the underlying SNP intensities. Moreover, comparing the position of parents and children in the distribution revealed false negative calls in parents resulting in *de novo* CNVs that were actually inherited.

Conclusions: The proposed *in silico* validation approach allows rapid detection of many false positive CNV calls smaller than 100 kb, which could thus be excluded from labor intensive and expensive experimental validation approaches. Ongoing research will validate included and excluded CNVs by qPCR to determine the sensitivity and specificity of the method.

P14.096

Checking the experts: compliance with author instructions regarding HGVS nomenclature and variant submission to databases in genetics and genomics journals

J. Osmani, P. Taschner;

Generade Center of Expertise Genomics, Leiden, Netherlands.

Introduction: Several genetics and genomics journals list requirements for use of HGVS nomenclature and/or submission of variants and phenotype information to public databases in their author instructions. The rationale is to improve the quality of variant descriptions in manuscripts and access to variant information in databases. We have investigated the January 2016 issue of several journals to determine how effective this is.

Materials and Methods: We used the list of genetics and genomics journals created by the Human Variome Project (HVP) (See <http://www.human-variomeproject.org/resources/genetics-and-genomics-journals.html>). A group of students has checked the publications first for the basic requirements: mentions of the reference sequence used to describe variants and the presence of the variants in public databases. The next step was to check variant and phenotype descriptions with specific attention for predicted protein effects.

Results: Authors include statements suggesting variants have been submitted to databases, but the variants were not found or phenotypic information was missing. Often, predicted protein effects in publications cannot be verified in case of altered splice sites without supporting RNA-level evidence or in case of insertions of unspecified nucleotides. Lack of supporting evidence complicates the assessment of disease-causing effects for diagnostic use.

Conclusions: In multiple cases, information missing in the publication was specified in public databases, indicating that submission of variants to databases prior to manuscript acceptance might improve the quality of publications. Reviewers and journal editors could help improving manuscript quality by enforcing the existing guidelines and insisting on compliance by authors prior to acceptance of manuscripts.

P14.097

Robustness of next generation sequencing-based preimplantation genetic screening (PGS) of chromosome aneuploidies from various cell types with a very low amount of template DNA

M. Libik, J. Chrudimska, L. Dvorakova, T. Slavik, J. Krajickova, K. Faldik, J. Drabova, H. Zunova, M. Macek jr, M. Macek sr;

University Hospital Motol, Prague, Czech Republic.

Introduction: Reliable chromosome aneuploidy detection in a single cell or from very limited amounts of template DNA is a prerequisite for preimplantation genetic screening (PGS) of chromosome aneuploidies. The aim of the study was to assess the minimum amount of DNA in terms of diagnostic robustness and time to diagnosis in next generation sequencing-based (NGS) PGS.

Materials and Methods: Single oocytes, polar bodies, blastomeres, trophoectoderm, somatic ovarian cells, cultured choriocytes / amniocytes and isolated DNA were used to assess the diagnostic reliability of whole genome amplification (WGA; SurePlex), followed by the VeriSeq NGS assays (Illumina; USA). Single sperm were examined using a modified WGA protocol (PMID: 23565289).

Results: All samples with known karyotype were accurately replicated by our diagnostic approach. Novel findings, previous undetected, were confirmed by MLPA and/or array CGH. During the course of the study we detected a broad variety of aneuploidies, one chaotic embryo and one error in second meiotic division. The ability to detect mosaicism was assessed by artificially mixing DNA derived from blood or cultured choriocytes / amniocytes with known chromosomal constitution. We are able to detect mosaicism in aberrant cells down to 40%, while lower mosaicism could be due to WGA/NGS artifacts.

Conclusions: The utilised NGS-based assay is robust and reliable for routine detection of aneuploidies in clinical PGS in DNA derived from various single cell types and is able to unambiguously detect eventual mosaicism.

P14.098

Whole Exome NGS at the Geneva Genome Clinic: Example of successful translation to diagnostics through a multidisciplinary team

E. B. Hammar¹, S. Fokstuen¹, P. Makrythanasis^{1,2}, M. Guipponi^{1,2}, E. Ranza¹, K. Varvagiannis¹, F. A. Santoni², A. Mauron³, S. A. Hurst³, C. Moret³, C. Gehrig¹, J. Bevilard¹, A. Vannier¹, S. Gimelli¹, E. Stathaki¹, A. Bottani¹, A. Paoloni-Giacobino¹, M. Lidgren¹, F. Sloan-Béna¹, L. D'Amato Sizonenko¹, T. Nouspikel¹, J. Blouin¹, S. E. Antonarakis^{1,2,4};

¹University Hospital of Geneva, Geneva, Switzerland, ²University Medical Center, Geneva, Switzerland, ³Institute of Ethics, History and Humanity iEH2, Geneva, Switzerland, ⁴Institute of Genetics and Genomics of Geneva (IGE3), Geneva, Switzerland.

The advances of next generation sequencing (NGS) technologies enable their application in clinical care. However, there are several significant challenges for their implementation in clinical diagnostics.

In Geneva, we use whole exome sequencing (WES) followed by targeted bioinformatics analysis of individual gene panels for the diagnosis of Mendelian disorders and we have created a multidisciplinary working group, the Genome Clinic Task Force which meets once a week. During these meetings, clinical cases and results are presented, the class of variant pathogenicity is debated and the final laboratory reports are critically discussed. Reimbursement and ethical issues such as informed consent, disclosure of incidental findings and/or variants of unknown clinical significance (VUS) are also addressed. In Switzerland, reimbursement of diagnostic NGS tests is integrated in the public health insurance since January 2015.

During the pilot year 2015, a total of 144 cases (41 with developmental delay (DD) and 103 with various other mendelian diseases (VDM)) were analyzed. We found pathogenic variants (class 4 or 5) in 27% of patients with DD and in 41% with VDM; the average detection rate of (likely) causative variants was 37%. The decision to report VUS was made on an individual case basis.

In order to render our diagnostic use of NGS even more efficient and patient-friendly, our current aims are to 1) improve different steps of the workflow in order to accelerate the analysis process 2) continuously update the variant interpretation methods 3) continuously learn from the challenges we encounter during the genetic counseling sessions.

P14.099

Dual genetic diagnosis as a valuable feature of whole exome sequencing

A. M. Bertoli Avella¹, O. Brandau¹, K. Kandaswamy¹, N. Nahavandi¹, D. Trujillano¹, P. Bauer¹, R. Abou Jamra², A. Rolfs^{1,3};

¹CENTOGENE GA, Rostock, Germany, ²Institute of Human Genetics, University of Leipzig Hospitals and Clinics, Leipzig, Germany, ³Albrecht-Kossel-Institute, University of Rostock, Rostock, Germany.

Introduction: When establishing a molecular diagnosis, we usually search for a single genetic variant which clarify the full phenotypic spectrum of the patient. However, many patients present with complex clinical features not allowing the clinician to make a clinical diagnosis. In these cases with unusual and blended clinical presentations whole exome sequencing (WES) is especially useful.

Results: Here we report 21 families for whom whole exome sequencing provided a clear dual genetic diagnosis. These cases presented with a broader or atypical phenotype that could not be explained by the finding of one unique variant.

In 5 of these families, the diagnoses were based on pathogenic/likely pathogenic variant for both disorders. The rest received a molecular diagnosis based on a pathogenic/likely pathogenic variant, and a second probable diagnosis based on a variant of unknown significance, with significant supportive evidence. These diagnoses are likely due to high compatibility of the gene-related disease with the clinical details and the mode of inheritance provided by the clinicians. Some relevant examples of dual diagnoses were spastic tetraplegia and intellectual disability (*SLC1A4* and *HNRNPU*) as well as Donohue syndrome and immunodeficiency type 28 (*INSR* and *IFNGR2*). Other cases included: cerebellar ataxia - deafness, distal hereditary motor neuropathy type VI - atypical Krabbe disease and primary microcephaly type 3 - Leber congenital amaurosis.

Conclusion: WES allows complete and dual diagnostic analysis and a better dissection of gene specific phenotypic characteristics positioning WES as a first line diagnostic tool.

P14.100

Clinical sequencing: WGS is the better WES

J. Meienberg¹, R. Bruggmann², K. Oexle¹, G. Matyas¹;

¹Center for Cardiovascular Genetics and Gene Diagnostics, Foundation for People with Rare Diseases, Schlieren-Zurich, Switzerland, ²Interfaculty Bioinformatics Unit and Swiss Institute of Bioinformatics, University of Berne, Berne, Switzerland.

Introduction: Current clinical next-generation sequencing makes use of gene panels and exome analysis, both of which involve selective capturing of target regions. However, capturing has limitations in sufficiently covering coding exons, especially GC-rich regions. **Materials and Methods:** We compared whole exome sequencing (WES, SureSelect Human All Exon v5+UTR) with the most recent PCR-free whole genome sequencing (WGS, Illumina TruSeq) for five female samples. We assessed the proportion of completely and sufficiently covered (>13×) RefSeq coding exons. Thereby we analyzed (i) the entire exome and subsets of clinically relevant exons, i.e. (ii) genes recommended by the American College of Medical Genetics or (iii) exons with mutations recorded in the Human Gene Mutation Database.

Results: PCR-free WGS appears to be insensitive to GC content and is thus able to provide hitherto unprecedented complete coverage of the coding region of the genome. Although the average read depth was less than half (65× in WGS vs. 154× in WES), the proportion of completely and sufficiently covered coding exons was significantly higher in PCR-free WGS for all analyzed set of exons.

Conclusions: The advantage of WGS does not only include the potential of identifying non-coding pathogenic variation but, in view of its more homogenous and complete exomic coverage, WGS is the better WES, thereby outweighing the higher costs. Thus, from a clinical/technical point of view capturing is no longer necessary for the most comprehensive genomic testing of Mendelian disorders.

Whole genome amplification effect on segmental copy-number changes and copy-number neutral loss of heterozygosity analysis by oligonucleotide-based array comparative genomic hybridization

A. Mikulasova^{1,2,3}, **J. Smetana**^{1,2,3}, **M. Wayhelova**², **H. Janyskova**¹, **R. Hajek**^{4,5}, **P. Kuglik**^{1,2,3}; ¹Department of Experimental Biology, Faculty of Science, Masaryk University, Brno, Czech Republic, ²Department of Pathological Physiology, Faculty of Medicine, Masaryk University, Brno, Czech Republic, ³Department of Medical Genetics, University Hospital Brno, Brno, Czech Republic, ⁴Faculty of Medicine, University of Ostrava, Ostrava, Czech Republic, ⁵Department of Haematology, University Hospital Ostrava, Ostrava, Czech Republic.

Introduction: Whole genome amplification (WGA) is an approach designed to overcome small amounts of DNA for genome-wide genetic tests. Various strategies of WGA have been developed; however, none of them can guarantee the absence of amplification bias.

Materials and methods: A total of 4 multiple displacement amplification (MDA)-based and 2 PCR-based WGA kits were compared in their effect on segmental copy-number (CN) changes and copy-number neutral loss of heterozygosity (cnLOH) detection by 3 microarray platforms: CGH/4×44K (Agilent), CGH+SNP/4×180K (Agilent) and CGH+SNP/4×180K (OGT). Genomic imbalances-rich cell line U266 was used as material.

Results: The main outcomes are as follows: 1) MDA-based WGAs showed higher tendency to generate false positive imbalances in contrast to PCR-based WGAs with higher risk of false negativity; 2) the specific risk of false positivity and/or negativity increased with decreasing CN segments size; 3) single-cell WGAs showed significantly worse effect on results in comparison to WGAs with nanogram level of DNA as input; 4) PCR-based WGAs were incompatible with cnLOH analysis based on SNP in restriction digestion sites and also showed higher risk of cnLOH false negativity when combined with analysis based on simple hybridization. Detailed data of each point are presented.

Conclusions: The results of this study help to choose WGA according to individual user requirements and options. Moreover, we have shown a strategy to verify and validate segmental CN changes detection by DNA array protocol including any WGA for any purpose to attain the highest efficiency without an unnecessary WGA bias. Supported by MHCZ-DRO (FNBr-65269705).

Whole-genome sequencing based strategy for diagnostics of rare inherited diseases - a collaboration between the academia and the Swedish healthcare

V. Wirta^{1,2,3};

¹Karolinska Institutet, Solna, Sweden, ²Science for Life Laboratory, Stockholm, Sweden, ³KTH Royal Institute of Technology, Stockholm, Sweden.

Clinical Genomics at Science for Life Laboratory is a research infrastructure providing access to clinical-grade (ISO 17025) sequencing services. Our vision is to support precision medicine initiatives in the Swedish healthcare by providing a cutting edge infrastructure for clinical-grade NGS work, and through multi-year collaborative projects to prospectively demonstrate the utility of NGS-based tests. The infrastructure includes automated strategies for preparation of samples for sequencing on HiSeq X, HiSeq 2500 or MiSeq

systems. Data analysis is carried out using primarily in-house developed software solutions.

Focus has been on establishing diagnostic strategies for rare inherited diseases. Briefly, exome or whole-genome sequencing is followed by identification and annotation of variants, followed by ranking based on expected pathogenicity. Variants associated with a pre-defined list of genes relevant for the specific disorder are reported.

During the last 24 months we have processed >1100 samples (700 cases) with suspected inborn errors of metabolism, skeletal dysplasia, primary immunodeficiency, unknown syndromes, and neuromuscular disorders. During the last six months a transition to whole-genome sequencing has been carried out and currently 40 to 100 samples are analysed monthly. The median turnaround time was 15 days in 2015. The impact has been dramatic with life-changing therapies initiated and several novel disease genes being identified. This collaboration has allowed clinical labs both with and without in-depth NGS and bioinformatic knowhow to implement WGS-based testing in routine settings.

We present a detailed description of the setup and the successful collaboration between the academia and the healthcare system.

P14.103

Is FISH and conventional chromosome analysis essential in genomic array era?

N. V. Shilova, **I. V. Kanivets**, **Y. O. Kozlova**, **Z. G. Markova**, **E. V. Musatova**; *Federal State Budgetary Institution, Moscow, Russian Federation.*

Introduction: Whole-genome chromosomal microarray is recommended as a first-tier clinical diagnostic test in cases of intellectual disability and/or multiple congenital anomalies. In the era of genomic arrays, a role for conventional karyotyping and FISH is widely discussed.

Results: High-resolution genome-wide array analysis using Affymetrix Cytoscan™ HD array platform was applied in 28 probands with abnormal phenotype. In each case genome imbalance was detected. FISH for every microarray results was performed not to confirm rather a visualization of the abnormal chromosomes. Double segmental imbalances was detected in 17 cases (61%) and in 15 of them a typical microarray pattern for an unbalanced translocation was shown. Parental carriers of reciprocal translocations were estimated by targeted FISH or conventional karyotyping. In two cases a gain and loss were located on the same chromosome and non-recurrent inv dup del (10q) and (5p) have been identified by targeted FISH and mBAND. Single segmental imbalances (or loss either gain) was detected in 11 cases (39%) and confirmed by targeted FISH in 9 cases. In one case a 8,7-Mb loss in 15q11.2q13.3 was revealed to be unbalanced translocation due to adjacent-2 malsegregation of paternal translocation (13;15)(q11.1;q13.3). In case, although microarray testing revealed a loss of entire chromosome, FISH combined with chromosome analysis diagnosed mosaicism 45,X/46,X,psu idic(X)(p11.2)/46,X,r(X)(p11.2q13).

Conclusions: FISH evaluation revealed more complex rearrangements than suspected based on the array results. The value of genome imbalance structure by FISH and conventional karyotyping is essential for identifying the type and origin of chromosomal rearrangement, providing accurate genetic counseling.

P14.104

Standardizing the quality control of any DNA isolation to safeguard the success of genetic testing

T. Martens, **T. Boonefaes**, **E. De Raeymaecker**, **T. Montoye**; *Trinean NV, Gentbrugge, Belgium.*

Genetic tests become ever more powerful, yet also more complex and costly, which is why it is prudent to include quality control steps throughout the preparation process to ensure the quality of the downstream data obtained. To make an informed go/no go decision and avoid analytical failures, a good assessment of the yield and purity of DNA/RNA isolations is essential, including the detection of carry-over constituents that may interfere with downstream tests. Here, we validate a novel approach for DNA quality assessment using a large DNA sample set derived from a variety of human tissues combined with a wide scale of extraction methods. This new QC tool employs the micro-volume spectroscopy on the Xpose™ 'Touch & Go' reader by Trinean combined with its spectral content profiling software to specifically quantify the isolated DNA as well as the amount of contaminating constituents in the sample contributing to the measured UV/Vis spectra.

Polymorphism of immune response genes in children with infectious complications during antileukemic therapy

M. Avdonina¹, I. Abramov¹, A. Ikonnikova¹, Y. Ammour², T. Nasedkina¹; ¹Engelhardt Institute of Molecular Biology, Russian Academy of Sciences, Moscow, Russian Federation, ²Federal Research Clinical Center of Pediatric Hematology, Oncology and Immunology named after Dmitrii Rogachev, Moscow, Russian Federation.

Introduction: Intensive polychemotherapy during treatment of acute leukemia is associated with pronounced immunosuppression, which is a risk factor for serious infectious complications that significantly worsen the prognosis and clinical outcome. Genetic variability of immune response genes may contribute significantly to the development of different infectious diseases and sepsis.

Materials and Methods: To search genetic markers defining susceptibility to infections 24 children with acute leukemia who had heavy infectious complications in the course of therapy were selected. Patient's DNA samples were prepared using Roche NimbleGen Sequence Capture of 17 candidate genes NOD2, NLRP3, STAT1, STAT3, CARD9, IL10, IL17RA, IL12RB1, IL1A, TLR1, TLR2, TLR3, TLR4, PTPN22, IL7R, IL7, MYD88. Pyrosequencing was performed on a Roche 454 GS Junior benchtop high-throughput sequencing platform.

Results: The analysis of next-generation sequencing data revealed 39 non-synonymous SNPs leading to amino acid substitutions, including informative genetic markers in the following genes: PTPN22 c.1858C>T (rs2476601), TLR1 c.1805G>T (rs5743618) and c.743A>G (rs4833095), TLR3 c.1234C>T (rs3775291), TLR4 c.896 A>G (rs4986790) and c.1196 C>T (rs4986791), IL7R c.197 T>C (rs1494555) and c.412G>A (rs1494558). Sanger sequencing was used to validate the results of next-generation sequencing.

Conclusions: Identification of genetic markers defining susceptibility to infectious diseases will allow estimating individual genetic risk to acquire heavy infections during treatment of acute leukemia in children in order to develop new approaches to accompanying therapy. The work is supported by Federal Target Program of Ministry of Education and Science of Russia (grant №14.604.21.0117, RFMEF160414X0117).

Genome-wide association study on treatment response to anti-VEGF therapy for age-related macular degeneration

L. Lorés-Motta¹, M. Riaz², M. Grunin³, J. Corominas⁴, F. van Asten¹, M. Pauper⁴, I. M. Heid⁵, E. K. de Jong¹, C. B. Hoyng¹, R. H. Guymer⁶, P. Mitchell⁶, S. Fauser⁷, A. I. den Hollander^{1,4}, P. Baird², I. Chowers²;

¹Department of Ophthalmology, Radboud university medical center, Nijmegen, Netherlands, ²Centre for Eye Research Australia, Royal Victorian Eye and Ear Hospital, Ophthalmology, Department of Surgery, University of Melbourne, Melbourne, Australia, ³Department of Ophthalmology, Hadassah Hebrew University Medical Center, Jerusalem, Israel, ⁴Department of Human Genetics, Radboud university medical center, Nijmegen, Netherlands, ⁵Department of Genetic Epidemiology, University of Regensburg, Regensburg, Germany, ⁶Centre for Vision Research, Department of Ophthalmology and Westmead Millennium Institute for Medical Research, University of Sydney, Sydney, Australia, ⁷Department of Ophthalmology, University Hospital of Cologne, Cologne, Germany.

Introduction: Age-related macular degeneration (AMD) is the most common cause of blindness in the industrialized world. Approximately 90% of the visual loss is attributed to the neovascular form of the disease (nvAMD). NvAMD can be treated with intravitreal injections of anti-VEGF agents. While this treatment revolutionized the prognosis of the disease, a remarkable variability in the response has been described. Candidate gene variant analyses have been inconsistent in explaining this variability, therefore, hypothesis-free approaches are needed in order to assess the role of genetic variation in treatment response.

Methods: Using a custom-modified HumanCoreExome array (Illumina), 678 patients of European descent recruited in five different clinics were genotyped. Response was defined as the change in best corrected visual acuity (VA) after the loading dose of three monthly ranibizumab or bevacizumab injections. An inverse normalization per sub-cohort was applied to the distribution of the phenotype to control for inter-clinic differences. After imputation and quality control steps, 6,464,434 variants with a minor allele frequency >5% were assessed for association with treatment response. Linear regression analysis was conducted adjusting for the first two principal components using EFACTS software.

Results: Suggestive peaks on chromosomes 2 and 18 were identified. The top associated variants had a $p=2.27 \times 10^{-6}$ (chromosome 2) and $p=3.83 \times 10^{-7}$

(chromosome 18), respectively. For the 34 known AMD lead variants, no variant showed significance to the 0.05/34 level.

Conclusions: We report the largest GWAS so far on response to anti-VEGF therapy for nvAMD. Replication of top variants may reveal novel genes influencing AMD treatment response.

P15.04

Paradigm of arsenic exposure in normal and triple negative breast cancer cells

O. L. Braicu, A. Jurj, L. Raduly, O. Zanoaga, L. Policiuc, R. Cojocneanu-Petric, C. Braicu, I. Berindan-Neagoe; ¹Research Center for Functional Genomics, Biomedicine and Translational Medicine, "Iuliu Hatieganu" University of Medicine and Pharmacy, Cluj-Napoca, Romania.

Introduction: Arsenic was widely used in traditional breast cancer treatment and recently the interest for therapeutic implication has increased, particularly for triple negative breast cancer (TNBC), subtype of breast cancer with the lowest survival rate. In this study were evaluated cellular and molecular effects for arsenic using in vitro models.

Material and methods: We evaluated the effect of 50 nM arsenic in normal (HMEC cells) and TNBC breast cancer cells (Hs578T cells) by multiple methods, such as MTT assay, invasion using a matrigel approach and apoptosis by fluorescence microscopy and transcriptomic profile using Agilent microarray technology.

Results: Our results showed a reduced cell proliferation and invasion, the activation of apoptosis in a dose-response and time-dependent manner, especially in Hs578T cells as response to arsenic exposure. For HMEC cells we had 1398 downregulated genes and 153 overexpressed genes, meanwhile for Hs578T cells were 1223 downregulated genes and 648 overexpressed genes based on a fold-change cut-off of ± 2 and $p\text{-value} \leq 0.05$. For Hs578T cells the main altered canonical pathways were related to kinases and cAMP-mediated pathways and for HMEC cells were related to immune response, particularly IL-17 pathway.

Conclusion: Our data reveals a complex role for arsenic, in normal cells was observed a proinflammatory effect, via IL-17 pathway, recognised as a prone factor for breast cancer-associated inflammation. Strong evidence of antitumoral activity for arsenic was observed in Hs578T, via p53 and MAPK pathways, with implication in TNBC management, as alternative or in tandem with classical chemotherapy.

This study is financed by PN-II-PT-PCCA-2013-4-0030, no.196/2014 (CANCERTER-p53).

Translarna™ (ataluren): A Novel Readthrough Drug for Treating Nonsense Mutation Genetic Disease

P. Trifillis¹, E. Welch¹, M. Weetall¹, D. Wang², K. M. Keeling³, D. M. Bedwell³, J. Rodriguez⁴, X. Luo⁵, G. Elfring¹, H. Kroger¹, P. Riebling¹, T. Ong¹, R. Spiegel¹, S. W. Peltz¹;

¹PTC Therapeutics, South Plainfield, NJ, United States, ²Horae Gene Therapy Center, University of Massachusetts Medical School, Worcester, MA, United States, ³University of Alabama at Birmingham, Birmingham, AL, United States, ⁴PTC Therapeutics, Madrid, Spain.

Translarna is a novel, orally administered small-molecule drug that enables the ribosome to read through a premature stop codon, allowing the formation of a full-length protein. It therefore has the potential to treat any nonsense mutation (nm) mediated orphan genetic disease. In nm Duchenne muscular dystrophy (DMD), Translarna increased dystrophin protein in muscle (Phase 2a trial) and slowed disease progression (Phase 2b and 3). Clinical benefit of Translarna, coupled with a strong safety profile, led to its European approval for nmDMD. In patients with nm cystic fibrosis (CF), Translarna induced functional CFTR protein (Phase 2a trials). In a Phase 3 trial, Translarna increased %-predicted forced expiratory volume compared to placebo in patients not receiving tobramycin inhalation, resulting in a 40% reduction in pulmonary exacerbation frequency. A second Phase 3 trial in nmCF is underway. Since ataluren crosses the blood-brain barrier, it can potentially treat neurologic symptoms associated with nm Mucopolysaccharidosis type I (MPS I) which are not treatable by enzyme replacement therapy. Ataluren reduced levels of glycosaminoglycans in the brain and multiple other tissues in a MPS I mouse model. Aniridia, a panocular developmental disease caused by mutations in the PAX6 gene, has no available treatment. Ataluren increased Pax6 protein in the retina and cornea and restored the iris in mice. Phase 2 trials in nmMPS I and nm aniridia are being initiated. nmCDKL5/Dravet has recently been selected as the 5th indication and selection of additional indications based on unmet medical need and other considerations is ongoing.

P15.06

A efficient and accurate end-to-end next-generation sequencing solution for identifying and interpreting disease causing variants in rare diseases

A. Joecker¹, S. Shah², B. Solomon³, J. Vockley³, G. Eley³, S. Tang², B. Oester¹, M. Hadjisavas²; ¹QIAGEN Bioinformatics, Aarhus, Denmark, ²QIAGEN Bioinformatics, Redwood City, CA, United States, ³Inova Translational Medicine Institute, Falls Church, VA, United States.

Identification of causal variants in rare and undiagnosed diseases can be both challenging and time consuming, with a lot of time invested in aligning variant calling, annotation, and interpretation workflows or investigating false positive and non-disease-associated variants. The QIAGEN Bioinformatics Hereditary Disease solution delivers increased sensitivity for identifying causal variants, while shortening the list of candidates to follow-up. This high performance is achieved with a novel, streamlined, one step, end-to-end workflow that includes Biomedical Genomics Workbench, Ingenuity Variant Analysis, and HGMD, that takes sequencing reads to biological insight. The workflow fully integrates variant calling with the QIAGEN Knowledge Base and HGMD to provide a scalable production grade environment to enable efficient and accurate causal variant discovery. To evaluate the performance of this approach we analyzed 15 TRIOs from the INOVA clinic and several exomes and whole genomes from different clinical labs for which the causal variants are already known. In all cases we are able to identify the disease-causing variant, while reducing the number of variants to investigate, by 94% to 100% using this easy one-step solution.

P15.07

Breast cancer and predictive protein biomarkers in different cell lines to personalized drug design

S. Jeibouei, H. Zali;

Shahid beheshti university of medical sciences and health services, Tehran, Iran, Islamic Republic of.

Introduction: As breast cancer accounts for about 30% of all cancers and is by far the most common type of cancer that affects women worldwide, and has heterogeneous patterns of protein expression, the resistance of cancer cells to chemotherapeutic drugs represents a major problem in treatment thereof. Analysis of proteomics data could be a new approach to targeted therapy of breast cancer. Materials and methods: In the present study we used data set containing glycoprotein expression of HER2 positive cell lines and ER positive cell lines to determine new predictive protein biomarkers related to drug resistance. Dataset of 180 glycoproteins in three HER2 positive cell lines, BT474, HCC1954, and SKBR3 in five ER positive luminal cell lines, BT474, HCC1428, MCF7, T47D, and ZR751 were selected and statistically compared. Network analysis was used to determine the important proteins based on the highest degree and betweenness centrality. Results: We found P07339, P20645, P11279 and P07602 were overexpressed in all HER2 positive cell lines. Furthermore, P05067 and P02751 had highly significant connectivity in glycoprotein network and high betweenness centrality proteins compared with others. Statistical comparison and network analysis in ER positive luminal cell lines showed that P07339, P07602, P13473 and P15586 were overexpressed and P05067 and P02751 had highly significant connectivity in glycoprotein network and the highest betweenness centrality compared with other proteins. Discussion: In addition to classical molecular index for these two breast cancer categories, we introduce new candidate predictive biomarkers to drug design and personalized medicine.

P15.08

Robust, sensitive and reliable analysis of formalin-fixed paraffin-embedded material using a single molecule molecular inversion probes-based cancer hotspot gene panel

A. Eijkelenboom, E. Kamping, A. Kastner-van Raaij, S. Hendriks-Cornelissen, R. Kuiper, A. Hoischen, M. Nelen, M. Ligtenberg, B. Tops; Radboudumc, Nijmegen, Netherlands.

Introduction: Mutation and CNV analysis of tumour DNA to predict the best treatment options calls for a sensitive technique analyzing multiple targets simultaneously with short turn-around time. To obtain sufficient coverage depth usually PCR-based enrichment strategies are used to analyze routinely obtained formalin-fixed, paraffin-embedded (FFPE) tissue, fine needle aspirates or smears. As in contrast to capture-based techniques, these strategies do not allow assessment of the amount of unique template molecules analyzed. We evaluated a single molecule Molecular Inversion Probe (smMIP)-based strategy which precludes false negative results due to unrecognized amplification of a too low amount of template molecules. Materials and Methods: A smMIP-based panel with (regions of) 26 genes that serve as predictive or differential diagnostic marker was designed and

evaluated on routine diagnostic tumour samples.

Results: The smMIP-based approach was able to detect all SNVs, small deletions and insertions (1-63 nt) and amplifications. Strand-specific amplification of both the sense and antisense strand allowed recognition of FFPE induced C>T artefacts. The merging of PCR-duplicates with identical 'single-molecule-tags' into consensus sequence reads provided true sequence coverage and eliminated the problem of PCR- and sequencing-artefacts allowing reliable mutation calling at only 3% mutant reads. The technique was robust minimizing the amount of rework and guaranteeing turn-around times of maximally 7 days.

Conclusions: smMIP-based library preparation combines the advantages of PCR- and capture-based enrichment strategies and fulfills all criteria for use in routine testing of FFPE tumours and small biopsies. It has replaced the PCR-based NGS method in our routine diagnostic workflow.

Phenotype of Fabry disease in patients with mutations amenable to migalastat

D. Hughes¹, D. G. Bichet², D. P. Germain³, R. Giugliani⁴, R. Schiffmann⁵, W. R. Wilcox⁶, J. P. Castelli⁷, E. R. Benjamin⁷, N. Skuban⁷, J. A. Barth⁷, C. Fernandez Almendros⁸; ¹University College London, London, United Kingdom, ²Hôpital du Sacré Coeur, University of Montreal, Montreal, QC, Canada, ³Hôpital Raymond Poincaré (APHP), University of Versailles–St. Quentin en Yvelines (UVSQ), Garches, France, ⁴Medical Genetics Service, Hospital de Clinicas de Porto Alegre, UFRGS, Porto Alegre, Brazil, ⁵Baylor Research Institute, Dallas, TX, United States, ⁶Emory University, Atlanta, GA, United States, ⁷Amicus Therapeutics, Cranbury, NJ, United States, ⁸Amicus Therapeutics, Madrid, Spain.

Introduction: Fabry disease (FD) is a lysosomal storage disorder caused by mutations in the α Gal A gene. Migalastat, a pharmacological chaperone, binds to α Gal A, increasing physical stability, lysosomal trafficking, and cellular activity. Study 011 (FACETS) enrolled 67 ERT-naïve FD patients; Study 012 (ATTRACT) enrolled 60 ERT-experienced FD patients. Based on Migalastat-Amenability assay, 50 patients from FACETS and 56 patients from ATTRACT studies had mutant forms of α Gal A amenable to migalastat. Baseline disease severity and literature-defined phenotype were assessed.

Materials and Methods: 600 FD-causing mutations were expressed in HEK 293 cells and α Gal A activity was measured in the presence/absence of 10 μ M migalastat. 268 amenable mutant forms were identified. Proportions of patients with FD-related involvement in ≥ 2 organ systems were determined and the phenotype (classic/nonclassic) of mutations assessed.

Results: In FACETS, all male patients and 88% of female patients with amenable mutations had FD manifestations in ≥ 2 organ systems, >90% of patients had elevated plasma lyso-Gb3, and, among mutations characterized in the literature, 60% of all patients had mutations associated with a classic phenotype; 87% of male patients had baseline α Gal A <3%. In ATTRACT, 81% of patients had multiorgan system disease, and 36% had mutations associated with a classic phenotype. Overall, 68% of mutations amenable to migalastat identified to date in medical literature are associated with a classic phenotype.

Conclusion: A majority of Phase 3 patients with amenable mutations had multiorgan system disease and a genotype associated with a literature-defined classic phenotype.

P15.10

IFNL3 rs4803217 polymorphism and treatment outcome in patients with chronic hepatitis C

B. Świątek-Kościełna¹, E. Kałużna¹, D. Januszkiewicz-Lewandowska^{1,2,3}, J. Rembowska¹, I. Mozer-Lisewska⁴, I. Bereszyńska⁴, J. Wysocka-Leszczynska⁴, J. Wysocki⁵, J. S. Nowak⁶; ¹Department of Molecular Pathology, Institute of Human Genetics of the Polish Academy of Sciences, Poznań, Poland, ²Department of Pediatric Oncology, Hematology and Bone Marrow Transplantation, University of Medical Sciences, Poznań, Poland, ³Department of Medical Diagnostics, Poznań, Poland, ⁴Department of Infectious Diseases, University of Medical Sciences, Poznań, Poland, ⁵Department of Preventive Medicine, University of Medical Sciences, Poznań, Poland.

Introduction: Polymorphisms near the interferon lambda 3 (IFNL3) / interleukin 28B (IL28B) gene are strongly associated with hepatitis C virus (HCV) elimination. Recently, the single nucleotide polymorphism rs4803217 within the 3' untranslated region of the IFNL3 gene has been proposed as a causal variant that affects HCV clearance by altering stability of the transcript. The aim of our prospective study was to examine the association between IFNL3 rs4803217 polymorphism and treatment outcome in chronic hepatitis C (CHC) patients.

Materials and Methods: The study included 196 CHC patients (HCV genotype 1a/1b) treated with pegylated interferon (IFN) α and ribavirin. rs4803217 genotyping was performed using high resolution melting analysis. Results

were confirmed by DNA sequencing.

Results: The rs4803217 GG, GT and TT genotypes were found in 54 (27.55%), 107 (54.59%) and 35 (17.86%) patients, respectively. One hundred thirty-seven patients completed 48-week therapy. 39.4% of them achieved sustained virological response (SVR). Relapse (end of treatment response without SVR) was observed in 39 patients (50.6%). The GG genotype was significantly associated with an increased SVR rate (GG vs GT+TT; OR=11.13, 95% CI: 4.80-25.81, $p=1.41 \times 10^{-9}$) and decreased risk of relapse (GG vs GT+TT; OR=0.18, 95% CI: 0.06-0.50, $p=0.0007$). No significant associations were found between treatment outcome (SVR, relapse) and age, gender, HCV genotype, baseline viral load as well as biochemical and histopathological parameters.

Conclusions: Based on the results obtained, it can be concluded that rs4803217 polymorphism is a useful marker for predicting SVR and virologic relapse in IFN-based therapy of chronic hepatitis C.

P15.11

Possible role of 82G/A polymorphism of RAGE gene in accelerated aging

Z. Verde¹, C. Santiago¹, P. Resano², I. Sánchez-Hernández³, J. M. Rodríguez González-Moro⁴, N. Garatachea⁵, F. Bandrés⁶, A. Lucia¹, F. Gómez-Gallego¹; ¹Universidad Europea de Madrid, Villaviciosa de Odón, Spain, ²Hospital de Guadalajara, Guadalajara, Spain, ³Hospital Carlos III, Madrid, Spain, ⁴Hospital Gregorio Marañón, Madrid, Spain, ⁵Universidad Zaragoza, Huesca, Spain, ⁶Universidad Complutense, Madrid, Spain.

Introduction: Aging is a dynamic process in which its rate and subsequent longevity of an organism are dependent upon the balance between the reactive intermediates of normal cellular metabolism and the ability of the body to reduce these by-products. Environmental, genetic, and accidental factors have influenced the human life span. Advanced glycation end products (AGEs) may play an important role in the processes of physiological aging. Ageing and smoking may also contribute to the acceleration of the formation of AGEs. The aim of the present study was to investigate any differences in the frequencies of receptor for the advanced glycation end products (RAGE) 82G/A polymorphism in subjects aged >100 years and individuals suffer from respiratory illness (accelerated aging).

Material and Methods: RAGE 82G/A (rs2070600) was analyzed in a cohort of 126 subjects aged >100 (107 women and 19 men) and 158 individuals with pulmonary disease (29 women and 107 men). Genetic marker was determined by RT-PCR. A logistic regression analysis adjusted for gender was performed.

Results: Regression analysis showed differences between (RAGE) 82G/A polymorphism frequency in both groups (OR=23.8, 95% CI=12.5-45.4). The number of women was larger among long-living subjects than in the unhealthy group.

Conclusions: Our data provide evidence that 82G/A polymorphism appears to confer sensitivity to respiratory illness and are in accordance with the fact that the SNP 82G/A is associated with lower levels of circulating RAGE than 82G/G genotype. The differences in the genetic regulation of inflammatory processes may influence the presence of aging disorders.

P15.12

An ITPA variant as a pharmacogenetic marker of thiopurines toxicity in Crohn's disease patients

J. Salazar^{1,2}, A. Altes³, M. Martínez¹, E. del Río¹, J. Gordillo¹, J. Llaó¹, M. Serès¹, M. Baiget¹, E. García-Planella¹;

¹Sant Pau Hospital, Barcelona, Spain, ²CIBERER U705, Barcelona, Spain, ³Fundació Althaia, Manresa, Barcelona, Spain.

Background: Thiopurine therapy is effective in Crohn's disease (CD) treatment, although 25% of patients will suffer toxicity. Polymorphisms in genes involved in thiopurines metabolism may affect toxicity. We aim to analyse the role of TPMT and ITPA functional variants as pharmacogenetic markers of thiopurines toxicity in CD.

Methods: Patients with CD treated with thiopurines and with TPMT enzyme activity levels >5 U/ml RBCs were included. We analysed 3 variants in the TPMT gene (c.238G>C, c.460G>A and c.719A>G) and 2 in the ITPA gene (c.94C>A and IVS2+21A>C). Genotyping was performed by real-time PCR.

Results: We included 109 CD patients. One hundred and four patients (95%) were treated with thiopurines in monotherapy. The mean follow-up period was 87.4 months (range 4-264). Thirty-three patients (30.3%) developed one adverse drug effect and 11 patients (10.1%) had more than one. The most frequent adverse events were lymphopenia (n=23, 21%), hepatotoxicity (n=15, 13.7%), nausea (n=9, 8.2%) and leucopenia (n=6, 5.5%). Forty patients (36.7%) discontinued thiopurine treatment because of toxicity. We found a statistical significant association between the IVS2+21A>C ITPA

variant and toxicity (OR=3.1 [95% CI, 1.18-8.24], $p=0.022$, in a dominant model). Toxicity was more frequent in patients carrying the C allele than in patients with an A/A genotype (55.6% vs. 35.4%). In addition, patients carrying the C allele had a higher risk of treatment discontinuation than homozygous A/A patients.

Conclusions: The IVS2+21A>C ITPA variant might be a predictor marker of thiopurines toxicity in CD patients with an intermediate or high TPMT activity.

P15.13

Influence of c.-889T>G variant on promoter activity of CYP2C19 gene

M. M. Novkovic, L. B. Rakicevic, J. S. Kusic-Tisma, D. P. Radojkovic; Institute of molecular genetics and genetic engineering, Belgrade, Serbia.

Introduction: CYP2C19 is an enzyme responsible for metabolism of about 10% of all clinically used drugs. Different variants in CYP2C19 promoter region influence transcription activity of the gene. Interindividual variability in CYP2C19 activity is responsible for pharmacokinetics, drug efficiency and adverse drug effects. In this study we examine the influence of -889T>G variant on CYP2C19 promoter activity.

Materials and methods: The 1705 bp of the promoter region of the CYP2C19 gene was cloned into pGL4.1 luciferase reporter vector and transfected in HepG2 cell line. To evaluate the basal activity of wild type and -889T>G promoters, dual luciferase assays were performed. Since *in silico* analysis revealed presence of glucocorticoid response element in the target region, we analyzed influence of dexamethasone as potent glucocorticoid agonist on both promoters.

Results: The basal activity of promoter containing -889T>G variant was about 33% lower in comparison to wild type promoter ($p<0,05$). Further, we observed difference in activity between these two promoter variants in response to dexamethasone treatment. Dexamethasone increased the activity of both promoter variants, however effect on -889T>G variant promoter was less noticeable.

Conclusion: Our results indicate that -889T>G variant decreases promoter activity of CYP2C19 gene. Dexamethasone differently influence the activity of wt and -889T>G promoter variants. Since, CYP2C19 c.-889T>G variant can contribute for interindividual variability in drug response, further characterization of this variant and evidence of transcription binding sites in this region are needed.

This work was funded by Ministry of Education, Science and Technological Development of the Republic of Serbia (Grant No.173008)

P15.14

Full-length and phased CYP2D6 variant genotyping using the PacBio RSII

H. Buermans, R. Vossen, Y. Anvar, S. White, H. Guchelaar, J. den Dunnen, J. Swen, T. van der Straaten; Leiden University Medical Center, Leiden, Netherlands.

The Cytochrome P450 2D6 enzyme, encoded by CYP2D6, is among the most important enzymes involved in drug metabolism. Specific variants in the gene are associated with changes in the enzyme's amount and enzymatic activity, which determines the rate at which drugs get metabolized. Different technologies exist to determine these sequence variants, such as the Roche AmpliChip CYP450 GeneChip, Taqman qPCR or Next Generation Sequencing. However, sequence homology between several cytochrome P450 genes and pseudogene CYP2D7 impairs reliable CYP2D6 genotyping and phasing (haplotyping). The PacBio RSII sequencing platform produces a combination of long reads and high-quality consensus sequences, enabling accurate variant calling and haplotyping.

We sequenced CYP2D6 in 24 samples with 12 different, clinically relevant, haplotypes using the PacBio sequencer and obtained full-length, phased CYP2D6 sequence reads, enabling accurate variant calling and haplotyping. Unphased diplotypes, previously determined with the Roche GeneChip, were confirmed for 21 samples, including a duplication of one of the haplogroup sequences for three samples. Two samples, originally showing a single haplogroup sequence, were subsequently demonstrated to contain either a deletion or tandem duplication. In total 62 unique variants were detected across the 24 samples, as well as variants not previously been associated with the described haplotypes. To aid analysis using standard reference sequences and HGVS nomenclature, we have established a LOVD-powered CYP2D6 variant database and added all reference haplotypes and data reported here.

In conclusion, our genotyping approach produces reliable CYP2D6 genotype calls, and reveals additional information about phasing and copy-number variation.

P15.15

Pharmacogenomics of membrane transporters and metformin response in Type 2 diabetic patients

S. Semiz^{1,2}, T. Dujic², Z. Velija-Asimi³, A. Causevic²;

¹International University of Sarajevo, Sarajevo, Bosnia and Herzegovina, ²University of Sarajevo, Faculty of Pharmacy, Sarajevo, Bosnia and Herzegovina, ³University Clinical Center of Sarajevo, Clinic for Endocrinology, Sarajevo, Bosnia and Herzegovina.

Introduction: Genetic variations of several membrane transporters, including organic cation transporters 1 and 2, encoded by *SLC22A1/2* genes, are implicated in the highly variable response to metformin, a first-line drug used to treat newly diagnosed Type 2 diabetes mellitus (T2D). Additional variants of *SLC47A1/2* genes, encoding multidrug and toxin extrusion protein 1 (MATE1) and MATE2-K, have been also recently related to treatment outcomes.

Materials and Methods: Since previous studies were mostly performed in healthy subjects, here we analyzed several common variants of *SLC22A1/2* and *SLC47A1/2* genes in 92 newly diagnosed T2D patients. We also collected phenotype data including, but not limited to, levels of fasting glucose (FG), insulin (FI), HbA_{1c} and anthropometric measures, prior to and 6 and 12 months post-metformin treatment.

Results: Our data demonstrated significant association of *SLC47A1* rs2252281 SNP with higher decrease of FI levels ($p < 0.05$) and lower HOMA-IR ($p < 0.05$) upon 6-month treatment. Interestingly, we showed that *SLC47A2* rs12943590 was associated with lower decrease of FI levels ($p < 0.01$) and higher decrease of HOMA-IR ($p < 0.01$) upon 6-month treatment in T2D patients, which is in line with the *in vitro* data showing that this SNP increases transporter activity resulting in decreased drug effect.

Conclusions: Our results indicated that both MATE genotypes were associated with the markers of insulin resistance, with variant carriers of MATE1 and MATE2-K having an increased and reduced levels of these markers post-metformin treatment, respectively. Thus, these findings suggest that MATE1/2 variants could play the key role in mediating insulin resistance and optimal response to metformin.

P15.16

Assessment of EGFR mutations by digital PCR in peripheral blood of non-small cell lung cancer patients

L. Camacho¹, A. Taus^{2,1}, G. Piquer¹, A. Hernandez², R. Longarón^{2,1}, G. Martínez^{2,1}, R. Correa^{2,1}, M. Vela², C. Montagut^{2,1}, J. Albanel^{2,1}, E. Arriola^{1,3}, B. Bellosillo^{1,2};

¹IMIM (Institut Hospital del Mar d'Investigacions Mèdiques), Barcelona, Spain, ²Hospital del Mar, Barcelona, Spain, ³University of Southampton, Southampton, United Kingdom.

Background: Assessment of molecular markers in circulating-free DNA is a novel approach to improve patient selection for precision medicine. Digital PCR (dPCR) is a promising tool that may provide the required sensitivity to accurately perform EGFR mutation detection in non-small cell lung cancer (NSCLC) patients. The aim of this study was to assess the detection of EGFR mutations in plasma samples from NSCLC patients.

Methods: Fifty-eight plasma samples from 25 EGFR mutant NSCLC patients were assessed for EGFR mutations by dPCR Quantstudio 3D using validated Custom TaqMan SNP Genotyping Assays specific for each mutation and compared to standard-of-care (SOC) EGFR testing in plasma samples by BE-AMing. Paired tumour biopsies were available for 28 samples. In addition 10 negative plasma controls from breast cancer patients were also tested by dPCR.

Results: Analysis by dPCR detected EGFR mutations in 54/58 plasma samples tested. Interestingly, in 4 cases in which no mutation was detected by SOC testing, dPCR provided a positive result. A significant correlation was found between dPCR and SOC results quantitative values ($R = 0.835$, $p < 0.001$), and this high correlation was observed among all EGFR mutations tested. No EGFR mutations were observed in any of the negative plasma samples tested. Paired plasma and tumoural samples were available in 28 samples. EGFR mutations were detected in plasma in 23/28 patients by dPCR showing a sensitivity of 82.1 %.

Conclusion: Digital PCR is a sensitive technique for detecting EGFR mutations in plasma samples.

Despite significant advances in our understanding of the basis of disease, the cause underpinning most human disorders remains fully or partially unknown. Identification of molecular changes provides an opportunity to understand their role in disease, and in a clinical setting to apply that understanding to prevention, diagnosis, and treatment. The advent of genome-wide sequencing has altered how molecular changes are identified and has transformed Medicine. We have 6 years of experience in the field of Clinical Genomics gathered as Molecular Diagnostic Labs, Freestanding and Children's Hospital Genomic Medicine Clinics, and through large NIH funded research programs. Currently, we achieve a ~38% diagnostic success rate via WGS application in a population that has in general undergone significant prior MDx. This shows that WGS is in many cases superior to conventional tests. Of note we are finding cases where patients have more than a single genetic diseases. In such cases an unbiased WGS approach significantly impacts care by finding all or most variants contributing to disease. Application of WGS has identified causal variants that would not have been uncovered through application of WES. In this talk we will discuss the technological, infrastructure, and process advances that have allowed us to perform lower cost Clinical WGS at HiSeqX scale. We will also present notable clinical findings that have helped us define the boundaries of the utility of this approach. Finally we will discuss how we have refined the methods used to apply WGS to the practice of medicine over the last 6 years.

A multiplexed NGS solution to evaluate potential tumor immune response and objectively stratify tumors by histopathology from FFPE samples

A. Mongan¹, W. Tom¹, J. Zheng¹, Y. Sun¹, S. Rozenzhak¹, G. Bien¹, T. Yoshino², W. Okamoto¹, H. Nishikawa³, F. Hyland², J. Godsey¹;

¹Thermo Fisher Scientific, South San Francisco, CA, United States, ²Department of Gastroenterology and Gastrointestinal Oncology, National Cancer Center Hospital East, Chiba, Japan, ³Division of Cancer Immunology, Exploratory Oncology Research and Clinical Trial Center, National Cancer Center, Tokyo, Japan.

The emergent T cell checkpoint therapy has offered durable and potential curative results for many NSCLC and melanoma patients. Nevertheless, fewer than half of subjects in trials exhibited positive response (Sharma, 2015). These results greatly illustrate the necessity for a better understanding of tumor microenvironment, tumor-lymphocyte interactions, and biomarkers that could predict drug sensitivity. In particular, PD-L1 expression has been reported to be a promising marker of response for PD-L1 therapies (Meng, 2015). However, standard methods for assessing PD-L1 protein level via immunohistochemistry have been shown to be inefficient and highly variable (McLaughlin, 2015) depending on selected antibodies, staining techniques, and site of tumors (Meng, 2015). Furthermore, as investigators are often also interested in measurements of many immune-related markers, a gene panel approach offers a convenient solution to objectively quantify expression levels. Here we describe the identification and characterization of a research panel of approximately 300 genes designed to evaluate the expression of immune checkpoint pathway, level of tumor infiltrating lymphocytes, T cell regulation, interferon signaling, and presence of various lymphocyte subsets. Our preliminary data shows that expression of the selected genes can stratify non-small cell lung cancer FFPE samples by histopathology. Furthermore, quantitative read out of the IFN γ is clear and unambiguous for IFN γ positive and negative controls. Gene expression was measured by NGS using Ion AmpliSeq™ technology. Technical replicates were found to have >0.99 correlation among each other. Assays on this research panel* were also found to be robust with respect to low input amount (1-10 ng RNA).

P15.19

Exome sequencing of severe Incontinentia Pigmenti phenotypes identifies frequent mutations in the cobalamin pathway

F. Fusco¹, M. I. Conte¹, A. Diociauti², M. F. Branda¹, M. B. Lioi², M. El Hachem², M. V. Ursini¹;

¹Institute of Genetics and Biophysics, Naples, Italy, ²Dermatology Unit, Bambino Gesù Children's Hospital-IRCCS, Rome, Italy, ³University of Basilicata, Potenza, Italy.

Incontinentia pigmenti (IP, MIM308300, 0.7/100,000) is an X-linked dominant neuroectodermal disorder, caused by NF-kappaB-Essential-MODulator (NEMO) gene mutation. The IP is always associated with skin defects while the other neuroectodermal tissue can be variably affected. Data from BBRMI Incontinentia Pigmenti Genetic Biobank at IGB Institute (IPGB, <http://www.igb.cnr.it/ipgb>) failed to reveal genotype-phenotype correlation in our IP cohort because of a high variable phenotype: the neurological alterations (mental handicap, epilepsy etc.) in 34% of IP cases (IP-CNS), did not correlate to specific NEMO mutations. We performed exome sequencing of 3 unrelated severe IP-CNS cases carrying the same loss of function NEMO del4-10 mutation, followed by targeted sequencing of 141 candidate genes clustered in cobalamin/folate and fatty acids oxidation pathways, in a cohort of 40 cases, 20 with severe IP-CNS (mental handicap, epilepsy etc.) and 20 mild-IP (only skin defect). We found a high frequency of genetic variations in cobalamin/folate metabolism among the IP severe cases (p-value < 0.05). Common variants in MTHFR, MTRR, CUBN, ABCD4 genes known to affect homocysteine metabolism and in ACACB gene were present in different combinations in 16 IP severe (80%) and in singly in four control subjects (20%). Moreover, among the damaging variants we found a previously described mutation in CPT2 and a new MTRR mutation, each in a single IP-CNS case. This implicates cobalamin/folate gene variants as risk factor for severe IP-CNS in the presence of the common NEMO deletion. These genetic variants are relevant biomarkers for clinical validation that will lead to the development of new targeted therapies for IP.

P15.20

Analysis of common MDR1 (ABCB1) genes C1236T and C3435T polymorphisms in patients with chronic myeloid leukemia (CML) in treatment with imatinib mesylate

E. P. Silveira-Lacerda, L. C. G. Pereira, C. A. S. T. Vilanova-Costa, A. P. Barbosa, E. C. Castelli, L. P. Felicio, R. S. Tavares;
Federal University of Goias, Goias, Brazil.

The multi-drug resistance 1 (MDR1) gene encodes for a P-glycoprotein (PGP), which acts against various kinds of xenobiotics. Several single nucleotide polymorphisms (SNPs) in this gene that may influence PGP level and function have been identified. The aim of this study was to analyze the frequency and prognosis of MDR1 SNPs, C3435T and C1236T, in the patients with Chronic Myeloid Leukemia (CML) in treatment with Glivec, to determine the significance of these SNPs with the clinical pharmacokinetics of oral Imatinib front of the treatment and to compare the results with other ethnic groups. We made genotype and haplotype analyses of the MDR1 gene in 96 CML patients. Genomic DNA was extracted and was analyzed by PCR-RFLP. Of the 96 CML samples, 31 were (CC), 13 (TT) and 52 (CT) for exon 12 (1236). For the exon 26 (3435), 35 were (CC), 12 (TT) and 49 (CT). All frequencies for both polymorphisms were in Hardy-Weinberg equilibrium (p=0.229 and q=0.414). We found percentage of association between polymorphisms and their distribution in different populations, and the response to treatment both cytogenetic and molecular difference was not statistically significant (p < 0.05). We conclude that the observed allele frequency for exons 1236 were 59.4% for C and 40.6% for T and the frequencies for the exon 3435 were 62.0% for C and 38.0% for T. The relationship between the frequencies of polymorphisms of MDR1 in populations of different geographic locations, can provide tools that help in choosing a more appropriate and effective treatment of CML.

P15.21

Monitoring treatment response in EGFR mutant non-small cell lung cancer patients in peripheral blood

B. Bellosillo^{1,2}, A. Taus^{1,2}, L. Camacho², A. Hernandez¹, G. Piquer², A. Dalmases^{1,2}, G. Martinez^{1,2}, R. Correa^{1,2}, L. Pijuan¹, D. Casadevall¹, C. Montagut^{1,2}, S. Serrano¹, J. Albanell^{1,2}, E. Arriola^{2,3};

¹Hospital del Mar, Barcelona, Spain, ²IMIM (Institut Hospital del Mar d'Investigacions Mèdiques), Barcelona, Spain, ³University of Southampton, Southampton, United Kingdom.

Background: EGFR mutation assessment is essential for deciding therapy of non-small cell lung cancer (NSCLC) patients. Mutation detection in circulating cell-free tumour DNA may be an alternative to tissue analysis at diagnosis and useful for tracking tumour clonal dynamics.

Methods: 112 plasma samples from 25 EGFR-mutant NSCLC patients treated with tyrosine kinase inhibitors (TKIs) were collected at baseline and along the course of the disease. EGFR mutations were quantified by BEAMing and/or digital PCR (dPCR).

Results: Comparison of 28 paired plasma and tumoural samples showed detection of EGFR mutations in plasma in 23/28 cases (8 cases M1a/M0; 15 cases M1b) showing a concordance of 82.1%. 4/5 plasma negative cases were M1a. 7 patients were analysed at radiological response to TKIs and showed undetectable EGFR mutation (n=5), decrease in mutant load (n=1) or increase (n=1). In one out of 2 responding patients with plasma samples previous to radiological evaluation, EGFR mutation was undetectable, being an early predictor of response.

Samples from 13 patients at radiological progression showed an increase in EGFR mutant load (n=5) or re-emergence of mutations (n=8). The p.T790M mutation of resistance was detected in 5/13 samples. In 4 cases, samples obtained prior to radiological progression, EGFR mutations reappeared (n=2) or increased (n=2).

Conclusion: A high association (82.1%) in the detection of EGFR mutations was found between plasma and tumour biopsies with BEAMing and/or dPCR. These technologies allow for early prediction of response and relapse and genetic characterisation of resistant disease in EGFR mutant NSCLC patients.

P15.22

Clinical and molecular characterization of a novel INS mutation in patients with diagnosis of MODY

R. Artuso¹, B. Piccini², B. Mazzinghi², A. Provenzano⁴, L. Giunti¹, V. Palazzo⁴, S. Landini⁴, S. Toni², S. Giglio^{1,4};

¹Medical Genetics Unit, Meyer Children's University Hospital, Florence, Italy, ²Tuscan Regional Centre of Pediatric Diabetes, Meyer Children's Hospital, Florence, Italy,

³Nephrology and Dialysis Unit, Meyer Children's University Hospital, Florence, Italy,

⁴Medical Genetics Unit, Department of Clinical and Experimental Biomedical Sciences, Mario Serio, University of Florence, Florence, Italy.

Maturity onset diabetes of the young (MODY) is a monogenic form of diabetes that accounts for 2-5% of all cases, frequently misdiagnosed as type 1 or 2 diabetes (T1D or T2D), whose symptoms are often overlapping. It is characterized by clinical and genetics heterogeneity with mutations in thirteen genes. In about 50% of MODY patients are not identified causative mutations.

We report a family with 4 members firstly diagnosed with T1D, in an age included between 5-10 years. A previous genetic test identified two heterozygous silent substitutions in HNF1α gene, according to which was made an ineffective attempt to stop insulin therapy, administering repaglinid and sulphonylureas. In order to clarify the genetic background and the reasons of treatment failure, we performed a target resequencing analysis investigating a set of 102 genes implicated in glucose metabolism. Interestingly, we identified in all affected members a novel INS gene mutation (c.125T>C). Until now 51 INS mutations have been identified, associated with a broad spectrum of clinical presentations including diabetes with severe neonatal onset and mild adult onset, suggesting allelic heterogeneity and distinct mechanisms underlying of the disease.

Our mutation is located in the insulin B-chain region recognized as important for insulin binding to its receptor, thus resulting in a significant impairment of insulin clearance. Our results broaden the spectrum of INS phenotypes and highlight the importance to study rare variants using NGS, with the aim to understand the molecular aetiology of diabetes and to provide a more personalised treatment for each genetic subtype.

P15.23

Prediction of methotrexate toxicity through the analysis of the single-nucleotide polymorphisms in the methylenetetrahydrofolate reductase gene in children with acute lymphoblastic leukemia

E. M. Kałużna¹, E. Strauss^{2,3}, O. Zajac-Spychała⁴, E. Gowin⁵, B. Świątek-Kościelna¹, J. S. Nowak¹, M. Fichna¹, P. Mańkowski⁶, D. Januszkiewicz-Lewandowska^{1,4,7};

¹Institute of Human Genetics of the Polish Academy of Sciences, Department of Molecular Pathology, Poznań, Poland, ²Institute of Human Genetics Polish Academy of Sciences, Department of Functions of Nucleic Acids, Poznań, Poland, ³Poznan University of Medical Sciences, Laboratory for Basic Research and Translational Medicine, Clinic of Internal and Vascular Surgery, Poznań, Poland, ⁴Poznań University of Medical Sciences, Department of Oncology, Hematology and Bone Marrow Transplantation, Poznań, Poland, ⁵Poznań University of Medical Sciences, Family Medicine Department, Poznań, Poland, ⁶Poznań University of Medical Sciences, Department of Paediatric Surgery Traumatology and Urology, Poznań, Poland, ⁷Department of Medical Diagnostics, Poznań, Poland.

Methotrexate (MTX) is a chemotherapy drug, which is commonly used to

treat acute lymphoblastic leukemia (ALL). Elimination and toxicity of MTX can be influenced by polymorphisms in genes encoding enzymes involved in its metabolism. The crucial role in MTX metabolism plays 5,10-methylenetetrahydrofolate reductase (MTHFR), encoded by the MTHFR gene. Therefore the aim of our study was to investigate the association between occurrence of C677T (rs1801133) and A1298C (rs1801131) polymorphisms in MTHFR gene and MTX-induced toxicity during treatment of children with ALL. We also examined the impact of simultaneous occurrence of analyzed polymorphisms in MTHFR gene on toxicity and elimination of MTX. Genotyping of MTHFR polymorphisms was performed on DNA samples, isolated from PBMCs, of 47 children treated according to intensive chemotherapy for childhood ALL, ALL IC BFM 2009.

The occurrence of 677T-1298A haplotype was associated with prolonged MTX elimination and higher incidence of MTX-related toxicity. On the other hand, the occurrence of 677C-1298A haplotype had protective effect on MTX clearance and toxicity, that was not observed for 677C-1298C haplotype. In the case of coexistence of studied variants, for both 677CT/1298AC heterozygotes and 677TT/1298AA homozygotes toxicity incidents were more frequently observed.

The results obtained indicate the association between the MTHFR allele 677T and haplotype 677T-1298A and elevated risk of MTX-induced toxicity in pediatric ALL patients. Genotyping of C677T and A1298C polymorphisms of MTHFR gene may help to minimize the risk of MTX toxicities, hence it can be considered as a useful tool for individualization of the MTX-based chemotherapy.

Association of pharmacogenetic variants with efficacy and toxicity in patients with osteosarcoma

H. I. Vos¹, M. J. Coenen¹, H. Gelderblom², T. van der Straaten², E. S. J. M. de Bont³, W. T. A. van der Graaf⁴, H. W. B. Schreuder⁴, L. C. M. Kremer⁴, F. N. van Leeuwen¹, H. Guchelaar², D. M. W. M. te Loo¹;

¹Radboud university medical center, Nijmegen, Netherlands, ²Leiden University Medical Center, Leiden, Netherlands, ³University Medical Center Groningen, Groningen, Netherlands, ⁴Emma Children's Hospital/Academic Medical Center, Amsterdam, Netherlands.

Background: Pharmacogenetics can be used to optimize treatment of patients with osteosarcoma. We previously identified genetic markers predictive of treatment outcome in genes of cisplatin and doxorubicin metabolic pathways. However, the complex metabolism of drugs used in osteosarcoma treatment involves a broader range of drug metabolic enzymes and transporters. Hence, we performed large scale screening of 1,936 genetic variants in 231 genes involved in drug metabolism and transport.

Methods: Germline DNA of two osteosarcoma patient cohorts (n=139 and n=177) treated with cisplatin and doxorubicin-based chemotherapy was genotyped using the DMET-Plus array and analyzed in a meta-analysis due to baseline differences for histological response and age. Associations between genetic variants and ototoxicity (SIOP grade 1-4) and 5-year Disease Free Survival (DFS) were assessed by logistic regression and Cox proportional hazards models respectively.

Results: 689 markers and 136 patients (cohort 1), and 669 markers and 174 patients (cohort 2) passed quality control. Upon meta-analysis, 16 markers in 14 genes were significantly associated (P<0.05) with ototoxicity, including *AOX1* encoding a protein involved in reactive oxygen species homeostasis. A total of 23 markers in 17 genes were associated with DFS. The genetic variant with the lowest p-value (0.007) was located in *SLC22A14* and we confirmed the association between an *ABCC5* variant and DFS. Validation of the findings is ongoing in 200 osteosarcoma patients.

Conclusion: We identified genes previously unknown to be related to cisplatin and doxorubicin metabolism and transport. Upon validation, these markers are of potential interest for optimizing therapy for osteosarcoma patients.

P15.25

Teaching Pharmacogenetics

C. B. García, M. Gómez, M. Uriel, M. P. Ribate; SAN JORGE UNIVERSITY, Zaragoza, Spain.

Pharmacogenetics is a recent science that studies how patients' genotype influences in the results of their drug treatments. It should be desirable that all kinds of health professionals involved in drug therapies of patients could know the importance and relevance of analyzing certain genes to optimize the effectiveness of the drugs or to avoid some adverse reactions.

The Vice-dean of Pharmacy Degree at San Jorge University recognizes a relevant paper of Pharmacogenetics in the academic training. Therefore, it has

been introduced as an optative subject in the healthcare orientation plan. Lecturers of this subject are not only geneticists but pharmacology and pharmacoeconomics lecturers to review important issues of these areas that complement the genetics point of view. Different professionals, mainly pharmacists, also collaborate with seminars for the students.

Besides, innovative teaching has been selected by the lecturers. It includes a review of one topic by each student (one gene or one drug therapy) that presents to the rest of the class. They also work in groups to solve a problem with real patients (with the same drug treatment but different results of effectiveness) by using a problem-based learning method.

Results of this educational project are that there are almost no failing grades among students and teacher's surveys are excellent.

If students have to develop part of Pharmacogenetics subject, analyze results shown by their colleagues and solve a problem with real patients, they are more involved with the subject and it is a more effective way to reach a significant learning.

P15.26

Pharmacogenetics in the clinics: Design and implementation of a customized pharmacogenetics genotyping array (PharmArray®)

P. Arias, I. Dapía, J. Tenorio, G. Gordo, M. Muñoz, A. Borobia, A. Carcas, P. Lapunzina; Medical and Molecular Genetics Institute (INGEMM), Madrid, Spain.

Introduction: The increasing evidence supporting the implementation of Pharmacogenetics (PhGx) information in the clinics as well as the development of pharmacoeconomic studies showing the cost-effectiveness of a preemptive approach should foster the transition to "personalized medicine" in the following years. In 2013 our group built a customized SNP-array (PharmArray®) which allowed genotyping of 192 SNPs previously related in the literature with drug-response. Basing in our experience these years and compiling recently described PhGx associations we have recently updated the original design to a second version of the platform.

Materials and Methods: For the SNPs selection process we decided to put together an in-house multidisciplinary team in order to achieve a good coverage of relevant PhGx associations in drug metabolism and transporter genes. After assessing many alternative genotyping platforms we finally chose the TaqMan OpenArray® technology as it resulted more suitable for the clinical approach in terms of simplicity of analysis, response times and economic expenses.

Results: The array includes 180 SNPs from 11 drug metabolism genes and 9 transporter genes with a relevant effect in the pharmacokinetic profile of some of the most frequently prescribed drugs these days. We also included some other genes with reported clinical relevance related to PhGx response. Conclusions: To date the adoption of PhGx into the clinical practice has been challenging mainly due to economic reasons and certain prescribers' skepticism and discomfort. However in our experience, the implementation of this platform resulted cost-effective and provided useful information for prescribers and clinicians.

P15.27

Is pharmacogenetic-guided treatment cost-effective?

M. Verbelen¹, M. E. Weale^{2,1}, C. M. Lewis¹;

¹King's College London, London, United Kingdom, ²Genomics plc, Oxford, United Kingdom.

Introduction: Pharmacogenetics has the potential to personalize pharmaceutical treatments and many pharmacogenetic associations have been discovered to date. However, for pharmacogenetic-guided treatment to be incorporated in standard health care it needs to be cost-effective as well as clinically beneficial.

Methods: We performed a review of economic evaluations for pharmacogenetic associations listed in the FDA Table of Pharmacogenomic Biomarkers in Drug Labeling (<http://www.fda.gov/Drugs/ScienceResearch/ResearchAreas/Pharmacogenetics/ucm083378.htm>). We determined the proportion of publications that found pharmacogenetic-guided treatment to be cost-effective or dominant over the alternative strategies and we estimated the impact of free genetic testing on these conclusions.

Results: The literature search yielded 44 economic evaluations related to 10 drugs. Most of the 130 entries in the FDA table had had no economic evaluation performed. Over half of the evaluations drew conclusions in favour of pharmacogenetic testing: the pharmacogenetic-guided strategy was cost-effective in 30% and even dominant (cost-saving) over the alternative option in a further 27% of analyses. In a setting where genetic testing is free, nearly three quarters of economic evaluations would support pharmacogenetic-guided treatment with 50% considering it dominant and 23% cost-effective. Conclusions: Pharmacogenetic-guided treatment can be a cost-effective and

even cost-saving strategy. Moreover, genetic tests are even more likely to be economically worthwhile if genetic testing was freely available on all individuals, which is a realistic future prospect. However, few drugs with pharmacogenetic associations have been studied and more economic evaluations are needed to support the uptake of genetic testing in clinical practice.

P15.28

Reporting of evidence for utility of pharmacogenomics: PGx for statins as an example

T. Rieger^{1,2}, M. E. Jansen^{1,2}, W. Rodenburg², S. W. J. Janssen², M. C. Cornel¹;
¹Department of Clinical Genetics, Section Community Genetics and EMGO Institute for Health and Care Research, VU University Medical Center, Amsterdam, Netherlands,
²Centre for Health Protection, National Institute for Public Health and the Environment, Bilthoven, Netherlands.

Introduction: Advances from pharmacogenomics (PGx) have not been implemented into health care to the expected extent. Several barriers hamper this implementation, such as lack of information on test characteristics, financial hurdles and regulatory issues. One gap that will be addressed in this study is a lack of reporting on relevant outcome measures in literature to enable decision makers and clinicians to evaluate the clinical validity and clinical utility of PGx-tests.

Methods: A systematic review of current reporting in scientific literature was conducted on publications addressing PGx in the context of statins. 87 articles between 1950 and 2016 were included and information was selected on: study characteristics, reported outcome measures, and accompanying conclusions on potential clinical consequences.

Results: Most articles reported odds ratios as the preferred measure for the association between a genetic variant and drug response. Often conclusions on the implementation of a PGx-test were based on this odds ratio, without explicit mention of other measures or factors influencing the clinical validity and clinical utility, such as the number needed to test, the positive predictive value, the availability of alternative treatments, and the perceived impact of use of a test (on patient and/or public level).

Conclusion: Often authors report an odds ratio to illustrate the association between a genetic variation and outcomes, such as adverse drug responses or ineffective dosage. However, to be able to gain insight in the effect on a population and select effective tests, additional outcome measures are needed to estimate the clinical utility.

P15.29

Detection of relevant pharmacogenomic variants and CYP2D6 copy number using a highly multiplexed next generation sequencing assay

F. Hyland, M. Manivannan, S. Chen, T. Chen, M. Anderson, D. Dewolf, T. Hartshorne, G. Liu;
 Thermo Fisher, South San Francisco, CA, United States.

Cytochrome P450 enzymes metabolize about 75% of drugs, with UGT enzymes metabolizing another 15%. Variations in gene sequence or in copy number may result in an inactive, defective, unstable, low expressed, or absent enzyme, an increase in enzyme activity, or an altered affinity for substrates. Pharmacogenomic genes may predict whether an individual is a poor or rapid metabolizer, facilitating understanding of dose optimization and adverse drug reaction.

We designed a highly multiplexed pharmacogenomics (PGx) research panel to profile 137 variants and CYP2D6 copy number in a single amplification reaction using Ion Torrent sequencing. We include sample ID primers for sample discrimination and gender determination. High quality sequencing libraries were produced from as little as 10 ng of input DNA from archived buccal swab and cell lines.

We initially developed the Ion AmpliSeq pharmacogenomics research panel by sequencing 91 Coriell cell lines. Next, we sequenced hundreds of buccal swab samples from 5 different labs. We multiplexed 8 to 96 samples per chip and achieved high uniformity of sequencing depth. We compared the AmpliSeq panel genotypes to annotated genotypes of the samples, and to TaqMan OpenArray PGx assay. The study showed genotype concordance >99.8%; genotype reproducibility > 99.8%, and no-call genotype rate 98%, with a no-call rate below 2%.

This customizable research panel facilitates accurate genotyping and copy number determination of key pharmacogenomic variants.

P15.30

Correlation of PIK3CA mutations with clinicopathological features in breast cancer

B. Kubová¹, J. Šimová^{1,2}, M. Uvírová^{1,2}, J. Žmolíková^{1,2}, S. Pitronová¹, Z. Bravencová², H. Tomášková², I. Urbanovská^{1,2}, L. Kalábová¹, D. Konvalinka¹, R. Měch¹, R. Ondruššek¹, I. Žebráková¹, A. Hopenštoková¹, J. Dvořáčková^{2,4};
¹CGB laboratory Inc., Laboratory of molecular genetics and pathology, Ostrava, Czech Republic, ²Faculty of Medicine, University of Ostrava, Ostrava, Czech Republic, ³Institute of Oncology, Faculty Hospital in Ostrava, Ostrava, Czech Republic, ⁴Institute of Pathology, Faculty Hospital in Ostrava, Ostrava, Czech Republic.

Introduction: Breast cancer is the most frequently diagnosed cancer in female. Molecular aberrations in the phosphatidylinositol 3-kinase (PI3K) pathway have been documented across cancers. But their prognostic/predictive and therapeutic implications are still controversial. Materials and Methods: Molecular profiling was performed on 266 breast tumour DNA samples isolated from FFPE. PIK3CA and AKT1 mutations were determined by primer extension method. Correlations between PIK3CA mutations and clinicopathological features were estimated with the chi-squared test (95% CI). Relaps-free survival (RFS) rates, in the subgroup of HER2+ breast cancer patient treated with trastuzumab were calculated, based on the Kaplan-Meier method, and the curves were compared using the log-rank test. Results: Frequency of PIK3CA mutations were detected in 25,9 %. Mutation p.E17K in AKT1 gene was detected in 1,9 %. PIK3CA mutations were significantly associated with ER+ (p=0,0004), PR+ (p=0,004) and borderly significant with low histopathological grade (p=0,05). In the subgroup of 50 HER2+ patients treated with trastuzumab, better RFS was observed in PIK3CA wild-type patients compared with mutated tumours (p=0,0001). Conclusions: This study confirm high prevalence of PIK3CA mutations and their significant correlation with some clinicopathological characteristics. In the present study, patients with activating mutations in PIK3CA had a poorer outcome than PIK3CA wild-type cases. Currently there is no sufficient evidence to recommend routine genotyping of PIK3CA in clinical practice, however further data collection is required to draw a definitive answer. P15.31

An open source web application for polygenic trait and disease risk prediction

B. J. Vilhjalmsson^{1,2}, U. Seren³, G. Athanasiadis¹, G. Bhatia², J. Cheng¹, T. Mailund¹, A. Borglum⁴, M. Nordborg³, M. Schierup¹;
¹Bioinformatics Research Centre, Aarhus University, Aarhus, Denmark, ²TH Chan Harvard School of Public Health, Boston, MA, United States, ³Gregor Mendel Institute, Vienna, Austria, ⁴Department of Biomedicine, Aarhus University, Aarhus, Denmark.

In recent years, predicting polygenic traits and disease risk from the genotype has become common practice in both clinical and non-clinical settings. Interpreting such predictions for individual genomes is nontrivial and results are typically obtained with proprietary software that is not publicly available. In non-clinical settings, 23andme and other private companies have led the charge in providing direct-to-consumer genetic testing, resulting in more than one million individuals being genotyped to date. This explosion of genetic data motivated us to develop an easy-to-install open source platform for polygenic trait and disease risk prediction. The platform is developed with both clinical and non-clinical settings in mind. It implements three main computational steps: 1) imputation, 2) ancestry inference, and 3) genetic prediction. Through careful choice of algorithms and efficient implementation, the whole pipeline can be applied to a 23andme genotype in about one minute, ensuring an interactive user experience for all of the three steps. To demonstrate how the application can be used in practice, we provide an online implementation (<http://theonestgene.github.io>), where users can upload their 23andme genotypes and obtain polygenic predictions for height and BMI. The polygenic risk prediction is carried out using LDpred weights, which are trained on publicly available GWAS summary statistics. To estimate the accuracy of the predictions we used self-reported height and BMI from 609 Danish high school students as validation data. The prediction R2 in the sample after adjusting for age, sex, and the first ten PCs was 25% for height and 11% for BMI.

P15.32

Pharmacogenetic nexus between limb development and metabolic syndrome

M. Krupkova, M. Janků, B. Chylikova, F. Liška, L. Šedova, D. Křenova, V. Křen, O. Šeda;
 Institute of Biology and Department of Medical Genetics 1st Faculty of Medicine, Charles University, Prague, Czech Republic.

The polydactylous rat PD/Cub is an established rat model of metabolic syndrome and aberrant limb development manifesting as preaxial polydactyly.

We have previously identified a limited, 7-gene region on PD/Cub chromosome 8 affecting both conditions and isolated it on the background of spontaneously hypertensive rat in SHR.PD-(D8Rat42-D8Arb23)/Cub (SHR-Lx) congenic strain. The aim of our study was to assess the potential pharmacogenetic interaction between this PD-derived genomic region and all-trans retinoic acid (ATRA), a potent morphogen with evidence of metabolic effects.

The adult SHR and SHR-Lx male rats were administered ATRA (15 mg/kg/day) or vehicle for 16 days. The same protocol was repeated with animals undergoing administration of 1mg/kg ATRA on 13th day of embryonic development (13ED). All rats were subjected to comprehensive metabolic and morphometric profiling. In a separate experiment, effect of prenatal (13ED) ATRA administration on manifestation of polydactyly in SHR (n=118) and SHR-Lx (n=178) offspring was assessed.

We identified significant interactions of both prenatal and postnatal administration of ATRA with the differential segment in SHR-Lx congenic strain. The sensitizing effect of the Lx was apparent for prenatal ATRA, affecting adiposity, HDL and small LDL cholesterol fractions, while postnatal ATRA affected significantly VLDL cholesterol and LDL triglycerides. SHR-Lx offspring developed front-feet preaxial polydactyly in 13.5 % cases; no such effect was observed in SHR.

The interaction of ATRA with chromosome 8 differential segment in SHR-Lx strain affects both the morphogenesis of the limb and the metabolic syndrome aspects, mimicking the effects observed in human conditions. Supported by GACR 15-04871S.

P15.34 Accurate and cost-effective analysis of bi- and tri-allelic DME SNPs using target-activated rhPCR genotyping assays

D. Tsang¹, S. Hansen¹, K. Beltz², Y. Wang¹, Y. Bao¹;

¹Integrated DNA Technologies, Redwood City, CA, United States, ²Integrated DNA Technologies, Coralville, IA, United States.

Introduction: Pharmacogenetic studies require a reliable method to test samples for inherited variations in drug metabolizing enzymes (DME) and associated transporter genes. Here we report a novel, target-activated, universal probe-based rhPCR genotyping assay for amplifying and detecting specific single nucleotide polymorphisms (SNPs), multi-nucleotide polymorphisms (MNP), and insertion/deletions (InDels). This technology utilizes a Type II RNase H (RNase H2) in conjunction with a novel mutant Taq DNA polymerase to achieve highly specific allele discrimination and eliminate primer dimers. A universal reporter system was used to achieve a cost-effective genotyping solution, and enable multiple fluorophore detection of multi-allelic variants in a single reaction. This approach is particularly useful in pharmacogenetics where increasing numbers of tri-allelic SNPs are found to have pharmaceutical and clinical value.

Materials and Methods: In this study, we designed a collection of >150 assays for detecting potentially causative SNPs, MNPs, or InDels in DME genes, including tri-allelic targets. The assays were designed using an optimized assay design algorithm, ensuring high target specificity. All assays were tested with 137 Coriell DNA samples from three populations and synthetic templates representing each genotype.

Result: We successfully demonstrated >95% coverage for the desired targets (including tri-allelic SNPs), and >99% call rate and 100% accuracy were achieved for the tested samples.

Conclusion: Our target-activated rhPCR genotyping technology provides a cost-effective and highly specific genotyping solution. Multiplexing with multiple universal probes allows us to perform multi-allelic genotyping in a single reaction, thereby reducing the cost per genotype.

P15.35 e:Med - systems medicine network of Germany

S. Argo¹, J. Erdmann², K. Rippe²;

¹e:Med Management Office, c/o German Cancer Research Center, Heidelberg, Germany, ²Institute for Integrative and Experimental Genomics, Universität zu Lübeck, Lübeck, Germany, ³German Cancer Research Center (DKFZ) & BioQuant Center, Research Group Genome Organization & Function, Heidelberg, Germany.

Introduction: The e:Med (www.sys-med.de) program aims at establishing systems medicine in Germany. e:Med promotes system-oriented research on diseases in order to develop improved prevention, more comprehensive diagnostics and individually adjusted therapy schemes in personalized medicine. The program brings together scientists with molecular-genetic, clinical, mathematical and information technology expertise, with the objective to advance research results into clinical applications. **Methods:** e:Med scientists systematically examine the complex interplay of pathophysiological

processes in the human body and with external factors by high-throughput 'omics' methods. This work is supported by the development of state of the art information technologies and data management tools. By recording and analyzing systems-wide data sets quantitative models on the disease state are developed. The resulting experimental and theoretical methods are translated into clinical applications. Results from the interdisciplinary e:Med research teams will be shown that work on cancer, neural and cardiovascular diseases and infection at 34 clinics and universities, 14 large research institutions and 6 industrial companies in 33 German cities, as well as at 3 universities outside Germany. The findings should contribute to an improvement in the design of clinical studies in the medium term. **Conclusion:** The nationwide e:Med research and funding concept advances systems medicine in Germany. e:Med is funded by the Federal Ministry of Education and Research (BMBF) since 2013.

P15.36 Maintenance therapy of childhood ALL patients induces TPMT gene expression in VNTR dependent manner

N. Kotur¹, B. Zukic¹, B. Stankovic¹, K. Klaassen¹, T. Karan-Djurasevic¹, M. Ugrin¹, M. Stojiljkovic¹, N. Tosic¹, G. Nikcevic¹, G. Milosevic², J. Lazic², L. Dokmanovic², D. Janic², S. Pavlovic¹;

¹Institute of Molecular Genetics and Genetic Engineering, University of Belgrade, Belgrade, Serbia, ²University Children's Hospital, Medical Faculty, University of Belgrade, Belgrade, Serbia.

Thiopurine S-methyltransferase (TPMT) is the most important enzyme involved in metabolism of thiopurine drugs, such as 6-mercaptopurine (6-MP). Great variability of TPMT activity cannot be explained considering just coding region variations. Variation of regulatory elements, such as VNTR architecture (i.e. number and types of repeats) in promoter, as well as chemotherapy drugs are shown to influence TPMT enzyme activity. However, it is not known whether these factors influence TPMT gene expression in ALL patients.

TPMT gene expression was measured in hematopoietic tissue of 57 childhood ALL patients, both before chemotherapy and during the maintenance therapy when 6-MP and methotrexate are administered.

Our results show that maintenance therapy strongly induces TPMT expression, more than 3 times, on average. For each ALL patient, TPMT expression was higher during maintenance therapy, than before chemotherapy (p<10⁻¹⁰). An interaction of maintenance therapy with VNTR region in TPMT promoter modified TPMT gene expression. Specifically, VNTR*5a/*5a carriers were found to be the highest expressers during the therapy (p=0.045), even though they were low expressers before chemotherapy. Our results confirm negative correlation between "A" repeats number of VNTR and TPMT gene expression (rs=-0.35).

Maintenance therapy strongly induces TPMT expression. This effect is modified by architecture of VNTR region of TPMT gene. It could be of great importance to consider TPMT genetic variations at the very beginning of the maintenance therapy for childhood ALL patients, especially for carriers of less expressed VNTR alleles.

P15.37 A rapid one week exome sequencing analysis for neonatal intensive care

K. Neveling¹, S. van den Heuvel¹, D. Zafeiropoulou¹, S. Castelein¹, J. H. Schuurs-Hoeijmakers¹, W. van Rens-Buijsman¹, R. Pfundt¹, E. J. Kamsteeg¹, A. Simons¹, A. R. Mensenkamp¹, L. SnijdersBlok¹, E. K. Vanhoutte², T. J. van Essen³, K. Diderich⁴, C. Gilissen¹, W. van Zelst-Stams¹, R. Mathijse¹, M. R. Nelen¹;

¹Radboud university medical center, Nijmegen, Netherlands, ²Maastricht university medical center, Maastricht, Netherlands, ³University of Groningen, Groningen, Netherlands, ⁴Erasmus medical centrum Rotterdam, Rotterdam, Netherlands.

Introduction: Exome sequencing has been widely introduced in clinical laboratories. However, batching of samples to run high throughput sequencers efficient results in relatively long turnaround times (TATs). For specific patient groups such as new-borns in neonatal intensive care units (NICUs), these TATs need to be reduced dramatically in order to have impact on clinical decision making.

Method: Trio analysis is performed to assist interpretation and enables *de novo* mutation detection. The Sureselect QXT protocol (v5,Agilent) is used for library construction which is sequenced on a NextSeq500 (Illumina). Median coverage is 200-300x. Automated file handling allows rapid BWA mapping, GATK variant calling and annotation. The TATs are aimed at 5 to 7 days: 1½ days for DNA isolation and library construction, 29 hours of sequencing, and ±1 day each for data analysis and data interpretation.

Results: Five cases have been sequenced to date using this workflow: two having ID, two movement disorder cases, and one immune disorder case. In two causative mutations were identified. One ID case carried a disruptive frameshift mutation in the recently identified ID gene *TRIP12* whereas one movement disorder patient carried two mutations in the recessive gene *RARS2*, leading to pontocerebellar hypoplasia type 6. The residual samples remained negative. Time to report was 6 working days.

Conclusion: We demonstrate a rapid exome analysis workflow using Next-Seq500 sequencing. Turnaround times of 5-7 days are well within reach. Trio sequencing combined with high median coverage aids in rapid interpretation and successfully identified causative mutations in 2 of 5 patients.

European Genome-phenome Archive (EGA) - A secure archive for human genomic and phenotypic data

J. P. Almeida-King¹, D. Spalding¹, J. Rambla², M. Alberich², A. Senf¹, P. Arce Garcia¹, A. Carreno-Torres², J. Kandasamy¹, G. Kerry¹, O. M. Llobet², A. Lloret i Villas², M. M. Quaresma², T. Smith¹, S. de la Torre², S. Ur-Rehman¹, P. Flice¹, A. Navarro², H. Parkinson¹; ¹European Bioinformatics Institute, Cambridge, United Kingdom, ²Centre for Genomic Regulation (CRG), Barcelona, Spain.

The European Genome-phenome Archive (EGA) facilitates the secure storage and controlled distribution of genetic and phenotypic data, for the purpose of biomedical research. As of January 2016, the EGA securely stores over 3 petabytes of data derived from over 700K unique samples and spread across ~1600 distributable datasets.

Our collections include reference data for rare and common diseases, including data derived from the UK10K project, Human Induced Pluripotent Stem Cells Initiative (HipSci) and the International Cancer Genome Consortium (ICGC).

We work closely with the rare disease platform RD-Connect, facilitating the brokering of raw -omics data to RD-Connect partners, for the purpose of downstream variant processing and VCF file generation. The RD-Connect workflow takes advantage of our secure data streaming service, which has recently been updated to support on the fly file decryption-using FUSE layer technology, implemented to streamline processing pipelines.

Additionally, with over 1000 rare disease samples accessioned and stored at EGA, the new EGA REST API allows further integration of the sample metadata in EGA and the RD-Connect platform allowing full mapping and tracking of these data across the whole RD-Connect ecosystem. Continuing developments on submission processes, such as the REST API and submission portal will further enable RD-Connect and other consortia to integrate EGA into their pipelines without having to deal with security and privacy issues. The EGA is maintained by European Bioinformatics Institute (EMBL-EBI) and the Center for Genomic regulation (CRG) and is available at <http://www.ega-archive.org>.

Highly Contiguous de novo Human Genome Assembly and Long-Range Snp Typing Phasing Using SMRT Sequencing

S. Picton, J. Ekholm, M. Ashby, J. Chin, L. Hon, J. Harting, P. Peluso, D. Rank, S. Kujawa, J. Korlach; Pacific Biosciences, Menlo Park, CA, United States.

Outside of the simplest cases such as haploid bacteria, or inbreds, genomic information is not carried in a single reference per individual, but rather has higher ploidy for almost all organisms. The existence of two or more highly related sequences within an individual makes it extremely difficult to build high quality, highly contiguous genome assemblies from short DNA fragments.

We have here developed a new algorithm and software called FALCON that is a polyploidy aware assembler for de novo haplotype reconstructions from SMRT® Sequencing data. We sequenced Craig Venter's well-studied genome at 85-fold coverage using long insert libraries (>20kb) as input for single-molecule sequencing. We then used the hierarchical genome assembly process (HGAP) to generate highly accurate pre-assembled consensus reads, which were fed into an overlap consensus assembler. FALCON was applied to enable a diploid representation of the genome while maintaining the relationship between the alternative alleles in the form of associate contigs. Altogether the genome was assembled into 3004 contigs where the longest contig was 34.6Mb in size.

In order to assess the quality of the assembly we looked at how efficiently

we captured the 4 Mb MHC region on chromosome 6. This region is known to be challenging since it is highly repetitive and polymorphic. Falcon successfully identified 20 significant structural variants between the homologous chromosomes proving that it is able to reconstruct highly heterozygous sequences yielding near-complete sequence of all homologous chromosome pairs.

¹Institute of Biomedical Technologies, National Research Council, Segrate, Italy, ²Department of Physics and Astronomy, University of Bologna, Bologna, Italy, ³INGM, National Institute of Molecular Genetics "Romeo ed Enrica Invernizzi", Milan, Italy, ⁴Scientific Institute, IRCSS Eugenio Medea, Bosisio Parini (LC), Italy, ⁵Scientific Institute, IRCSS Eugenio Medea, Brindisi, Italy, ⁶Department of Chemistry and Biology, University of Salerno, Fisciano (SA), Italy.

Introduction: Molecular interaction networks are crucial for the interpretation of genome-wide data of pathologies characterized by a marked genetic heterogeneity like Autism Spectrum Disorders (ASDs). Indeed biological functions involved in a specific pathology are likely to be more conserved than individual genetic variations. We define the network regions enriched in genetic variations associated with ASDs. Compared with previous studies, we consider several reported evidences and the whole network topology to predict relevant interacting partners of ASDs genes.

Materials and Methods: Lists of genes associated with ASDs were collected from a manually curated database and genomic studies. A diffusion-based method was used to identify genes in network proximity to those from the lists. Direct and indirect protein-protein interactions were collected from five different databases. The Italian cohort (195 cases and 87 controls) was genotyped with a high-density platform.

Results: We defined genome-wide scores summarizing the proximity of each gene to the gene lists associated to ASDs. We highlighted the network regions, with corresponding biological functions, differently represented in the considered genomic studies. We found significant number of genes in network proximity to genes associated with ASDs among the genes reported in the literature as having a minimal evidence of association with ASDs and the genes containing alleles associated with ASDs in our Italian cohort.

Conclusions: We summarise the network regions densely populated by ASDs associated genes providing a network-based tool to quantify the functional relation of novel genes with those already associated with ASDs.

P16.04

Enforcement of consistent implementation of standards and guidelines for reporting of CNV and SNV events through software automation

A. Venier¹, A. O'Hara², V. Wasnikar², S. Shams²;

¹BioDiscovery, Stevenage, United Kingdom, ²BioDiscovery, Hawthorne, CA, United States.

Recommended standards and guidelines for clinical case review for copy number variations (CNVs) and single nucleotide variants (SNVs) have been published by several European, American, and individual national genetic and cytogenetic associations which include ESHG, ECA and ACMG. These guidelines provide means to classify variants into different well-defined classes (e.g. Pathogenic, Benign, etc.). Integrated into the NxClinical software system is the Variant Interpretation Assistant (VIA), which uses a decision tree machine learning approach to set up rules for automatic pre-classification of events to be reviewed and interpreted by laboratory personnel. The system allows users to embed guidelines for consistent reporting. Benign, likely benign, pathogenic and likely pathogenic regions are pre-classified based on public copy number polymorphism databases and publications, including ClinGen, OMIM, and DECIPHER, and on previous in-house case classification results. VIA tracks results in real time from previously annotated samples to allow for interpretation of newly uploaded samples. Additionally, the system allows for multiple review and edits, as needed, with extensive user-based audit trailing. A set of previously reviewed samples with a mix of benign and pathogenic classified calls were imported into the system. VIA then pre-classified the samples and the results were compared. The system was able to correctly identify pathogenic results in known affected samples while finding no pathogenic results in known normal samples. VIA is capable of quickly and reliably classifying and reporting CNV and SNV

events while adhering to the standards recommended by ESHG, ECA, ACMG and national guidelines.

Bioinformatic analysis of mRNA expression on apoptotic and autophagy genes shows changes in biological pathways involved in lung diseases

R. Al-Ali^{1,2}, J. de Las Rivas^{3,2}, R. González Sarmiento^{1,3,2};

¹University of Salamanca - Faculty of Medicine-Department of Medicine, Salamanca, Spain, ²Biomedical Research Institute of Salamanca (IBSAL), Salamanca, Spain,

³University of Salamanca-Cancer Research Center/ CSIC (CiC-IBMCC), Salamanca, Spain.

Several genes were reported to have splicing variants (isoforms) that have contradictory effects. The question that we tackle is the extent of these isoform-diseases, specifically in lung related illnesses. In order to be able to analyze the data from biological point of view, we focus on autophagy and apoptosis, two important pathways with known controversial changes in cancer and chronic obstructive disease (COPD).

We have chosen 87 RNA-Seq samples from ENA/EBI (European Nucleotide Archive), all were via Illumina technologies. The samples are from lung tumors (NSCLC), COPD lung tissue and normal lung tissue. We analyzed the samples using Tophat/Cufflinks on Galaxy platform, with quality trimmer when needed. We selected a panel of 60 genes relate to autophagy and apoptosis, and studied gene and isoform expression. Our study evaluated each gene and isoform in face of both software misinterpretation and biological significance.

We were able to track the sequence of mRNA expression and analyze the theoretical effect on the pathways they are involved in. Our results show that changes in the expression of caspases isoforms are able to turn the pathway from non-apoptotic to anti-apoptotic and vice-versa. While the main isoform change in autophagy pathway was present in mTOR. Those changes could be involved in development of cancer and COPD.

Our study shows that RNA-Seq data can be used to track a sudden change in biological pathways if treated with previous biological knowledge, and that further improvement on software analysis and data interpretation is due.

P16.06

GeVaCT - Genomic Variant Classifier Tool

D. Daneels¹, I. Grau^{2,3}, D. Sengupta², M. Bonduelle¹, D. M. Farid², D. Croes¹, A. Nowé², S. Van Dooren¹;

¹Centre for Medical Genetics, Reproduction and Genetics, Reproduction Genetics and Regenerative Medicine, Vrije Universiteit Brussel (VUB), UZ Brussel, Brussels, Belgium,

²Como - Artificial Intelligence Lab, Vrije Universiteit Brussel (VUB), Brussels, Belgium,

³Department of Computer Sciences, Universidad Central de Las Villas, Santa Clara, Cuba.

High throughput screening (HTS) techniques, like mendeliome, whole exome and genome screening, are becoming a routine in a clinical diagnostic setting. However, classifying the identified genomic variants as benign or (likely) pathogenic, is still a tedious and time consuming process for the (clinical) geneticist. To facilitate this variant classification process, we have developed GeVaCT, a standalone Java based tool that implements and automatizes a published variant classification scheme for autosomal dominant disorders. GeVaCT currently supports annotated variant files from Alamut Batch (Interactive Biosoftware), with future plans to support input from other variant annotation tools.

The variant classification process currently implemented in GeVaCT is based on a published scheme in the context of cardiac arrhythmias (Hofman et al., 2013). The implemented scheme consists of two phases: pre-processing and variant classification. During pre-processing, the annotated variant file from Alamut Batch is imported and filtered based on the presence of the variant in databases with described variants or a local database, the variant location, the coding effect and the variant allele frequency in an ethnically matched population. The variant classification workflow depends on the type of variant: either missense or nonsense/frame-shift. Each attribute used gets a weighted score that is summed up with the others to come to a first variant classification. This first score is updated based on familial and functional information obtained for the variant-of-interest. The final result is a classification of the variant in one out of five classes ranging from non-pathogenic to pathogenic.

P16.07

Application Specific Barcoding Strategies for SMRT Sequencing

R. Vogelsang;

Pacific Biosciences, Menlo Park, CA, United States.

Over the last few years, several advances were implemented in the PacBio® RS II System to maximize throughput and efficiency while reducing the cost per sample. The number of useable bases per SMRT® Cell now exceeds 1

Gb with the latest P6-C4 chemistry and 6-hour movies. The new SMRT Cell yields could be in excess relative to project needs for applications such as microbial sequencing, targeted sequencing, Iso-Seq™ full-length isoform sequencing and Nimblegen's target enrichment. To this end, barcoding is a viable option for multiplexing samples.

Here, we present specific examples on strategies and best practices for multiplexing samples for five different applications using SMRT Sequencing. For microbial samples we studied the performance of 2- to 8-plex sequencing of *H. pylori* stains using modified SMRTbell™ adapters. For full-length amplicon sequencing we used barcoded adapters to multiplex five Class I and Class II HLA genes (~3.3 - 5.8 kb) for 96 patients. For Iso-Seq full-length cDNA sequencing, RNA samples from 6 maize tissues were multiplexed to generate barcoded cDNA libraries. The NimbleGen SeqCap Target Enrichment method, combined with PacBio's long-read sequencing, provides comprehensive view of multi-kilobase contiguous regions, capturing both exonic and intronic regions. Here we successfully multiplexed 12 samples using the NimbleGen Neurology panel.

The workflow system based on Hadoop for bio-big data analysis

P. Kim, G. Ko, J. Yoon, B. Lee, R. Kim;

Korean Bioinformation Center, KRIBB, Daejeon, Korea, Republic of.

Because of the exponential growth of biological data since the introduction of next generation sequencing technology, the analysis of massive bio data became a more complicated and difficult problem. To find out meaningful information from these massive data, researchers need IT skills to compose and run complicated bioinformatics analysis processes which are constituted many open-source programs. IT infra such as computing servers, network devices, and storages is also essential to run analysis pipelines for massive data. To address this problem, we developed BioExpress which provides cloud service for massive bio data. BioExpress consist of two systems: OpenBio and CLOSHA. OpenBio is hybrid cluster system which can run Hadoop and Linux programs. It is based on HDFS which can run not only Hadoop programs but also Linux programs applying the disk caching technique which transfers a file in HDFS into general Linux file system in each request. This system is economic than general cluster system with shared storage because it is based on HDFS which is cheaper than shared storage. BioExpress also supports parallel processing feature using MapReduce in Hadoop. CLOSHA is an automatic workflow-modeling system that enables researchers to represent the process of bio-data analysis as a workflow which is composed of a sequence of analysis tools by connecting the output of preceding tool and the input of following tool in sequence, with same formats. Users can easily analysis the complicated and massive bio-data through CLOSHA.

P16.09

Combining multiple strategies for prioritizing variants using exome sequencing data in familial Meniere's disease and autosomal diseases

T. Requena¹, A. Gallego-Martinez¹, L. Frejo¹, C. Martin-Sierra¹, J. A. Lopez-Escamez^{1,2};

¹Otology & Neurotology Group CTS495, Department of Genomic Medicine, GENYO - Centre for Genomics and Oncological Research - Pfizer/University of Granada/ Junta de Andalucía, PTS, Granada, Spain, ²Department of Otolaryngology, Complejo Hospitalario Universidad de Granada (CHUGRA), Granada, Spain.

Introduction: The identification of disease-causing variants in autosomal dominant (AD) diseases using exome-sequencing data remains a difficult task in small pedigrees. We describe a combined strategy using multiple variants prioritization tools, and phenotype ontology for identifying disease-causing variants in AD diseases tested in a) familial Meniere's disease (FMD), b) AD sensorineural hearing loss (AD-SNHL) and c) central nuclear myopathy (CNM).

Materials and Methods: Three methods (Pathogenic Variant -PAVAR score, Variant Annotation Analysis and Search Tool -VAAST + Phevor and Exomiser-v2) were compared in FMD exome-sequencing datasets. The effectiveness to filter and prioritize causal variants in small pedigrees was validated in silico using variants described in HGMD for AD-SNHL and CNM.

Results: The combination of prioritizing methods in exome datasets from small pedigrees in FMD can filter the variants to a reduced number of candidates (4.6 ± 2.1, ranked in the top 20 by each method). Benchmarking analyses of the AD-SNHL and CNM show that Exomiser-v2 and VAAST+Phevor tools ranked variants of HGMD in the top 20 in more than 90% of the simulations, illustrating that only deleterious variants with a possible phenotype association remained. Selecting and combining the top 20 ranked variants by the three methods yielded a high predictive performance (AUC=0.823).

Conclusions: Our results demonstrate that the combination of multiple vari-

ant-prioritization algorithms provides an effective method to filter and rank heterozygous variants in AD diseases despite the observed genetic heterogeneity in AD diseases.

Raising awareness of clinical bioinformatics - can we MOOC a difference?

A. C. Davies, F. Hooley, K. O'Malley, A. Brass;

The University of Manchester, Manchester, United Kingdom.

Within healthcare genomic sequencing approaches are generating huge quantities of data, requiring Clinical Bioinformaticians to design the IT infrastructure, data governance and pipelines to allow the analysis of these genomic data sets. They have an important responsibility for interrogating its quality to ensure the best possible outcomes for patients. A skill set currently desperately lacking in the UK.

Massive Online Open Courses (MOOC) are a popular and accessible way to educate large numbers of people, now expanding to include many more health focussed topics. In late 2015 we at The University of Manchester set out on a journey to write, produce and deliver the first MOOC aimed at raising the awareness of this new discipline to healthcare professionals: "Clinical Bioinformatics – Unlocking Genomics in Healthcare".

Over the past 3 years we have been delivering the Masters programme in Clinical Bioinformatics to educate and train trainee Clinical Scientist Bioinformaticians, the first cohort will graduate in summer 2016.

The MOOC is hosted on the FutureLearn platform, based on a social media approach, it allows learners to follow one another if an interesting discussion thread develops and also encourages peer review of co-learners work. We have worked with Clinical Geneticists and Clinical Bioinformaticians within the Manchester Centre for Genomic Medicine to include clinical case studies for learners to study. Here we will describe the platform, educational ethos and our learning journey to final production.

The MOOC can be found: <https://www.futurelearn.com/courses/bioinformatics/1>

Screening of thrombophilia-related phenotypes and pathways in a gene expression family study

S. Picart-Armada¹, A. Ziyatdinov², A. Martinez-Perez², A. Viñuela², J. Souto², E. Dermizakis³, A. Perera¹, J. Soria², A. Buil⁴;

¹Universitat Politècnica de Catalunya, Barcelona, Spain, ²Institut d'Investigació Biomèdica, Sant Pau, Barcelona, Spain, ³Department of Genetics Medicine and Development, University of Geneva, Geneva, Switzerland, ⁴Mental Health Center Sct. Hans, Roskilde, Denmark.

Introduction: Family studies offer an opportunity to assess the inherited and acquired nature of the quantified traits. Here, we analyse phenotypes related to thrombophilia by partitioning the explained variance into a genetic component, a transcriptomic component and the residual effect.

Materials and methods: Our data corresponds to the GAIT2 project on idiopathic thrombophilia, whose cohort includes 935 individuals stemming from 35 pedigrees. 481 quantitative phenotypes were measured at time of recruitment, including anthropometric measurements, hemogram, hemostasis traits, as well as phenotypes related with platelet activity, homocysteine metabolism, inflammation and flow cytometry. We also sequenced the mRNA transcriptome from whole blood.

We perform variance component analysis on linear mixed effect models that explain the phenotypes in terms of the kinship structure and the gene expression. Additionally, we extend these models conceiving a pathway enrichment technique that tests whether including the gene expression similarity based on a particular pathway improves the explained variance in the phenotype.

Results and conclusions: On one hand, models involving kinship and expression recover previously reported heritability estimates for known phenotypes. Furthermore, their error term decreases by introducing expression in the models, therefore explaining former residual variance in terms of ambient factors. On the other hand, relevant pathways improve specific phenotype models, such as platelet activation explaining platelet abundance in blood.

Gibbon-human chromosomal breakpoints show a distinctive epigenetic signature

N. Lazar, K. Nevenon, L. Carbone;

Oregon Health & Science University, Beaverton, OR, United States.

Chromosomal rearrangements are large-scale mutations that generate drastic structural changes in the genome. These events occur throughout evolution and are a hallmark of cancer. Despite their biological relevance, their mechanistic origins are poorly understood. While the study of chromosome fragility has been mainly focused on the sequence and architecture of chromosomal breakpoints, we hypothesize that other factors, above all epigenetic conditioning, should be considered.

In particular, we are using the gibbon genome as a model, as this species displays an unusually high occurrence of evolutionary chromosomal rearrangements and we have characterized the position of chromosomal breakpoints at very high resolution. We are employing a comprehensive strategy to explore the epigenetic landscape surrounding gibbon-human synteny breakpoints. This includes measuring DNA methylation, CTCF binding, histone marks and chromatin conformation (HiC-seq) in gibbon and five additional primate species and correlating these data through bioinformatics analysis.

Through this integrated analysis, we discovered that the epigenetic landscape of gibbon breakpoint regions is distinct from other genomic regions and remarkably conserved when compared to orthologous regions in other primates, indicating that the epigenetic state of breakpoints preceded gibbon speciation and was preserved after the genome reshuffling. Surprisingly, we find that the two sides of the breakpoints noticeably differ from each other in the distribution of DNA methylation rates and CpG density. This lack of chromatin homogenization could indicate a selection for chromosomal topological domains driven by functional effects. This is a remarkable finding given the recent and extensive reshuffling of the gibbon genome.

P16.13

TruePrime™ liquid biopsy: Tuning whole genome amplification towards improving the sensitivity of circulating tumor DNA analysis

Á. J. Picher¹, L. Blanco², T. Caldes³, K. Pantel⁴, A. Schneider⁵;

¹Sygnis Biotech SLU, Madrid, Spain, ²Centro de Biología Molecular Severo Ochoa (CSIC-UAM), Madrid, Spain, ³Hospital Clínico San Carlos, Laboratory of Molecular Oncology, Medical Oncology Department, Madrid, Spain, ⁴University Medical Center Hamburg-Eppendorf, Department of Tumor Biology, Center of Experimental Medicine, Hamburg, Germany, ⁵SYGNIS Bioscience GmbH & Co KG, Heidelberg, Germany.

TruePrime™ is the name of a novel technology dedicated to the amplification of genomic DNA. While the current gold standard MDA (multiple displacement amplification) relies on short oligonucleotides to start off the amplification, TruePrime™ is based on a combination of Phi29 DNA polymerase with the recently discovered primase/polymerase TthPrimPol. In this setup, TthPrimPol synthesizes the DNA primers needed for Phi29 DNA pol in the course of the reaction, which allows for the exponential amplification of genomic DNA. Key advantages of the TruePrime™ technology for amplification of single cell genomes include complete absence of primer artefacts, superior sensitivity down to the femtogram range, high reproducibility, little bias in genome coverage, and superior variant detection. Moreover, the TruePrime™ workflow is easy and reaction products work well with major NGS platforms. We are currently tuning the TruePrime™ technology towards the amplification of cell free DNA from plasma and serum with the intention to improve sensitivity and reliability of the method. Results on the feasibility of this approach will be presented.

P16.14

Low frequency variant detection from FFPE and cell-free DNA using target capture and molecular tagging

M. Light¹, S. Groenewold², M. McNeill², M. Jarosz²;

¹Integrated DNA Technologies, Redwood City, CA, United States, ²Integrated DNA Technologies, Coralville, IA, United States.

Introduction: Low frequency variant detection from clinically relevant samples poses significant challenges: degraded DNA from FFPE samples and low inputs from small biopsies and/or circulating cell free DNA make achieving deep coverage with high sensitivity and specificity difficult. Here we present how the use of degenerate bases during the synthesis of NGS adaptors can significantly reduce sequencing error rates, thus allowing for more accurate detection of low frequency mutations. Furthermore, we show how these molecular tagging techniques can be combined with IDT hybridization probes for extremely even and deep coverage of targeted genomic regions of interest.

Materials and Methods: Cell-free and FFPE DNA underwent library construction using sequencing adapters containing unique molecular barcodes. Libraries were then captured using either a pre-designed 1176kb panel or custom 82kb panel. Variants were called on samples with known mutation frequencies using MuTect v1.7.7.

Results: Capture with hybridization probes achieved >20% of the mean coverage for >98% of targeted bases. Mutations present at 1-5% were detected using as little as 10ng high quality DNA, 25ng FFPE DNA and <10ng cell-free DNA. Furthermore, application of error correction using molecular barcodes allowed for accurate detection of mutations present at <0.5%.

Conclusions: The extremely uniform target coverage achieved with IDT's pre-designed and custom enrichment panels minimizes the amount of sequence data needed to achieve deep coverage of targeted bases. When combined with the increased accuracy gained from molecular tagging strategies, researchers can achieve highly sensitive somatic variant detection even when starting with minimal amounts of clinically relevant samples.

P16.15

Development and implementation of a diagnostic pipeline for CNV calling using targeted NGS data

A. Parrish¹, C. Watson², S. Ellard^{1,3};

¹Royal Devon & Exeter NHS Foundation Trust, Exeter, United Kingdom, ²St. James's University Hospital, Leeds, United Kingdom, ³Institute of Biomedical and Clinical Science, University of Exeter, Exeter, United Kingdom.

Copy number variants (CNV) are a major cause of monogenic disease, with over 30,000 CNVs reported in the DECIPHER database. A number of tools are designed to use read depth data from targeted Next Generation Sequencing (NGS) panels to identify CNVs, but in order to do so with the highest degree of sensitivity it is necessary to make modifications to account for the biases inherent in the data. Factors such as GC content and ambiguous mapping of reads due to repetitive sequence elements and pseudogenes are the principal components of technical variability. In addition, the algorithms used to interrogate the data favour detection of multi-exon CNVs, and are reliant on suitably matched normal dosage samples for comparison. We developed a strategy for calling CNVs using read depth in targeted NGS panels that divides the target intervals into 120bp windows, and utilises a pool of historic samples for comparison to overcome these limitations for use in a diagnostic laboratory. We validated our strategy against an unmodified pipeline to assess sensitivity using the R software package ExomeDepth, using a cohort of 109 samples with MLPA detected heterozygous CNVs (91 deletions, 18 duplications in 26 genes), which included 25 single exon CNVs. The unmodified strategy detected 104/109 CNVs, giving a sensitivity of 89.62% to 98.49% at the 95% confidence interval. Since our protocol detected 109/109 CNVs, we have 95% confidence that the modified strategy sensitivity is $\geq 96.67\%$, allowing the use of NGS read depth analysis for diagnostic CNV detection in a diagnostic setting.

P16.16

Search of CNVs from whole exome sequencing data and confirmation by array in patients with multiple congenital malformations and neurological disabilities

É. A. Zanardo¹, A. T. Dias¹, F. A. R. Madaia¹, A. M. Nascimento¹, G. M. Novo-Filho¹, M. M. Montenegro¹, J. G. Damasceno¹, T. V. M. M. Costa¹, C. Milani¹, M. Rocha^{1,2}, F. B. Piazzon^{1,3}, F. Monteiro³, L. S. A. Costa^{4,5}, C. A. Kim⁶, F. Kok^{6,7}, L. D. Kulikowski^{1,2};

¹Laboratório de Citogenômica, Departamento de Patologia, Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil, ²Centro de Reprodução Humana e Genética, Departamento de Saúde Coletiva, Faculdade de Medicina do ABC, Santo André, Brazil, ³Mendelics Análise Genômica, São Paulo, Brazil, ⁴Unidade de Genética, Departamento de Pediatria, Instituto da Criança do HC/FMUSP, São Paulo, Brazil, ⁵Departamento de Neurologia, Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil.

Detection of the copy-number variations (CNVs) is essential for investigating many genomic disorders. To date the screening by arrays allows a better detection of the CNVs making possible the conclusion of diagnosis for most patients. Recently developed, the whole exome sequencing (WES) aims to complete assessment of exonic sequences in all genes, identifying mutations in rare and genetically heterogeneous diseases. However the identification of CNVs is not used routinely in this technique and this evaluation could increase its versatility as a detection method of the variants in the genome. In this study, we evaluated 16 patients with multiple congenital malformations and neurological disabilities by WES technique for CNVs assessment. We used the array for comparison and confirmation of the results and excluding the possibility of the other CNVs. We identified several different genomic alterations in all patients by the array and/or WES, but the CNVs were confirmed in 62,5% of the patients by both techniques. Among the alterations,

deletions correspond to ~36,8% and the duplication to ~63,2%. The larger alteration found was to 10q23.12-q26.3 (12,433,500bp) in deletion and to 15q11.2-q13.3 (9,764,036bp) in duplication, and the smaller alteration found was to 9p24.2 (104,767bp) in deletion and to 12p13.31 (124,833bp) in duplication. The extraction of CNVs information obtained from the WES is an advantageous approach. Thus this study can upgrade the resolution and accuracy of search pathogenic CNVs, and improve the cost-effectiveness and reduce the number of genomic tests required to diagnosis and thus lead to a deeper understanding of disease mechanisms.

Integrative Computational Pathogenicity Testing of GWAS Loci Assorted the important role of CCR2 gene in the Celiac Disease

N. A. Shaik^{1,2};

¹King Abdulaziz University, Jeddah, Saudi Arabia, ²Department of Genetic Medicine, Faculty of Medicine, King Abdulaziz University, Jeddah, Saudi Arabia.

Celiac disease (CD) is a gluten intolerance disorder with underlying genetic influences. Recent fine mapping and European GWAS studies identified 57 non-HLA CD susceptible loci, majority of which are non-coding variants and with no annotated function. So, we undertook the integrative computational approach to uncover plausible mechanisms connecting these CD specific loci to the disease pathology. At first, 1,008 linked variants ($r^2 \geq 0.8$) of 57 CD lead loci were ranked from deleterious to benign using CADD, GWAVA, and FATHMM algorithms. The mRNA levels of highest deleteriously ranked genes were tested in gene expression profiles of intestinal tissues and lymphocyte data. Pathway analysis was done to identify potential pathways influencing highly deleterious CD loci. We found that 2% (22 variants in 13 genes) were highly deleterious (Rank I) and 4.3% of 1065 CD variants (22 variants in 29 genes) were deleterious (Rank II). By concordant gene expression and pathway analysis we identified that deleterious SNPs localized in CCR2 gene may influence its expression and elicit cascade of immunological events associated with intestinal gluten intolerance. This study demonstrates the utility of integrative annotations, gene expression and pathway analysis for filtering the potential CD relevant variants from a large-scale genomics data.

P16.18

The linked-read exome: improved variant calls, inaccessible regions, compound heterozygotes and SV's from a single library

A. N. Fehr¹, K. Giorda¹, H. Ordonez¹, B. Galvin¹, J. Lee¹, A. Xu¹, P. Marks¹, I. Yousif¹, E. Lin², M. Isaaksson², F. Useche², K. Jeong², M. Visitation², D. Roberts², M. Corioni², A. Vadapalli², D. Church²;

¹10x Genomics, Pleasanton, CA, United States, ²Agilent Technologies, Santa Clara, CA, United States.

Exome sequencing has become a mainstay of gene-disease association in both the research and clinical settings. Despite this success, overall clinical research identifies roughly 25% of causal phenotypes, suggesting the need for improved methods. To this end, we have developed an enhanced exome that utilizes the barcoding of long DNA molecules, updated capture probes and improved informatics to produce a more complete exome assay. Of note, the new long-range information allows phasing of >90% of the genes in the exome from a single library and the addition of supplemental baits offers further increase. Additionally, the assay allows for analysis of genomic regions that are inaccessible to standard methods. For example, genes such as RPS17, which have numerous paralogs in the genome, are typically not analyzed in standard assays due to alignment ambiguity of short reads. Importantly, this approach also increases sensitivity to detecting complex variants, including CNVs and gene fusions, allowing us to phase these complex variants with SNVs. We will show examples of both germline and cancer events (copy-gain, copy-loss and copy-neutral) including a CTNS/SHPK compound heterozygote, a TMPRSS2 double-exon deletion, and an EML4-ALK fusion. The ability to detect a wide range of variant types and sizes allows for a single, integrated assay that provides a more complete view of every sample.

P16.19

Human copy number variants are enriched in regions of low-mappability

J. Monlong^{1,2}, C. Meloche³, G. Rouleau⁴, P. Cossette³, S. L. Girard^{5,1}, G. Bourque^{1,2};

¹Department of Human Genetics, McGill University, Montreal, QC, Canada, ²McGill University and Genome Quebec Innovation Center, Montreal, QC, Canada, ³Centre de Recherche du Centre Hospitalier de l'Université de Montreal, Montreal, QC, Canada, ⁴Montreal Neurological Institute, McGill University, Montreal, QC, Canada, ⁵Departement des sciences fondamentales, Université du Québec à Chicoutimi, Chicoutimi, QC, Canada.

Germline copy number variants (CNVs) are known to affect a large porti-

on of the human genome and have been implicated in many diseases. Although whole-genome sequencing can help identify CNVs, existing analytical methods suffer from limited sensitivity and specificity. Here we show that this is in large part due to the non-uniformity of read coverage, even after intra-sample normalization, and that this is exacerbated in regions of low-mappability. To improve on this, we propose PopSV, an analytical method that uses multiple samples to control for technical variation and enables the robust detection of CNVs. We show that PopSV is able to detect up to 2.7 times more variants compared to previous methods, with an accuracy of about 90%. Applying PopSV to 640 normal and cancer whole-genome datasets, we demonstrate that CNVs affect on average 7.4 million DNA bases in each individual, a 23% increase versus previous estimates. Notably, we find that regions of low-mappability are enriched in CNVs in contrasts with somatic CNVs that are nearly uniformly distributed. We also observe that CNVs locates more than expected near centromeres and telomeres, in segmental duplications, in specific types of satellite repeats and in some of the most recent families of transposable elements. Although depleted in protein-coding genes, we identify 7206 genes with at least one exonic CNV, 324 of which harboured CNVs that would have been missed if low-mappability regions had been excluded.

P16.20

Improving detection of gene duplications in whole-genome sequencing data using allelic depth imbalance

P. Stromwasser^{1,2}, T. Stokowy^{1,2}, S. Johansson^{1,2}, V. M. Steen^{1,2}, K. Petersen¹, I. Jonassen¹;

¹University of Bergen, Bergen, Norway, ²Haukeland University Hospital, Bergen, Norway.

Copy-number variants (CNVs) are responsible for an equal share of genetic variation among humans as single-nucleotide variants (SNVs). However, detection and genotyping of CNVs using short-read sequencing is more challenging compared to calling SNVs. Four types of information are currently used to discover CNVs using whole-genome sequencing (WGS) data: (1) read depth, (2) read-pair information, (3) split reads, and (4) loss of heterozygosity (in case of deletions). Bioinformatics tools utilize these types of information, alone or in combinations, but they provide variable performance and show low concordance between the results, especially for duplications. Here we explore the utilization of an additional type of information - allelic depth imbalance (ADI) - to improve detection of duplications.

We used WGS data from a widely studied CEPH trio, and two complementary datasets of known duplications as gold-standards. The known duplications and a set of randomly selected negative control regions were ranked using ADI score. The score was based on allele ratio in heterozygous SNV calls within the duplications and control regions.

Our results show that ADI score differs between diploid and higher copy-number state regions. The score was able to classify known duplications with 67% sensitivity and 6% precision. When combined with read-depth, ADI score achieved up to 9% improvement in sensitivity and up to 7% decrease in false-positive calls, compared with read-depth alone.

Although ADI alone cannot discriminate false-positives sufficiently, used together with other signals, it can improve detection of duplications in whole-genome sequencing data

Funding: Bergen Research Foundation.

Cytogenomic data from a cohort of 98 Brazilian patients with congenital malformations and neurological disabilities using CytoSNP-12 BeadChip Array

J. G. Damasceno¹, É. A. Zanardo¹, T. V. M. M. Costa¹, C. Milani¹, G. M. Novo-Filho¹, M. M. Montenegro¹, F. A. R. Madia¹, R. L. Dutra¹, A. T. Dias¹, F. B. Piazzon¹, A. M. Nascimento¹, M. Rocha^{1,2}, F. A. Marchi³, D. M. Christofolini², A. F. L. Carvalho⁴, M. I. Melaragno⁵, C. A. Kim⁶, L. D. Kulikowski^{1,2,6};

¹Laboratório de Citogenômica, Departamento de Patologia, Faculdade de Medicina da USP, São Paulo, Brazil, ²Centro de Reprodução Humana e Genética da Faculdade de Medicina do ABC, Santo André, Brazil, ³Laboratório NeoGene, AC Camargo Câncer Center, São Paulo, Brazil, ⁴Departamento de Biologia Geral, Laboratório de Genética Humana e Metagênese, Universidade Federal da Bahia, Salvador, Brazil, ⁵Departamento de Morfologia e Genética da Escola Paulista de Medicina, UNIFESP, São Paulo, Brazil, ⁶Unidade de Genética, Departamento de Pediatria, Instituto da Criança, HC/FMUSP, São Paulo, Brazil.

Introduction: The advances in genomic array approaches have provided a huge improvement to detection of DNA structural variants. Here, we report on some of these variables found in patients from Cytogenomic Laboratory of FMUSP. In this study we profiled genomic alterations such as Copy Number Variations (CNVs) and Loss of Heterozygosity (LOH) in a cohort of patients with congenital anomalies and neurological disabilities that were examined beforehand with SNP-Array.

Materials and Methods: Ninety eight (98) patients were analyzed using cytogenomic and bioinformatics techniques in order to establish a genomic profile of Brazilian patients. All patients were submitted to the CytoSNP-12 BeadChip Array from Illumina; the data was analyzed by KaryoStudio and then post-processed with Microsoft Excel, using improved built-in functions. Results: The post-processed data revealed a total of 300 genomic alterations from 82 patients while 16 patients presented no alterations at all. From these 300 alterations, 55 were duplications, 113 were deletions and 132 LOHs. Chromosomes X and 22 presented the majority of structural alterations, 33 (10.5%) and 24 (7.6%) respectively and the duplications were prevalent in both chromosomes. Whereas chromosomes 21 and Y showed only a single duplication (0.32%).

Conclusion: With the application of arrays became possible to identify structural variants and LOH in patients with congenital anomalies and neurological disabilities that were never investigated before and also permitted an adequate genetic counseling. Our study allows drawing a novel genomic profile identifying common copy number alterations and LOH regions relevant to correlate with rare phenotypes in Brazilian patients.

P16.22

RD-Connect workshop for patient registries in Rome: "a Bring Your Own Data for beginners" on data linkage and ontologies

C. Carta¹, M. Roos², R. Kaliyaperuma¹, S. Gainotti¹, M. Thompson², P. Torreri¹, D. Taruscio¹;

¹Istituto Superiore di Sanità, Rome, Italy, ²Leiden University Medical Center, Leiden, Netherlands.

Data on rare disease (RD) patients are collected in patient registries, biobanks and databases and represent important tools to improve diagnosis, patient management and to speed up research. However, poor interoperability and access restrictions keep data siloed.

Based on the experience from the 1st RD-Connect „Bring Your Own Data“ (BYOD), November 2014 and the results of a survey, February 2015, it was decided to organize a “BYOD for beginners”. This workshop was held in Rome on September, 2015 and was organized by Istituto Superiore di Sanità in collaboration with the RD linked data and ontologies task force, the Leiden University Medical Center, EBI, Elixir and DTL.

The workshop had as main aims: promote data sharing, show basic principles and benefits of the “data linkage approach”. Introductory lectures and a tutorial were prepared specifically for beginners. Attendees first used a traditional approach to create two mock registries and perform simple count statistics. Secondly, a “data linkage approach” was followed using Uniform Resource Identifiers for all terms linked to ontologies to define the meaning of the terms. This facilitated merging the registries with reliable counts.

A follow up survey showed that the main lesson was clear to most participants: ontology-based data linkage makes data linkable and clearly identifiable at the source, which has the benefit of readily obtaining unambiguous answers to questions that require data from several sources.

We greatly thank participants and contributors to the workshop. Workshop was sponsored by RD-Connect and DTL/Elixir. CC, MR equally contributed to the work.

P16.23

A statistical framework for cell level predictions and eQTL deconvolution

R. Aguirre-Gamboa, N. de Klein, J. Di Tommaso, D. Zhernakova, P. Deelen, M. Bonder, Z. Borek, I. Ricaño-Ponce, BIOS Consortium, M. Swertz, I. Jonkers, S. Withoff, V. Kumar, C. Wijmenga, L. Franke, Y. Li;

University Medical Centre Groningen, Department of Genetics, Groningen, Netherlands.

We introduce a computational approach for deconvolution of expression quantitative trait loci (eQTL) effects into eQTL effects specific for cell subsets present in these complex samples. The proposed statistical framework (Decon2) consists of two components: 1) Decon-cell, that estimates cell counts using molecular profiling data (e.g. expression data or methylation results obtained from heterogeneous samples) and 2) Decon-eQTL, which subsequently deconvolutes the overall eQTL effect into cell type-specific eQTL effects.

We observed that estimated cell counts obtained with Decon-cell agree very well with the measurements determined experimentally. The correlation coefficient between predicted and measured cell/tissue proportion range from 0.75 to 0.99 using 9 different datasets. Subsequently we applied Decon-eQTL to whole blood RNA-seq and cell count data obtained from 626 individuals. We were able to replicate 40% of published neutrophil eQTLs determined using purified neutrophils [Andiappan et al. 2015]. We also redistribute the eQTLs of cis-genes in a 1Mb region around the 518 immune

disease associated SNPs from GWAS studies. Strikingly, we observed that SNPs associated with IBD (Inflammatory Bowel Disease) are over-represented in neutrophils and lymphocytes. This is in line with the recent findings [Cader et al 2013].

In summary, our method provides a universal tool which allows for redistribution of general eQTL effects of disease associated SNPs into cell type-specific eQTL effects, and this subsequently allows for implication of specific cellular subsets in a particular disease context.

P16.25

Identification of potential immune targets in controlling Endometrioid Endometrial Carcinoma metastatic progression

J. Billaud, S. Tugendreich, D. Toburen, E. Dubus;
QIAGEN Applied Advanced Genomics, Redwood City, CA, United States.

Introduction: Endometrioid Endometrial adenocarcinoma (EEC) is a common cause of gynecological cancer death in Europe and North America. At diagnosis, 75% of women have the disease confined to the uterus, (Stage One). Five-year survival for Stage One patients is 80%, however, 15-20% develop metastasis.

Materials and Methods: Total RNA extracted from tissues obtained after surgical resection from three women at stage one EEC was subjected to RNA-sequencing. The publicly available dataset (SRP045645) was downloaded directly from the Sequence Read Archive and the FASTQ files were processed with Biomedical Genomics Workbench for secondary analysis including mapping, quantification and differential expression analysis. Through streamlined integration the data was uploaded to Ingenuity Pathway Analysis (IPA) for biological interpretation.

Results: QIAGEN Bioinformatics solutions enabled us to analyze the biological parameters involved in EEC metastatic progression from early stage in three patients diagnosed at Stage One. By comparing these patients' RNA-seq results, we determined that key Canonical Pathways and other biological processes differentiated the three patients from one other. In particular, the predicted transcriptional program allowed us to visualize key upstream drivers. Three of these transcriptional drivers are immune related molecules (two cytokines: CXCL14 and GDF15 and one growth factor FGF3). They have been predicted to be potential master regulators of a Causal Network that drives increase of EEC, metastasis, epithelial-to-mesenchymal-transition (EMT), and cellular invasion in one of the three patients.

Conclusion: Based on these results we propose these three immune molecules as possible therapeutic targets to counteract the metastatic processes in EEC.

P16.26

Epistatic SNP associations between APP and ephrin receptors APHA4 and EPHA5 in late-onset Alzheimer's disease: Enrichment of Epistatic Effects

A. Caceres, J. R. Gonzalez;
CREAL, Barcelona, Spain.

Introduction: Amyloid toxicity remains the main hypothesis in Alzheimer's disease (AD); however, genome-wide association studies have failed to link the common genetic variability of APP (amyloid precursor protein) with late-onset Alzheimer's disease (LOAD). We hypothesized that epistatic interactions of APP with other genomic locations could mediate the link between its common variability and LOAD.

Material and Methods: We performed a novel genome-wide enrichment analysis of epistatic effects for 25 SNPs that spanned the APP genomic region. 8 APP SNPs were consistently enriched in interactions with the ephrin receptor family comprising 13 genes. We tested 36 significant interactions derived from the previous analysis in two additional validation studies.

Results: 14 interactions remained significant in the meta-analysis over the three studies (total cases/controls=3,935/2,103), confirming the epistatic enrichment of the ephrin family with APP. In particular, two interactions of APP, one with APHA4 (rs380417*rs1025369, pvalue=0.0003) and another with APHA5 (rs2186302*rs12499393, pvalue=0.001), were also significant in one of the validation studies. Functional data of 127 healthy brains showed 1) eQTL effects of rs380417 in both APP and APHA4 in the singular cortex (13/27 significant transcripts in APP, 10/23 in APHA4), and 2) eQTL effects of the interaction rs2186302*rs12499393 in both APP (19/27) and APHA5 (12/23) over the whole brain.

Conclusions: Common genetic variation of APP may be associated with LOAD through interactions with EPHA4 and EPHA5; two genes previously associated with LOAD and familial AD, respectively. Transcriptomic data showed eQTL effects of numerous APP transcripts for the SNPs mediating the interactions.

P16.27

Cis-regulatory annotation of genomes in Ensembl

T. Juettemann, D. R. Zerbino, S. Wilder, A. Lyle, M. Nuhn, I. Lavidas, A. Datta, E. L. Gallego, K. Taylor, M. Ruffier, A. Yates, L. Clarke, P. Fliece;
European Bioinformatics Institute, Hinxton, United Kingdom.

Ensembl is a leading source of information on the structure and function of the genome. The Ensembl Regulatory Build synthesises public epigenomic datasets produced by projects such as ENCODE, Roadmap Epigenomics or BLUEPRINT. We process them through a unified pipeline and make them available through a single interface. Regulatory elements annotated in isolation have limited utility; therefore we are simultaneously developing a database of cis-regulatory interactions attaching them to their target genes. Currently, two main approaches are being used to detect these interactions: genetics (e.g. eQTLs) and chromatin conformation (e.g. Hi-C). We have developed new technologies to store and display these datasets, using in particular HDF5 indexing for fast retrieval. This technology allows us to store all the GTEx summary eQTL data. Using our RESTful API, it is possible to retrieve this data simply and efficiently for any gene, variant or region, along with all other Ensembl annotations such as LD calculations from the 1000 Genomes dataset Phase 3, conservation scores, etc. It is thus possible to quickly develop advanced functional analysis pipelines without having to download or process massive data files. Finally, we are also developing high performance tools for basic research in epigenomics. The GenomeStats browser allows users to remotely compute statistics on the BLUEPRINT datasets, without downloading data or software. Thanks to the underlying WiggleTools library, it is capable of processing dozens of files simultaneously and efficiently. This means that even naïve users can try out complex hypothesis testing without getting slowed down by file management issues.

P16.28

Exome sequencing in consanguineous populations: developing a clinical diagnostic algorithm.

G. Hernández-Poveda¹, A. Romera-López², D. Cantalapiedra-De la Fuente¹, V. Felipe-Ponce¹, E. Mesa-Rísquez¹, Y. Moreno-Sáez¹, M. L. Bellón-Robles¹, C. Collado-Micó¹, R. Rodríguez-De Pablos¹, A. Silveyra-González¹, O. Rodríguez-Cruz¹, C. Buares-Gomis¹, C. Casañ-Martínez¹, K. Al-Thihli², D. Valero-Hervás¹, S. Santillán-Garzón¹;
¹Sistemas Genómicos, Paterna (Valencia), Spain, ²Sultan Qaboos University Hospital, Muscat, Oman.

Clinical use of whole-exome sequencing (WES), especially in patients with complex differential diagnosis and previous negative genetic tests by traditional approaches, is increasing. In certain populations, consanguinity is a frequent situation and the risk of autosomal recessive disease is directly proportional to the degree of parental relationship. In this condition, WES becomes a challenge when there is no other affected individual in the family. Developing an accurate testing strategy is necessary to reach a high diagnostic rate, avoiding wasting time and effort. We present results of a cohort of patients from unrelated consanguineous families, analysed using the Illumina HiSeq2500 platform and the SureSelectXT Human All Exon 50Mb V5 Kit (Agilent Technologies).

We obtained an average of 64,034 variants per case, which were filtered using our in-house diagnostic algorithm. We identified a homozygous disease-causing variant: c.290G>A (p.Trp97*) in the *NDUFS4* gene, in a patient with clinical suspicion of Leigh Syndrome; and a variant of uncertain significance: c.1027G>A (p.Glu343Lys) in the *PKLR* gene in a patient with congenital hemolytic anemia on regular transfusion, providing a compatible diagnosis. Both variants were identified in large regions of homozygosity (RoH>5Mb). This points out the importance of focussing analysis on homozygous variants located in RoH in a first approach, but also looking for variants in genes implicated in the differential diagnosis and variants outside RoH in a second instance if necessary, thus establishing a useful algorithm for these families.

Barcelona, Spain, ⁹CNAG-CRG, Centre for Genomic Regulation (CRG), Barcelona Institute of Science and Technology (BIST), Baldori i Reixac 4, 08028, Barcelona, Spain, ¹⁰Genetic Epidemiology, Twin Research and Genetic Epidemiology, King's College, London, United Kingdom, ¹¹Department of Clinical Genetics, Maastricht University Medical Centre, 6229 HX, Maastricht, Netherlands, ¹²German Research Center for Environmental Health, 85764, Neuherberg, Germany.

Introduction: Reliable tools discerning between rare and common genetic polymorphisms within a local context are essential for effective analysis of NGS clinical data for disease studies. Initiatives like 1000Genomes and ExAC have released population allele frequencies (AF) for single nucleotide polymorphisms (SNPs) and insertion-deletions polymorphisms (INDELs). Albeit useful, they consider Europe as an entity, are biased towards a few European subpopulations, and require centralised raw data processing.

Materials and Methods: GEEVS (GEUVDIS European Exome Variant Server) integrates multi-centre restricted-access AF data, and offers country-specific variant characterisation. Contributing centres apply standardised GEEVS protocols for variant calling (integrating several tools and custom filters), quality control, and variant aggregation. Only aggregated AF and coverage profile data are shared with the central server. The "master aggregator" function performed at the central server subsequently produces European and country specific AFs, and enriches each variant with functional information, damage predictions (SIFT, PolyPhen2), and OMICs information (dbSNP, 1000Genomes, EVS, UCSC Genome Browser).

Results: GEEVS aggregates variants from 2817 individuals of European ancestry, by integrating anonymised, restricted-access data from five European contributors. GEEVS checks data quality in terms of AF distribution, Ti/Tv ratio, AF concordance with 1000Genomes, and haplotype concordance with Genome In A Bottle gold standard. GEEVS achieved quality values similar to ExAC without requiring centralised processing.

Conclusions: GEEVS extracts high-quality aggregated AFs from restricted-access clinical NGS data and computes country-wise variant characterisations, providing precise local-context information for disease studies. GEEVS, available from <http://geevs.crg.eu/>, or <http://www.ebi.ac.uk/eva> (European Variation Archive), accepts new submissions of European aggregated AF data.

Coen**⁸, **M. Vrijheid**^{2,3,4}, **X. Estivill**^{1,2,4}, ¹Centre for Genomic Regulation (CRG), The Barcelona Institute of Science and Technology, Barcelona, Spain, ²Universitat Pompeu Fabra (UPF), Barcelona, Spain, ³ISGlobal, Centre for Research in Environmental Epidemiology (CREAL), Barcelona, Spain, ⁴CIBER Epidemiología y Salud Pública (CIBERESP), Madrid, Spain, ⁵Grupo de Medicina Xenómica – Universidad de Santiago de Compostela, Santiago de Compostela, Spain, ⁶CIBER Enfermedades Raras (CIBERER), Madrid, Spain, ⁷Fundación Pública Galega de Medicina Xenómica (SERGAS), Santiago de Compostela, Spain, ⁸Biomolecular Medicine, Division of Computational and Systems Medicine, Department of Surgery and Cancer, Imperial College London, London, United Kingdom.

The exposome is defined as the totality of human environmental exposures from conception onwards, and it complements the genome. Thus, it might explain part of the variation in complex phenotypes.

The European FP-7HELIX project (The Human Early-life Exposome) aims to elucidate the effect of the exposome on child health (growth and obesity, lung health, and neurodevelopment), and to understand the molecular mechanisms underlying these associations by the use of new multiple's omics technologies.

Over 1,200 children aged 6-9 years from six existing birth cohorts across Europe participate in the study. The exposome was assessed through multiple biomarkers of exposures (e.g. metals and organic pollutants), questionnaire (e.g. diet), geographic information systems (e.g. air pollution), and personal monitors (e.g. physical activity).

In the same children, the metabolome, proteome, transcriptome and epigenome were analyzed. Methylation of DNA in leukocytes was analyzed with the Human Methylation 450 BeadChip array. Whole blood gene expression was quantified using the Affymetrix HTA 2.0 array and more than 2,000 miRNAs were measured using the Agilent SurePrint Human miRNA Microarray rel 21. Untargeted nuclear magnetic resonance spectroscopy (NMR) and targeted profiling with the BiocratesAbsoluteIDQ p180 assay kit were used to analyze metabolites in urine and serum, respectively. Finally, a set of proteins related to inflammatory and metabolic signaling were analyzed using the antibody-based multiplex platform Luminex. Genome-wide genotyping data is available for one third of the children.

This unique molecular dataset will help to elucidate the molecular mechanism through which the exposome affects health.

P16.31

Prediction of genome-wide SNPs effects for testis weight in a house mouse

B. Karacaören;
Akdeniz University, Antalya, Turkey.

Introduction: Genome-wide association studies (GWASs) used to detect candidate genes for complex traits. However assumptions regarding underlying genetic architecture of the traits are still under discussion referring the „missing heritability“ problem. For instance one may assume either major genes or numerous small genes that might control trait of interest. The objective of this study was to prediction of SNPs effects (by assuming both major gene and polygenic inheritance simultaneously) using testis weight of house mouse to detect fertility related loci.

Material and Methods: We used 185 house mouse (Turner and Harr (2014)) with 156202 SNPs for mapping variants for relative testis weight. We assumed mixture of different normal distributions for the SNP effects to be predicted. We also used single SNP model to evaluate only major gene assumption for fertility trait.

Results: Single SNP approach detected genomic signals from 8 loci (chromosomes of 1, 6, 12, 14, 17, X). However after multiple hypothesis testing correction we could only confirm suggestive genomic signals using single SNPs approach. When we assumed polygenic inheritance 1123 SNPs explained all of genomic variance. Most of those SNPs (>0.98 of them) had tiny effect. JAX00486833 at chromosome 2 had the highest explanatory variance (0.057).

Conclusion: These findings show that assuming different effect sizes for the SNPs lead to better genomic predictions for testis weight. This stresses the importance of the assumptions regarding genetic architecture of the complex traits used in GWAS.

The study was supported by Akdeniz University Scientific Research Projects Unit, project number: FBA-2015-1117.

P16.32

Gene expression data signal correction to identify disease gene signals

S. van Dam;
UMCG, Groningen, Netherlands.

Disease phenotypes manifest both at physical and genetic level. The alterations in the physical state of a patient can help to identify its underlying cause such as the presence of a genetic abnormality or an infection. However, often it is not possible to identify these abnormalities, underlying a phenotype or only on a broad level, using the limited number of variables derived from the physical state of a patient. Using gene expression profiles as a marker for disease, the expression of each gene can be used as a variable greatly extending the number of measurable variants. We have previously shown that it is possible to identify over expressed genetic regions in cancer patients, which proved to correlate with genomic duplications. These could potentially be used as biomarkers for different cancer types. In this project we aim to extend this analysis to other phenotypes using RNA-seq data, which is more sensitive. Using RNA-seq blood data from over 5,000 extensively phenotyped patients, we aim to identify gene expression variation that is unique to patients that share specific phenotypes, such as obesity, smoking and depression. To achieve this, we correct samples from patients harnessing the phenotype with signals that occur in individuals that do not have this phenotype. The residual signal then represents/explains the abnormal genetic phenotype. These signals can be investigated to identify key players underlying the phenotype and potentially be used as biomarkers for diagnosis that potentially allow to differentiate between different sub-types of disease.

Introduction: Besides single marker-based analysis classically used in genome-wide association studies (GWAS), network-based approaches have become promising to identify the joint effect of multiple genetic factors. Most of network-based methods proposed to date aim at finding genetic units that are connected in a biological network, no matter the strength of connections. This can be problematic since loose connections are non-robust to

noise from either the GWAS signals or the biological resource used to build the network.

Methods: We propose digNet, a novel network-based method integrating GWAS outcomes and protein interaction network (PIN) to identify a densely interconnected gene sub-network enriched in association signals. Our method is based on zero-one quadratic optimization, which can be solved exactly and efficiently through min-cut algorithms. The digNet approach possesses two desirable properties: (i) the selected genes are densely interconnected, thus functionally related; (ii) the results are robust against noise. **Results:** We applied digNet to the outcomes of two meta-analyses of 9 childhood-asthma GWASs each (~3000 cases/3000 controls in each meta-analysis). We identified a gene sub-network of 172 genes that was consistent across the 2 datasets. This network is significantly associated with childhood asthma ($P < 10^{-5}$) and shows strong interconnection ($P = 7 \times 10^{-5}$). Out of the 172 genes, 5 are known asthma genes while 148 genes, with nominally significant gene-wise P-values, represent novel candidates. Nine immune-related gene families and KEGG pathways were found enriched in these genes. These results show the advantage of our method to identify novel functionally related candidate genes for asthma.

Independent components of gene expression in endurance runners

M. Maqueda^{1,2}, **E. Roca**³, **J. M. Soria**⁴, **A. Perera**^{1,2};

¹Universitat Politècnica de Catalunya, Barcelona, Spain, ²Biomedical Research Networking Center in Bioengineering, Biomaterials and Nanomedicine, Barcelona, Spain, ³Universitat de Girona, Girona, Spain, ⁴Institut de Recerca de l'Hospital de la Santa Creu i Sant Pau, Barcelona, Spain.

Introduction: This study assessed the gene expression (GE) response from a group of 16 endurance runners after participating in an 82km competition. **Material and Methods:** We used microarray technology (HuGene2.0st from Affymetrix, Inc., California) to analyse the genome-wide GE profile of runners' blood samples that were collected before and after the race. A linear regression model was fit to each transcript cluster (TC) expression value considering gender and completed distance as covariates. Statistically significant differentially expressed TCs were obtained from a moderated t-statistics performed for each coefficient in the model (adjusted p-value 5%, FDR). An over-representation analysis was applied to the differential TCs querying KEGG PATHWAY and The Gene Ontology (GO) databases. An independent component analysis (ICA) was computed to extract the independent expression modes among the differential TCs.

Results: 5084 distinct genes were prioritized being 37% down-regulated and 63% up-regulated. Over-represented biological pathways were mostly associated with: genetic information processing, infectious disease and immune system. ICA identified seven independent regulation expression modes as response to exercise.

Conclusions: The intervention impacted heavily on the gene regulation processes, so that up to one fourth of the total variance related to coding RNA activity was captured as response to the exercise. This response produced extensive alterations in several pathways in the human biology, which we decomposed through a statistical method targeting independent expression modes.

TumOnc: differential algorithm of identification of driver mutations in oncogenes and tumor suppressor genes

F. Bezrukov, **S. Nikolaev**, **S. E. Antonarakis**;
University of Geneva, Geneva, Switzerland.

Cancer is a genetic disorder associated with high rates of accumulation of somatic mutations. However the majority of mutations are neutral and have no impact on the cell, and only few are under positive selection and are observed in cancer more frequently than expected by chance.

Several statistical algorithms exist to detect putative cancer driver genes, however they do not exploit the mutational properties of oncogenes and tumor suppressors.

TumOnc, the novel algorithm for detection of driver mutations in cancer estimates the non-uniform genomic background mutation rates as a function of tumor type specific mutational profile in three-nucleotide context, DNA replication timing, chromatin state and transcriptional activity. The principal novelty of the TumOnc algorithm is based on the assumption that the oncogene may contain a very limited number of sites which upon gain-

of-function mutation turn proto-oncogene to oncogene and subsequently are characterized by recurrent mutations.

In combination with the calculated background mutation rates per nucleotide and per patient this allowed us to identify significantly recurrent mutations, with sensitivity for oncogenes superseding existing algorithms. TumOnc is also designed for the detection of tumor suppressor genes searching for loss-of-function variants in both alleles. TumOnc has been recently tested in Basal Cell Carcinoma which has very high mutation rates (65M/Mb) and its usage has identified novel driver mutations (Bonilla et al., Nature Genetics in press).

P16.36

GWAS2Target: A gene prioritization approach to identify new therapeutic concepts exemplified for Schizophrenia

E. Simon;
Boehringer Ingelheim Pharma GmbH & Co KG, Biberach, Germany.

The identification new therapeutic concepts for human diseases is challenging because it requires a deep understanding of the molecular pathology. Genome wide association studies (GWAS) have become a powerful tool to disclose new molecular mechanisms of complex diseases. However, the development of new therapies based on these findings is hampered by additional hurdles i.e. causal gene mapping and target efficacy & feasibility.

We have developed a new gene prioritization approach using weighted scores for target gene feasibility, function, specificity & novelty. Each score is derived from multiple sub-scores which again can be weighted according to specific requirements. We applied this approach to a recent GWAS for Schizophrenia (SZ) including 108 loci.

Causal gene mapping has been parameterized by using the number of coding genes per loci as an inverse estimate for target feasibility. As additional sub-score for this dimension we applied the gene protein product class and the homology to model organisms. Gene function has been parameterized by GWAS significance & literature evidence. Target specificity has been derived from genome wide expression datasets in different sub-categories (brain vs. periphery, cell type specific and pattern in cortical sub-regions). Target novelty has been estimated from the inverse number of SZ related publications.

The combined scores with flexible weighting allows interactive ranking of the 340 coding genes. Using default weight parameters predicts some well-known SZ target genes at top ranks i.e. CACNB2 (#1), DRD2 (#2) or GRM3 (#10). In the near future, we plan to integrate additional datasets for gene mapping and function.

P16.37

A high-performance and scalable genomics platform for variation exploration using clinical traits

M. Haimel¹, **J. Colf**, **A. Rendon**², **N. Morrell**¹, **S. Gräf**^{1,3}, **I. Medina**⁴;

¹Department of Medicine, University of Cambridge, Cambridge, United Kingdom, ²Genomics England, London, United Kingdom, ³Department of Haematology, University of Cambridge, Cambridge, United Kingdom, ⁴High Performance Computing Service, University of Cambridge, Cambridge, United Kingdom.

Large-scale genomic studies are generating trillions of variant calls and tens of terabytes of data per day. The integration of this data with other heterogeneous information adds to the challenges in data processing. An integrated analysis of high-throughput whole genome sequencing data of tens-of-thousands of individuals requires a scalable system that enables the continuous addition, normalization, merging and annotation of variants.

Apache Hadoop is a scalable framework for storage and large-scale, distributed processing of petabytes of data. HBase, an add-on module based on Hadoop, enables storing and querying large amounts of heterogeneous data returning results in a matter of milliseconds for basic queries and just a few seconds for more complex queries.

We present a software platform that is designed to continuously normalize, transform and load gVCF files into HBase, as well as provide up-to-date variant annotations and allele counts for large cohorts. Interactive response times allow user authenticated genome exploration through a web browser, command line or API for custom analysis provided by the open-source OpenCGA platform.

Here we demonstrate the performance of our implementation of this platform using data generated from more than 5,000 whole genomes sequenced by the NIHR BioResource Rare Diseases Study, coupled with phenotypic information. Integration of other 'omics' data is ongoing to facilitate the discovery of novel pathogenic variants even beyond the protein-coding space.

The development of interactive tools for data exploration is now feasible due to quick response times and the ability to undertake complex queries across the Hadoop infrastructure.

P16.38

Variant calling performance of a next generation sequencing panel for single nucleotide and indel variants in hereditary spastic paraplegias

P. Cacheiro¹, A. Ordóñez-Ugalde¹, B. Quintáns², J. Amigo², Á. Carracedo^{1,2}, M. J. Sobrido²; ¹Grupo de Medicina Xenómica, CIBERER, CIMUS, Universidad de Santiago de Compostela, Santiago de Compostela, Spain, ²Fundación Pública Galega de Medicina Xenómica, Instituto de Investigación Sanitaria de Santiago de Compostela, Santiago de Compostela, Spain.

Introduction: Hereditary spastic paraplegias (HSP) are genetically heterogeneous neurodegenerative disorders expected to benefit from next-generation sequencing (NGS) technologies. However, the optimal parameters for variant detection and filtering still need careful evaluation in order to standardize these techniques for clinical applications. In this study we analysed the performance of several variant calling programs on an HSP gene panel. **Materials and Methods:** The dataset derives from a targeted panel of 30 HSP genes sequenced in 83 samples, in which 187 SNPs and indels (56 unique) were also detected by Sanger sequencing. The variant calling efficiency of 3 algorithms (Lifescopy, GATK UnifiedGenotyper and GATK HaplotypeCaller) was examined. Genotyping quality, depth of coverage and percentage of variant allele were considered to assess the quality of the calls.

Results: Discrepancies between NGS results and those from Sanger were found for 7 variants. Two SNPs were not detected by any of the variant calling algorithms because the individuals were homozygous for the rare allele but concordant with the reference sequence. One SNP in a low coverage region (6X) was only detected by two algorithms. Four indels were called differently by each of the callers, with ambiguities regarding annotation and zygosity.

Conclusions: In NGS protocols the calling efficiency may differ among callers, influenced by variant type and coverage. Variant detection protocols need to account for the presence of rare variants in the reference sequence and for ambiguities in indel calling. Threshold for quality scores should be cautiously established.

Human Knockout in Italian isolated population

C. Barbieri¹, M. Mezzavilla², M. Cocca³, C. F. Sala⁴, P. Gasparin^{2,3,4}, N. Soranzo^{5,6}, D. Toniolo¹;

¹San Raffaele Scientific Institute, Division of Genetics and Cell biology, Genetics of common disorders Unit, Milan, Italy, ²Division of Experimental Genetics, Sidra Medical and Research Center, Doha, Qatar, ³Department of Medical, Surgical and Health Sciences, University of Trieste, Trieste, Italy, ⁴Medical Genetics, Institute for Maternal and Child Health IRCCS "Burlo Garofolo", Trieste, Italy, ⁵The Wellcome Trust Sanger Institute, Wellcome Trust Genome Campus, Hinxton CB10 1HH, Cambridge, United Kingdom, ⁶Department of Haematology, University of Cambridge, Long Road, Cambridge CB2 0PT, United Kingdom.

Null mutations in homozygous state could generate 'human knockouts' for a gene. The study of these variants can provide insight into gene function. Our approach was focused on Italian isolated populations, from North (Friuli Venezia Giulia and Val Borbera) and South (Carlantino), to find out natural gene knockouts.

926 individuals were sampled and sequenced from nine different isolated villages, resulting in a catalogue of up to 19 millions variants (43% common between all villages) with 41% to 50% private variants at lower frequencies (MAF < 1%). Loss of Function (LOF) variants were investigated in the following functional categories: frameshift, stop lost, initiator codon, splice acceptor, splice donor, stop gained. Only variants with at least 1 individual homozygote for the alternative allele were selected and a set of ~2300 null mutation was created.

Among these: 90% was found in 1000 Genome Phase III panel and the remaining 10% was novel.

The site-frequency spectrum for these null mutations showed that 0.3% of the total is rare (AF<0.05) and about the 30% is common (AF>0.4).

Our analysis revealed the presence of up to 2200 genes in knock out state, the majority shared between the three isolated populations, while fewer genes are specific of each population.

Preliminary analysis of frameshift variants shows that in many instances only few of the alternative transcripts in a gene appear interrupted, suggesting a limited effect for most LOFs.

Our findings in combination with phenotypic data available in our cohorts will provide a focal point into understanding specific gene functions.

P16.40

Improved in silico protein predictions for missense variants in genes involved in congenital hypogonadotropic hypogonadism

D. Cassatella^{1,2}, J. Acierno², C. Xu^{1,2}, B. Stevenson³, N. Pitteloud^{1,2};

¹University of Lausanne, Lausanne, Switzerland, ²Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland, ³Vital-IT, Swiss Institute of Bioinformatics, Lausanne, Switzerland.

Congenital hypogonadotropic hypogonadism (CHH) is a rare disorder characterized by absent or incomplete puberty, and infertility due to a lack of GnRH secretion. CHH is a rare disorder with more than 30 genes known to underlie the phenotype. These genes code for a heterogeneous group of proteins with a significant proportion of reported mutations being missense changes. This underscores the importance of prediction algorithms in determining whether these variants are pathogenic or benign.

To assess the accuracy of the available in silico prediction tools, published pathogenic (n=158) and benign (n=27) missense variants from the ClinVar database and our own functionally-validated mutations in CHH known genes were evaluated. dbNSFP was queried to annotate functional predictions from 12 algorithms: SIFT, PolyPhen2_HDIV, PolyPhen2_HVAR, LRT, MutationTaster, MutationAssessor, FATHMM, PROVEAN, VEST, CADD, MetaSVM and GERP++.

ROC curves, area under the curve (AUC) and Matthews Correlation Coefficient (MCC) calculations showed that the most accurate predictors were VEST (AUC=0.87, MCC=0.49), PolyPhen2_HDIV (AUC=0.84, MCC=0.45) and CADD (AUC=0.81, MCC=0.42). Pairwise analysis of all prediction tools demonstrated improved performance relative to individual tools, with the top three combinations being VEST+PolyPhen2_HDIV and VEST+CADD (both, MCC=0.54, accuracy=89.2%, sensitivity=94.9%, specificity=55.6%), followed by PolyPhen2_HDIV+CADD (MCC=0.53, accuracy=85.4%, sensitivity=87.3%, specificity=74.1%).

Given these results, the combination of PolyPhen2_HDIV+CADD was chosen as it provides an improved balance between accuracy, sensitivity, and specificity. Future studies will evaluate larger datasets of mutations, with more balanced numbers of pathogenic and benign changes, to validate this finding of improved tool combinations to assess clinically relevant missense variants in CHH genes.

P16.41

Computational analysis on Pathogenic mutations of Human Interleukin Receptor Alpha Gene

B. Banaganapalli;

King Abdulaziz University, Jeddah, Saudi Arabia.

Introduction: Interleukin 10 receptor alpha (IL10RA), is a one of the key partner in inflammatory pathway, recent advent of GWAS studies and - exome studies has started to uncover known/novel pathogenic variations in IL-10RA gene in several autoimmune diseases. However, the structural and functional impact of these genetic mutations is not well identified. Hence, this study has performed the computational analysis of clinically potential missense and untranslated region mutations of human IL10RA gene.

Materials and Methods: In this study a combination of empirical rule and support vector machine based in silico algorithms were employed to predict the pathogenic potential of non-synonymous mutations of IL10 gene. Additionally, molecular modeling and secondary structure analysis was performed to confirm their impact on the stability and secondary properties of IL10RA protein.

Results: Besides, the mutations corresponding to p.Y57C, p.T84I, p.Y91C, p.R101W, p.R117C, p.R117H and p.G141R in exonic region; c.*1537T>C, a regulatory region variant was also found to potentially influence the structural and functional deviations of IL10RA activity. Moreover, the molecular docking analysis of IL10RA with substrate (IL10) and mutated forms of IL10RA was found to be three mutated proteins of IL10RA are (p.Y57C, p.R117C and p.G141R) most interesting residues for mutagenesis and affect the selectivity and affinity of IL10RA towards IL10.

Conclusion: Our findings are expected to help in narrowing down the number of IL10RA genetic variants to be screened for auto immune disease association studies and also to design a better competitive inhibitors for mutated forms IL10RA protein.

Genetic genomics of hepatic transcriptome in recombinant inbred rat models of metabolic syndrome

B. Chylikova, M. Hodulova, M. Krupkova, L. Šedova, D. Křenova, V. Křen, O. Šeda; Institute of Biology and Medical Genetics First Faculty of Medicine Charles University in Prague, Prague, Czech Republic.

The genetically designed set of recombinant inbred rat strains PXO serves as a model of human metabolic syndrome. Aim of this study was to analyse the genomic architecture of the metabolic syndrome features in this model set using an integrated genomic, phenomic and transcriptomic approach.

We have accumulated over 100 directly measured metabolic, morphometric and hemodynamic parameters in the complete set of 16 PXO strains and their progenitors, SHR-Lx and BXH 2 rat strains. Total RNA was isolated from liver of adult males of all strains, its integrity was checked by Agilent 2000 BioAnalyzer. The transcriptomic assays were run using Affymetrix® Rat Gene 2.1 ST Array Strip. Using the genomic information of > 20,000 SNPs, we have performed a genetical genomic study and correlated the expression profiles with the phenomic dataset. Resulting data were subjected to systems biology-level analyses using Partek Genomics Suite and Ingenuity Pathways Analysis.

We have identified over 55 transcripts and their respective cis- and trans-eQTLs significantly (FDR < 0.05) distinguishing the PXO strains and at the same time correlated to determinants of metabolic syndrome (including Echdc2, Tmem14c, Miox and Rarres2). Integrative analysis revealed several networks likely to drive the main differences in metabolic syndrome aspects in the PXO set with Il1b, Sirt2, Ppara, Ppargc1b, Atp7b genes as their major nodes.

Using integrative approach, we have identified major biological networks contributing to the pathophysiology of several aspects of metabolic syndrome in the recombinant inbred model set.

Supported by MSMT LK 11217.

P16.43

Deconvolution of cancer cell hierarchies through large-scale analysis of gene expression

L. Järnström¹, U. Gullberg, B. Nilsson;
Lund University, Lund, Sweden.

Introduction: Increasing evidence supports that some solid tumors and leukemias are organized as cellular hierarchies, sustained by cancer stem cells. Molecular markers for different stages in these hierarchies could potentially be exploited for targeted therapies.

Materials and Methods: Here we introduce a novel, computational approach to characterize tumor cell hierarchies. In sharp contrast to traditional approaches, which rely on physical cell sorting and analysis of sorted cell fractions, we exploit high-dimensional matrix decomposition to identify genes that discriminate the different stages in cancer cell hierarchies through deconvolution of gene expression profiles of unsorted tumor cells. Importantly, our approach completely avoids the need for physical cell sorting. Instead, genes that discriminate different stages in the neoplastic hierarchy are identified by mathematical unmixing. To obtain robust results, the process is constrained by L1 regularization and a priori information about normal cell development in the same tissue.

Results: In systematic validation experiments, we demonstrate that our approach is capable of recovering cell type-specific markers, and cell frequencies, from real and simulated expression profiles of mixed cell populations. Particularly, using large-scale unmixing of unsorted Acute Myeloid Leukemia samples, we were able to identify both known and new markers for leukemic stem cells.

Conclusion: Our work establishes deconvolution of expression profiles of mixed tumor cell populations as an innovative approach to characterize tumor cell hierarchies, potentially facilitating the development of therapies towards cancer stem cells.

P16.44

Assessing tumour heterogeneity and evolution in non-Hodgkin lymphoma (NHL) using liquid biopsies and single cell sequencing

R. D. Morin¹, S. Yu¹, M. Alcaide¹, B. Grande¹, S. Assouline², K. Mann², N. Johnson²;
¹Simon Fraser University, Burnaby, BC, Canada, ²Jewish General Hospital, Montreal, QC, Canada.

Introduction: Apoptotic tumour cells shed DNA that ultimately becomes circulating tumour DNA (ctDNA), which can be recognized in plasma by the presence of tumour-specific alterations. Dynamics in the level of ctDNA can reflect changes in tumour burden within a patient and, as such, its measurement is a highly specific and potentially versatile biomarker for solid cancers.

Materials and Methods: Various methods for quantifying ctDNA exist including those relying on massively parallel sequencing. We use these to quan-

tify ctDNA in patients with NHLs and evaluate its utility as a biomarker and with molecular tagging strategies, are exploring ctDNA as a substrate for non-invasive genetic characterization. Computational approaches facilitate inference of clonal populations within tumours populations and we used these to determine whether ctDNA recapitulates this clonal structure.

Results: We have detected ctDNA in most relapsed NHL patients with many cases exhibiting levels that facilitate genetic characterization. We show high specificity for ctDNA changes in predicting treatment response. Our methods enable non-invasive characterization of tumour heterogeneity including mutations in plasma that were poorly supported in the matched biopsy. Sequencing of serial plasma samples has also revealed clonal evolution including the emergence of mutations in genes that likely contributed to treatment resistance including STAT6, MS4A1 and NR3C1. We used single cell sequencing methods to confirm and refine clonal populations in NHLs allowing resolution of evolutionary history of treatment-resistant tumours.

Conclusion: Sequencing of ctDNA is a powerful means to study somatic tumour genetics non-invasively and can inform on clonal complexity and evolution in NHLs.

Assessing the Ion Torrent technology for its use in human lung microbiome profiling with 16S rRNA amplicon sequencing

B. Guillen-Guío¹, A. Espuela-Ortiz², F. Lorenzo-Diaz^{1,2,3}, A. Baez-Ortega⁴, J. Alcolba⁵, T. E. Klassert⁶, H. Slevogt⁶, M. Pino-Yanes^{1,7}, C. Flores^{1,2,7};

¹Research Unit, Hospital Universitario N.S. de Candelaria, Tenerife, Spain, ²Applied Genomics Group (GZA), Section of Genetics, Department of Biochemistry, Microbiology, Cell Biology and Genetics, Universidad de La Laguna, Tenerife, Spain, ³Genetics Laboratory, Instituto Universitario de Enfermedades Tropicales y Salud Pública de Canarias, Universidad de La Laguna, Tenerife, Spain, ⁴Department of Veterinary Medicine, University of Cambridge, Cambridge, United Kingdom, ⁵Microbiology Unit, Hospital Universitario N.S. de Candelaria, Tenerife, Spain, ⁶Septomics Research Centre, Jena University Hospital, Jena, Germany, ⁷CIBER de Enfermedades Respiratorias, Instituto de Salud Carlos III, Madrid, Spain.

Introduction: Sepsis is a major cause of death in the adult intensive care units worldwide. Lung microbiome shifts may associate with severity in sepsis. Here we assessed the performance of the Ion Torrent sequencing platform for microbiome profiling.

Materials and Methods: We used the Ion Torrent PGM (Thermo Fisher) for 16S rRNA V4 amplicon-based sequencing. Performance was assessed by using pooled genomic DNA from 20 bacteria compared to that of a MiSeq instrument (Illumina). Then, a mixture of 12 clinical bacterial strains commonly isolated from lungs was used to compare the performance of distinct DNA extraction procedures. Pre-processing, taxonomic classification, and diversity analyses were done with a QIIME-based pipeline.

Results and Conclusions: While virtually all reads were full-length for MiSeq, these constituted only 33.4% of the reads for Ion Torrent. We found good agreement between the relative bacterial abundance at the genus level between the two platforms only if fragment size filtering was relaxed in the Ion Torrent reads. Furthermore, the use of DNA extraction methods combining chemical and mechanical lysis significantly improved diversity and abundance estimates, allowing to better recapitulate the bacterial community. These results have major practical implications for the following studies being conducted in specimens of human origin.

P16.46

GIML: greedy inference of methylation levels

E. Raineri;
CNAG, Barcelona, Spain.

Changes in methylation along the DNA are often revelatory of what regulatory activities are taking place in a cell. Such variations have been observed in promoter regions, along gene bodies, in enhancers, at splicing sites and elsewhere. Whole genome bisulfite sequencing can measure cytosine methylation with 1bp resolution over an entire genome; the interpretation of these data needs analysis tools which discern noise from relevant structures.

Here I explain a simple greedy algorithm designed to analyze methylation by first segmenting it into homogeneous regions. The definition of homogeneous can be tuned to the problem at hand, given that this procedure can find both many small (almost constant) stretches or fewer large blocks which contain more substantial variation. The package (called GIML) analyzes an entire genome at ~30000 positions/sec.

I ran the algorithm on data generated by the Blueprint consortium looking for positions where one region of very low methylation is consistently surrounded by stretches of very high methylation: these „jumps“ are enriched in transcription start sites. GIML can also find differentially methylated regions with different lengths across samples.

Multiscale smoothing algorithms play an essential role in unraveling epigenetic measurements, by making visualization easier and distinguishing experimental artifacts from the underlying biological signal. The long term question is how do these experimental data correlate with each other and what do they tell us about molecular mechanisms: I think that the kind of quick, principled simplification of methylation data performed by GIML is an useful step in answering that question.

Estimating interaction of host genetics to the microbiome structure on the large Dutch population cohort

A. Kurilshikov^{1,2}, M. J. Bonder¹, P. Deelen¹, E. Tigchelaar¹, L. Franke¹, C. Wijmenga¹, J. Fu¹, A. Zhernakova¹;

¹University Medical Center Groningen, Groningen, Netherlands, ²Novosibirsk State University, Novosibirsk, Russian Federation.

Introduction: The gut microbiome inhabiting human intestine plays important role in the processes occurred in human body. Many environmental and intrinsic factors are linked with gut microbiome, with both one-way causalities (age, gender) and reciprocal relations (BMI, blood lipid level, medication). It was shown earlier that some bacteria inhabiting human gut are heritable, so the human genome can influence the microbiome. In this work, we performed statistical analysis to estimate the effect of SNPs to the microbiome structure.

Materials and methods: The data from 981 individuals from the LifeLines-DEEP population cohort was used. For each individual, both genotyping (ImmunoChip, Illumina) and metagenomic sequencing (paired-end Illumina reads) were performed. The preprocessing of the microbiome data included QC control and filtering from human DNA followed by MetaPhlan2.2 mapping. Multiple distance matrices (Bray-Curtis, Jaccard, weighted/unweighted UniFrac) were used as a dependent variable to estimate the SNP effect on microbial structure.

Results: The MicrobiomeGWAS pipeline was applied to 106,912 immune SNPs passed QC and MAF filtering steps. We identified one significant (FDR q-value < 0.1) association (for the chr5:721791) using Jaccard binary dissimilarity and 16 associations (rs4481881, rs1020822, rs11130380, rs16928058, 12 SNPs near the HLA locus) with weighted UniFrac distances. Across the distance methods, the p-value estimations are consistent within groups of weighted/unweighted distance measures.

Conclusions: we identified 17 candidate SNPs that influence the microbiome structure. Overall the effect of genetics on the microbiome is moderate.

P16.48

Host genetics have a moderate influence on the gut microbiome composition

M. Bonder¹, A. Kurilshikov¹, P. Deelen¹, E. F. Tigchelaar¹, M. Schirmer², T. Vatanen², S. Smeekens², Z. Mujagic³, L. Joosten³, D. Jonkers³, M. Netea⁴, R. Xavier², J. Fu¹, L. Franke¹, C. Wijmenga¹, A. Zhernakova¹;

¹University Medical Center Groningen, Groningen, Netherlands, ²The Broad Institute of MIT and Harvard, Boston, MA, United States, ³Maastricht University Medical Center, Maastricht, Netherlands, ⁴Radboud University Medical Center, Nijmegen, Netherlands.

Introduction: A recent twin study has suggested that microbial composition in human's gut is heritable and can be affected by the genetics of the host. However, up to date very few association was detected at single SNP level. In this study we related host genetic variation to the bacterial abundance and function in the human gut in 1,561 individuals.

Materials and Methods: Using imputed SNP genotypes and metagenomics sequencing data of three Dutch population cohorts, LifeLines-DEEP (n=1021), 500Fg (n= 435), MIBS (n=105), we linked genome wide SNPs to the abundance of bacteria (bQTLs) and activity of bacterial pathways (bpQTLs). We used the LifeLines-DEEP cohort as a discovery dataset and replicated the associations between SNPs and bacterial taxonomies or pathways in the two other datasets.

Results: In the LifeLines-DEEP cohort we identified 9,423 suggestive bQTLs and 5,192 suggestive bpQTLs at P < 5x10⁻⁵. None of the bQTLs were significantly replicated, but we do observe a trend of low p-values. Five of the top bQTL combinations reach genome wide significance in a meta-analysis over all three cohorts.

Conclusions: Even though the gut microbiome is shown to be heritable we observed that the overall effect of single SNPs on microbiome is modest and observe a weak replication of the relations between species and pathways

in the gut microbiome and host genetics. We believe a roughly twice as large sample size is necessary to identify the complex relations between the host and microbiome composition and function.

P16.49

MIPPIT: a fully automated tool to analyse MIPs sequencing data

B. de Koning¹, M. van de Vorst², S. Castelein², D. Zafeiropoulou², M. Nelen², A. Hoischen², W. van Dijk¹, L. Claes¹, A. van den Wijngaard¹, C. Gilissen²;

¹Maastricht UMC+, Maastricht, Netherlands, ²Radboudumc, Nijmegen, Netherlands.

Molecular inversion probes (MIPs) is a target enrichment technology that allows simultaneous screening of 1 to 80 genes in large cohorts at a cost of less than €1,- per gene per sample. However analysis of resulting data is complicated by intrinsic properties of MIPs. This limits current freely available software for robust analysis of MIPs data.

Therefore MIPPIT was developed: a fully automated JAVA based tool that enables fast, and robust analysis of MIPs data. It runs multi-threaded on a single node or workstation with a minimum of configuration. During mapping, using the BWA algorithm, reads are subsequently demultiplexed using barcode sequences, stripped of probe sequences in a probe specific manner, and deduplicated per individual sample on the basis of random tags. The resulting BAMs are automatically used for multi-sample variant calling using GATK, and annotated using gencode, dbSNP, ExAC, and several other publicly available data sources. MIPPIT supports variable target lengths, and can handle different strategies for random tag incorporation.

To test MIPPIT, it was used to detect variants within a dataset of 75 samples sequenced for BRCA mutations. Running MIPPIT took 7.5 hours on a 8 CPU computing node. Outcomes were compared to results obtained using commercial software (seqNext). MIPPIT reported all variants detected by seqNext, however in addition it also reported some variants that were overlooked by the latter.

To conclude we believe that MIPPIT is able to analyse MIPs sequencing outcomes in an efficient, reliable and robust manner.

Altered gene expression associated with microRNA binding site polymorphisms

U. Vösa¹, T. Esko², S. Kasela², T. Annilo²;

¹University Medical Center Groningen, Department of Genetics, Groningen, Netherlands, ²Estonian Genome Center, University of Tartu, Tartu, Estonia.

Allele-specific gene expression associated with genetic variation in regulatory regions can play an important role in the development of complex traits. We hypothesized that polymorphisms in microRNA (miRNA) response elements (MRE-SNPs) that either disrupt a miRNA binding site or create a new miRNA binding site can affect the allele-specific expression of target genes. By integrating public expression quantitative trait locus (eQTL) data, miRNA binding site predictions, small RNA sequencing, and Argonaute crosslinking immunoprecipitation (AGO-CLIP) datasets, we identified genetic variants that can affect gene expression by modulating miRNA binding efficiency. For the first time, all identified MRE-SNPs were classified based on whether the allelic direction from eQTL analysis was supported by the logic of miRNA-mediated regulation (concordant or C-type associations) or not (unconcordant or U-type associations). No significant overrepresentation of C-type associations was observed from our analyses (Chi-square test, P>0.05). However, some of the most suggestive eQTL-associated MRE-SNPs locate in the miRNA response elements (MREs) that are supported by experimental evidence.

We also identified MRE-SNPs located in regions associated with complex traits, indicating possible causative mechanisms associated with these loci. The results of this study expand the current understanding of gene expression regulation and help to interpret the mechanisms underlying eQTL effects. This study was supported by the Center of Excellence in Genomics (EXCEGEN) and University of Tartu (SP1GVARENG), EU FP7 grant 306031 (Bestag-eing), Estonian Research Council Grant IUT20-60. The funders had no role in study design, data collection and analysis, decision to publish, or preparation of the manuscript.

miRNA-mRNA prediction tools: use or forget?

O. M. Plotnikova¹, D. A. Zubtsov¹, M. Y. Skoblov^{1,2};

¹Moscow Institute of Physics and Technology, Moscow, Russian Federation, ²Research Centre for Medical Genetics, Moscow, Russian Federation.

Introduction: miRNAs play a key role in regulation of gene expression. Nowadays it's known more than 2'500 miRNAs, but the question about the

identification of miRNA-mRNA interaction is still open. There are five widely used miRNA-mRNA interaction predictive tools: TargetScan, Pictar2, PITA, RNA22 and miRanda. It was impossible to understand if can we trust these predictions. However recently the new method «CLASH» was developed to identify all miRNA-mRNA interactions.

Materials and Methods: We created algorithm to compare experimental data from “CLASH” experiment with predicted miRNA sites by all five algorithms from “StarBase” database. Expression data for mRNA and miRNA were used from FANTOM5 and GEO.

Results: We estimated working of miRNA-mRNA prediction programs by the following criteria: sensitivity, positive predicted value, predictions in different mRNA regions (3’UTR, CDS, 5’UTR), predictions for different types of interactions (5 classes), predictions of “canonical” and “noncanonical” interactions, and testing by using random data for miRNA binding sites. We compared miRNA binding sites predicted by programs with “CLASH” data and we found 602 miRNAs: 218 were observed only in “CLASH” data, 216 - only in predicted data and 168 - either in “CLASH” and predicted data. Expression analyze of miRNA revealed several interesting groups: highly expressed miRNAs without any interactions, highly expressed miRNAs with small number of interactions and lowly expressed miRNAs, which take a part in a lot of interactions with mRNAs.

Conclusions: Comparing miRNA-mRNA prediction programs revealed that all tools generate mostly the same result, which is still far away from experimental data.

Identification of candidate gene pathways for Müllerian duct anomalies by transcriptome profiling of murine mesonephric tissue

M. Ruiz-Rosario^{1,2}, A. Marmolejo-Valencia³, E. Martínez-Peñafiel¹, R. Ruiz-Esparza Garrido⁴, A. C. Velázquez-Wong⁵, O. Sepúlveda-Robles⁵, S. H. Kofman^{5,1}, D. J. Arenas-Aranda⁴, H. Merchant-Larios⁵, F. Fernandez¹;

¹Laboratorio de Sistemas, Unidad de Genética, Hospital General de Mexico, Mexico, Mexico, ²Regional Center For Biomedical Research UCLM, Albacete, Spain, ³Instituto de Investigaciones Biomédicas, UNAM, Mexico, Mexico, ⁴Unidad de Investigación en Genética Humana, CMN Siglo XXI, IMSS, Mexico, Mexico, ⁵Facultad de Medicina, UNAM, Mexico, Mexico.

Introduction: More than 1 in 4500 women suffer from Müllerian duct anomalies (MDA), which are often associated with renal, skeletal or cardiac malformations. The etiology of these conditions is unknown, and the molecular basis of the female reproductive tract (FRT) differentiation is not fully understood. Murine FRT morphogenesis begins in embryonic day E13, in which the mesonephros harbours both Wolffian and Müllerian ducts, and concludes in E17 with fully differentiated FRT and regressed Wolffian ducts. **Materials and Methods:** In order to identify genes involved in the morphogenesis of the FRT, we performed microarray analysis of global RNA expression of CD-1 male and female murine mesonephric tissue, during the embryonic days E13 and E15. For each assay, three biological replicates were pooled and microarrays were performed by duplicate.

Results: Differential expression patterns were observed among age and gender, and an E15-female signature was identified, corresponding to genes expressed at the midpoint of the FRT differentiation window. Wnt ($p=7.8e-05$) and TGF-Beta ($p=7.1e-05$) signalling pathways, among other biological processes, were statistically overrepresented in these data. For instance, WNT4 mutations were previously associated to a hyperandrogenic form of Müllerian aplasia in humans. Other components of such pathways participate in MDA, formation of limbs, and cardiac abnormalities in mice, suggesting that these mutant phenotypes in humans may result from functionally coherent orthologous gene sets.

Conclusions: Our results will be useful to prioritize candidate genes for MDA and will contribute to the current knowledge on FRT morphogenesis. This project was supported by CONACYT-133273 and UNAM-IN219912 grants.

CentoMD®, a comprehensive genotype-phenotype database for rare diseases

D. Trujillano;
Centogene AG, Berlin, Germany.

Our ability to discover genetic variants in a patient runs far ahead of our ability to interpret them. Databases with accurate descriptions of the causal relationship between the variants and the phenotype are valuable since these are critical tools in clinical genetic diagnostics. Here we introduce CentoMD®, a comprehensive genotype-phenotype database with the main focus on rare diseases. CentoMD® is a browser based software that enables access to a comprehensive, curated, and growing repository of genetic

and clinical information. Its main goals are to aid professionals in the evaluation of genetic variants, to enhance the validity of the genetic analytical workflow, and to facilitate genetic diagnosis and the evaluation of treatment options for patients with hereditary diseases. CentoMD® correlates the clinical information of consented patients and probands of different ethnical backgrounds (>90 countries) with a large dataset of genetic variants and biomarkers (when available). More than 61,000 genetically screened individuals are documented in CentoMD®, resulting in more than 120 million variant detections. Approximately 55% of the mutations in CentoMD are novel. CentoMD® is also a valuable research tool that could allow and facilitate the identification of new disease genes by correlating novel genetic variants with specific, well defined phenotypes.

P16.54

MUText: a bioinformatic tool to validate human mutations in HGVS standard format.

E. Rizzo^{1,2}, I. Limongelli^{1,2,3};

¹enGenome srl, Pavia, Italy, ²Department of Electrical, Computer and Biomedical Engineering, University of Pavia, Pavia, Italy, ³IRCCS Fondazione Policlinico S. Matteo, Pavia, Italy.

Molecular laboratories make use of commercial and/or public resources to build up internal knowledge databases of genomic variants in order to improve classification of pathogenic mutations. Matching mutations identified by a laboratory and those collected by these resources is often challenging, due to different formats used.

Human Genome Variation Society (HGVS) established therefore a standard format to improve knowledge sharing of genomic variants. However, even implementing HGVS recommendations can be error prone, especially if variants are manually curated or specific genomic databases (e.g. transcript subversions) are not used.

For this reasons, we developed MUText, a bioinformatic tool freely available online (<http://engenome.com/mutext>) that checks and converts mutations represented in HGVS v2.0 format.

MUText not only performs a syntax check of variants according to HGVS guidelines, but also tests the consistency of each variant with respect to a specific transcript subversion that can be chosen after selecting a reference genome and a transcript database (e.g. RefSeq and GENCODE for GRCh37/h38). MUText returns error messages highlighting these inconsistencies by checking if the replaced nucleotides match the reference genome in the corresponding genomic positions. Variants are then converted to genomic coordinates and formatted according to ANNOVAR in order to be easily integrated in a custom database.

We tested MUText on the Retinoblastoma LOVD (http://rb1-lsdb.d-lohmann.de/home.php?select_db=RB1) reporting 1734 unique variants on RB1 gene (NM_000321.2) in HGVS format. Errors were reported for 103 mutations: 48 did not match the genomic reference with the replaced nucleotides while 55 were not properly formatted according to HGVS.

P16.55

Robust method to genotype large ancestral chromosomal inversions using NGS data

C. Ruiz-Arenas¹, L. Pérez-Jurado², J. González¹;

¹CREAL, Centre for Research in Environmental Epidemiology, ISGlobal, Barcelona, Spain, ²Department of Experimental and Health Sciences, Universitat Pompeu Fabra, Barcelona, Spain.

Introduction: Chromosomal inversions, rearrangements where a fragment of DNA become reversely oriented, can explain part of diseases’ genetic causes. Whereas small inversions can be detected using NGS techniques, detection of large chromosomal inversions requires cytogenetic techniques that are not suitable for a high throughput scanning of the samples. Large ancestral chromosomal inversions generate regions with lower recombination rates resulting in the formation of haplotypes. This information can be used to cluster individuals in different inversions genotypes using data from SNP arrays. One of the main limitations of this approach relies on large sample size and SNP coverage requirements. This can be overcome by using NGS data.

Material and methods: Differences between the consensus sequence of the standard and the inverted haplotype are used to properly genotype inversions using NGS data. Whole genome sequencing and SNPs array data from 1000 Genomes project have been used to demonstrate our method’s performance. When consensus reference is not available, we propose an algorithm that can infer the consensus reference for the different haplotypes using the variants found in the samples.

Results: We have applied our method to inversions 17q21.31, 8p23.1 and

16p11 in 503 European samples. Our results have been compared with invClust, a standard tool to detect inversion haplotypes using SNP array data, showing high concordance.

Conclusions: Our proposed method is useful to genotype large chromosomal inversions at individual and population level. This can be used in genomic studies which are using NGS as standard genotyping method.

P16.56

A likelihood ratio based method to predict exact pedigrees for complex families from next-generation sequencing data

V. Heinrich¹, T. Kamphans², P. N. Robinson³, P. M. Krawitz²;

¹Max Planck Institute for Molecular Genetics, Berlin, Germany, ²Smart Algos, Berlin, Germany, ³Institute for Medical Genetics and Human Genetics, Charité Universitätsmedizin Berlin, Berlin, Germany.

Next generation sequencing (NGS) technology considerably changed the way we screen for pathogenic mutations in rare Mendelian disorders.

However, the identification of the disease-causing mutation amongst thousands of variants of partly unknown relevance is still challenging and efficient techniques that reduce the genomic search space play a decisive role.

Usually segregation- or linkage analysis are used to prioritize candidates, however, these approaches require correct information about the degree of relationship among the sequenced samples.

For quality assurance an automated control of pedigree structures and sample assignment is therefore highly desirable in order to detect label mix-ups that might otherwise corrupt downstream analysis.

We developed an algorithm based on likelihood ratios that discriminates between different classes of relationship for an arbitrary number of genotyped samples.

By identifying the most likely class we are able to reconstruct entire pedigrees iteratively, even for highly consanguineous families.

We tested our approach on exome data of different sequencing studies and achieved high precision for all pedigree predictions.

By analyzing the precision for varying degrees of relatedness or inbreeding we could show that a prediction is robust down to magnitudes of a few hundred loci.

P16.57

Proposals for improvement of next-generation sequencing (NGS) pipeline validations in diagnostic applications

F. Scharf¹, L. Laner¹, A. Nissen¹, A. Benet-Pages¹, E. Holinski-Feder¹;
MGZ - Medical Genetics Center, Munich, Germany.

Validation and assessment of variant calling pipelines for NGS in routine diagnostics is a challenging field because of adjustments to specific genetic analyses, different platforms and absence of solid reference datasets. A common approach is to build datasets from Sanger or Microarray data which makes validation time-consuming, expensive and still not reliable. Here we present a detailed evaluation of the validation procedure for routine diagnostic pipelines and suggest useful adaptations.

Concerning reference datasets, the Genome-In-A-Bottle NGS data (NIST-RM8398) is suitable and offers more high-confidence variant calls compared to the 1000Genomes data. Large discrepancies between 1000Genomes and our data required additional Sanger sequencing for clarification (90% of discordant calls were in fact FPs and FNs from 1000Genomes). For statistical evaluation, we propose to use the positive predictive value instead of analytical specificity, which is misleading due to the disproportion of TNs to the number of variants. We performed a detailed analysis of different filter settings for variant calling to determine which parameters have the most influence on FP and FN calls. Additionally, we set thresholds for coverage and quality adapted to each type of variant. It is crucial to determine and report the limitations of the pipeline because of pseudogenes, paralogues and repeat sequences. These low-confidence regions need to be identified for further verification of variant calls with other methods if necessary. Finally, re-validation should be scheduled periodically and not only if relevant changes are implemented, thereby preventing possible failures through unnoticed third-party software changes.

P16.58

Meta-alignment: Combining multiple sequence aligners to improve alignment quality

B. Wolf^{1,2}, P. Kuonen¹, T. Dandekar³, D. Atlan⁴;

¹University of applied sciences and arts western switzerland, Villars-sur-Glâne, Switzerland, ²University of Würzburg, Würzburg, Switzerland, ³University of Würzburg, Würzburg, Germany, ⁴Phenosystems SA, Wallonia, Belgium.

Introduction: Many different tools have been developed to perform sequence alignment, a central part of NGS data analysis. Choosing the right tool with the right parameters for a given dataset is a difficult task. Often different aligners perform better than others on parts of the same dataset, making it hard to choose the right tool and configuration.

Materials and Methods: We propose a new approach called meta-alignment, which combines the output of multiple sequence aligners to build the best possible alignment. Based on a score matrix, the best possible alignment for every aligned sequence is chosen among the different aligners.

Our approach has been tested on multiple simulated datasets, comparing the results of multiple sequence aligners with the results of meta-alignment which combines their individual results.

Results: We could show that combining the output of multiple aligners increases the amount of aligned sequences as well as increasing the amount of correctly aligned sequences.

This result especially holds true if the sequencing data contains a high amount of errors.

Conclusion: We could show that at the expense of analysis time, the result of sequence alignment can be improved by combining the results of multiple sequence aligners. The results are consistent throughout the different tests, and are especially pronounced for datasets with high error rates.

P16.59

Highlander: variant filtering made easy

R. Helaers¹, M. Vikkula¹;

Laboratory of Human Molecular Genetics, De Duve Institute (Université catholique de Louvain), Brussels, Belgium.

A substantial amount of data is being produced by NGS at ever-increasing rates. The technology generates considerable numbers of false positives, and their differentiation from true mutations is difficult. Moreover, the identification of changes-of-interest among thousands of variants requires annotation from various sources and advanced filtering capabilities. We developed *Highlander*, a Java software coupled to a local database, in order to centralize all variant data and annotations, and to provide powerful filtering tools that are easily accessible to the biologist. Data can be generated by any NGS machine and most variant callers. Variant calls are annotated using DBNSFP (providing predictions from 6 different programs, splicing predictions, prioritization scores from CADD and VEST, MAF from 1000G and ESP), ExAC, GoNL and SnpEff, subsequently imported into the database. The database is used to compute global statistics, allowing for the discrimination of variants based on their representation in the database. The GUI easily allows for complex queries to this database, using shortcuts for criteria such as "sample-specific variants", "variants common to specific samples" or "combined-heterozygous genes". Users can browse through query results using sorting, masking and highlighting of information. Highlander also gives access to useful additional tools, including visualization of the alignment, an algorithm that checks all available alignments for allele-calls at specific positions, and a module to explore the 'variant burden' gene by gene. Highlander is Open-Source (available at <http://sites.uclouvain.be/highlander/>) and also used by genetic centers of two university hospitals in Brussels, as well as in the BridgeIris project (<http://bridgeiris.ibsquare.be/>).

Improved infrastructure, user interface and genomic mapping in the NHGRI-EBI genome-wide association study (GWAS) catalog

J. Morales¹, T. Burdett¹, M. Cerezo¹, F. Cunningham¹, L. Gil¹, P. N. Hall¹, E. Hastings¹, L. A. Hindorf², H. A. Junkins², J. A. L. MacArthur¹, A. Milano¹, D. Welter¹, P. Flicek¹, H. Parkinson¹;

¹European Molecular Biology Laboratory, European Bioinformatics Institute, Hinxton, United Kingdom, ²Division of Genomic Medicine, National Human Genome Research Institute, National Institutes of Health, Bethesda, MD, United States.

The NHGRI-EBI GWAS Catalog (www.ebi.ac.uk/gwas) is a manually curated repository and visual summary of all published GWAS and SNP-trait associations. It was originally created by the NHGRI in 2005 and since 2010, has been produced jointly with EMBL-EBI. The Catalog covers a wide range of human diseases and phenotypes and an expanding number of ancestral backgrounds. As of February 2016, it contains 2,390 studies and 16,775 SNP-trait associations.

To make the GWAS Catalog more intuitive and further increase its utility in identifying and understanding disease loci, the resource has been undergoing a user-focused re-design since 2015. A new infrastructure, curation platform and search interface have been developed to improve functionality, expand scientific content and enhance data display. Specifically, the Catalog now provides enriched ontology-driven search capabilities, accurate display

of complex interaction studies and haplotype analyses, and structured ancestry information for studies published in 2011 and onwards. To complement these efforts, enhancements have been made to the genomic mapping of Catalog data. A new pipeline has been developed to improve mapping quality and provide additional mapping information. This new pipeline is designed to enable future integration of relevant data, such as linkage disequilibrium and regulatory information. The new user interface provides a range of data download options and is fully interactive, with links to related catalog data and to external resources, such as Ensembl. Ultimately, these developments will improve user-experience and facilitate efforts to identify causal variants and forward our understanding of human disease.

P16.62

pBRIT: advanced Prioritization of candidate genes using Bayesian Regression & Information-Theoretic approach

A. A. Kumar^{1,2}, L. V. Laer¹, B. Loeys¹, G. Vandeweyer^{1,2};

¹Department of Medical Genetics, University of Antwerpen, Antwerpen, Belgium,

²Biomedical informatics, Antwerp University Hospital, Antwerpen, Belgium.

Identification of top candidate genes from a pool of large data sets is computationally challenging. Existing prioritization tools typically utilize fusion of different annotation sources. However, these tools have important shortcomings. First, outdated annotation sources lead to annotation errors propagating to downstream analysis. Second, data fusion approaches generally fail to address sparsity and dependencies in annotation sources. Finally, high-throughput scalability is limited.

We propose pBRIT, a fast and adaptive tool integrating ten different annotation sources (PubMed, GO, HPO, Pathway, Interactions, Disease Ontologies, GAD, HuGe, BLAST, Mouse Ontologies) into the prioritization approach. Our hypothesis states that genes involved in similar disease types share similar "functional and phenotype" characteristics that can be used in disease gene identification.

pBRIT is based on an Information-Theoretic approach that models dependencies and sparsity of annotation sources for effective feature mining. Bayesian regression is applied to a training set, consisting of known disease genes, to learn a linear mapping between functional and phenotype annotations. Based on this mapping, candidate genes are ranked according to their relatedness to the training genes.

We validated pBRIT on 1154 genes from 12 different disease classes and compared performance against four existing tools (ChenB et al BMC Med Genomics 2015).

We achieved an average AUC of 0.91 as compared to 0.83 for the best scoring existing tool, indicating excellent sensitivity and specificity. Variation of average AUC score across 12 disease classes is minor, proving robustness of pBRIT. Moreover, pBRIT is fast and can be easily parallelized for analyzing thousands of samples.

P16.63

A methodology for the reliable analysis of amplicon-based NGS data

S. ZUCCA^{1,2}, M. Valente¹, S. Gagliardi¹, G. Grieco¹, J. Garau¹, M. Plumari¹, A. Asaro¹, P. Magni², C. Cereda¹;

¹Center of Genomics and post-Genomics, C. Mondino National Institute of Neurology Foundation, Pavia, Italy, ²Laboratory of Bioinformatics, Mathematical Modelling and Synthetic Biology, Department of Electrical, Computer and Biomedical engineering, University of Pavia, Pavia, Italy.

Background: Genetic testing plays an important role in the diagnosis and management of neurological disorders. Next generation sequencing (NGS) has revolutionized the traditional diagnostic approach, by inferring phenotypes directly from genetic testing. Amplicon-based targeted resequencing is a commonly adopted solution for NGS applications focused on specific genomic regions. NGS techniques generate high-throughput genomic data and specific analysis procedures (bioinformatic pipelines) are currently developed to extract the information of interest from the large amount of raw data generated as output.

Objective: Definition and validation of bioinformatic pipeline to analyze amplicon-based NGS data managing allele drop-out artifacts.

Methods: Seven True Seq Custom Amplicon Illumina gene panels specific for Parkinson Disease, Aicardi-Goutières Syndrome, Intracerebral Hemorrhage Diseases, Familial Hemiplegic Migraine, Leber Congenital Amaurosis and Septo Optic Dysplasia and Ocular Malformation were designed. A total of 309 samples was sequenced (Illumina MiSeq). A customized pipeline has been designed, implemented and validated to analyze data and manage allele drop-out (ADO) artifacts. Results have been compared to state-of-the-art techniques.

Results: Panel characterization in terms of coverage, read depth, number of variants found and allele drop-out potential impact has been carried out. Data analysis showed the presence of new non-synonymous mutations and classical pathogenic mutations. The most interesting data concerned the identification of one false negative mutation and 80 false positive, both confirmed via Sanger sequencing.

Conclusions: In this work, we focused on ADO-related artifacts and we developed a bioinformatic methodology to manage such issue, in order to maximize the information retrieved from available sequencing data.

P16.64

Droplet digital PCR (ddPCR)-based validation and genotyping of human inversions

M. Puig¹, S. Pacheco¹, D. Izquierdo¹, J. F. Regan², G. Karlin-Neumann², M. Cáceres^{1,3};

¹Institut de Biotecnologia i de Biomedicina, Universitat Autònoma de Barcelona,

Bellaterra (Barcelona), Spain, ²Digital Biology Center, Bio-Rad Laboratories, Pleasanton, CA, United States, ³Institució Catalana de Recerca i Estudis Avançats (ICREA), Barcelona, Spain.

The last years have seen a great interest in genomic structural variation and despite the difficulty of their study, an increasing amount of information is starting to accumulate about human inversions. However, one important limitation in the case of inversions is the presence of large inverted repeats (IRs) at the breakpoints, which precludes determining the orientation of the intervening region by most simple methods. Here we describe a new linkage-based application of droplet digital PCR (ddPCR) for the validation and genotyping of inversions mediated by IRs. First, we established that the strategy works for a few known human inversions with defined genotypes, including the well-characterized Chr. 17 inversion. Next, we developed ddPCR assays for a total of 18 inversions, with sizes ranging from 6.8 to 747 kb and IRs from 6.3 to 134 kb, and we genotyped them across 15 individuals of diverse origins. Our analysis allowed us to confirm all the tested inversions, except two, for which the inverted orientation was not found in our small sample or the assay could not distinguish both orientations. In addition, by comparing with previous data and independent replicates, we have shown that the technique is highly accurate and reproducible. This work illustrates the power of partitioning in ddPCR for diverse applications. Furthermore, it makes it possible for the first time to screen quickly a large number of samples to assess the potential functional effects and clinical implications of these rearrangements.

Support: European Research Council (ERC) Starting Grant (INVVEST) and Bio-Rad Laboratories.

P16.65

A novel unsupervised clustering approach with multiple data types to reveal fine-level structure

K. Chaichoompu^{1,2}, S. Tongshima³, P. J. Shaw⁴, A. Sakuntabhai^{5,6}, K. Van Steen^{1,2};

¹GIGA-R Medical Genomics, University of Liege, Liege, Belgium, ²Montefiore Institute, University of Liege, Liege, Belgium, ³Genome Technology Research Unit, National Center for Genetic Engineering and Biotechnology, Pathum Thani, Thailand, ⁴Medical Molecular Biology Research Unit, National Center for Genetic Engineering and Biotechnology, Pathum Thani, Thailand, ⁵Functional Genetics of Infectious Diseases Unit, Institut Pasteur, Paris, France, ⁶Centre National de la Recherche Scientifique, Paris, France.

Introduction: Several methods exist to identify population substructure that is due to shared genetic ancestry or regional proximity. These may be SNP-based or haplotype-based (Price et al. 2006, Lawson et al. 2012). Here, we present a flexible unsupervised clustering approach that is built on the ipPCA machinery (Intarapanich et al. 2009).

Methods: Our method supports both numeric and categorical data, and can be applied to panels of SNPs and/or haplotypes, or gene-based integrative summaries (Fouladi et al. 2015). Unlike ipPCA, our method involves an iterative process using binary and ternary splits based on multivariate Gaussian mixture modeling of PCs and Clustering EM (CEM) estimation as in (Lebet et al. 2015). To assess performance, we considered different simulated scenarios of $F_{ST}=[0.0005,0.006]$, 5,000-20,000 independent SNPs in HWE, 500-8,000 individuals, and 2-4 populations (Balding and Nichols 1995), with 100 replicates for each scenario. SNPs were treated as categorical or continuous (including ancestry-corrected SNPs). Haplotype-based runs used HapMap 3 data: CHB-JPT ($F_{ST}=0.007$) and CEU-TSI ($F_{ST}=0.004$).

Result and Conclusion: In simulated scenarios of extremely subtle structure ($F_{ST}=[0.0009,0.002]$), a population classification accuracy of 92.56% or greater was obtained, which was superior to ipPCA. Promising results to detect fine structure were also obtained in case of the HapMap populations. We believe that the ability of our approach to detect subtle structure, including outlier individuals, will be important in molecular reclassification studies of patients from whom underlying population patterns have been

removed.

P16.66

Genotyping of all public RNA-sequencing data for large scale trans-eQTL and ASE studies

N. P. de Klein¹, F. van Dijk^{1,2}, P. Deelen^{1,2}, M. Bonder¹, J. Karjalainen¹, P. Folkertsma¹, F. Kelpin^{1,2}, J. Jetten^{1,2}, A. Claringbould¹, M. Swertz^{1,2}, L. Franke¹;

¹University of Groningen, University Medical Center Groningen, Department of Genetics, Groningen, Netherlands, ²University of Groningen, University Medical Center Groningen, Genomics Coordination Center, Groningen, Netherlands.

Genome wide association studies (GWAS) and expression quantitative trait locus (eQTL) analyses have recently identified hundreds of disease- and expression-associated genetic loci. However, finding the causal SNP in a locus remains challenging, especially for rare variants. Additionally, studies show that eQTL effects are often cell type and tissue specific, so there is a need for large numbers of cell type specific samples. We have previously shown that public RNAseq data from 9500 samples can be used to identify eQTL effects for 8,034 unique genes (Deelen et al., 2015). By analyzing public RNAseq samples at an even larger scale, we will further increase our detection power.

For this purpose we developed a pipeline to genotype and quantify gene expression for all RNAseq samples in the European Nucleotide Archive (ENA). In August we retrieved 33,000 samples from ENA, which includes, among others, eight tissues with each over 500 samples. Of the 33,000 quantified samples, 9,000 have been haplotype-called and approximately 5,000 are of sufficient quality to continue with genotyping.

This strictly quality controlled re-use of freely available data will allow us to find many previously undetected allelic imbalanced SNPs and eQTLs. Moreover, we expect the sample size to be large enough to also find tissue specific trans-eQTLs and to contribute meaningfully in large scale trans-eQTL or ASE studies. By overlapping eQTLs with other sources of SNP information, such as methylation QTLs and DNaseQ QTLs, we can assist in the interpretation and prioritisation of likely pathogenic variants.

P16.67

GenCor - a tool for quality control and validation of whole-exome sequencing data through incorporation of array-based genotyping

S. Sivalingam¹, A. Hofmann¹, S. Herms^{2,1}, T. Kätzel¹, K. U. Ludwig¹, S. Heilmann-Heimbach¹, A. J. Forstner¹, M. M. Nöthen¹, P. Hoffmann^{2,1,3};

¹Institute of Human Genetics; Department of Genomics; Life & Brain Center; University of Bonn, Bonn, Germany, ²Human Genomic Research Group, Department of Biomedicine, University Hospital and University of Basel, Basel, Switzerland, ³Institute of Neuroscience and Medicine; Research Center Jülich, Jülich, Germany.

Whole-exome sequencing (WES) is the targeted sequencing of the protein-coding regions of the human genome. It is routinely used in human genetic studies and is a cost-efficient method for identification of rare variants. Many bioinformatics pipelines have been developed for variant calling in WES data. The performance of these pipelines depends on the applied algorithms and the implemented filter strategies. Given the complexity of large scale sequencing projects sample mix-ups can interfere with the final results. Here we present GenCor, a tool for quality control of WES data by incorporation of array-based genotyping.

For assessing the quality of WES data, GenCor calculates the genotype concordance between WES called variants and array-based genotypes. For the evaluation of GenCor, WES data from five human DNA samples were used. Exome capture was performed using SureSelectXT Human AllExon V5. Libraries were sequenced on a HiSeq2500 with 2x125 bp. Raw data were processed using the default BWA/GATK v.3.4 pipeline. The same set of samples was processed on Infinium CoreExome-24 BeadChip that comprises >269,000 markers.

In our data set no sample mix-ups in WES preprocessing could be identified. For variant quality control, an average agreement of 10,135 variants per sample between WES variants and array-based genotypes was observed. In total, 99% concordance of WES variants and array-based genotypes were found. We recommend the incorporation of array-based genotyping for improved quality control in WES projects. The GenCor tool can also be applied to whole-genome sequencing and is in principle compatible with genotype data from other genotyping platforms.

The Pan-Cancer Analysis of Whole Genomes (PCAWG) project has put together a cohort of nearly 3000 cancer whole genomes from 47 projects covering 20 different tissues. All of this data is processed in a homogeneous way, primarily to identify somatic mutations, allowing a wide range of analyses within and across cancer types. However, as the sequencing was done by different sequencing facilities, with varying protocols and over a long period of time, careful attention must be paid to the quality of the genomes.

To capture the quality of the genome sequences provided, the PCAWG Quality Control working group developed a framework to assess the quality and provide a succinct summary for PCAWG. The framework consists of five different measures of quality and a star rating system. The measures computed, for both the normal and the tumour genome, are the mean coverage, the evenness of coverage, somatic mutation calling power, paired reads mapping to different chromosomes, and paired reads of which one read fails to map. We summarised these into a star rating, with five stars representing the highest quality cancer genomes, passing all thresholds set for each measurement, and the rest on a descending scale in half star steps. The star rating system provides an easy to capture description of the quality of the sequences and flags problematic samples that should be eliminated from downstream use. We believe that this is an effective framework of quality measures for similar large-scale studies that look to use sequences from different sources.

Interactive software for the integrated analysis and identification of rare and undiagnosed diseases using NGS data

S. Pabinger¹, D. Katic², A. Krol³, T. Hirschmugl³, K. Boztug^{3,4,5}, A. Kriegner², K. Vierlinger¹;

¹AIT Austrian Institute of Technology, Vienna, Austria, ²Platomics, Vienna, Austria, ³CeMM Research Center for Molecular Medicine of the Austrian Academy of Sciences, Vienna, Austria, ⁴Department of Pediatrics and Adolescent Medicine, Medical University of Vienna, Vienna, Austria, ⁵CeRUD Vienna Center for Rare and Undiagnosed Diseases, Vienna, Austria.

The growing number of known rare diseases is estimated to be larger than 7,000, with more being discovered each day. Recent advances in next-generation sequencing (NGS) have revolutionized genomics allowing physicians and scientists to examine patients at an unprecedented. Nowadays, the challenge with NGS technologies is the meaningful interpretation and analysis of data.

Here we present an integrated solution that facilitates analysis and identification of potential causing mutations in rare and undiagnosed diseases from NGS-based genome sequencing studies. All complex analysis steps are abstracted from the end user and results are presented in an intuitive and interactive way. The application annotates identified variants with over 50 properties, including descriptive statistics, prediction scores, frequencies from public databases, and information from disease related databases. An interactive filtering, prioritization, and classification mechanism is included offering new ways to analyze variants. Family studies can be collectively analyzed using sophisticated querying and filtering methods including graphical representations of the relationships. The whole system is available as a web-based application integrated into the Platomics platform, which offers powerful features for heterogeneous data handling of samples, and performing analysis runs using optimized parameter settings.

As a proof of principle, using the new software we have analyzed targeted sequencing data in a cohort of patients with primary immunodeficiency disorders (PIDs) of unknown molecular origin. The new application will contribute to fast and reliable diagnosis, which could have a major impact for the PID patient treatment, as well as for personalized medicine.

Promoting data sharing and aiding variant interpretation in rare genetic disorders using the DECIPHER platform

G. J. Swaminathan, S. Brent, B. Hutton, D. Perrett, P. Bevan, M. Hurles, H. Firth; Wellcome Trust Sanger Institute, Cambridge, United Kingdom.

DECIPHER (<https://decipher.sanger.ac.uk/>) is a collaborative data sharing and interpretation platform that enables the secure upload, analysis and subsequent sharing of anonymised phenotype-linked patient variant data. DECIPHER is a worldwide user community of over 250 clinical genetics centres and research groups from over 40 countries that utilise the built-in tools for aiding the interpretation of variants as well as to discover other patients that share similar phenotype and genomic findings. As a collaborative tool, DECIPHER encourages contact between depositors and mediates contact requests from external users on cases that have been made open-access following informed patient consent. These have resulted in over 1000 peer-reviewed publications in scientific literature using DECIPHER data since 2010, leading to new discoveries that further understanding of gene-phenotype relationships. DECIPHER is also a founding member of the MatchMaker Exchange (MME) project (<http://www.matchmakerexchange.org/>), an initiative aimed at facilitating the matching of cases across geographically diverse locations and databases using standard procedures and a common application programming interface (API).

As part of our continuing efforts to make phenotype-linked variant data more meaningful in modern clinical genetics, we have developed new visualisation methods and interpretive tools within the DECIPHER platform. These include an interactive phenotype browser to explore and identify gene-phenotype correlations, dosage sensitivity scores for deposited copy-number variants, enabling the capture of extended patient information (growth curves, phenotype modifiers, development milestones) among others. Our presentation will highlight these new developments as well as focus on the implementation of the MME API within DECIPHER for data discovery and collaboration.

P16.71

Simple and effective variant filters to complement GATK-VQSR in WES data analysis

A. Larionov¹, M. Goldgraben¹, E. Fewings¹, J. Redman¹, P. Concannon², J. Bernstein³, WECARE, J. Hadfield⁴, D. Conti⁵, M. Tischkowitz¹;

Biostatistics, Memorial Sloan-Kettering Cancer Center, New York, NY, United States,

⁴Genomics Core, Cancer Research UK Cambridge Institute, Cambridge, United Kingdom,

⁵Division of Biostatistics, Department of Preventive Medicine, University of Southern California, Los Angeles, CA, United States.

Introduction: Standard settings recommended by GATK-Best-Practices for WES pipelines produce a large number of low quality variants that need further filtering before down-stream analyses. We describe a simple set of filters, which significantly improve variant quality metrics when added to the standard GATK-VQSR procedure.

Methods: Filtering options were compared on 3 WES germline datasets (Nextera-Rapid-Capture, HiSeq2500, PE75-125). Initially, a standard VQSR filtering was performed according to the current GATK-Best-Practices. Then this was complemented by reducing the padding allowance (to 10bp) and by adding two more hard filters for average DP (min 10x) and for QUAL (corresponding to TiTv>2).

Results: are summarised in table

	Dataset-A	Dataset-B	Dataset-C
N of samples	512	42	45
Raw variants called by GATK HC (default settings)			
N of variants	794,680	268,147	300,757
TiTv (SNPs)	2.11	2.35	2.26
Standard VQSR filtering and padding (SNP TS 97%, INDEL TS 95%, padding 100bp)			
N of variants	552,535	227,766	247,421
TiTv (SNPs)	2.31	2.47	2.38
Standard VQSR filtering + set of custom filters			
N of variants	239,100	90,332	108,698
TiTv (SNPs)	2.91	2.89	2.84

Plotting VQSLOD histograms was an informative addition to standard GATK practices. Clear multi-modal VQSLOD distributions confirmed suitability of VQSR for SNP-filtering. In contrast, VQSLOD distributions in INDELS showed that they cannot be successfully filtered by VQSR. Analysis of DP distributions made it clear that GATK-recommended padding (100bp around targets) was arbitrary and excessive. Reducing it to 10bp removed a high number of poor quality variants, while preserving essential splice sites. Distributions and utility of other filters have been also explored.

Conclusion: Three simple and intuitive hard filters added to the standard

GATK-VQSR procedure were sufficient to dramatically reduce the total number of variants and to improve their quality, making the metrics consistent with those expected in WES studies.

Whole Genome Sequencing of successfully aging long-lived Polish Caucasians and creation of a reference database

A. M. Boguszewska-Chachulska¹, E. Matczynska¹, P. Lyszkiewicz², M. Krawczyk¹, D. Kowalczyk², R. Szymanczak¹, A. Piotrowska³, M. Mossakowska⁴, M. Puzianowska-Kuznicka⁵, M. Zagulski¹;

¹Genomed SA, Warsaw, Poland, ²24 Godziny Sp. z o.o, Warsaw, Poland, ³Institute of Genetics and Biotechnology, Faculty of Biology, University of Warsaw, Warsaw, Poland,

⁴International Institute of Molecular and Cell Biology, Warsaw, Poland, ⁵Mossakowski Medical Research Centre, Polish Academy of Sciences, Warsaw, Poland.

The aim of the project was to characterise genome sequence variation in the Polish population and to combine it with collected clinical data for diagnostic and scientific applications.

Whole genomes of 130 successfully aging Polish 90+ years old subjects were sequenced with a mean 30x coverage using the Illumina technology. An in-house developed bioinformatic pipeline, including BWA, GATK and VEP, was applied to identify and annotate sequence variants.

The genomic data were combined with a large set of clinical and biochemical records. Mitochondrial genomes were analysed and identified variants, in 780 positions when compared to rCRS, were added to the database. An analysis of structural and copy number variations was performed.

Approximately 21.3 mln variants in the nuclear genome were found, including 16.9 million SNVs and 4.4 million indels. 72% of variants have been already present in the dbSNP database, 58% in the 1000 Genomes Project. Almost 4.0 mln novel SNVs and 2.5 mln novel indels were detected. The search for rare variants categorised by the Human Gene Mutation Database as disease-causing (DM) yielded 764 variants with MAF<0.5%, which corresponds to 6 distinct rare DM variants per each long-lived person.

The results of this project shed a new light on the effect of previously characterised disease-causing mutations on the individual health and life span. The reference database of successfully aging long-lived Caucasians constitutes a valuable tool for the clinical and prophylactic applications in the field of personalised medicine.

³Biotech Research & Innovation Centre (BRIC), University of Copenhagen, Copenhagen, Denmark.

Introduction: Recent studies have shown that retrotransposition activity is not limited to germline cells, but is also typical for somatic cells. Most research on somatic retrotransposition are focused on brain, since retroelement (RE) insertions are speculated to contribute to neurons plasticity. Whereas somatic RE insertions are very rare, their identification is complicated even with the use of the most robust high-throughput sequencing platforms. Thus, several hybridization and amplification-based methods are used to target sequencing to selected subgroups of REs. However, none of these approaches could provide specific enrichment for somatic insertions. We developed a new normalization-based method to enrich for somatic RE insertions.

Materials and methods: Sequencing libraries were prepared from the DNA sample of 50000 nuclei from human brain cortex. First, the selective amplification with AluYa5-specific primer was performed. The amplicon was then subjected to two rounds of normalization using duplex-specific nuclease. Sequencing data was analyzed by unique bioinformatics pipeline to generate the list of high-confident somatic Alu insertions.

Results: The use of genomic normalization increased the number of fragments, flanking somatic Alu insertions in the sequenced sample by 20-fold, and the number of identified somatic insertions 6,5-fold. We identified 399 somatic insertions, 65 of which were present in more than one cell.

Conclusions: The developed approach could significantly increase the efficiency of somatic REs identification in normal and malignant cells. Moreover, the use of molecular identifiers provides the direct estimation of the number of cells bearing a particular somatic insertion.

Identification of Rheumatoid Arthritis specific pathways from exome data in multiplex families.

M. Veyssiere¹, J. Perea¹, L. Michou², A. Boland-Auge³, V. Meyer³, J. Deleuze³, F. Cornelis⁴, E. Petit-Teixeira¹, V. Chaudru¹;

¹GenHotel-EA3886 - Evry University, Evry, France, ²Division of Rheumatology, CHU de Québec, Department of Medicine, Québec, QC, Canada, ³Centre National de Génotypage, Genomic Institute, CEA, Evry, France, ⁴GenHotel-Auvergne, EA4679, Auvergne University, Genetic Department, CHU Clermont-Ferrand, Clermont-Ferrand, France.

Introduction: The genetic component of Rheumatoid Arthritis (RA) is not fully defined. Identification of rare variants through NGS analysis could help us to characterize a part of the missing heritability.

Materials and Methods: To identify rare RA-associated variants, we have analyzed exome sequences from 30 individuals (22 RA and 8 unaffected subjects) belonging to families with at least four cases of RA and/or other autoimmune diseases. Exons were captured with Agilent SureSelect Human All Exon V5 kit and sequenced with an Illumina HiSeq2000 sequencer. After alignment, targeting of captured regions, variant calling and quality filtering, we selected variants with allele frequency lower than 1% or absent in databases. We then performed association studies (Fisher test) between RA and pathways enriched in genes containing RA-specific variants (identified with DAVID).

Results: We identified 262030 rare variants carried by at least one individual. In order to conduct pathway analysis, we selected variants present in all RA cases of a same family but absent in all other individuals (n=607 variants). The number of variants found in a particular family varied from 12 (2%) to 132 (22%). All the variants, spread across 580 genes, allowed us to identify 2 pathways significantly associated with RA: the cadherin signaling pathway (PFisher=4*10⁻³) and the focal adhesion pathway (pFisher=4*10⁻²).

Conclusions: Analysis will be completed by taking into account the RA status with or without other autoimmune diseases. Selected variants will be further validated by genotyping all available members of each family in order to perform segregation analysis.

Regulation of transcribed intergenic regions in human substantia nigra and putamen

M. S. Gueffi^{1,2}, J. Vandrovcova^{1,2}, J. A. Botia^{1,2}, K. D'Sa^{1,2}, M. E. Weale², J. A. Hardy¹, M. Ryten^{1,2};

¹Department of Molecular Neuroscience, UCL Institute of Neurology, London, United Kingdom, ²Department of Medical & Molecular Genetics, King's College London, London, United Kingdom.

Expression Quantitative Trait Loci (eQTL) studies are a successful approach to study how genetic variation influences transcription. A current limitation in most eQTL studies is that they rely on annotated references to measure transcript abundance. While existing annotation is likely to be accurate for many human tissues, the complexity of gene expression and splicing in human brain implies that existing references are less accurate, and this view is supported by recent RNA-sequencing (RNA-Seq) analyses. In this study, we investigate regulation of transcribed intergenic regions in two brain tissues: putamen and substantia nigra. We performed RNA-seq on healthy post-mortem brain tissues from the UKBEC dataset to identify and quantify transcribed regions in a reference-agnostic manner with Derfinder R package. After filtering steps, we combined the abundance of the intergenic transcribed regions with genotype information to perform cis-eQTL mapping analysis, detecting 1954 independent cis-acting eQTL signals in putamen and 744 in substantia nigra. Finally, applying exon-junction identification and co-expression analysis, we investigated the independence of these regions from the nearest annotated genes. Using these approaches, we identified the existence of intergenic transcribed regions with high correlation with the nearest gene and shared eQTLs suggesting incomplete annotation of known genes. However, we also identified transcribed intergenic regions with independent eQTLs suggesting the existence of novel regulated transcribed regions. Both types of genomic regions represent as yet unexplored candidate regions for the identification of potentially pathogenic variation. Therefore, these findings are of direct relevance to the prioritisation of variants in clinical diagnostics.

A critical comparison between Sanger and Next Generation Sequencing

H. Fridman^{1,2}, M. Einhorn³, Y. Porat³, C. Bormans⁴, A. Bormans⁴, L. Sanchez⁴, E. Levy-Lahad^{1,2}, D. Behar^{1,3,4};

¹Shaare Zedek Medical Center, Jerusalem, Israel, ²Hebrew University-Hadassah School of Medicine, Jerusalem, Israel, ³Data Analysis Group, Genoox, Tel Aviv, Israel, ⁴Genomic Research Center, Gene by Gene, Houston, TX, United States.

Background: Clinical uses of Next Generation Sequencing (NGS) are continuously expanding. However, unbiased systematic comparisons of performance of NGS and Sanger-sequencing is still lacking. We present a comparative evaluation based on ~1.3% of the exome of a single individual.

Materials and Methods: Genomic DNA was extracted from peripheral leukocytes. Sanger-sequencing was performed for 258 genes. Whole exome sequencing (WES) was done on the Illumina HiSeq2500 using the Nextera (FC-140-1006) capture kit (coverage 70x). WES data was analyzed using standard NGS analytic pipelines with predefined quality thresholds.

Results: Sanger-sequencing encompassed a total of 4,755 exons spanning 1,212,319 bp. The Nextera capture kit overlaps 99.4% of the coding sequence and 94% of the coding sequence including intron/exon boundaries (±8bp). Within this extended overlap region, 427 and 430 variants were detected by Sanger-sequencing and NGS, respectively. 419 variants were concordant in both platforms. Of the eight variants identified by Sanger-sequencing only, four were in genomic positions with ≤2 NGS coverage, and four were not detected despite good coverage. A total of 11 variants were identified only by NGS. Further results from buccal-driven WES and the Agilent (SureSelectQXT) Capture kit will be presented.

Conclusions: The overall concordance between Sanger-sequencing and NGS was 98.1% (419/427). On an exome-wide scale, we extrapolate that ~150-200 variants would be discordant. Sanger-only variants may be explained by NGS-coverage failure, either specific or random. NGS-only variants may reflect Sanger-sequencing primer binding-sites polymorphisms, or mosaicism. Single-platform variants may also represent errors. Geneticists should be aware of these limitations.

P16.78

Bioinformatics analysis of schizophrenia risk variants: a novel methodology for uncovering potentially causal variants within a locus

E. Jamieson^{1,2}, B. D. Collier³, C. D. Marren⁴, D. J. Scherschel⁴, E. Eastwood⁴;

¹Eli Lilly and Company, Surrey, United Kingdom, ²University of Glasgow, Glasgow, United Kingdom, ³Lilly, Indiana, IN, United States, ⁴Lilly, Surrey, United Kingdom.

Introduction: Genome-wide association studies can be difficult to interpret because the unit of association is genetic polymorphism which marks regions of the genome rather than specific genes. We present a methodology which combines multiple bioinformatic variant effect prediction tools to create a single score used to identify potentially causal variants within a GWAS locus, to assist the SNP-to-gene mapping process. **Materials and methods:** A KNIME workflow was used to implement a novel variant-scoring methodology which combines the weighted effects of variants in a locus to produce a list of genes ranked in order of their predicted contribution to schizophrenia risk. Factors used to determine the weighted effect include a GWAS p-value and a PHRED-scaled CADD score. **Results:** TCF4 and FES, both strongly probably schizophrenia risk genes, appear within the top three positions in the ranked gene list, providing confidence that the method is useful in SNP-to-gene mapping and ranking associations. TCF4 has a large number of non-coding variants in its vicinity, of which only rs143743309 scores highly, whereas FES has three highly-scoring variants in its locus. Two of these are missense variants and one is a frameshift. In this case the frameshift variant is likely to be causal of the association at the locus. **Conclusions:** This methodology will improve our understanding of what causes a locus to be associated with risk for complex genetic diseases, along with aiding in assessment of which gene is affected to allow us to approach drug target discovery with better validated genetic evidence.

P16.79

Optimization of RNA isolation from small volumes of serum to enable small RNA sequencing

R. Pluvinet, G. Rech, L. Sumoy;

IMPPC, Badalona, Spain.

Introduction: Circulating miRNAs have been extensively explored for their use as biomarkers of disease. The aim of the present study was to optimize procedures for RNA extraction from low volume human serum samples for subsequent library preparation for small RNA-seq.

Materials and Methods: We compared two different methods of RNA extrac-

tion (Qiagen miRNeasy serum/plasma kit vs Exiqon miRCURY RNA Isolation kit-Biofluids), with different starting serum volumes (600, 400, or 200 µL) and different carriers (MS2 RNA vs glycogen). Quality control for hemolysis and intersample normalization was performed with the Exiqon serum QC qPCR panel.

Three different commercially available small RNA-seq library kits were tested (Illumina Truseq small RNA vs New England Biolabs NEBNext Multiplex small RNA Library prep kit vs BiooScientific NEXTflex small RNA sequencing kit). Pooled libraries were size-selected using the Pippin Prep system, quantified by KAPA qPCR and sequenced on an Illumina HiSeq2500 sequencer with 1x50 nt single reads and analyzed with sRNAbench v07\14 software. Results: The best miRNA extraction yield was obtained when 200 µL of serum were processed using Exiqon's miRCURY kit. NEBNext library preparation kit produced the highest miRNA representation in small RNA-seq results. Illumina's TruSeq showed the highest rate of mappable reads with a better adjustment in size distribution around the 22nt expected in mature miRNAs.

Conclusions: Adaptation of standard commercial protocols allows quantitative assessment of the circulating miRNAs by small RNA-seq from low volumes of serum. This has application to studies where limited amounts of sample are available.

High-Throughput Isolation and Selection of Single Cells using the ICCELL8™ Single-Cell System

M. Srinivasan, A. Mir;

WaferGen BioSystems, Fremont, CA, United States.

Single-cell RNA-seq analysis has been used extensively to identify new cell types in complex tissues based on gene expression differences. ICCELL8™ Single-Cell System utilizes imaging to identify single-cells and selectively process only those single-cells for RNA-seq applications with >98% accuracy. The ICCELL8™ System is comprised of a scalable micro-fabricated metal scaffold containing 5,184 nano-wells (ICCELL8™ chip), a multi-sample nanodispenser (MSND) that precisely dispenses reagents and fluorescently-labeled cells into the nano-wells, an imaging station to image all 5,184 wells in 3 min per channel, and CellSelect™ software to unambiguously identify and select wells that contain single cells for further processing for RNA-seq applications. The ICCELL8™ chip platform is proven for its flexibility in processing up to 8 samples in a single chip as well as batch-processing precious samples (such as freshly-excised human tumors) in up to 10 chips a day to yield ~15,000 cells/day. Using human-mouse mixed species experiments, we will present data to

1. Validate the reproducible dispensing of individual cells at Poisson distribution.
2. Demonstrate CellSelect™ software ability to unambiguously identify single-cell containing wells.
3. Establish the increased diversity of genes captured per cell.

FindTranslocations - a structural variant calling toolkit

J. Eisfeldt¹, F. Vezzi², D. Nilsson¹, A. Lindstrand¹;

¹Karolinska institutet, Stockholm, Sweden, ²Stockholms universitet, Stockholm, Sweden.

A structural variant is traditionally defined as a balanced or unbalanced genetic rearrangement larger than 1kb but recent advances in genetic technology has enabled the detection of increasingly smaller rearrangements. In genetic diagnostic, currently applied techniques such as FISH and microarray studies have limited resolution. Massively parallel whole genome sequencing (WGS) is a promising technique that may be used to identify a large proportion of genomic structural variation in a single experiment. However, the detection of structural variants from WGS data is complicated by the vast amount of normal variants and reference errors and currently relies on using multiple variant callers, increasing the overall computational cost. FindTranslocations is a structural variant detection algorithm using discordant read pairs and coverage information to identify balanced and unbalanced structural variants while consuming less than 5 cpu hours per 30X whole genome sample. It contains a built in database function allowing the user to create local variant frequency databases, that may be used to filter out rare variants or detect variants that are common within a group. FindTranslocations goes beyond mere structural variant calling providing positional information for specific rearrangements to help make a correct interpretation of the clinical significance. We have used FindTranslocations in a validation set of 61 samples with previously identified clinically relevant structural variants for which we have 30x WGS data. FindTranslocati-

ons has a 89% sensitivity for unbalanced rearrangements (35/40 detected duplications, 21/23 detected deletions) sized from 5 kb to 5000 kb and 84% sensitivity for balanced rearrangements (21/25 detected).

France, ⁴HelixVenture, Mérignac, France, ⁵Institut de cancérologie Lucien Neuwirth,

Saint Priest en Jarez, France, ⁶INTS - Institut National de la Transfusion Sanguine, Paris,

France.

Introduction: Blood Platelets in stored blood components (PCs) for transfusion release panoply of molecules thought to be associated with transfusion adverse events (AEs). Successive measures taken overtime to minimize AEs proved to be successful but PC transfusion still leads to unwanted inflammatory reactions in a certain number of patients. The rationale of this study is to decipher the transcriptome of PCs involved in acute transfusion reactions (ATRs).

Methods: Total RNAs were extracted from 5 leukodepleted PCs implicated in ATR and 5 PC matched controls. We investigated the transcriptome using the Proton platform (Ion torrent, Life Technology). Data were mapped using CLC Bio software (Aarhus, Denmark). Transcript were counted using HTSeq-count software. Differentially expressed genes were identified using DESeq2 package (Bioconductor) and then underwent a functional enrichment analysis by PANTHER (www.Pantherdb.org).

Results: The analysis showed a highly complex transcriptional setting. The analysis of upregulated genes identified mainly two enriched pathways related to platelet activation (e.g. Integrin signaling pathway - P00034) and inflammatory process (e.g. chemokine signaling pathway - P00031). Functional analysis considering the Biological process identified proteins related to platelet metabolic and cytoskeletal rearrangement (e.g. GO: 0008152; GO: 0050896) as most enriched and then followed by apoptotic process (GO: 0006915).

Conclusion: Our results suggest that platelets are more activated in ATR inducing PCs. The activation of chemokine signaling pathway could explain findings of several single studies that identified biological response modifiers upregulated in PCs involved in ATR.

Integrated variant annotation and filtering using R/Bioconductor and the VariantFiltering package

D. M. Elurbe¹, P. Puigdeval¹, M. Milà², R. Castelo²;

¹Radboud University, Nijmegen, Netherlands, ²Universitat Pompeu Fabra, Barcelona,

Spain, ³Hospital Clínic, Barcelona, Spain.

The steady decrease in DNA sequencing costs facilitates the adoption of whole-exome sequencing (WES) in clinical genetic testing settings. The identification of disease-causing non-synonymous coding rare variants from WES data is straightforward with currently available software and databases. However, the larger number of diseased individuals being genetically profiled using WES technology also increases the number of pathogenic variants that remain uncharacterized. This typically happens with variants that do not appear in curated databases and occur in non-coding regions, often having a reduced penetrance in the population. To approach the identification of such pathogenic variants, approaches based on the integration of multiple annotation sources and filtering strategies are needed. One of the software platforms which can potentially offer the required flexibility and interoperability for this goal is the R/Bioconductor project and its DNA variant analysis infrastructure. On top of this infrastructure, we have built the VariantFiltering package with the aim of facilitating the annotation and filtering of both, coding and non-coding genetic variants. The main features of this software are: 1. integration of multiple annotation sources tracing provenance; 2. programatic filtering with multiple strategies for both coding and non-coding variants, such as inheritance model, protein damage potential, minor allele frequency, gene and nucleotide conservation, (cryptic) splice site strength, etc., which can be extended by the user; 3. minimization of end-user scripting tasks with an interactive shiny web app.

ALLEXES: A variant reference data repository for clinical routine diagnostics

B. Liesfeld¹, R. Abou Jamra², S. Leye¹, R. Ewald¹;

¹Limbus Medical Technologies GmbH, Rostock, Germany, ²Institut für Humangenetik, Universitätsklinikum Leipzig, Leipzig, Germany.

The ever increasing number of detected variants poses great challenge for routine diagnostics. Many attempts have been made to address this problem. Current approaches have several shortcomings: 1) genotypic and phenotypic information of patients is not captured comprehensively, 2) handling continuously changing variant information is not supported, and 3) manual data curation is required, which adds an unacceptable effort to the clinical routine. As a result, most data silos are either short-lived or contain outdated information.

We evaluate the ALLEXES system that integrates variant annotation and curation into automated clinical processes from VCF file to the medical report. A cohort study of whole exome cases from different institutions was processed. Aggregated genotypic and phenotypic information was shared in an automated fashion. ALLEXES is a regulated medical device which is compliant with harmonized international standards for medical device software and usability.

The time required to evaluate clinically relevant variants was reduced significantly compared to conventional annotation and reporting methods. Allele frequency and clinical information related to variants were available in near-time to all participants in the ALLEXES network. Confidentiality of patient data was maintained.

Existing and upcoming new regulation of genetic testing imposes increasingly strict rules on data handling. On the other hand, the overwhelming amount of variant data can only be tackled by leveraging information that is currently distributed across many isolated data silos. This study demonstrates that suitable technology is available to tackle the challenge of interpreting variants while being compliant with strict regulations regarding security and patient safety.

Benchmarking quality and performance of WES/WGS variant calling workflows from next-generation sequencing data

S. Laurie^{1,2}, M. Fernandez-Callejo^{1,2}, S. Marco-Sola^{1,2}, J. Trotta^{1,2}, S. Heath^{1,2}, S. Beltran^{1,2};

¹Centro Nacional de Análisis Genómico (CNAG-CRG), Center for Genomic Regulation, Barcelona Institute of Science and Technology (BIST), Barcelona, Spain, ²Universitat Pompeu Fabra (UPF), Barcelona, Spain.

A number of factors must be taken into account when establishing a variant calling pipeline for high-throughput processing of whole exome (WES) and whole genome (WGS) sequencing reads. These include accuracy, time required, RAM and CPU usage, and ease of implementation. We have tested combinations of two aligners (GEM3 and BWA-MEM), and 3 variant calling algorithms (GATK Hapotype Caller, SAMtools and FreeBayes) for both WES and WGS experiments on the HapMap sample NA12878. We used publicly available Illumina Platinum WGS reads, and WES libraries generated and sequenced in-house for NA12878 as input. Accuracy was determined through comparison with a gold standard set of variant calls published by NIST. In addition we recorded the amount of time required, and estimates of memory and CPU usage for each step of the workflow. In general we find a relatively small number of differences between the variants identified using each workflow, with concordance with calls in the NIST set generally in excess of 99% for SNVs and 98% for short indels. However, we find large differences in demands on computing resources between the algorithms, which affects time and cost of analyses. In addition we have observed cases where there is good evidence for a variant position that is not recorded within the NIST reference variants set, indicating that while a valuable resource, it is not perfect. It should also be noted that there remains a large part of the genome (15-25%) where it is unclear if current algorithms can successfully identify short-variants.

MutationInfo: A tool to quick retrieve genomic position from HGVS variants

A. Kanterakis, E. Kartsaki, G. Potamias;

Foundation for Research and Technology Hellas, Heraklion, Greece.

Today one of the most prominent nomenclatures for reporting genomic variants is HGVS (<http://www.hgvs.org/mutnomen/>). According to this, variations are reported in alliance to their relative position in a reference sequence. This sequence can be a transcript, a chromosome, a database accession number, just to name few. The complexity of HGVS and the sub-

sequent non-adherence from researchers makes the unique genomic positional identification of a variant, a cumbersome task. The most known tool that performs this task is mutalyzer (www.mutalyzer.nl) that requires strict HGVS adherence and is able to identify only 43% of the variants reported in PAH, BRCA2 and HbVar databases. Here we present MutationInfo, a tool that performs various heuristics in order to perform the same task through less strict and fuzzy methods. These heuristics include (1) the lookup in databases like UCSC tables, Variant Effect Predictor, mutalyz and LOVD, (2) the use of existing HGVS parsers like biocommon/hgvs, (3) correct for common HGVS mistakes and (4) perform BLAT alignment search of the fasta sequence in the reference assembly. We also report the significant increase of identified variants on public databases including pharmGKB. We conclude that this tool can improve the identification of already reported variants in sequencing studies and therefore contribute to the clinical application of genetics.

A whole genome reference panel for South European Populations

M. Cocca¹, M. Mezzavilla², C. Barbieri³, C. Sala³, N. Soranzo^{4,5}, D. Toniolo³, P. Gasparin²;

¹University of Trieste, Trieste, Italy, ²Experimental Genetics Division, Sidra, Doha, Qatar, ³San Raffaele Scientific Institute, Division of Genetics and Cell biology, Genetics of common disorders Unit, Milano, Italy, ⁴The Wellcome Trust Sanger Institute, Wellcome Trust Genome Campus, Hinxton, United Kingdom, ⁵Department of Haematology, University of Cambridge, Cambridge, United Kingdom.

Imputation with large reference panels from whole genome sequenced DNAs is a common practice to improve variant coverage in a study sample, particularly for rare variants. Incorporating a large number of populations with different ancestries, as in 1000G, increases the accuracy of imputation but it was also demonstrated that adding haplotypes belonging to the same ancestry of the study sample will increase accuracy even more.

However in the current 1000G reference panel used for imputation there are few South European populations, which could hinder the imputation effort for populations close to the Mediterranean area.

To address this issue we generated low coverage WGS data of 926 samples belonging to 3 villages from Northern and Southern Italy participating to the INGI network. We describe here a reference panel of 1852 haplotypes composed by 20,829,813 SNPs and 2,490,202 INDELS selected after passing a strict QC: 43% of the selected sites are shared among all three Isolates, with 41 to 50% low frequency variants (MAF<1%) private to the INGI-cohorts with respect to the EUR samples from 1000G Phase 3.

We show that joining this panel with the standard 1000G reference, as well as with other references deriving from Northern European populations, increases imputation's accuracy of low frequency variants in Italian genotyped cohorts and possibly in other southern European cohorts: we noticed an 11% increment on average quality, using the merged INGI-1000G panel. This new resource will allow researchers to carry out imputation and GWAS for South European population in a more efficient way.

Two thousand Japanese whole genome reference panel in Japan and Bioinformatics

M. Nagasaki, Y. Kawai, K. Kojima, T. Mimori, K. Misawa, T. Shibata, Y. Yamaguchi-

Kabata, Y. Sato, R. Yamashita, N. Fuse, S. Ito, N. Nariai, Y. Kuroki, I. Danjoh, S. Saito, F.

Katsuoka, J. Yasuda, M. Yamamoto, ToMMo Japanese Reference Panel Project;

Tohoku University, Sendai, Miyagi, Japan.

Introduction: Tohoku University Tohoku Medical Megabank Organization (ToMMo) located at the north-eastern Japan is developing a biobank with 150,000 volunteers that combines medical and genome information during the process of rebuilding from the Great East Japan Earthquake on Mar/11/2011. One of the missions of ToMMo is to reveal a fine genetic architecture of Japanese population to tackle the further genome wide associate study analysis by combining the knowledge, which is daily accumulated in this project, e.g. questionnaire data, physiological data, medical treatment records and other omics data from serum, plasma and immortalized lymphocytes.

Materials and Methods: We have created the reference panel with one thousand samples to cover MAF > 0.5% variants including short insertion, deletion, and large structural variants in Japanese for constructing the Japanese whole-genome reference panel (1KJPN). Currently we are constructing the second reference panel with two thousand samples (2KJPN). In these panels, to minimize the biases caused by the different equipment, protocol and bioinformatics analysis, we performed whole genome sequencing of thousands samples with 30x high coverage using the HiSeq 2500 rapid run mode and analyzed by the same bioinformatics pipeline.

Results and Conclusions: We demonstrate our bioinformatics analyses, e.g. HLA-typing and CNVs, preliminary findings to 1KJPN and 2KJPN, and another effort to construct Japanese reference genome with thousands novel insertions in genome wide.

This work was supported (in part) by Tohoku Medical Megabank Project (Special Account for reconstruction from the Great East Japan Earthquake).

KGSeq: a software platform for a comprehensive downstream analysis in large-scale whole genome sequencing studies

J. Li, Y. Q. Song, P. Sham, M. X. Li;

The University of Hong Kong, Hong Kong, Hong Kong.

With the development of next-generation sequencing (NGS) technology, the cost of sequencing has tremendously decreased, which promotes the application of many sequencing methods in genetic studies, disease diagnose and so on. Especially, the whole genome sequencing (WGS) is a very promising method for geneticists because it can provide the comprehensive information of genotypes in both coding and non-coding regions, common and rare variants. However, the Big Data problem emerged at the same time due to the large-scale dataset of WGS and currently no professional tool can solve it at all points. KGSeq is a software platform for comprehensive downstream analysis of whole-genome sequencing data. It is comprised of six functional modules: quality control, filtration, annotation, pathogenic prediction at variants, pathogenic prediction at genes and statistical tests, which can meet almost all researchers' demands for WGS data analysis. The original bit-block genotype storage mode can save 90% space and be much faster than existing tools. The gap-filled annotation rescue over 1000 exonic variants that are ignored by other tools. Moreover, KGSeq reads the compressed variant call format (VCF) file by blocked GNU Zip format in parallel and parses the byte input stream directly. A heuristic algorithm is also used to facilitate the extracting information from text files. Finally, we compared KGSeq with the existing tools by 1000 Genomes Project AFR panel, and KGSeq always provided a more reasonable annotation and had a higher consistency with dbSNP database.

Alteration of *Sus Scrofa* duodenum gene expression profile as response to a low dose of ZEA: extrapolation and analysis in the context of human health

C. Braicu^{1,2}, R. Cojocneanu-Petric¹, A. Jurj¹, D. Marin³, I. Taranu³, I. Berindan-Neagoe¹;

¹Research Center of Functional Genomics, Biomedicine and Translational Medicine, Iuliu Hatieganu Univ, Cluj-Napoca, Romania, ²Department of Functional Genomics and Experimental Pathology, The Oncological Institute "Prof. Dr. Ion Chiricuta", Cluj-Napoca, Romania, ³Laboratory of Animal Biology, National Institute for Research and Development for Biology and Animal Nutrition, Balotesti, Romania.

Introduction: Zearalenone (ZEA) is a mycotoxin produced by *Fusarium* species, initially capturing the attention for its function of estrogenic mimic role. But the mechanism of this mycotoxin remains unclear. Therefore we evaluated the effect of 100ppb ZEA on transcriptomic pattern at duodenum level, first physical and chemical barrier in animals and humans.

Material and methods: The alteration of gene expression pattern caused by Zea exposure at *Sus scrofa* duodenum was done using a custom microarray design (AMADID: 056850, Agilent technology). Data were analyzed with Features Extraction and Gene Spring. Then the data were extrapolated to human orthologues and analyzed in the context of human health using Ingenuity Pathways Analysis (IPA). The validation was done for six genes by qRT-PCR and three cytokines by ELISA.

Results: We had 1576 upregulated transcripts and 2446 downregulated transcripts as response to ZEA exposure at duodenum level considering as cut-off value fold-change \pm 2 and p-value<0.05. The qRT-PCR and ELISA data confirmed the microarray results. The extrapolated human orthologues used for IPA analysis, revealing the activation of immune response, mitogen-activated-protein kinases, Toll-like receptors and carcinogenic pathway.

Conclusions. The effects of ZEA are complex at duodenum level, being connected not only with the alteration of the immune response but also the activation of the genes related to early colorectal carcinogenesis. The effects concerning the carcinogenic risk represent an important issue for future studies, particularly in the context of co-occurrence with other mycotoxins or environmental risks factors, targeting multiple genetic alterations.

DNA methylation and hydroxymethylation patterns in non-cultured human uterine leiomyoma cells

A. S. Koltsova^{1,2}, A. A. Pendina^{1,2}, O. A. Efimova^{1,2}, A. V. Tikhonov^{1,2}, N. S. Osinovskaya², O. V. Malysheva², N. Y. Shved², T. V. Kuznetsova^{1,2}, V. S. Baranov^{1,2};

¹Saint Petersburg State University, St. Petersburg, Russian Federation, ²D.O.Ott Research Institute of Obstetrics, Gynecology and Reproductology, St. Petersburg, Russian Federation.

We have studied DNA methylation and hydroxymethylation patterns in cells from human histologically confirmed uterine leiomyomas (ULs). We performed our study in non-cultured cells because culture conditions may alter hydroxymethylation pattern. UL samples were obtained by surgery, suspended in collagenase type IV solution, then treated with hypotonic solution (0.9% sodium citrate + 0.55% potassium chloride) and fixed on slides with methanol:acetic acid, 1:1. 5-methylcytosine and 5-hydroxymethylcytosine were detected by indirect immunofluorescence.

We compared hydroxymethylation patterns between ULs positive and negative for MED12 mutation, as well as between ULs excised in follicular and lutein phase. In all 22 ULs, we detected 3 types of nuclei: strongly hydroxymethylated, averagely hydroxymethylated, and non-hydroxymethylated. Hydroxymethylation level was estimated visually by fluorescence intensity and then assessed in ImageJ. When comparing hydroxymethylation patterns between ULs positive and negative for MED12 mutation, no significant difference was detected (Unpaired t-test with Welch's correction, P=0.7854). When comparing hydroxymethylation patterns between ULs excised in different menstrual phases, we found that 5-hydroxymethylcytosine level was significantly higher in ULs excised in follicular phase. We have shown a negative correlation between the 5-hydroxymethylcytosine level and the day of menstrual cycle at the time of UL excision (Spearman correlation coefficient=-0.473, P<0.05). DNA methylation was detected in all nuclei of all 22 ULs and difference among nuclei was not pronounced.

Our results suggest that genome activity in ULs, determined by their hydroxymethylation pattern, varies during menstrual cycle.

P17.02

ADP-ribosylation of distal cis-regulatory chromatin regions of proinflammatory cytokines as a mechanism, which determines their transcription in proinflammatory macrophages M1

E. Wiśnik, A. Robaszkiewicz;

Department of Environmental Pollution Biophysics, Institute of Biophysics, University of Lodz, Lodz, Poland.

Introduction: Proinflammatory macrophages M1 derived from are responsible for the secretion of proinflammatory factors such as cytokines attracting other immune cells to accumulate in the site of the inflammation. As the differentiation and polarization of macrophages is followed by extensive chromatin remodeling we checked whether transcription of cytokines is solely regulated by NF- κ B (p50/p65) binding to proximal cis-regulatory elements or involves enhancers and epigenetic events such as ADP-ribosylation carried out by PARP1 within these regions.

Materials and Methods: Human monocytes isolated from peripheral blood were differentiated and polarized with GM-CSF, while human monocyte cell line THP1 with PMA. Expression of macrophage markers and cytokines was analyzed with real-time PCR, association of NF- κ B with chromatin and epigenetic modifications with ChIP, gene silencing with siRNA/shRNA. The interaction of chromatin proximal and distal regulatory elements was studied with 3C method.

Results: The differentiation of macrophages is accompanied by activation of distal regulatory elements and their ADP-ribosylation inhibition of which enhances NF- κ B (p50/p65) binding to chromatin and expression of cytokines. The silencing of lineage determining factor - PU.1, which enables NF- κ B (p50/p65) interaction with enhancers restores the monocyte-like gene expression. Moreover, inhibition of ADP-ribosylation as well as PARP1 silencing facilitates the chromatin looping resulting from enhancer interaction with cytokine promoters.

Conclusions: ADP-ribosylation of chromatin distal regulatory elements, undergoing activation during terminal macrophage differentiation, regulates the interaction of NF- κ B with these regions.

Investigating the involvement of long non coding RNA in ALS

S. Gagliardi¹, S. Zucca^{1,2}, O. Pansarasa¹, L. Diamanti³, M. Bordoni^{1,4}, M. Valente¹, M. Ceroni³, C. Cereda¹;

¹Center of Genomics and post-Genomics, C. Mondino National Institute of Neurology Foundation, Pavia, Italy, ²Laboratory of Bioinformatics, Mathematical Modelling and Synthetic Biology, Department of Electrical, Computer and Biomedical engineering, University of Pavia, Pavia, Italy, ³Neurology Department, IRCCS National Neurological Institute C. Mondino, University of Pavia, Pavia, Italy, ⁴Department of Brain and behavioral science, University of Pavia, Pavia, Italy.

Introduction: The importance of various classes of regulatory non-coding RNAs (ncRNAs) in diseases is increasingly being recognized. We propose to perform a systematically profile, by RNA-Seq approaches, of the lncRNAs and mRNAs in human ALS lymphocytes mutated, unmutated and controls with the aim of extending our knowledge on molecular alterations of transcriptome and obtaining new data about its regulation.

Materials and Methods: three cohort of ALS mutated patients (FUS, SOD1 and TARDBP) have been recruited and have been compared with healthy subjects and ALS sporadic (non mutated) patients. RNA libraries have been prepared by TruSeq Stranded Total RNA with Ribo-Zero Gold kit (illumina). **Results:** 28 common genes were found differentially expressed in all groups compared to controls. About lncRNA, the data showed that in SOD1 group 32 linc were found differentially expressed, 18 in TARDBP, 5 in FUS and 8 in SALS group respectively.

Discussion: Whole transcriptome analysis showed a general down-regulation in genes expression in all the studied groups. Moreover our preliminary data showed a comparable regulation between two groups positive for mutations in TARDBP and FUS, both involved in the same pathways, while a different profile arises from SOD1 and SALS groups. About lncRNAs the 56 lincRNAs are down-modulated by different extent in healthy donors and one SALS and one SOD1 sample. On the other side they are mainly up-modulated in the other disease samples. This preliminary analysis seems to indicate that it is not possible, with this set of lincRNAs, to discriminate between the different mutation states.

P17.05

Interethnic DNA methylation difference and its implications of cancer drug response

S. Chu^{1,2,3}, H. Yang^{1,2};

¹Institute of Statistical Science, Academia Sinica, Taipei, Taiwan, ²Bioinformatics Program, Taiwan International Graduate Program, Institute of Information Science, Academia Sinica, Taipei, Taiwan, ³Institute of Biomedical Informatics, National Yang-Ming University, Taipei, Taiwan.

Introduction: Using DNA methylation variants for predicting drug response represents an important application in pharmacoepigenetics. However, how these variants are influenced by the ethnic difference is still not studied systematically.

Materials and Methods: We collected DNA methylation and gene expression data of primary tumor tissues of four cancer types (breast, colon, head and neck, and uterine corpus) from The Cancer Genome Atlas and lymphoblastoid cell lines from The International HapMap Project for African and European ancestry populations. The methylation data were generated by the Infinium HumanMethylation450 BeadChip and gene expression data were generated by RNA sequencing experiments. After data quality control, regression models with batch effect adjustments were used to examine the association between CpG sites and ethnic population as well as to investigate the relationship between differential methylation and gene expression. **Results:** We identified 264 CpG sites in drug response genes significantly associated with ethnicity. Among them, differential methylation in 19 CpG sites was highly related to the differential expression of the corresponding genes (e.g., *SLC7A5* gene expression and its intronic CpG site cg27560818). A further comparison of the ethnicity associated CpG sites in cancers and HapMap datasets revealed significant methylation differences in both of global distributions and individual CpG sites.

Conclusions: Our results demonstrate ethnic effects on pharmacoepigenetics and the patterns may change by tissue types. These findings provide useful information for pharmaco-response prediction in clinical practices and future pharmacoepigenetic research.

Aberrant promoter methylation of matrix and transmembrane proteins encoding genes in breast cancer

O. A. Simonova¹, E. B. Kuznetsova^{1,2}, E. V. Poddubskaya², R. A. Kerimov³, V. V. Rudenko¹, A. S. Tanas^{1,4}, V. V. Strelnikov^{1,4}, D. V. Zaletaev^{1,2};

¹Research Centre for Medical Genetics, Moscow, Russian Federation, ²Sechenov First Moscow State Medical University, Moscow, Russian Federation, ³Blokhin Russian Research Center for Oncology (FSBI N.N.Blokhin), Moscow, Russian Federation, ⁴Pirogov Russian National Research Medical University, Moscow, Russian Federation.

Introduction. Matrix and transmembrane proteins play fundamental role in cell's live regulation. They are involved in maintenance of tissue architecture, signals transduction, wound healing, adhesion and play significant role in tumor development.

Materials and methods. We evaluated epigenetic regulation of 12 laminin-encoding genes (*LAMA1, LAMA2, LAMA3A, LAMA3B, LAMA4, LAMA5, LAMB1, LAMB2, LAMB3, LAMC1, LAMC2, LAMC3*), 8 integrins (*ITGA1, ITGA2, ITGA3, ITGA4, ITGA6, ITGA7, ITGA9, ITGB1*), 2 nidogens (*NID1, NID2*), the dystroglycan gene *DAG1* and 10 matrix metalloproteinases-encoding genes (*MMP2, MMP14, MMP15, MMP16, MMP17, MMP21, MMP23B, MMP24, MMP25, MMP28*) and 4 genes of tissue inhibitors of metalloproteinases (*TIMP1, TIMP2, TIMP3, TIMP4*) in 186 samples of breast cancer, 186 paired adjacent nonmalignant samples and 6 samples of normal mammary gland from autopsy by methylation sensitive PCR and bisulfite sequencing.

Results. Promoters of the *LAMA3A, LAMB2, LAMB3, LAMC2, MMP14, MMP21, TIMP1, TIMP4* genes were constitutively methylated in breast tissues. Promoters of 15 genes have demonstrated abnormal methylation in BC (table). In small number of cases genes *LAMA1, LAMA2, LAMB1, NID1, ITGA4, ITGA9* were methylated not only in BC, but also in paired adjacent nonmalignant samples.

Conclusions. Complex alteration of the studied genes methylation can be important for understanding of the dramatic changes in tissue architecture and signal transduction during tumor growth and development.

This study was funded by RFBR, research project 14-04-01792.

Capture Hi-C identifies compelling candidate causal genes and enhancers for multiple sclerosis in the 6q23 region

P. Martin¹, A. McGovern¹, K. Duffus¹, A. Yarwood¹, S. Schoenfelder², N. J. Cooper³, A. Barton^{1,4}, C. Wallace^{3,5}, P. Fraser², J. Worthington^{1,4}, S. Eyre¹, G. Orozco¹;

¹Arthritis Research UK Centre for Genetics and Genomics, Centre for Musculoskeletal Research, Institute of Inflammation and Repair, Faculty of Medical and Human Sciences, Manchester Academic Health Science Centre, The University of Manchester, Manchester, United Kingdom, ²Nuclear Dynamics Programme, The Babraham Institute, Cambridge, United Kingdom, ³JDRF/Wellcome Trust Diabetes and Inflammation Laboratory, Department of Medical Genetics, NIHR Cambridge Biomedical Research Centre, Cambridge Institute for Medical Research, University of Cambridge, Wellcome Trust/MRC Building, Cambridge, United Kingdom, ⁴NIHR Manchester Musculoskeletal Biomedical Research Unit, Central Manchester Foundation Trust, Manchester Academic Health Science Centre, Oxford Road, Manchester, United Kingdom, ⁵MRC Biostatistics Unit, Cambridge Institute of Public Health, Forvie Site, Robinson Way, Cambridge Biomedical Campus, Cambridge, United Kingdom.

Introduction: Genome wide association studies (GWAS) have been successful in identifying variants associated with complex disease, including multiple sclerosis (MS). Many of these variants lie in enhancer regions, although it is often unclear which gene they affect. Capture Hi-C (CHI-C) can be used to study long-range interactions at high resolution between enhancers and target genes. The 6q23 region is a pan-autoimmune locus associated with multiple autoimmune diseases. Our aim was to identify MS causal genes in the 6q23 region by studying chromatin interactions involving MS associated variants and further refining the causal variants.

Methods: Interactions with MS associated regions in the 6q23 locus, defined

as SNPs in $r^2 \geq 0.8$ with the lead association, were identified by CHi-C. SNP causality was further refined using HaploReg, RegulomeDB and eQTL data. Results: Complex long-range interactions were observed between MS associated regions and eight gene promoters, as well as between each other. These interactions implicate several genes including *AHI1*, *SGK1*, *BCLAF1*, *IL20RA*, *IL22RA2*, *IFNGR1* and *TNFAIP3*, some representing compelling autoimmune and MS candidates. Bioinformatics analysis of SNPs involved in these interactions further refined the SNPs to enhancer regions and identified many of the target genes as actively transcribed regions. Conclusions: This investigation has identified many compelling genes which could be involved in MS pathogenesis. Additionally, it has refined the associations further, in some cases to specific enhancer regions which will require further functional validation. This work has the potential to provide novel therapies or drug repositioning and improving patient outcome.

Alanine expansions associated with Congenital Central Hypoventilation Syndrome (CCHS) impair PHOX2B homeodomain-mediated dimerisation and nuclear import

D. Belperio¹, S. Di Lascio¹, R. Benfante^{2,1}, D. Fornasari^{1,2};

¹University of Milan, Milan, Italy, ²CNR-Neuroscience Institute, Milan, Italy.

Introduction: Polyalanine expansions in the 20-residues region of the human PHOX2B gene, a key regulator of autonomic nervous system development, lead to Congenital Central Hypoventilation Syndrome, a neurodevelopmental disorder characterised by a failure in the autonomic control of breathing. Elongation of the alanine stretch leads to a protein with altered DNA-binding, transcriptional activity, nuclear localisation, and cytoplasmic aggregates formation. Previous studies support the idea that PHOX2B mutant proteins display both loss and new toxic gain of function, resulting in a dominant-negative effect. As PHOX2B forms homodimers and heterodimers with its paralogue PHOX2A in vitro, we tested the hypothesis that the dominant-negative effect of the mutated proteins are due to non-functional interactions with the wild-type protein or PHOX2A. Moreover we investigated the effects of the longest polyalanine expansions on the homeodomain-mediated nuclear import.

Material and methods: To study hetero- and homo-dimerisation we used co-immunoprecipitation assay, and mammalian two-hybrid system. Deletion analysis and immunocytochemistry were used to study the consequences of alanine expansion on the sub-cellular localisation.

Results and conclusions: Our findings show that PHOX2B forms homodimers, heterodimerise weakly with mutated proteins, exclude the direct involvement of the polyalanine tract in dimer formation, and indicate that mutated proteins retain partial ability to form heterodimers with PHOX2A, with a possible role in the pathogenic process. Moreover our data show that the expanded C-terminus interferes with nuclear import process. These results provide novel insights into the effects of the alanine tract expansion on PHOX2B folding and activity.

P17.09

Newly identified PHOX2B target genes as drug targets in Congenital Central Hypoventilation Syndrome (CCHS)

S. Cardani¹, D. Belperio¹, S. Di Lascio¹, R. Benfante^{2,1}, D. Fornasari^{1,2};

¹University of Milan, Milan, Italy, ²CNR-Neuroscience Institute, Milan, Italy.

Introduction: Congenital Central Hypoventilation Syndrome (CCHS, MIM 209880) is a rare neonatal disease characterized by abnormal ventilatory response to hypoxia and hypercapnia, owing to failure of autonomic respiratory control. Frameshift mutations (5%) and polyalanine triplet expansions (95%) have been detected in the coding region of the transcription factor PHOX2B, responsible for the proper development and function of the autonomic nervous system. Consistent with its role as transcriptional regulator, it is reasonable to suppose that transcriptional dysregulation might be an important mechanism of CCHS pathogenesis. Current research on treatments of CCHS is focused on counteracting the toxic effects of the mutated PHOX2B protein, and stemming from the fortuitous observation that progesterin Desogestrel can relieve some symptoms of the disease, by a not yet identified molecular mechanism, lead us to identify new PHOX2B target genes as potential pharmacological targets for alternative molecules without contraceptive effects.

Methods: Identification of PHOX2B regulated genes has been carried-out by ChIP-seq analysis in IMR32 cells. The expression of PHOX2B target genes will be selectively validated by comparing wild-type and CRISPR-CAS9 Knocked-down PHOX2B expressing IMR32 cells.

Results and conclusion: Gene Ontology analysis of the set of peak-associated genes identified several enriched terms in categories consistent with PHO-

X2B role during autonomic nervous system development and maintenance. Further, we show that Desogestrel enhanced the expression of some relevant PHOX2B target genes in a promoter specific manner, by acting on the activity of the wild type as well as mutant protein.

Identification of key regulator elements in acute celiac response through whole genome coexpression analysis

I. Romero-Garmendia¹, K. Garcia-Etxebarria¹, H. Hernandez-Vargas², A. Jauregi-Miguel¹, L. Plaza-Izurieta¹, M. Legarda³, I. Irastorza³, Z. Herceg², N. Fernandez-Jimenez^{1,2}, J. Bilbao¹;

¹Immunogenetics Research Laboratory, Department of Genetics, Physical Anthropology and Animal Physiology, University of the Basque Country-UPV/EHU and BioCruces Health Research Institute, Leioa, Spain, ²Epigenetics Group, International Agency for Research on Cancer (IARC), Lyon, France, ³Pediatric Gastroenterology Unit, Cruces University Hospital (UPV/EHU), Barakaldo, Spain.

Introduction: In celiac disease (CD) gliadin provokes a coordinated response and the disruption of the coexpression in gene networks. The aim of this study was to analyze coexpression in the whole genome under acute gliadin exposure, and to identify regulator elements that could underlie these alterations in the context of CD.

Materials and Methods: We identified differentially coexpressed genes in an expression microarray from gluten-free diet (GFD) CD biopsies cultured with/out gliadin. We performed miRNA and transcription factor (TF) enrichment analyses and selection of candidate regulators. Expression of candidates was measured in clinical samples and the activation of one of the TFs (IRF1) was further characterized in C2BBE1 cells upon gliadin challenge. Binding of IRF1 to the in silico-predicted targets was measured by chromatin immunoprecipitation (ChIP).

Results: Two miRNAs and 3 TFs were selected as final candidates. One miRNA was underexpressed while 2/3 TFs were overexpressed in active disease. IRF1 was overexpressed at a protein level in the nuclear fraction of the C2BBE1 cells after gliadin exposure, although we did not see notable differences in the immunofluorescence assay. Finally, the IRF1 ChIP experiment performed in cells showed altered binding upon gliadin exposure in genes that were differentially coexpressed/expressed in acute CD.

Conclusions: Gliadin alters coexpression in CD. Moreover, our pipeline was able to identify regulators that could be relevant to disease. Particularly, IRF1 showed differential expression in patients and altered binding to several targets upon gliadin challenge in C2BBE1 cells, suggesting a general effect of gluten in physiological conditions.

GC-rich DNA activates NFkB signaling pathway in different types of human cells via TLR9 receptor

V. Sergeeva¹, S. Kostyuk¹, E. Ershova¹, L. Kameneva¹, E. Malinovskaya¹, N. Veiko¹, N. Mordkovich², V. Veiko², N. Okorokova²;

¹FSBI "Research Centre For Medical Genetics", Moscow, Russian Federation, ²Bach Institute of Biochemistry, Russian Academy of Sciences, Moscow, Russian Federation.

Introduction: It has been established that cell-free DNA circulates throughout the bloodstream, affecting cells. Diseases can cause GC-enrichment of cfDNA pool (cerebral atherosclerosis, heart attack, rheumatic arthritis, cancer). Our aim was to investigate the exact mechanism of cfDNA-cell interaction.

Materials and methods: GC-rich DNA fragments were obtained by inserting the CpG rich fragment of rDNA in a vector (pBR322). mRNA was isolated from different types of human cells (MSCs, HUVECs, PBMCs, HELFs) using an RNeasy Mini kit (Qiagen, Germany). Gene expression level was assessed using RT-PCR (TBP and GAPDH as internal standards). Statistics was performed using Statgraphics software.

Results: GC-rich DNA plasmid (50 ng/ml, 3h incubation) increases TLR9 and its adapter MyD88 level in human MSCs, HUVECs, PBMCs and HELFs (TLR9 3-, 2,5-, 2,8-, 3,7-fold and MyD88 3-, 2,5-, 2,8-, 3,7- fold, respectively). GC-rich DNA plasmid activates NFkB signaling pathway in these types of cells, NFkB translocates to the nucleus and genes of NFkB signaling pathway: MAP3K1, MAP4K4, NFKB1A, REL, IKKB, RelA (p65), NFRKB, NFKB1 and NFKB2 increase 2 - 5,5-fold. Expression of NFkB target genes TNF, IL1B, IL8, IL6, TNFRSF1A increase 2 - 4-fold in all types of cells. Combination of chloroquine with GC-rich DNA neither leads to the increment in MyD88 level nor activates NFkB signaling pathway. The vector itself doesn't affect TLR9 pathway.

Conclusion: GC-rich DNA increases expression of transcription factor gene NFkB and its target genes in MSCs, HUVECs, PBMCs and HELFs via TLR9 receptor.

Hypomethylation of long interspersed nuclear element-1 (LINE-1) in T-Lymphocytes from patients with CF

E. Kvaratskhelia^{1,2}, **N. Dabrundashvili**¹, **E. Maisuradze**¹, **M. Gagua**¹, **L. Margvelashvili**³, **E. Abzianidze**²;

¹Tbilisi State Medical University, Institute of Medical Biotechnology, Tbilisi, Georgia, ²Tbilisi State Medical University, department of Molecular and Medical Genetics, Tbilisi, Georgia, ³Hospital „New Life“, Department of Medical genetics and Diagnostics, Tbilisi, Georgia.

BACKGROUND: T-lymphocytes from patients with CF are characterized by reduced expression of anti-inflammatory cytokines and elevated levels of pro-inflammatory cytokines. Although mechanisms responsible for cytokine dysregulation is not entirely clear epigenetic mechanisms such as DNA Methylation might contribute. Previous studies have identified abnormal DNMTs level in T-Lymphocytes from CF patients which was correlated with amount of IL-10. In this study we examined the methylation levels of genomic DNA (5-mC content) and long interspersed nuclear element 1s (LINE-1) in CD4+ T - Lymphocytes derived from CF individuals and healthy subjects. **METHODS:** This study was approved by the ethic committee of TSMU. Peripheral blood was obtained by venepuncture from CF and healthy subjects. CD4+ T cells were isolated from PBMC using the CD4+ T Cell Isolation Kit (Miltenyi Biotec GmbH). Genomic DNA was extracted using Quick-DNA Universal Kit (Zymo Research) and Global DNA methylation was measured using the Methylated DNA Quantification Kit (abcam). Methylation levels of LINE-1 in normal and CF CD4+ T Lymphocytes were examined by the combined bisulfite restriction analysis- long interspersed nuclear element 1s (COBRA-LINE1).

RESULTS: Global DNA methylation was significantly reduced in CF CD4+ T cells compared with controls. In addition, hypomethylation of LINE-1 was prominent and the methylation level of LINE-1 was correlated with global genomic 5-methylcytosine content in CF CD4+ T lymphocytes.

CONCLUSIONS: Abnormal DNA methylation especially hypomethylation of interspersed repetitive sequences can have a crucial effect on gene expression resulting in aberrant immune responses in CF CD4+ T cells.

Dasatinib regulates lncRNA expressions in chronic myeloid leukemia

C. Kayabasi, **S. Yilmaz Süslüer**, **T. Balci**, **B. Özmen Yelken**, **Z. Mutlu**, **C. Çalişkan Kurt**, **B. Göker Bağca**, **Ç. Biray Avcı**, **F. Şahin**, **G. Saydam**, **C. Gündüz**;
Ege University, Izmir, Turkey.

Dasatinib is an ATP-competitive tyrosine kinase inhibitor used for the treatment of Chronic Myeloid Leukemia (CML). Long noncoding RNAs (lncRNAs) are transcripts longer than 200 nucleotides that play pivotal roles in modulating the cancer epigenome through regulating gene expression by variety of mechanisms including transcription, posttranscriptional processing, chromatin modification, genomic imprinting. We aimed to determine the changes of lncRNA expression profile in consequence of dasatinib treatment.

Cytotoxic and apoptotic effects of dasatinib on K562 cells was evaluated with WST1 and Apo-DIRECT with flow cytometry, respectively. lncRNA expression levels were examined with real-time RT-qPCR.

IC50 dose of dasatinib was calculated as 23.47 µM. Dasatinib induced apoptosis 5.32 fold compared to untreated control cells. Dasatinib upregulated H19 that plays role in epigenetic regulation through DNA methylation 16.44 fold and tumor suppressor RMST 16.2 fold. ANRIL that suppresses the expression of DNA damage response genes INK4a, INK4b, ARF, was down-regulated 12.64 fold with dasatinib treatment. Dasatinib down-regulated poor prognostic biomarker HOTAIR 3.83 fold, HOTAIRM that is cell cycle progression regulator during myeloid maturation 6.01 fold and oncogenic MIAT 9.12 fold. Interestingly, members of prostate specific regulator of cell proliferation are all suppressed with dasatinib treatment in CML cells (PCAT43, PCAT1, PCAT32, PCAT29 down-regulated 13.29, 9.04, 8.9, 7.56 fold, respectively).

These novel findings showed that dasatinib has significant effects on lncRNA expression levels which are associated with tumorigenesis. Further researches for determining the target genes of these lncRNAs is essential in order to clinical understanding of the CML molecular pathogenesis and new treatment strategies.

P17.14

Hsa-miR-451 expression in white blood cells of CML patients: differential expression in optimal imatinib responders and resistants

I. Soltani, **K. Douzi**, **H. Gharbi**, **I. Ben hassine**, **M. Teber**, **S. Abbas**, **S. Menif**;
Pasteur Institute Tunisia, Tunis, Tunisia.

Introduction: The treatment of chronic myeloid leukemia (CML) has been greatly revolutionized by the development of imatinib mesylate (IM). Despite high efficiency of IM, acquired resistance has been observed in a significant proportion of patients. Aside mutations of the BCR/ABL gene, downstream factors may contribute to treatment failure. Accumulating evidence for aberrant expression of miR-451 in several types of human cancer suggests that it may play a critical role in treatment response to IM in patients with CML.

Materials and Methods: 29 responders (molecular remission) and 30 non-responders were included in this study. Both miR-451 expression and MYC transcript expression were measured by real-time quantitative RT-PCR assay. Analysis of relative expression of miR-451 and MYC between groups was calculated according to the 2-ΔCt method. Putative targets of miR-451 were predicted by TargetScan and Microcosm. In addition, we used Pach algorithm to identify transcription factor binding sites (TFBSs) in promoter region sequences of miR-451.

Results: Down-regulation of the expression of miR-451 was observed in non-responders as compared to responders. Furthermore, in silico analyses identified MYC as a potential target of miR-451 which in turn may regulates miR-451 expression as a transcription factor. Increased level of MYC was also detected in resistant patients when compared to optimal imatinib responders. Combination of these findings suggests that there may exist a feedback loop between miR-451 and MYC.

Conclusions: Our findings suggest that miR-451/MYC mini-circuitry may act as a potential therapeutic target and disruption of suggested regulatory loop could help to improve CML therapy.

Methylation analysis of DNA repair genes in peripheral blood of Alzheimer's disease patients and healthy controls

A. Stocco^{1,2}, **P. Tannorella**¹, **L. Chico**³, **G. Siciliano**³, **U. Bonuccelli**³, **F. Coppede**³, **L. Migliore**¹;

¹Department of Translational Research and New Technologies in Medicine and Surgery, Section of Medical Genetics, University of Pisa, Pisa, Italy, ²Doctoral School in Genetics Oncology and Clinical Medicine, Department of Medical Biotechnologies, University of Siena, Siena, Italy, ³Department of Clinical and Experimental Medicine, University of Pisa, Neurological Clinic, Pisa, Italy.

Introduction: Several hypotheses have been formulated and tested over the last few years in order to explain the observed impairment in DNA repair activities in Alzheimer's disease (AD) neurons and peripheral tissues, including those involving the influence of gene polymorphisms, without reaching conclusive results. We hypothesized that this could partially result from epigenetic modifications of DNA repair genes, resulting in altered gene expression in those tissues. In the present study we searched for gene specific DNA methylation levels of a panel of DNA repair genes in peripheral blood cells of AD and healthy controls.

Materials and Methods: In a first step blood DNA of a subgroup composed by late-onset AD (LOAD) patients and healthy matched controls was screened with a commercially DNA methylation array able to evaluate the methylation levels of a panel of 22 genes involved in major DNA repair pathways. We then applied the cost-effective PCR based methylation sensitive-high resolution melting technique (MS-HRM), in order to evaluate the promoter methylation levels of some of the major DNA repair genes, namely *OGG1*, *PARP1*, *MRE11A*, *BRCA1*, *MLH1*, and *MGMT* in blood DNA from a wider cohort.

Results: Both approaches showed that all the investigated genes were largely hypomethylated in LOAD and control blood DNA, and no difference between groups was observed.

Conclusions: In summary, the present investigation suggests that there is no impairment in promoter methylation of the investigated DNA repair genes in blood DNA of AD patients.

Differential DNA methylation and comparison between boys and girls with ADHD

T. V. M. M. Costa¹, F. A. Marchi², C. Milani¹, J. G. Damasceno¹, E. A. Zanardo¹, G. M. Novo-Filho¹, M. M. Montenegro¹, F. A. R. Madia¹, A. T. Dias¹, F. B. Piazzon¹, R. L. Dutra¹, A. M. Nascimento¹, M. Rocha², C. A. Kim⁴, V. Schuch⁵, C. B. Mello⁵, M. Muszkat⁵, L. D. Kulikowski^{1,3,4},

¹Faculdade de Medicina da USP, Sao Paulo, Brazil, ²Laboratório NeoGene, AC Camargo Cancer Center, Sao Paulo, Brazil, ³Centro de Reprodução Humana e Genética, Faculdade de Medicina do ABC, Santo Andre, Brazil, ⁴Unidade de Genética, Departamento de Pediatria, Instituto da Criança, Sao Paulo, Brazil, ⁵Núcleo de Atendimento Neuropsicológico Infantil Interdisciplinar (NANI), Departamento de Psicobiologia da Escola Paulista de Medicina, UNIFESP, Sao Paulo, Brazil.

Attention deficit hyperactivity disorder (ADHD) is one of the most common neurobehavioral disorder diagnosed in childhood. ADHD is etiologically heterogeneous and has high heritability (around 80%). However, the genetic architecture of ADHD is still largely unknown. DNA methylation is the most stable epigenetic mark and is related to gene silencing. Therefore, the establishment of methylation profile in ADHD patients is important to guide the research key epigenetic factors in this disorder. DNA methylation profile was performed using DNA extracted from blood lymphocytes of 13 ADHD patients (9 boys and 4 girls, ages 06-14) by Illumina Infinium HumanMethylation450 BeadChip. We analyzed the array data using specific packages within the environment R and used the BRB-ArrayTools to make the cluster. We performed two analyzes: a comparison between boys and girls and a differential analysis of all the samples.

In the comparison between boys and girls we obtained 249 probes with $\Delta\beta +0.20$. In the differential analysis of all the samples, we selected 3,348 probes using $SD > 0.1$ as selection criteria. We used the β values these 3,348 selected probes to make the samples cluster, which showed a strong separation of patients into two groups: the first formed of 4 girls and the second formed of 9 boys.

Thus, we suggested that it is quite probable that differences in DNA methylation profiles of boys and girls may be associated with the genetic basis of ADHD.

P17.18

Differential DNA methylation related to HDL functionality: an epigenome-wide approach

S. Sayols-Baixeras^{1,2}, Á. Hernández^{1,3}, I. Subirana^{4,1}, C. Lluis-Ganella¹, M. Fitó^{1,3}, J. Marrugat¹, R. Elosua¹,

¹IMIM (Hospital del Mar Medical Research Institute), Barcelona, Spain, ²Universitat Pompeu Fabra (UPF), Barcelona, Spain, ³CIBEROBN CIBER de Fisiopatología de la Nutrición y la Obesidad, Madrid, Spain, ⁴CIBER Epidemiology and Public Health, Madrid, Spain.

Background: Cholesterol level in high-density lipoproteins (HDL-c) is a powerful predictor of cardiovascular risk. However, Mendelian randomization experiments and clinical trials do not support a causal association between HDL-c levels and cardiovascular disease. Therefore, the study of HDL biological functionality has become a hot topic in cardiovascular research. Epigenetics in general and DNA methylation in particular, are also associated with cardiovascular traits. However, there is a lack of data of the relationship between methylation and HDL functionality.

Aim: To assess the association between the two main HDL functions (cholesterol efflux capacity and proinflammatory index) and DNA methylation.

Methods: A discovery epigenome-wide association study was designed including 645 individuals of the REGICOR population-based cohort. Peripheral blood cell DNA methylation was analyzed using the Illumina HumanMethylation450 BeadChip. Cholesterol efflux and proinflammatory capacities were analyzed in plasma using standardized methods. Robust multivariate linear regression models adjusted for age, sex, smoking, HDL-c levels and surrogate variables were used in the statistical analyses. We declared as statistical significant those associations with p-values that fulfill Bonferroni criteria ($<1.17E-07$).

Results: We discovered two CpGs located in two genes (PEX5 and HOXA3) related to cholesterol efflux capacity; and one CpGs located in GABRR1 related to the proinflammatory index. These CpGs explained 4.94% and 0.83% of the variability of the cholesterol efflux capacity and of the proinflammatory index, respectively.

Conclusions: We have identified three potential loci associated with HDL functionality located in the genes PEX5, HOXA3 and GABRR1. Additional studies are warranted to validate these findings in other populations.

DNA methylation and the localization and post-translational modification of nucleosomes are interdependent epigenetic factors contributing to the generation of distinct phenotypes from genetically identical cells. The BLUEPRINT Epigenome project has produced DNA methylation maps (whole genome bisulfite sequencing) and histone modification maps (chromatin immunoprecipitation sequencing for six post-translational modifications) for nearly 200 samples, covering a range of immune system effector cells and the cancers that arise from them. Here we analyze the global evolution of DNA methylation patterns and their relationship with stably positioned nucleosomes during lineage commitment and maturation of 112 hematopoietic samples. The innate and adaptive lineages of the human immune system show distinct trends, both globally and in relation to consistently positioned nucleosomes, including a progressive loss of methylation in developing lymphocytes. Cancer samples from the two lineages become further polarized, suggesting the involvement of opposing lineage-specific epigenetic mechanisms.

Although DNA methylation is generally restricted to CG dinucleotides, we note the consistent occurrence of non-CG methylation in naive T lymphocytes and uncommitted hematopoietic progenitor cells, at levels similar to those seen in neurons and stem cells. We also examine sporadic occurrences of localized non-conversion in a few samples, suggesting the possibility of dense exon-specific non-CG methylation. We anticipate broad utility for this resource as a basis for further comparative analyses.

The research leading to the results described here received funding from the European Union's Seventh Framework Programme (FP7/2007-2013) under grant agreement no. 282510-BLUEPRINT.

Association of DNMT1/3a and H3K4 methyltransferase levels with size, grade and phenotype of invasive ductal carcinoma of breast

K. Kankava, T. Kvaratskhelia, E. Kvaratskhelia, E. Abzianidze,
^{Tbilisi State Medical University, Department of Molecular and Medical Genetics, Tbilisi, Georgia.}

Introduction: The aim of our pilot study is to analyze correlation of changes in the levels of methyltransferases in nuclear extracts with different morphological characteristics of breast cancer.

Materials and Methods: 21 breast cancer patients and 10 healthy controls were selected for the study. The levels of DNMT1, DNMT3a and H3K4 were measured in nuclear extracts of peripheral blood mononuclear cells (PBMC). Nuclear extracts were prepared using nuclear extraction kit (Abcam). ELISA based DNMTs assay kits (Abcam) were used to measure the amount of DNMT1/3a and H3K4 methyltransferases. Three pathologists performed blind assessment of tumors' morphological and phenotypic characteristics. Results: The results showed that the level of DNMT1 was highest in the control group but didn't correlate with the grade. The level of DNMT1 increased together with the level of Estrogen receptor expression. DNMT3a was found in highest level in Grade III cancer group, followed by Grade II and Grade I groups. In the control group the level of DNMT3a was also rather low. An opposite pattern was seen for H3K4 methyltransferase. DNMT3a level was higher in larger tumors, while the level of H3K4 methyltransferase was lowest. In HER2neu positive cases levels of both - DNMT1 and DNMT3a were increased, while H3K4 methyltransferase was decreased.

Conclusions: This primary study showed that there are some changes in methyltransferase levels in PBMC from breast cancer patients. Continuing observation is planned to specify this and possibly identify an additional diagnostic/prognostic feature for breast cancer.

Epigenetic Alterations in Human Thyroid Oncogenesis

A. Botezatu¹, I. V. Iancu¹, O. Popa², A. Plesa¹, D. Manda², M. Bostan¹, S. Vladioiu², I. Huica¹, G. Anton¹, C. Badiu²;

¹"Stefan S. Nicolau" Institute of Virology, Bucharest, Romania, ²"CI Parhon" National Institute of Endocrinology, Bucharest, Romania.

Thyroid carcinoma is the most common endocrine malignancy worldwide with the most common histological type - papillary thyroid cancer (PTC). Aberrant methylation of tumor suppressor genes (TSG) is a hallmark for many types of cancers.

We aim to profile tumor samples and evaluate the methylation status for 22 TSG promoters (APC, BRCA1, CDH1, CDH13, CDKN2A, DAPK, ESR1, FHIT, GSTP1, MGMT, MLH1, NEUROG1, PDLIM4, PTEN, RARB, RASSF1, RUNX3, SOCS1, TIMP3, TP73, VHL, WIF1), to correlate methylation level with biological phenotypes.

We performed a methylation analysis (Human TSG EpiTect Methyl II Signature PCR Array-Qiagen) in PTC samples compared with normal thyroid tissue. Preliminary, we evaluated the promoter methylation for TP73, PDLIM4, WIF1 genes in 120 patient's samples, consisting of 60 PTC and follicular adenoma specimens and their adjacent normal tissue, with qMS-PCR using bisulphite treated DNA samples.

The methylation percentage was found to be increased in PTC samples than control ($p < 0.001$). Higher methylation percentage (MP) values were found for TP73 (85.16%) BRCA1 (76.94%), WIF1 (75.8%), PDLIM4 (67.74%).

The methylation level was correlated with tumor grade. TP73 gene promoter methylation seem to be a characteristic for follicular adenoma samples and PTC follicular variant. Methylation of PDLIM4 gene promoter was found from the incipient state of neoplasia, also found in a higher percentage in patients with PTC and PTC follicular variant.

These results illustrate the involvement of epigenetic alterations in thyroid oncogenesis. We consider that the TSG promoter's methylation profile may be a starting point for diagnosis, prognosis of PTC.

Differential expression of microRNAs in Familial Mediterranean fever patients

Y. Akkaya Ulum, E. Batu, O. Karadag, F. Kara, A. Ertenli, S. Kiraz, S. Ozen, E. Yilmaz, B. Balci Peynircioglu;

Hacettepe University, Ankara, Turkey.

Introduction: Familial Mediterranean fever (FMF), one of the most common autoinflammatory disorders, is an autosomal recessively inherited disease. Phenotypic heterogeneity is very important in FMF. Different modifier factors such as epigenetic factors need to be investigated for their role in influencing the phenotype variability seen in FMF patients. Alteration of microRNAs (miRNAs) in biological processes can lead many disorders including inflammatory disorders. We aimed to explore the potential involvement of miRNAs in pathogenesis of FMF.

Materials and Methods: The expression levels of miRNAs in total blood, obtained from healthy controls, patients (homozygotes and heterozygotes) and healthy heterozygotes, were compared with GeneChip miRNA 2.0 Array (Affymetrix). The raw data was analyzed by Multi Experiment Viewer (MeV) and miRNA target genes were determined in miRWalk and clustered in DAVID v6.7 through BioCarta and KEGG pathway maps.

Results: MiR-20a-5p, miR-197-3p, let-7d-3p, miR-574-3p were significantly differentially expressed in homozygous patients and heterozygotes patients. Array results were validated using qPCR. All these miRNAs were found to be known regulators in TGF-beta and Toll-like receptor signaling pathway, apoptosis and actin cytoskeleton regulation.

Conclusions: We showed for the first time that there are differentially expressed miRNAs which may target mRNAs clustered in inflammatory pathways such as cytokine secretion, apoptosis and cell migration. Thus our findings provide initial evidence that miRNAs may play role in FMF pathogenesis.

The potential role of mir-548c-5p as a regulator of FOXC2 transcription to control podocyte differentiation

A. Christofides¹, G. Papagregoriou¹, H. Dweep², N. Gretz², K. Felekis³, C. Deltas¹;

¹Molecular Medicine Research Center, University of Cyprus, Nicosia, Cyprus, ²Medical Research Center, University of Heidelberg, Mannheim, Germany, ³Department of Life and Health Sciences, University of Nicosia, Nicosia, Cyprus.

Podocytes are highly differentiated epithelial cells outlining the glomerular vessels. FOXC2 is a transcription factor essential for inducing podocyte differentiation. We hypothesize that the transcription of FOXC2 and consequently the differentiation of podocytes, can be controlled by miR-548c-5p through a predicted 21nt long target region located 8kb upstream the FOXC2 transcription start point. By using luciferase reporter constructs, it became apparent that the DNA target site acts as a conventional miRNA-binding site. During early differentiation of AB8/13 human podocytes, miR-548c-5p mimics effectively diminished endogenous FOXC2 levels, while a more dynamic model of this interaction was observed when investigating other time points, suggesting a dependence on target site availability. Therefore, the role of this miRNA target site as a distal enhancer/repressor element was investigated using Chromosome Conformation Capture. Evidence indicates a correlation between podocyte differentiation events and the interaction levels between the miRNA target site and the FOXC2 proximal promoter regions.

Identification of novel candidate genes for Hirschsprung disease by differential expression analyses in human enteric precursor cells

A. Torroglosa^{1,2}, R. M. Fernández^{1,2}, L. Villalba-Benito¹, M. J. Moya-Jiménez³, G. Antiñolo^{1,2}, S. Borrego^{1,2};

¹Institute of Biomedicine of Seville (IBIS), University Hospital Virgen del Rocío/CSIC/University of Seville, Seville, Spain, ²Centre for Biomedical Network Research on Rare Diseases (CIBERER), Seville, Spain, ³University Hospital Virgen del Rocío, Seville, Spain.

Hirschsprung disease (HSCR: OMIM 142623), the most common neurocristopathy in humans (1:5000 newborns), is attributed to a failure of neural crest cells to migrate, proliferate, differentiate or survive in the bowel wall during embryonic Enteric Nervous System (ENS) development. This process requires a wide and complex variety of molecules and signaling pathways which are activated by transcription factors. Although some genes involved in this pathology are well characterized, many aspects remain poorly understood. In this study we aimed to identify novel genes implicated in the pathogenesis of Hirschsprung disease. For this goal, through TaqMan Gene Expression Assays, a differential expression study was performed on a set of genes involved in human stem cells pluripotency as well as on a set of genes encoding transcription factors that participate in different stages of the colonization process. These assays were conducted on Neurosphere-like bodies and gut tissues from both HSCR and control individuals. A total of eleven genes resulted to present statistically significant differential expression among patients and controls. Five of them are implicated in cell proliferation and migration (NESTIN, FN1, LAMC1, PECAM, and SEMA3A), four encode for transcription factors (CDYL, MEIS1, STAT3 and PAX6) and one encodes for a de novo methyltransferase (DNMT3B). This approach allowed us to characterize the precursors of human ENS and to identify a group of excellent candidate genes to be implicated in the ENS development and in the onset of HSCR.

A transcription factor binding site-driven approach to identify cis-regulatory variants

S. Kumar^{1,2}, G. Ambrosini^{1,2}, P. Bucher^{1,2};

¹Swiss Institute for Experimental Cancer Research, Swiss Federal Institute of Technology Lausanne (EPFL), Lausanne, Switzerland, ²Swiss Institute of Bioinformatics, Lausanne, Switzerland.

Introduction: Transcription factor (TF)-target site interactions are the elementary molecular events of gene regulation. Identification of SNPs disrupting such interactions and having an effect on chromatin state may shed light on the mechanistic principles of regulatory genetic variation.

Methodology: We developed a discovery pipeline for extracting SNPs that abolish, create, or significantly change the affinity of predicted TF binding sites. Input is a comprehensive variant list, a reference genome plus a set of position weight matrices defining the binding specificity of TFs. Output is a subset of SNPs along with their predicted effects on TF binding. This subset is then used in GWAS studies to identify various kinds of cis-regulatory QTLs. Unlike other approaches, our pipeline can identify de novo created TF binding sites not present in the reference genome.

Results: To test the pipeline we selected 48 TFs and extracted a list of 248,676 SNPs affecting TF binding. As phenotypes we used ChIP-seq data from Waszak et.al. (Cell, 2015) for 45 genotyped individuals. We identified

multiple TF binding variants that are associated with histone modifications: 3799 for H3K27ac, 2187 for H3K4me3 and 476 H3K4me1 (FDR \leq 0.01). Interestingly, SNPs affecting binding sites of BRCA1 and IKZF1 showed high association rate, suggesting that these TFs mostly act through histone modifications.

Conclusions: Our approach is effective in identifying cis-regulatory SNPs that affect predicted TF binding sites. Our SNP list with annotated effects on TF binding may also help in elucidating the mode of action of already known regulatory QTLs. Grant reference: SNSF-CRSII3_154500.

Introduction. Imprinting disorders (IDs) are syndromes characterized by (epi)genetic alterations affecting imprinted genomic regions. Most of ID patients show epimutations limited to the disease-specific locus, but several exhibit multilocus methylation imprinting disturbances (MLIDs). MLID may account for the variable presentation and the phenotypic overlap between IDs, that make clinical diagnosis often difficult and highlight the need for a reliable method for methylation analysis at multiple imprinted loci.

Materials and Methods. We developed a quantitative methylation test by MassARRAY approach to detect alterations at 12 imprinted regions in 15 pre- and post-natal patients with Beckwith-Wiedemann syndrome (BWS) and 25 patients with pseudohypoparathyroidism type 1 (PHP1), previously diagnosed by pyrosequencing or MLPA. The MassARRAY methylation platform has been set up on 40 normal controls to define methylation ranges at each analyzed CpG site.

Results. 33% of BWS patients showed MLID, with loss of methylation at maternally imprinted loci only. PHP1 patients exhibited both gain and loss of methylation at maternally/paternally imprinted loci and MLID was more frequent in patients with complex clinical presentation.

Conclusions. MassARRAY platform allows a higher frequent detection of MLID in ID patients compared to literature data, thanks to the accurate analysis of several imprinted genes. In BWS patients the detection of MLID confined to maternally imprinted loci, suggests alterations in trans-acting factors involved in the methylation establishment/maintenance in the oocyte. Next generation sequencing is ongoing to identify alterations at these factors. Conversely, MLID patterns in PHP1 patients suggest different/multiple causative mechanisms.

Histone H4 hyperacetylation is altered in patients with impaired spermatogenesis

F. Barrachina¹, C. Mallofré², O. Bogle¹, A. Goudarzi³, A. Soler-Ventura¹, A. Melnick⁴, J. Corral⁵, S. Rousseaux³, J. Ballescà⁶, R. Oliva⁷;

¹Molecular Biology of Reproduction and Development, IDIBAPS, Faculty of Medicine, University of Barcelona, and Hospital Clinic, Barcelona, Spain, ²Department of Anatomical Pathology and Otorhinolaryngology, University of Barcelona, and Hospital Clinic, Barcelona, Spain, ³Institut National de la Santé et de la Recherche Médicale U823 and Université Grenoble Alpes Institut Albert Bonniot, Grenoble F-38700, France, ⁴Department of Urology, IDIBAPS, Hospital Clínic, Barcelona, Spain, ⁵Clinic Institute of Gynaecology, Obstetrics and Neonatology, Hospital Clínic, Barcelona, Spain.

Spermatogenesis is a differentiation process characterized by extremely marked chromatin and cellular changes leading to the highly specialized sperm cell. Histone H4 hyperacetylation (acH4) during spermatogenesis is involved in gene activation and in sperm chromatin remodelling in the final stages, and therefore may affect the imprinting of the mature sperm cell. Thus, we hypothesized that acH4 expression pattern during sperma-

togenesis is different between normal and pathological samples. We used a semi-quantitative approach to compare both the intensity and distribution of acH4 immuno-detection in testicular biopsies (n=23) with normal and abnormal spermatogenesis (hypospermatogenesis, spermatogenic arrest and Sertoli cell-only Syndrome). Immunofluorescence was used to further localize acH4 in ejaculated sperm cells. acH4 immuno-detection was high in spermatogonia, decreased in spermatocytes, and increased again reaching a maximum in elongating spermatids in normal spermatogenesis. The immuno-detection of acH4 in all spermatogenic cell types decreased in patients with hypospermatogenesis or spermatogenic arrest, but increased in the presence of tubular atrophy and fibrosis. Stronger acH4 immuno-detection was observed in Sertoli cells from patients with Sertoli cell-only Syndrome (absence of germinal cells). The localization of acH4 in the mature sperm nucleus indicates the acetylation of retained H4 histones. In conclusion, we found that acH4 is deregulated in patients with altered spermatogenesis. The results from this study implicate acH4 involvement in the remodelling of chromatin during the histone-to-protamine transition through spermatogenesis which may play a role in chromatin imprinting anomalies. P17.31

A long non-coding RNA that is associated with susceptibility to celiac disease

A. Castellanos-Rubio¹, N. Fernandez-Jimenez², R. Kratchmarov¹, X. Luo³, G. Bhagat¹, P. H. R. Green¹, R. Schneider⁴, M. Kiledjian³, J. Bilbao³, S. Ghosh¹;

¹Columbia University, NYC, NY, United States, ²UPV-EHU, Leioa, Spain, ³Rutgers University, Piscataway, NJ, United States, ⁴NYU, NYC, NY, United States.

Recent studies have begun to implicate long noncoding RNAs (lncRNAs) as regulators of many important biological processes. In this study we have identified a novel lncRNA (lnc13), harboring a celiac disease-associated SNP block, that helps maintain expression of certain inflammatory genes at basal levels. lnc13 regulates gene expression by binding to a member of the family of ubiquitously expressed heterogeneous nuclear ribonucleoproteins (hnRNPs) that interacts with the NuRD chromatin-remodeling complex. Under inflammatory conditions, the level of lnc13 is decreased, thereby removing the repressive effect of lnc13 bound to the hnRNP and enhancing the inflammatory environment. Interestingly, lnc13 levels are significantly decreased in celiac disease intestinal mucosa suggesting that downregulation of lnc13 contributes to the inflammation seen in celiac disease. Furthermore, the lnc13 risk variant binds the hnRNP less efficiently, thus helping to explain the contribution of the SNPs to celiac disease and showing a new mechanism of gene expression control by a SNP located in a non-coding transcript.

P17.33

lncRNAs expression profiles in pancreatic cancer

I. V. Iancu¹, A. Botezatu¹, A. Plesa¹, C. C. Diaconu¹, G. Anton¹, R. Florea², V. Ilie², A. Sorop², V. Tica², S. O. Dima², I. Popescu²;

¹“Stefan S. Nicolau” Institute of Virology, Bucharest, Romania, ²Fundeni Clinical Institute, Gastroenterology and Hepatic Transplantation Center, Bucharest, Romania.

Introduction: Pancreatic cancer represents an aggressive disease, being the seventh leading cause of cancer deaths, and its early detection remains a major challenge. Development and progression of pancreatic adenocarcinoma (PDAC) involve gradual accumulation of various genetic and epigenetic alterations. Despite the accumulating evidence that links long non-coding RNAs (lncRNAs) expression to neoplastic transformation, little is known about the role of lncRNAs in PDAC.

The aim of this study is to analyse lncRNAs expression profiles in pancreatic cancer.

Materials and Methods: From 5 paired samples (normal/pancreatic adenocarcinoma) total RNA was obtained and lncRNAs expression levels were assessed using Human LncProfiler qPCR Array Kit (System Biosciences). For lncRNAs validation qRT-PCR was used.

Results: 42 lncRNAs presented significant differences in expression levels between PDAC tissues and corresponding normal tissues (> 2-fold change; p < 0.05). lncRNAs expression profiling showed that 27 were significantly upregulated (among them: Alpha 280, E2F4 antisense, Evf1, Evf2, Hoxa11as, Tsix, Meg3, Malat1) while 15 were significantly downregulated (EgoA, SRA, Lust, PCGEM1, Gomafu, and Tmevpg1). In order to validate the results, two lncRNAs (Malat1 and Meg3) were selected and expression levels were evaluated for 30 sample pairs. Results indicate that both lncRNAs display a high expression level in pancreatic cancer compared with adjacent normal tissues (p < 0.001; respectively p=0.02) especially in advanced stages of the

disease (III-IV).

Conclusions: In this study different lncRNAs expression patterns were associated with PDAC, thus implying a potential biomarker role for these epigenetic factors in pancreatic cancer.

Correlation of metastasis-related miR-205 with different clinical outcome in primary cutaneous malignant melanoma

B. Sánchez Sendra¹, C. Monteagudo²;

¹INCLIVA, Valencia, Spain, ²Pathology Department, Medicine Faculty, University of Valencia, Valencia, Spain.

Introduction: Cutaneous malignant melanoma has a high propensity to spread throughout the body causing a high mortality. There is cumulative evidence that miRNAs, which control many pathological processes acting as gene expression regulators, mediate melanoma invasion and metastasis. Here, we sought to investigate the role of miR-205 in governing patient clinical outcome at the time of primary tumor as a way to differentiate patients with higher risk.

Materials and Methods: We obtained frozen primary human melanoma samples from 65 patients. We selected miR-205 as a good metastasis-related miR. We determined miR-205 expression of these primary tumors by miRNA RT-qPCR and these results were correlated with the clinical outcome.

Results: miR-205 expression was detected in all cases. 49 cases did not metastasize and 16 cases metastasized (24,6%) to distant organs. Clinical follow-up ranged from 10 to 134 months (mean 88 months). From our data, miR-205 was differentially expressed between metastatic versus non-metastatic primary melanomas. It was down-regulated in the former compared with the latter. Furthermore, the cumulated survival stratified by miR-205 expression is significantly different between both primary melanoma groups (Kaplan-Meier curves, Log-rank test).

Conclusions: The miR-205 expression in primary melanoma tumors is able to segregate patients regarding their metastatic ability. Altogether, these findings unravel a key role for miR-205 in distant metastatic melanoma. Given its critical role in metastatic melanoma, miR-205 holds potential as therapeutic target and biomarker.

Cyclic and constant increased glucose levels variation has important effects DNA methylation profiles

P. Rentero-Garrido¹, G. DeMarco¹, L. Olivares¹, V. Adam¹, C. Ivorra², F. Chaves^{1,3};

¹Biomedical Research Institute INCLIVA, Valencia, Spain, ²Sequencing Multiplexing S.L., Valencia, Spain, ³CIBER of Diabetes and Associated Metabolic Diseases (CIBERDEM), Barcelona, Spain.

Introduction: DNA methylation is an epigenetic mechanism used by cells to regulate their interaction with ambient. The methylation of different regions can be changed as a regulatory response. Carbohydrate levels variation introduce important stress to body cells. Our objective is measuring the influence of cyclical variations of glucose levels in DNA methylation patterns. **Material and methods:** we cultured HUH7 cells (derived from hepatocytes), and subjected them to different conditions: 5 mM glucose, 30 mM glucose and 30 mM mannitol used as a control, all of them with constant supply or cyclical supply every 8 hours for 7 days. Subsequently, the cell pellet was collected and DNA extracted. To study the patterns of DNA methylation we used bisulfite treatment and Illumina Human Methylation450K BeadChip was performed. Bioconductor packages for debugging, normalization and statistical analysis of the methylation data were used.

Results: Among the different analyses we have found 36 CpG sites deltateta greater than 20% and p.value less than 0.05 and 51 regions with p value less than 0.005, among which genes are related liver carcinogenesis (HEPN1) activating enzymes of protein kinases (PAK3), enzymes pyruvate cycle (PC), angiogenesis inhibitors (ISM1) and enzymes of oxidative stress (NR2C2).

Conclusion: Peaks in energy inputs vary methylation patterns of enzymes and proteins involved in important cellular pathways and the modification produced by cyclical and constant carbohydrate increase are different. These data can have important applications in human health and to understand the mechanisms involved in metabolic diseases.

P17.36

MicroRNA profiling in patients with upper tract urothelial carcinoma associated to Balkan endemic nephropathy

K. Popovska-Jankovic¹, P. Noveski¹, L. Jankovic-Velickovic², S. Stojnev², R. Cukuranovic³, V. Stefanovic⁴, D. Toncheva⁵, R. Staneva⁶, M. Polenakovic¹, D. Plaseska-Karanfilska¹; ¹Macedonian Academy of Sciences and Arts, Research Centre for Genetic Engineering and Biotechnology, Skopje, Macedonia, The Former Yugoslav Republic of, ²Institute of Pathology, Faculty of Medicine, University of Nis, Nis, Serbia, ³Clinic of Nephrology, Medical Faculty, University of Nis, Nis, Serbia, ⁴Department of Clinical Research, Faculty of Medicine, University of Nis, Nis, Serbia, ⁵Department of Medical Genetics, Medical University of Sofia, Sofia, Bulgaria.

Balkan endemic nephropathy (BEN) is a disease that affects people that live in the alluvial plains along the tributaries of the Danube River in the Balkan region. BEN is a chronic tubulointerstitial disease with a slow progression to terminal renal failure and has strong association with upper tract urothelial carcinoma (UTUC). Aberrantly expressed miRNAs have been shown to be associated with many types of cancers including UTUC.

A total of 15 FFPE kidney biopsies were included in this study [4 with normal kidney tissues, 7 with BEN-UTUC and 4 with UTUC from non-endemic Balkan regions (non-BEN-UTUC)]. Total RNA was extracted using commercial FFPE DNA/RNA Kit from Qiagen. Microarray analysis was performed using Agilent SurePrint G3 Human v16 miRNA miRNA 8x60K microarray kit. Statistical analysis of the microRNA expression data was performed using R Bioconductor software and GeneSpring v12.5 software.

Statistical analysis using both softwares revealed 10 microRNAs in BEN-UTUC (hsa-miR-205↑, hsa-miR-4322↑, hsa-miR-99b*↑, hsa-miR-3620↑, hsa-miR-373*↑, hsa-miR-3656↑, hsa-miR-1290↑, hsa-miR-30a↓, hsa-miR-127-3p↓, hsa-miR-154↓) and 15 in non-BEN-UTUC patients (hsa-miR-205↑, hsa-miR-205*↑, hsa-miR-224↑, hsa-miR-224*↑, hsa-miR-197↑, hsa-miR-182↑, hsa-miR-183↑, hsa-miR-96↑, hsa-miR-203↑, hsa-miR-149↑, hsa-miR-141↑, hsa-miR-200c↑, hsa-miR-1260↑, hsa-miR-210↑, hsa-miR-663b↓) compared to normal samples, that showed significant difference in the expression (p < 0.05) and at least two log-fold changes.

In conclusion, miRNA signature determined in BEN-UTUC patients differ from the non-BEN-UTUC patients; only miR-205 was mutual in both groups. This might impose that different mechanisms/pathways could be responsible for the process of carcinogenesis in UTUC in patients from BEN regions.

P17.37

Is there any association between nasal polyposis and ADAMTS gene expressions?

A. Tatar¹, S. Tasdemir², I. Sahin², Z. I. Ocak²;

¹Ataturk University Department of Otorhinolaryngology, Erzurum, Turkey, ²Ataturk University Department of Medical Genetics, Erzurum, Turkey, ³Kanuni Sultan Suleyman Research Hospital Department of Medical Genetics, Istanbul, Turkey.

Introduction: Nasal polyposis, which is originated from nose and paranasal sinus mucosa, is a chronic inflammatory disease. It has been accepted a hereditary predisposition because of the increased frequency in some families. A disintegrin and metalloproteinase with thrombospondin type 1 motifs (ADAMTS) genes regulate the structures and functions of different tissues. They are associated with angiogenesis and tumorigenesis, and may therefore be involved in the pathogenesis of nasal polyps. The objective of this study was to show the expression levels of ADAMTS-5, ADAMTS-8 and ADAMTS-9 gene in nasal polyposis and make a contribution to the etiopathogenesis.

Materials and Methods: The study included a total of 48 subjects, of whom 34 patients suffered from nasal polyposis and 14 healthy tissues were control subjects. After histopathological diagnosis, 1x1 cm of nasal polyposis tissue samples used for gene expression studies. The levels of ADAMTS-5, ADAMTS-8 and ADAMTS-9 gene expressions were measured from each sample belonging to the patient and control groups by real time PCR.

Results: We detected an important decrease of expression levels of the ADAMTS-5 and ADAMTS-9 genes in nasal polyp tissues. Expression levels of ADAMTS-8 gene in nasal polyp tissues were similar when compared with the normal nasal tissues.

Conclusion: This is the first time an association has been found between ADAMTS and nasal polyposis. We concluded that ADAMTS-5 and ADAMTS-9 genes may play an important role in the development of nasal polyposis.

Towards the development of a Lab-on-a-Chip for the identification of trisomy 21 from maternal plasma

S. Kyriakou¹, M. Antonana², M. Ioannides³, E. Papageorgiou^{1,3}, E. Kypriti^{1,3}, G. Koumbaris^{1,3}, J. M. Ruano-Lopez², P. C. Patsalis^{1,3},
¹The Cyprus Institute of Neurology and Genetics, Nicosia, Cyprus, ²IK4-Ikerlan S.COOP, Arrasate Mondragon, Spain, ³NIPD Genetics LTD, Nicosia, Cyprus.

Introduction: The discovery of circulating fetal DNA in maternal circulation was a breakthrough in the field of prenatal diagnosis. Our group has successfully identified differentially methylated regions (DMRs) between fetal and maternal DNA on chromosomes 13, 18 and 21, and developed a non-invasive prenatal methodology utilizing methylated DNA immunoprecipitation in combination with digital PCR, for the detection of trisomy 21. This study aims to implement MeDIP-dPCR on a Lab-on-a-chip (LOC) for a fast and simplified automated screening.

Materials and Methods: The prototype consists of two Chip Units (CU), the MeDIP CU and the pH shift CU. Twenty experiments using λ -meth- and -unmethylated spiked-in samples were used to test the units separately and integrated. Spiked-in samples underwent MeDIP in tube as well as on CUs, followed by qPCR to compare their performance. Finally, CVS spiked-in plasma of non-pregnant women (20%, 10%, 5%), simulating real pregnancies were subjected to MeDIP-dPCR in tube and on the integrated CU system and were evaluated with two 4-plex reactions including six DMRs and two controls.

Results: The prototype of the CU revealed an excellent MeDIP performance in terms of control markers and spike-in trend. The comparison of in-tube and on-chip methods exhibited almost identical results as well as excellent reproducibility of the CU protocol.

Conclusion: The transfer of MeDIP methodology on a LOC format is promising. Further validation on actual cases will be performed on the CU to assess the performance of the system for the non-invasive prenatal detection of trisomy 21.

P17.41

Sapiens-specific genetic changes affecting oxytocin pathways

C. Theofanopoulou¹, C. Boeckx²,
¹Universitat de Barcelona, Barcelona, Spain, ²ICREA/Universitat de Barcelona, Barcelona, Spain.

Introduction: A growing literature suggests that oxytocin pathways (oxr + receptors) must have played a key role in the emergence of human sociality and communication. We wish to provide genetic evidence for this by exploiting recent discoveries in the domain of archaic human genomics.

Materials and Methods: We have relied on robust findings in the genetic foundations of language (FOXP2-CNTNAP2 pathway), an extensive database oxytocin-related search (Pubmed), predictive protein interaction program (String 10), and results from archaic human genomics.

Results: We put forth a sapiens-specific change (compared to archaic humans) affecting the functional connection between OXT, POU3F2, FOXP2, YY1, and CNTNAP2. POU3F2 is known to be necessary for oxytocin cell differentiation. Crucially, a DNase I hypersensitive site accelerated in the human lineage on Chromosome 6 lies in a gene desert 300 kb from POU3F2, which regulates FOXP2 in a sapiens-unique manner. Two of the substitutions in this site strengthen a putative YY1 transcription factor binding site. YY1 has been implicated in one of the variants of the CNTNAP2 5' promoter as risk factors for autism spectrum disorders. YY1 is among the top 10 enriched transcription factors in differentially methylated regions in sapiens vs. archaic humans. YY1 binds in a methylation-sensitive fashion to an insulator sequence within Peg3. Peg3 knockouts show reduced hypothalamic oxytocin neurons.

Conclusion: We suggest that all these oxytocin-related changes are linked and could underlie cognitive and behavioral differences at the heart of our communicative abilities, and open up new avenues in the field of behavioral endocrinology.

Identification of p53-target genes in Danio rerio

B. Mandriani^{1,2}, S. Castellana³, C. Rinaldi⁴, M. Manzoni⁴, G. Borsani⁴, E. Monti⁴, T. Mazza³, G. Merla¹, L. Micalè¹;

¹Medical Genetics Unit, IRCCS Casa Sollievo della Sofferenza Hospital, San Giovanni Rotondo, Italy, ²PhD Program, Molecular Genetics applied to Medical Sciences, University of Brescia, Brescia, Italy, ³Bioinformatics Unit I.R.C.C.S. „Casa Sollievo della Sofferenza“, Istituto Mendel, Roma, Italy, ⁴Department of Molecular and Translational Medicine, University of Brescia, Brescia, Italy.

Introduction: To orchestrate the genomic response to cellular stress signals, p53 specifically recognizes and binds DNA containing p53-responsive elements (REs). Differences in RE sequences can strongly impact p53 transac-

tivation capacity and occur even between closely related species. Although p53 functions have been studied in a wide range of species, not much is known about the p53-mediated transcriptional signature in Danio rerio.

Materials and Methods: We applied an array of computational approaches followed by functional studies to map and characterize p53 binding sites (BS) in the Danio rerio genome.

Results: A total of 3,033 hits were found in the zebrafish genome. First, 10 predicted p53REs were selected according to defined series conditions and functionally validated by performing luciferase-based assays. All tested sequences were significantly responsive to p53. Next, expression level of candidate genes associated to the predicted p53RE in ZF embryos treated with both R-roscovitine or injected with p53 antisense morpholino (p53MO), were qPCR profiled, detecting a symmetrical change of mRNA levels in 7 out of 10, respectively.

Based on the first 10 experimentally validated Danio rerio p53RE, 21 additional putative p53BS were then selected through a position-specific scoring matrix, and subsequently validated by qPCR. We observed a significant activation in 12 out of 21 candidate genes in embryos treated with R-roscovitine and a reduced mRNA level of all 21 genes in embryos injected with p53MO. **Conclusions:** This study identified and validated functional p53 responsive elements and novel p53 target genes in the Danio rerio genome.

P17.43

Transcriptional regulation of GBA and GBAP1 genes

V. Rimoldi¹, G. Rovaris¹, L. Straniero¹, S. Goldwurm², G. Soldà¹, R. Asselta¹, S. Duga¹;
¹Department of Biomedical Sciences, Humanitas University, Rozzano, Milan, Italy, ²Parkinson Institute, Milan, Italy.

Introduction: Parkinson disease (PD) is a complex disorder characterized by the loss of dopaminergic neurons of the substantia nigra. To date, mutations in the GBA gene, encoding the lysosomal glucocerebrosidase, are considered the main genetic risk factor for PD, and glucocerebrosidase downregulation was demonstrated to have a crucial role in PD.

We previously described a miRNA-mediated regulatory circuit linking GBA and its pseudogene (GBAP1) expression. GBA/GBAP1 resulted co-expressed in most tissues (ratio: 2 to 200). Furthermore, we demonstrated that GBAP1 levels are downregulated by the nonsense-mediated mRNA decay (NMD) pathway.

GBA and GBAP1 share a similar genomic structure, characterized by a proximal (P1) and a distal (P2) promoter; no data on the expression regulation of GBAP1 as well as on the relative contribution of the two promoters are available so far.

Methods: We cloned 1kb of the 4 promoters in a luciferase vector and produced serial 5'-deletion constructs for each promoter. These plasmids were transfected in different cell lines.

Results: At difference with what observed for endogenous transcripts, we demonstrated that P2 promoters are stronger than P1s for both genes, and that GBA and GBAP1 promoters have comparable activities. Two Transcription-Factor EB (TFEB) binding sites resulted the main drivers of P1s transcriptional activity, with TFEB overexpression having a stronger up-regulating effect on GBA transcripts.

Conclusions: Besides differences in epigenetic regulation, not faithfully modeled in our system, NMD is likely to be the major determinant of the relative expression of GBA/GBAP1 transcripts.

Funding: This work was supported by Cariplo Foundation, grant#2015-1017.

Yevdokimov“ The Ministry of Public Health of Russia, Moscow, Russian Federation.

Prostate cancer (PCa) is the most common cancer in men worldwide. In Russia, the annual incidence is increasing by an average of 8.7%. A large number of experimental data reveal the role of genetic (mutations) and epigenetic (DNA methylation) factors in the pathogenesis of prostate cancer, which allows us to consider some of them as potential markers for diagnosis.

The study included paired PCa and adjacent benign tissue samples from 12 radical prostatectomy patients. Epigenetic profiling was done using the Infinium HumanMethylation450 BeadChip. Linear models that accounted for the paired study design and False Discovery Rate q-values were used to eva-

luate differential CpG methylation.

In total, 21610 differentially methylated CpG sites were identified in PCA versus adjacent benign tissue (q -value < 0.01), the majority of which were hypermethylated (~85%). 186 top-ranked hypermethylated CpGs had a mean methylation difference of at least 40% between tissue types, and for 14 genes over 50% of promoter region CpGs were hypermethylated. We selected a panel of 9 highly hypermethylated sites. This set was successfully cross-validated using methylation data from 40 paired samples from the prostate cancer project The Cancer Genome Atlas consortium (specificity ~95%, sensitivity ~97%, the area under the ROC curve ~ 0,96).

In summary, this study reports a large number of loci with novel differential methylation statuses, which may potentially be used for the development of future epigenetic-based diagnostic tests.

The work was supported by Ministry of Education and Science of the Russian Federation (grant No. 14.607.21.0068, ID RFMEFI60714X0068)

Investigating the role of long non-coding RNA that are genetically associated with rheumatoid arthritis susceptibility

J. Ding, A. McGovern, P. Martin, S. Eyre, J. Worthington;
University of Manchester, Manchester, United Kingdom.

Introduction and Methods: Rheumatoid arthritis is a chronic, autoimmune, inflammatory disease that affects ~1% of adults in the UK. Genetic factors account for ~60% of the variation in disease susceptibility and are well defined through a strong history of genetic studies. As is common for complex genetic disorders, the majority of the ~100 loci associated with rheumatoid arthritis susceptibility lie outside of protein coding regions. How these loci contribute to susceptibility is largely unknown. Bioinformatic analysis of susceptibility loci was used to identify and prioritise loci that overlap long non-coding RNA: a class of molecules that have been demonstrated to occupy various important functions. Loci situated some distance from the nearest protein coding genes, and where a physical, DNA looping interaction was observed from in-house generated Capture Hi-C data were prioritised. Nine potentially interesting candidates were subjected to expression analysis, performed using the Nanostring platform, aiming to identify expression in relevant stimulated and unstimulated tissues and cell types, in both total and nuclear RNA.

Results and Conclusion: As is typical for long non-coding RNA, expression was generally very low and highly tissue specific. This analysis identifies a selection of long non-coding RNA that will be the focus of future work to investigate the impact of disease risk genetic variance on both the long non-coding RNAs and downstream targets. Of particular interest are lnc-IRF8-5 and lnc-RPLP1-2, which are expressed in synovial tissue, and peripheral blood mononuclear cells, situated over 300kb from their target gene and containing variants significantly associated with RA.

P17.47

Epigenetic study in patients with sepsis

D. Tzoneva¹, D. Nikolova², S. Yankova², Z. Hammudeh², S. Maslyankov¹, I. Dimova²;
¹University Hospital Aleksandrovska, Sofia, Bulgaria, ²Department of Medical genetics, Medical University Sofia, Sofia, Bulgaria.

Lack of potential diagnostic or prognostic markers for sepsis makes it dreadful disease, which holds the highest mortality. Genetic studies have shown that the type of infecting organism, outcome of infections and mortality can be predetermined by analyzing an individual's genome. Genetic/epigenetic studies build up hope for newer diagnostic/prognostic methods in the treatment of sepsis, as well as understanding of its pathogenesis. In our study we have analyzed DNA methylation changes in 22 genes, connected to cellular stress and toxicity. We collected blood samples from 21 surgical patients with sepsis ending in exitus lethalis and 20 control healthy individuals. The promoter methylation status of 22 genes was analyzed using The Human Stress & Toxicity Pathway Finder EpiTect Methyl II Signature PCR Array. Seven genes were successfully analyzed in all samples - CSTB, DNJC15, Gadd45a, Gadd45G, Prdx2, Tp53 and Xpc. The average methylation level for these genes in control subjects was respectively 0, 0.09, 0, 0, 0.07, 0 and 0. In patients with sepsis it was as follows - 0.025, 0.18, 0.1, 0.22, 0.11, 0,1 and 0.06. The highest increase in the methylation fraction was observed for the gene Gadd45G, which encodes cytokine-responsive protein. This study highlights the link between epigenetic changes in inflammatory genes and pathogenesis of sepsis. Further studies are needed for validation of the role for epigenetic markers in the pathogenesis of sepsis. Sepsis genomics will help us in directing treatment against this complication.

P17.48

Tissue-specific and developmental stage-specific expression of sphingomyelin synthase genes

I. B. Filippenkov, T. A. Kolomin, E. O. Kalinichenko, V. G. Dmitrieva, L. V. Dergunova, S. A. Limborska;
Department of Molecular Bases of Human Genetics, Institute of Molecular Genetics, Russian Academy of Sciences, 123182, Moscow, Russian Federation.

Introduction: Sphingomyelin synthase genes (SGMS1 and SGMS2) encode the vital enzymes SMS1 and SMS2 which catalyze the synthesis of sphingomyelin and diacylglycerol from phosphatidylcholine and ceramide. SMS1 and SMS2 are involved in the processes of membrane transport, cell proliferation and apoptosis. However, the structural and functional features of sphingomyelin synthase genes are poorly understood.

Materials and Methods: We present a study of mRNA expression of sphingomyelin synthase genes in adult and embryonic tissues using real-time PCR. The transcript amounts were estimated relative to the average mRNA level of housekeeping genes (LDHA, GAPDH and RPL3).

Results: Human, rat and mouse adult tissues as well as rat brains at embryonic days 7, 9, 13, 17 and 21 were investigated. In adults we found similar mRNA expression of sphingomyelin synthase genes in non-brain tissues, but the level of the SGMS2 mRNA was significantly lower in the brain tissues. In embryonic rat brains the mRNA expression of sphingomyelin synthase genes is varied in developmental stage-specific manner. We have previously determined the circular RNAs (circRNAs) emerging from exons of the 5' untranslated region of SGMS1 gene. These circRNAs are evolutionarily conserved and highly represented in human, rat and mouse adult brain. The expression of circRNAs for SGMS1 was raised during rat embryonic brain development.

Conclusions: Sphingomyelin synthase genes have tissue-specific and developmental stage-specific expression. We assume that the circRNAs are involved in the regulation of sphingomyelin synthase activity in different tissues and developmental stages.

P17.49

Glycemic control and telomere length in juvenile patients with type 1 diabetes

T. Tesovnik¹, J. Kovač¹, T. Hovnik¹, K. Dovč¹, N. Bratina¹, T. Battelino^{1,2}, K. Trebušak Podkrajsšek^{1,2};

¹University medical centre Ljubljana, University childrens hospital, Ljubljana, Slovenia, ²University of Ljubljana, Faculty of medicine, Ljubljana, Slovenia.

Introduction: Type 1 diabetes (T1D) is a chronic disease with characteristic state of hyperglycemia, caused by autoimmune destruction of pancreatic β -cells producing insulin. The chronic state of hyperglycemia has been associated with increased oxidative stress and inflammation and leads to development of diabetic complications. The aim was to evaluate telomere length (TL) and its dynamics as a biomarker in juvenile patients with T1D in relation with glycemic control.

Materials and Methods: In our research, we included 44 juvenile T1D patients, 17 with poor (HbA1c>9%) and 27 matched patients with good glycemic control (HbA1c<7.5%). We assessed 237 chronological DNA samples (3 to 5 per each patient) for chronological analysis of relative TL, telomere dynamics and its comparison with the matched controls.

Results: Results indicate no statistical difference of telomere dynamics between matched patients with good and poor glycemic control, but the linear regression of all relative TL measurements indicates the impact of T1D duration, even adjusted to the age of participants (slope= -0.2638, r²= 0.077, p<0.0001).

Conclusion: Results of our study indicate that telomere dynamics is a complex process. We could not confirm a glycemic control related decrease of TL in T1D patients probably due to the short investigated period of time. Nevertheless, the observed relative TL indicates the negative impact of the disease duration on the telomere dynamics, although a larger number of chronological samples over longer period of disease duration is required to confirm our findings.

Introduction: Global hypermethylation of DNA has been found in several malignancies [1]. Studies on thyroid tumors have shown controversial results. In this study, we aimed to examine the role of DNA methylation of CpG74a in Rap1gap gene among thyroid cancer subtypes.

Methods: we analyzed 95 thyroid tumor samples including normal thyroid (33 cases), benign nodule (36cases), papillary thyroid cancer (PTC) (20 cases), follicular thyroid cancer (FTC) (3 cases) and Anaplastic thyroid cancer (ATC) (3 cases) from Erfan grand hospital, Tehran, Iran. Rap1gap gene expression was assessed using SYBR Green Real-Time PCR. CpG74a Island within the promoter region of this gene was selected; DNA methylation pattern was examined using methylation specific PCR (MSP).

Results: this study showed that Rap1gap was frequently lost or downregulated in various types of tumors, particularly in the most invasive and aggressive forms of thyroid cancer. DNA methylation status of this CpG showed that this alteration is mostly associated with Rap1gap gene downregulation in the differentiated thyroid cancers (PTC, FTC)(80%). However, this value was 16% in undifferentiated thyroid cancer (ATC). CpG74a was methylated in 66% and 72% of individuals with normal thyroid and benign nodule respectively.

Conclusion: this study demonstrates that Rap1gap is likely to serve as an important tumor suppressor gene in thyroid cells and its downregulation during aberrant methylation contributes to differentiated tumor progression and invasion.

Key words: thyroid cancer; RAP1gap; DNA methylation

Characterization of telomeric abnormalities in ICF syndrome types II - IV

S. Toubiana, H. Katzir, S. Yehezkel, S. Selig;

Molecular Medicine Laboratory, Rambam Health Care Campus and Rappaport Faculty of Medicine and Research Institute, Technion - Israel Institute of Technology, Haifa, Israel.

ICF (Immunodeficiency, Centromeric instability, Facial anomalies) syndrome type I patients carry biallelic mutations in DNMT3B which encodes the enzyme that *de novo* methylates repetitive sequences during embryonic development. ICF type I cells display severely hypomethylated subtelomeric regions, abnormally high TERRA levels and short telomeres and ICF type I fibroblasts enter senescence prematurely. ICF syndrome is genetically heterogeneous and three additional genes responsible for this syndrome have recently been identified; ZBTB24 (type II), CDCA7 (type III) and HELLS (type IV). These gene products were not previously linked with the processes of DNA methylation. While many phenotypic aspects of ICF types II-IV are similar to type I, the telomeric phenotype of these patients' cells has not yet been explored. To this end we are studying subtelomeric methylation, TERRA expression and telomere length in lymphoblastoid cells, fibroblasts and blood. Our initial findings in lymphoblastoid cells suggest that ICF types II-IV display subtelomeric methylation patterns that vary from those of ICF type I. NBL-1 subtelomeric repeats are hypomethylated as in type I, while the HuteI subtelomeric repeats, which contain many of the TERRA promoters, are not. In concordance with the normal methylation of HuteI repeats, these cells display normal low TERRA levels. Further characterization of the telomeric phenotype in all cell types will reveal the extent of the telomeric abnormalities in these ICF patients. The findings stemming from this research will further elucidate the mechanisms by which subtelomeric methylation is generated and maintained, and how disrupted subtelomeric methylation can lead to an abnormal telomeric phenotype.

¹CIBERES, Instituto de Salud Carlos III, Madrid, Spain, ²Hospital Universitario N.S. de Candelaria, S/C de Tenerife, Spain, ³Hospital Universitario Dr. Negrin, Las Palmas de Gran Canaria, Spain, ⁴Intensive Care Unit, Hospital Clínico Universitario de Salamanca, Salamanca, Spain, ⁵Intensive Care Unit, Hospital General Universitario de Ciudad Real, Ciudad Real, Spain, ⁶Intensive Care Unit, Hospital Clínico de Valladolid, Valladolid, Spain, ⁷Intensive Care Unit, Hospital Universitario Río Hortega, Valladolid, Spain, ⁸Intensive Care Unit, Hospital Río Carrión, Palencia, Spain, ⁹Intensive Care Unit, Hospital Virgen de La Luz, Cuenca, Spain, ¹⁰Department Anesthesia, Hospital Universitario NS de Candelaria, S/C de Tenerife, Spain, ¹¹Intensive Care Unit, Fundació ALTHAIA, Manresa, Spain, ¹²Department of Pulmonary/Critical Care, University of Chicago, Chicago, IL, United States.

Introduction. The role of the wingless integration signaling site family, member 5A (WNT5A) protein is central to mechanisms of lung healing and fibrosis, including those triggered during lung damage in the acute respiratory distress syndrome (ARDS). We investigated whether common single nucleotide polymorphisms (SNPs) across the WNT5A gene contribute to the development of ARDS in patients with severe sepsis.

Methods. We conducted a prospective, multicenter, genetic association study in a cohort of 387 critically ill patients fulfilling international criteria for severe sepsis. All patients were followed for the development of ARDS. Patients developing moderate and severe ARDS were analyzed as a single group (n=215) and the remaining patients served as controls (n=172). Seven tagging SNPs of the WNT5A gene were genotyped. After imputation, association testing with ARDS susceptibility was examined for 37 SNPs using logistic regression analysis.

Results. We identified three SNPs in high linkage disequilibrium (0.75r2\leq1) that were associated with ARDS susceptibility as a single association signal. The most significant SNP (rs77344209) had an odds ratio of 0.56 for the T allele (95% confidence interval, 0.39-0.80; p=0.001). Based on its location, functionality assessments revealed that this SNP may participate in the modulation of WNT5A gene expression.

Conclusions. Common variants of the WNT5A gene are significantly associated with the development of sepsis-induced ARDS. Further studies in independent population of patients with ARDS are ongoing to confirm our findings.

Genetic signals of adaptation to climate in native populations of North Eurasia

V. Stepanov^{1,2}, V. Kharkov^{1,2}, K. Vagaitseva^{1,2}, A. Cherednichenko¹, A. Bocharova¹;

¹Institute for Medical Genetics, Tomsk, Russian Federation, ²Tomsk State University, Tomsk, Russian Federation.

Introduction: Natural selection probably has played the substantial role in shaping the genetic and phenotypic structure of human populations. The current work aims at search of natural selection signals, providing the adaptation of native North Eurasian populations to cold climate of the region, using candidate genes approach.

Materials and Methods: 28 SNP in genes and genomic regions demonstrating positive signals of natural selection in recent genome-wide studies and involved in pathways and processes potentially implicated in adaptation to cold or resistance to low temperatures (thermoregulation, response to temperature stress, energy metabolism, regulation of muscle constriction etc.) were selected for the study. SNPs were genotyped by multiplex PCR and MALDI-TOF mass spectrometry in 11 native populations representing Northern part of Eurasia - Chukchi, Siberian Eskimo, Nivkh, Koryak, Yakut, Buryat, Khant, Ket, Udmurt, Kirghiz and Uzbek.

Results: The trend of reducing the genetic diversity from southwest to northeast was found. The high total level of genetic differentiation was observed (Fst = 0.764). Detection of loci under selection from F-statistics using coalescent simulations to generate the null distribution of F-statistics under the hierarchical island model of population structure reveals signals of

selection in 10 out of 28 genetic markers including MKL1, COL19A1, CPT1A, UCP3, SLC2A12, and MYOF genes, as well as in several RNA coding loci.

Conclusions: Genetic diversity genetic regions associated with adaptation to cold climate in North Eurasia populations demonstrate non-neutral patterns in North Eurasian populations.

Genome-wide identification of microRNA-related variants influencing the risk of age-related macular degeneration

M. Ghanbari, A. Colijn, O. Franco, A. Dehghan, S. Erkeland, C. Klaver, M. M. Meester; Erasmus medical Center, Rotterdam, Netherlands.

Introduction: Age-related Macular Degeneration (AMD) is one of the major causes of blindness worldwide which part of the pathogenesis remains to be elucidated. Polymorphisms in miRNAs and miRNA-binding sites may affect miRNA function and could therefore contribute to disease risk.

Methods: We investigated the extent to which variants located in miRNAs and their binding sites are associated with AMD using the largest available genome-wide association study (GWAS). We integrated our findings with different biological and computational data to provide evidence for the functionality of the identified variants. We further experimentally examined the effect of associated-variants on the expression levels of related miRNAs and target genes.

Results: Out of 2347 miRNA-variants, 431 were present in the AMD-GWAS, we found three variants that were significantly associated with AMD. In-silico analysis indicated that the mutant alleles could impact on the miRNA hairpin structures. Our subsequent analysis highlighted target genes that may mediate the effect of these miRNAs on AMD. We are currently performing functional experiments to validate the effect of variants on the levels of mature miRNAs and the highlighted target genes. In addition, we examined the association of 82,051 miRNA-binding site variants with AMD and identified 76 associated-variants that could potentially affect miRNA-mediated regulation of their host genes. We, based on GWAS results, eQTL analysis and gene expression data, selected two of these variants to experimentally show an allele-specific regulation of the host genes by related miRNAs.

Conclusions: We provide evidence supporting the role of miRNAs in the pathogenesis of AMD.

Estimation of allele frequency in Chinese population and association study using large scale of low-coverage sequencing data of plasma cell-free DNA

F. Chen^{1,2}, H. Xu¹, Y. Gao¹, X. Jin¹, Y. Zhang¹, P. Xiao¹, S. Li¹, L. Fang¹, X. Xu¹; ¹BGI-Shenzhen, Shenzhen, China, ²Section of Molecular Disease Biology, Department of Veterinary Disease Biology, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark.

Introduction: Previous allele frequency of Chinese Population was calculated using whole exome/genome sequencing data from 1000 Genomes Project. Since 2012 to 2013, we have accumulated low-coverage whole-genome sequencing data of more than 140,000 clinical samples. The purpose of this study was to develop a method to calculate allele frequency in Chinese population using this big and low-coverage data.

Method and Material: Plasma cell-free DNA of each sample was sequenced to obtain ~0.1X whole genome sequencing depth. Maximum-likelihood and site frequency spectrum were used to estimate allele frequency, and the results were compared to the 1000 Genome Project results. Genetic hearing loss was used as a disease model to evaluate the accuracy of allele frequency estimation. As the application of this method, allele frequency of height and diabetes was used for association studies.

Result: The allele frequency spectrum of 140,000 samples was consistent to the 1,000 Genomes Project results, while more variants of ultra-low frequency could be detected. Validated by mass spectrometry results, allele frequency ranging from 0.1% to 1% of 11 loci of genetic hearing loss could be accurately detected. Association study of height-related loci revealed five potential targets (ACAN, GABRA1-GABRG2, PMCH-IGF1, FERMT1-BMP2 and FADS1. One suggestive susceptibility locus of diabetes, LAMC2 at rs942617, was also identified.

Conclusion: It is possible to use the big data of low-coverage sequencing results to calculate allele frequency. Our findings were compatible with previous reports in Chinese population and reveal certain features of molecular prevalence of genetic diseases in China.

Engineering, Universidad de La Laguna, Santa Cruz de Tenerife, Spain.

Introduction: Ancestry assignment in medical and forensic applications results inadequate if based on self-perceptions. Using genetic information for the inference usually requires a large number of SNPs, being impractical and cost-prohibitive in some settings. In addition, the most cost-effective SNP sets consistent on less than a dozen SNPs, only permit the assignment to four out of the seven continental groups. Here we aimed to provide a reduced informative SNP set, preserving a sufficient assignment capacity to seven continental groups, providing a technology-unconstrained low-cost solution.

Materials and Methods: We explored the use of a Monte-Carlo Tree Search (MCTS) algorithm, which allowed evaluating millions of combinatorial models based on a tree search automatically bypassing the ancestry information redundancy provided by the SNPs. We utilized 60% of the human DNA samples from the CEPH-HGDP, determined for 650K SNPs, to derive the SNP sets consistent in 5 to 12 SNP combinations. The reminder 40% of the CEPH-HGDP samples was used for testing their assignment capacity based on differences in likelihood assignments to each group. An additional validation was performed in data from the 1000 Genomes Project (1KGP) populations.

Results: The SNP sets with <12 SNPs were able to assign up to 52.3% of the testing sample. We derived six equivalently optimal 12-SNP sets demonstrating, on average, a correct assignment of 87% of CEPH-HGDP and 88% of the 1KGP samples.

Conclusions: The 12-SNP sets constitute novel solutions for blind, cost-effective and precise assignment of a subject's ancestry to one of the seven continental groups.

Determination of mitochondrial haplogroups of individuals from a medieval cemetery on Devín Castle using analysis of ancient DNA

L. Šebest¹, M. Baldovič¹, C. Bognár¹, L. Kádasi^{1,2}, **K. Kyselicová**³, R. Beňuš³;

¹Department of Molecular Biology, Faculty of Natural Sciences, Comenius University,

Bratislava, Slovakia, ²Institute of Molecular Physiology and genetics, Slovak Academy of

Sciences, Bratislava, Slovakia, ³Department of Anthropology, Faculty of Natural Sciences, Comenius University, Bratislava, Slovakia.

Introduction: Despite the low concentrations of ancient DNA (aDNA) in historical samples and the risk of its contamination with modern DNA, aDNA provides valuable information from various historical periods. The aim of this study was to isolate and analyse aDNA from human remains from medieval cemetery on Devín Castle (Slovakia) dated to 11th and 12th century for the purpose of mitochondrial haplogroups determination. Due to the proximity of the Devín Castle to the medieval overland a river trade routes, we expected the occurrence of haplogroups atypical for this region.

Materials and Methods: As a samples for the aDNA isolation were used 40 human teeth and bones. All worksteps were carried out in accordance with strict recommendations for working with aDNA. Determination of mitochondrial haplogroups was performed on the basis of the HVRI sequencing followed by analysis of polymorphisms in this region.

Results: We determined 11 different haplogroups (H, H1, H1a, H5, J2b, K, T1a, T2, U5a, V and W) with 16 various haplotypes.

Conclusions: Although we detected haplogroups with higher frequencies in regions of present day Hungary (W) and northeastern Germany (H1a), all of the observed haplogroups are commonly distributed in central Europe (where the Devín Castle is also located) and one of the possible explanations of the absence of more „exotic“ haplogroups may be lower importance of Devín Castle as a part of the medieval trade routes.

P18.009

Ancient DNA study of a mysterious lake of Himalaya.

N. Rai¹, G. Chaubey², L. Singh¹, K. Thangaraj¹;

¹Centre for Cellular and Molecular Biology, Hyderabad, India, ²Estonian Biocentre, Tartu, Estonia.

The high-altitude (5029 meters) Roopkund lake is situated in the Himalayan Mountains within the Northern Indian state of Uttarakhand. Here, 70 years ago, several hundred human skeletons were found, in the lake itself and in its vicinity. This discovery was puzzling as the reasons for which so many

people would have travelled and found their end there remained elusive. This is the first study to address the origin of these individuals through genetic and biological analysis of the 82 skeletal remains. Using amelogenin marker, it was found that the majority of the individuals were males. In the same time, AMS dating of the bones revealed that the individuals had lived in the 8th century AD. To address the ancestry of this population, DNA was extracted from the bones of 80 individuals and the complete mitochondrial genome of each of them was sequenced; furthermore, for 25 of them, 200,000 autosomal markers were also genotyped. The comparative genetic analysis, which includes modern day data from both 700 individuals living in the vicinity of the Roopkund site and 22,000 individuals from across India, suggests that the 8th century Roopkund population comprised two groups of genetically distinct individuals. The majority showed genetic affinity with present day contemporary higher caste group and also middle eastern populations, while the others displayed common haplogroups with the Austro-Asiatic population of the North Indian Himalayas.

Application of Artificial Neural Networks for revealing risk factors linked to thymic pathology in Myasthenia Gravis

A. Lopomo^{1,2}, R. Ricciardi^{3,4}, M. Maestri⁵, A. De Rosa⁶, E. Grossi⁵, F. Coppedè¹, L. Migliore¹; ¹Department of Translational Research and New Technologies in Medicine and Surgery, University of Pisa, Pisa, Italy, ²Doctorate school in Genetics, Oncology and Clinical Medicine, Department of Medical Biotechnologies, University of Siena, Siena, Italy, ³Department of Clinical and Experimental Medicine, Neurology Unit, University of Pisa, Pisa, Italy, ⁴Division of Thoracic Surgery, Robotic Multidisciplinary Centre for Surgery, Cardiothoracic and Vascular Surgery Department, University of Pisa, Pisa, Italy, ⁵Semeion Research Centre of Sciences of Communication, Rome, Italy.

Introduction: Myasthenia Gravis (MG) is a rare autoimmune disease characterized by muscle weakness and fatigue, is B-cell mediated, and is associated with autoantibodies to components of the postsynaptic muscle endplate (in most cases, directed to the acetylcholine receptor, AChR). The role of thymus in the pathology is highlighted by the presence of frequent histological abnormalities, as thymoma and hyperplasia, and by the benefit of thymectomy. To reveal risk factors linked to thymic pathology in MG, we applied a mathematical approach based on an artificial adaptive system called Auto Contractive Map-Auto-CM algorithm (Auto-CM), a special kind of Artificial Neural Network (ANN) able to find associations among variables.

Materials and methods: A total of 491 AChR+ MG patients were characterized for age, gender, onset of pathology, Osserman classification of MG and thymic pathology. They were also genotyped for *MTHFR* 677C>T, *MTRR* 66A>G, *MTR* 2756A>G, *TYMS* 28bp repeats, *DNMT3B* -149C>T, *DNMT3B* -579G>T polymorphisms by PCR-RFLP technique (as alterations in folate metabolism have been implicated in the development of various diseases in humans, like cancer). Data were analyzed with the ANN, able to understand non-linear relationships among studied variables and to highlight through a graph the complexity of connections among them.

Results: Interesting correlations among gender, onset of pathology, Osserman classification and thymic pathology emerged. By selection of specific variables a correlation among thymoma, polymorphisms and Osserman classification was observed.

Conclusions: ANN revealed the complexity of the interconnections among factors linked to thymic pathology in MG.

Introduction: Opioid therapy is a mainstay in acute and chronic pain management especially for cancer related pain. Genetic causes for inter-individual variability of the clinical response to opioids have been proved for several years. Mu opioid receptor (MOR) is the primary target of morphine for cancer pain treatment. KAPPA opioid receptor (KOR) has a functional interaction with MOR activation pathway and COMT (Catechol-O-methyltransferase) is a key enzyme that metabolizes catecholamines in the nervous system and has been linked to substance abuse. In this study, we focused on six polymorphisms in Mu and Kappa opioid receptors and COMT genes

(OPRM1; OPRK1 and COMT respectively), and their association to morphine dose needed to decrease the pain intensity in tunisian cancerous patients. **Materials and Methods:** We collected 129 blood samples from cancerous patients under morphine treatment at different doses. DNA extraction was achieved for all patients. By Simple Probe probes on Light Cycler, we screened for the 6 SNPs in OPRM1, OPRK1 and COMT genes. Statistical analysis were performed by "R" software.

Results: We detected significant association of one SNP in the OPRK1 gene and bone metastasis ($p=0.02783$).

Conclusion: We showed, for the first time, an association between one SNP in OPRK1 and bone metastasis. No evident association of the other polymorphisms screened and the dose of morphine needed for pain relief was proved in our population.

This research was supported by funds from TWAS (The Academy of Sciences for the Developing World).

Integrating transcriptomic and genomic data to identify genes involved in acute respiratory syndrome

M. Pino-Yanes^{1,2}, N. Hernández-Pacheco^{1,3}, M. Acosta-Herrera^{1,2,4}, A. Corrales^{1,2}, A. Barreto-Luis¹, B. Guillen-Guio¹, E. Zavala^{2,5}, J. Belda⁶, S. Ma⁷, J. Villar^{2,4}, C. Flores^{1,2,3}; ¹Research Unit, Hospital Universitario N.S. de Candelaria, Tenerife, Spain, ²CIBER de Enfermedades Respiratorias, Instituto de Salud Carlos III, Madrid, Spain, ³Applied Genomics Group (G2A), Section of Genetics, Department of Biochemistry, Microbiology, Cell Biology and Genetics, Universidad de La Laguna, Tenerife, Spain, ⁴Multidisciplinary Organ Dysfunction Evaluation Research Network (MODERN), Research Unit, Hospital Universitario Dr. Negrin, Gran Canaria, Spain, ⁵Surgical Intensive Care Unit, Department of Anesthesia, Hospital Clinic, Barcelona, Spain, ⁶Surgical Intensive Care Unit, Department of Anesthesiology and Intensive Care, Hospital Clínico Universitario de Valencia, Valencia, Spain, ⁷Pulmonary & Critical Care Medicine, University of Chicago, Chicago, IL, United States.

Introduction: Acute respiratory distress syndrome (ARDS) is one of the main causes of mortality in adults admitted to the Intensive Care Units (ICU) and it can be caused by the progression of sepsis. Many previous studies have demonstrated the contribution of genetic variants in the susceptibility and outcomes of this syndrome. In this study, we aimed to identify novel genes implicated in sepsis-derived ARDS susceptibility and/or survival.

Materials and Methods: We performed a prioritization of candidate genes by means of the integration of genomic data from a transcriptomic study in an animal model and from a genome-wide association study of trauma-induced ARDS in humans. From them, three single nucleotide polymorphisms (SNPs) from three different genes were selected to conduct a genetic association study. DNA samples from unrelated individuals with ARDS derived from sepsis (n=349) and from population-based controls (n=900) were genotyped using competitive allele-specific PCR assays.

Results: A SNP from *FLT1* gene (rs9513106) was associated with ARDS susceptibility, with an odds ratio (OR)= 0.81 for the C allele, 95% confidence interval (CI): 0.65-1.00, $p=0.037$. Moreover, a SNP from *ITGA1* gene (rs16880534) was associated with ICU mortality among ARDS patients (OR= 2.94 for the G allele, 95%CI: 1.46-5.94 $p=0.003$).

Conclusions: Albeit the validation of these results is ongoing, the integration of genomic data from different sources constitutes a promising method to identify new candidate genes involved in ARDS susceptibility and progression.

A pathway-based enrichment analysis identifies FZD6-CTHRC1 as a novel asthma susceptibility locus

A. Barreto-Luis^{1,2}, M. Pino-Yanes^{1,3}, A. Corrales^{1,3}, M. Acosta-Herrera^{1,3,4}, C. Gonzalez-Colino⁵, J. Villar^{3,4}, P. Campo⁶, J. Cumpido⁷, J. Martinez-Tadeo⁵, M. Blanca⁶, T. Carrillo^{2,3}, C. Flores^{1,2,3};

¹Research Unit, Hospital Universitario N.S. de Candelaria, Tenerife, Spain, ²Applied Genomics Group (G2A), Section of Genetics, Department of Biochemistry, Microbiology, Cell Biology and Genetics, Universidad de La Laguna, Tenerife, Spain, ³CIBER de Enfermedades Respiratorias, Instituto de Salud Carlos III, Madrid, Spain, ⁴Multidisciplinary Organ Dysfunction Evaluation Research Network (MODERN), Research Unit, Hospital Universitario Dr. Negrin, Gran Canaria, Spain, ⁵Allergy Unit, Hospital Universitario N.S. de Candelaria, Tenerife, Spain, ⁶U.G.C. Allergy, Regional University Hospital of Málaga-IBIMA, Málaga, Spain, ⁷Allergy Unit, Hospital Universitario Dr. Negrin, Gran Canaria, Spain.

Introduction: Accumulated association evidence in genes related by biological pathways can reveal novel asthma genes.

Materials and Methods: Based on summary data from our genome-wide association study (GWAS) of asthma, we identified significant biological

pathways using a gene-set enrichment analysis. We then mapped all tested single nucleotide polymorphisms (SNPs) on the genes contributing to significant pathways, and prioritized those with a disproportionate number of nominal significant associations for replication studies. Replication was performed for selected SNPs from those genes in independent case-control samples (n=1,793) using logistic regressions, and results were meta-analyzed with those from the GWAS.

Results: Two biological processes were significantly enriched: the cytokine-cytokine receptor interaction (p=0.002) and the WNT signalling pathway (p=0.012). Out of the 417 genes interacting in these two pathways, nine showed an excess of nominal associations, including two firm asthma susceptibility genes (SMAD3 and CSF2-IL3) and seven other novel candidate genes. From the latter, 14 SNPs were followed-up and one of them located in the FZD6-CTHRC1 locus was replicated (p=9.90x10⁻⁴), which had a consistent direction of effects with the GWAS findings (meta-analyzed odds ratio=1.49; p=5.87x10⁻⁶).

Conclusions: This study revealed the importance of two biological pathways in asthma pathogenesis and evidenced that the FZD6-CTHRC1 locus contributes to asthma susceptibility.

Background: The number of genetic factors identified for asthma remains limited. The study of gene-by-environment interactions may facilitate the discovery of new genes. Early environmental tobacco smoke (ETS) exposure (in utero or during infancy) is a known risk factor for childhood-onset and late-onset asthma.

Objective: Our goal was to identify genetic variants interacting with early ETS exposure that influence time-to-asthma onset (TAO).

Methods: We conducted a large-scale meta-analysis of five genome-wide interaction studies (GEWIS) of TAO (totaling 3,643 exposed (ETS+) and 5,275 non-exposed (ETS-) individuals of European ancestry) using survival analysis methodologies. Two tests were performed: 1) a joint test of SNP effect and GxETS interaction and 2) a test of GxETS interaction alone.

Results: While the joint test confirmed two asthma regions (9p24 & 17q12-q21) interacting with ETS on TAO at the genome-wide significant level (P<5x10⁻⁸), the interaction test revealed three new loci: 13q21, 16p13 and 19q13 (6.7x10⁻⁷-P<10⁻⁶). Further analysis of the 9p24 and 17q12-q21 loci stratified on asthma age-of-onset (before and after six years) confirmed the known ETSx17q12-q21 interaction in childhood-onset asthma and evidenced a complex effect of 9p24 top SNP on asthma risk with: 1) the strongest effect in ETS+ early-onset subjects (HR [CI]=1.41 [1.25-1.58]), 2) an intermediate effect in both ETS- early-onset (HR=1.23 [1.12-1.34]) and ETS+ late-onset subjects (HR=1.26 [1.14-1.39]) and 3) no effect in ETS- late-onset subjects (P=0.38).

Conclusion: This study suggests an important role of early ETS exposure and 9p24 genetic variants in asthma age-of-onset.

Genetic susceptibility loci for coronary artery disease and large artery stroke are associated with human atherosclerotic plaque characteristics

S. W. van der Laan¹, M. A. Siemelink¹, S. Haitjema¹, H. Foroughi Asf¹, M. Mokry¹, J. van Setten¹, R. Malik³, M. Dichgans³, B. B. Worrall⁴, N. J. Samani^{5,6}, H. Schunkert⁷, J. Erdmann⁷, U. Hedin², G. Paulsson-Berne², J. L. M. Björkegren², G. de Borst¹, F. W. Asselbergs^{1,8,9}, H. M. de Ruijter¹, P. I. W. de Bakker¹, G. Pasterkamp¹; ¹UMC Utrecht, Utrecht, Netherlands, ²Karolinska Institutet, Stockholm, Sweden, ³Institute for Stroke and Dementia Research, Munich, Germany, ⁴University of Virginia, Charlottesville, VA, United States, ⁵University of Leicester, Leicester, United Kingdom, ⁶Glenfield Hospital, Leicester, United Kingdom, ⁷Deutsches Herzzentrum München, Munich, Germany, ⁸Durrer Center for Cardiogenetic Research, Utrecht, Netherlands, ⁹University College London, London, United Kingdom.

Background: Tens of genetic susceptibility loci associate with large artery ischemic stroke (LAS) and coronary artery disease (CAD), but deciphering their underlying mechanisms to identify putative therapeutic targets is challenging. Atherosclerosis is cardinal to cardiovascular diseases (CVD) and histological studies have identified plaque characteristics that associate with clinical outcome. To what extent common variation associated with CVD relates to these characteristics remains unknown. We studied the impact of sequence variation on plaque characteristics, and tissue-specific gene expression by combining data from independent biobanks comprising patients with clinically significant arterial stenosis.

Methods: We genotyped 1,439 patients from Athero-Express, 127 patients from BiKE, and 109 patients from STAGE. We tested 61 CVD susceptibility loci for association to seven plaque characteristics, and gene expression using regression modeling, correcting for age, sex, 10 principal components, and study specific covariates.

Results: We report a ~5.2-fold enrichment of CAD variants associated with plaque characteristics (p = 3.6x10⁻⁸, 16 out of 61 variants). The CAD risk reducing alleles of rs12539895 and a nearby deletion (chr7:106,901,393 TG > T) on 7q22 associated with less fat in plaques (p < 5.1x10⁻⁶), and lower circulating LDL levels. Circularized chromosome conformation capture in monocytes revealed many regional genes physically interacting with rs12539895. Additional analyses revealed tissue-specific effects on HBP1, COG5, and GPR22 expression, further prioritizing the list of 11 regional genes for future studies.

Conclusion: Our study supports the view that genetic loci conferring susceptibility to CAD and LAS, play a role in the underlying pathophysiology of the atherosclerotic plaque.

Bardet Biedl syndrome shows a distinctive genetic epidemiology in Iran: targeted next generation sequencing revealed 15 novel mutations in 6 genes previously reported for the disease

M. Keramatipour, Z. Golchehre, D. Kooshavar, A. Karamzade, M. Razipour, M. Entezam, M. Saberi; Tehran University of Medical Sciences, Department of Medical Genetics, Tehran, Iran, Islamic Republic of.

Bardet Biedl Syndrome (BBS) is a rare autosomal recessive (AR) and genetically heterogeneous ciliopathy characterized by retinitis pigmentosa, obesity, polydactyly, learning disabilities, renal involvement, and genital abnormalities. So far 21 genes have been identified to cause BBS. In this study 18 unrelated patients with clinical diagnosis of BBS were investigated by target region capturing of 18 BBS-related genes (*BBS1*, *BBS2*, *ARL6*, *BBS4*, *BBS5*, *MKKS*, *BBS7*, *TTC8*, *BBS9*, *BBS10*, *TRIM32*, *BBS12*, *MKS1*, *CEP290*, *SDCCAG8*, *WDPCP*, *TMEM67*, *LZTFL1*) followed by next generation sequencing (NGS). NGS results were then validated by Sanger sequencing. The genetic diagnosis was achieved in 15 patients (83.33%) including 15 novel and 1 previously reported variants in 6 genes (one case was compound heterozygote). The novel variants were absent in population and disease-specific databases, were predicted to be disease causing by multiple *in silico* predictive tools, and changed nucleotides were evolutionally well conserved. All variants were shown to be segregating in the family. Based on the American College of Medical Genetics and Genomics (ACMG) guidelines for the interpretation of sequence variants, they are classified as pathogenic/likely pathogenic variants. The most commonly involved genes were *BBS9* and *BBS12*, each with a frequency of 26.66%, followed by *TTC8*, *BBS10*, *BBS7*, with a frequency of 13.33% each, and *MKKS* with 6.66% frequency. Detailed data will be presented at the meeting. Due to distinctive spectrum of causative genes with mostly novel mutations, it seems that the genetic epidemiology of the disease in Iran is different from that of other reported populations.

P18.018

Genome-wide association study of bitter taste perception of quinine in an isolate population of Croatia

A. Relja¹, I. Patarčić², A. Miljković², C. Hayward², I. Rudan², I. Kolčić¹;

¹Medical School, University of Split, Split, Croatia, ²Institute for Genetics and Molecular Medicine, University of Edinburgh, Edinburgh, United Kingdom, ³Usher Institute, University of Edinburgh, Edinburgh, United Kingdom.

Aim: Taste perception plays an important role in the diet composition, which is the leading lifestyle risk factor for cardiovascular diseases and cancer. The aim of this study was to investigate genetic background of bitter taste perception.

Materials and methods: Subjects from the 10,001 Dalmatians cohort were involved in the bitter taste recognition threshold measurement, based on water solution of quinine, starting from 1E-06 M and increasing by 0.22 log value. A GWAS meta-analysis was performed using 317,500 SNPs in a sample of 936 individuals from the Island of Korcula and Vis, and the City of Split, Croatia, controlling for age, gender and kinship.

Results: Bitter taste threshold was strongly associated with 8 SNPs from PRH1-PRR4, PRH1, TAS2R19 and TAS2R20 gene, with P values between 1.5E-11 to 8.8E-39, belonging to the following SNPs: rs4763602, rs10772420, rs12226919, rs12226920, rs10845279, rs7307031, rs10845289 and rs10492102. Additionally, we detected marginally suggestive SNP at chromosome 6, belonging to ADGRF5 gene (rs1004018; P= 4.4E-07).

Conclusion: While the finding of the PRH1-PRR4, PRH1, TAS2R19 and TAS2R20 genes confirms the previous studies, the ADGRF5 gene is reported for the first time, suggesting even greater complexity of the genetic basis of bitter taste perception. These results could be used in numerous applications, including personalized dietary planning, fitness and other health-related utilization. Further refinement of these results in the imputed data and increased sample sizes is under way.

Rare variant association tests for survival outcomes in population and family structured studies

Y. Chiu¹, L. Chien², D. Bowden²;

¹National Health Research Institutes, Zhunan, Taiwan, ²Academia Sinica, Taipei, Taiwan, ³Wake Forest School of Medicine, Winston-Salem, NC, United States.

Functional variants are likely to be aggregated in family studies enriched with affected members, and this aggregation increases the statistical power for rare variant detection. In addition to the identification of associations with qualitative and quantitative traits under a generalized linear model framework, associations of rare variants with time-to-event traits are of growing interest. However, very limited approaches are available for the analysis of rare variant associations with time-to-event traits in family or hybrid designs. Therefore, we developed novel pedigree-based burden and kernel association tests for family time-to-event outcomes with right censoring, and used Cox proportion hazard models to relate a time-to-event trait with rare variants. We describe how to employ Cox models in commonly used pedigree-based burden and kernel tests. Furthermore, we demonstrate the robustness of our proposed tests when the proportional hazard assumption is violated. Statistical inferences can be made through asymptotic distributions of the proposed tests, permitting their application to large-scale whole-genome sequencing data. The proposed tests are appropriate for practical use under a wide range of misspecified Cox models, as well as for hybrid population- and pedigree-based designs. Extensive simulation studies were conducted to compare the proposed tests with existing gene-based rare variant association tests for family survival outcomes. We applied the proposed tests to the exome chip data from the Diabetes Heart Study to identify variants associated with age at onset of type 2 diabetes.

Genetic structure and demographic history of the Caucasus: insights from whole-genome sequences

M. Mezzavilla^{1,2}, M. Haber², Q. Ayub², Y. Xue², P. Gasparini^{1,3}, C. Tyler-Smith²;

¹Sidra Medical and Research Center, Doha, Qatar, ²The Wellcome Trust Sanger Institute, Wellcome Genome Campus, Cambridge, United Kingdom, ³University of Trieste, Trieste, Italy.

Archaeological findings suggest that modern humans have inhabited the Caucasus since Paleolithic times but little is known about their origin and how they have interacted with neighboring populations. Previous genetic studies of present-day populations from the Steppe suggested the Caucasus

acted as a barrier, leading to genetic discontinuity between the Caucasus and the East European Plain. Furthermore, geography, ethnicity, and language are also expected to influence the mating patterns of the populations inhabiting the Caucasus and thus create genetic structure within this region. Here we use whole-genome genotyping and sequencing data to fully understand the genetic diversity of the Caucasus and its role in the demographic process that shaped modern Eurasian genomes.

Combining data from 12 high-coverage whole-genome sequences, four each from Georgia, Armenia, and Azerbaijan with SNP-genotype data from more than 250 individuals from the same populations, we present one of the most comprehensive datasets for this region. Principal component analyses, followed by model-based clustering, reveal previously unreported structure among the Caucasus populations. In particular, we discovered three different clusters among Georgians and two in Azerbaijan, in addition to different ancestral proportions in these clusters. MSMC analysis of the whole genomes shows Caucasus populations have diverged in the last 20,000 years from other Eurasians and have experienced different demographic changes in recent times

We thus provide a detailed analysis of the past and present demography of the Caucasus which will be useful for understanding the genetic diversity of this region and the relationship with European populations.

P18.021

A novel mutation in MTMR2 gene causing CMT4B1; A founder effect in Ashkenazi Jews

T. Abdalla¹, A. Peleg¹, O. Sadeh¹, K. Badarneh¹, G. Larom-Khan¹, F. Fares²;

¹Department of human Genetics, Carmel medical center, Haifa, Israel, ²Department of Human Biology, University of Haifa, Haifa, Israel.

Charcot-Marie-Tooth type 4B1 (CMT4B1) is a rare type of the CMT group caused by mutations in the Myotubularin-related protein 2 (MTMR2) gene. A novel frame-shift mutation was found in an Ashkenazi Jewish patient, diagnosed with CMT in childhood. Whole exome sequence indicated that the patient is homozygous for the mutation c.1877_1878insAGAG in the MTMR2 gene. To our knowledge, this mutation was never reported. Both parents are healthy, no consanguinity reported, and DNA sequencing analysis indicated that both are heterozygote for this mutation. Such surprising finding, made us suspect a founder mutation in the Ashkenazi population.

We conducted a research aiming to examine the prevalence of this novel mutation in Ashkenazi Jews. If it is indeed a common mutation, it is worth considering including it in the genetic screen offered for this population in Israel.

We assumed that if the prevalence of this variant was 1:100 among Ashkenazi Jews, then the study should include at least 400 samples, in order to detect at least one heterozygous object (confidence interval for 0% is <1%). PCR analysis followed by DNA sequencing was performed, on a total of 450 samples. No heterozygous were found, hence the prevalence of this novel mutation in Ashkenazi Jews is less than 1:100. Another explanation for this finding is an unknown or unreported consanguinity between parents.

Therefore, at this stage, based on our results, it is not recommended to include this novel mutation as a part of the genetic screening for Ashkenazi Jews.

Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, ³University of Geneva, Geneva, Switzerland, ⁴Cardiovascular Medicine Unit, Department of Medicine Solna, Karolinska Institutet, Stockholm, Sweden, ⁵Unitat de Trombosis i Hemostasia. Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, ⁶Institut of Biological Psychiatry, Mental Health Snc. Hans, Roskilde, Denmark.

Introduction: Chronic Venous Disease (CVD) is a common multifactorial and complex disease characterized by an abnormal reflux of blood in veins. Despite the high prevalence of CVD, the hereditary component is still unknown. The purpose of this study is to quantify the genetic basis of the CVD and its relationship to venous thromboembolism, (VTE).

Methods: The sample consisted of 895 individuals (60 patients with CVD) belonging to 35 extended pedigrees in the GAIT2 Project. Patients were diagnosed by venous Doppler ultrasound technique following the guidelines of the American Venous Forum. We correlated this disease with other thromboembolic diseases and 86 hemostatic phenotypes using variance component in SOLAR. The genome-wide association study (GWAS) was performed with 9M SNPs using a mixed model and the analysis of association of RNAseq ex-

pression with CVD was performed using bivariate mixed models in Solarius. Results: Heritability of the CVD was 76%. More interestingly, we found a highly significant genetic correlation with VTE, 0.76. Only suggestive signals were found from the GWAS and RNAseq studies.

Conclusions: To our knowledge this is the most extensive study (clinical and biological phenotypes, GWAS and RNAseq data) performed to date to unravel the genetic components of CVD and other related venous diseases. Despite this huge amount of data we did not find any clear signal to explain the high heritability observed and the genetic correlation between CVD and VTE. These results emphasized the high complexity of the genetic basis underlying this disease.

Evolutionary ancient human genes accumulate intronic deletions

M. Rigau, D. Juan, A. Valencia, D. Rico;

Spanish National Cancer Research Centre, CNIO, Madrid, Spain.

Genomic copy number variants (CNVs) are thought to account for an important part of human variability. The number, location and type of CNVs that are annotated in the different studies depend largely on the techniques and algorithms used for their detection. We have compared five of the most comprehensive high resolution CNV maps published in 2015 (Handsaker et al.; Zarrei et al.; Sudmant et al., Science; Sudmant et al., Nature; Abyzov et al.) and evaluated the potential impact of the CNVs on protein-coding genes by classifying them in different gene ages. In all maps, we see that CNVs that encompass whole genes (thus influencing their gene dosage) are significantly enriched in Primate-specific genes and significantly depleted in more ancient genes, confirming and extending our previous results (Juan et al, Biology Open, 2013).

The higher resolution of the integrated experiments allows us to uncover that when CNVs are overlapping with exons, they accumulate in recent genes, a similar pattern to that of whole-gene CNVs. However, partial CNVs located within introns are over-represented in ancient genes. More precisely, genes born before the ancestor of human and bony fish show an excess of intronic deletions in current human populations. We will present our ongoing analyses characterising the genomic, epigenomic and functional characteristics of the ancient genes showing these intronic deletions.

Taken together, our results show how the precise mapping of CNVs in combination with phylogenetic information allows us to understand the differential impact of duplications and deletions in protein-coding regions.

Viladecans, Spain, ⁴University Southern California, Los Angeles, CA, United States,

⁵University of Barcelona, Barcelona, Spain.

Introduction: Colorectal cancer (CRC) is a complex disease with both genetic and environmental risk factors contributing to susceptibility. The analysis of gene-environment interactions (GxE) can identify new susceptibility loci but statistical power is reduced in part because agnostic searches require adjustment for millions of tests. To reduce this burden and improve power in a GxE analysis, one option is to incorporate functional genomics data to prioritize the candidate SNPs.

Materials and methods: We are generating RNA-seq data from 300 normal colon biopsies from voluntary subjects undergoing colonoscopy within a screening program. Detailed environmental and lifestyle risk factor information is requested by personal interview. Here we focus on the analysis of the association between gene expression and environmental variables (eQTL analyses will follow). Linear models have been used, adjusted for age, sex and education. Empirical Bayes adjustments and false discovery rates are calculated to reduce false-positive results. Gene-Set Enrichment Analysis has been also performed to identify pathways modified by each environmental exposure.

Results: To date, 145 samples have been fully analyzed and preliminary results indicate that significant associations can be identified for genes with expression correlated to red meat, processed meat, vegetables, fruits, alcohol, smoking, physical exercise, aspirin and BMI.

Conclusions: Environmental variables known to be risk factors for CRC modify the expression of specific genes in the normal colon mucosa. Genetic variation in these genes may provide further insight into the complex etiology of CRC.

Funding: ISCIII-co funded by FEDER grant PI14/0613 and NCI U19-CA148107

P18.026

A novel gene-gene interaction test for rare variants in complex disease studies using case-control samples.

C. Kang, R. Chung;

Division of Biostatistics and Bioinformatics, Institute of Population Health Sciences, National Health Research Institutes, Zhunan, Taiwan.

Introduction: Gene-gene interaction can play an important role in complex disease etiology. With the advancement of next-generation sequencing, many rare variants have been discovered. However, current gene-gene interaction tests are mainly developed for common variants. Therefore, a gene-gene interaction test accounting for rare variants is desirable.

Materials and Methods: We developed a powerful gene-gene interaction test, which includes several steps: (1) for a pair of genes, odds ratios of interaction for all pairs of rare SNPs between the two genes are calculated; (2) the SNP pairs are ranked by the odds ratios, and the pairs with rank in the highest and lowest 2.5% are selected; (3) calculate the overall genotype counts for the selected pairs. The interaction statistic based on odds ratios (IOR) or goodness-of-fit (IGOF) is calculated using the genotype counts. (4) Permutations are used to calculate the p-value.

Results: We used simulations to evaluate the type I error rates and compare the power of the proposed tests with another interaction test for rare variants (SPAR). Our simulation results suggest that the IOR and IGOF have appropriate type I error rates. Moreover, IGOF is generally more powerful than IOR, while both tests have higher power than SPAR.

Conclusions: In conclusion, the IOR and IGOF will be very useful to detect gene-gene interactions for rare variants. We implemented the IOR and IGOF into an efficient software with C++ incorporating threads and MPI. This study was supported by a grant from the Ministry of Science and Technology in Taiwan (MOST 104-2221-E-400-004-MY2).

Characterization of CNVs not previously described, among Valencian population: local reference database

C. Monzó Cataluña¹, P. Marín Reina², I. Quintela García², D. Albuquerque do Santos⁴, L. Gandía Artigues¹, C. Guzmán Luján¹, G. Marcaida Benito¹, M. Aleu Pérez-Gramunt², R. Rodríguez López³;

¹Genetics Laboratory. General Hospital of Valencia, Valencia, Spain, ²Department of Pediatrics. General Hospital of Valencia, Valencia, Spain, ³National Genotyping Centre, NODE, Santiago de Compostela, Spain, ⁴Research Center for Anthropology and Health (CIAS), Coimbra, Portugal.

Introduction: The diagnostic algorithm for intellectual disability which was described in the Consensus for the Implementation of Arrays 2012, has generated the massive identification of new copy number variations (CNVs). Their functional assessment requires a comparison with the described CNVs and with our population scope.

Patients and Methods: We analyzed the CNVs identified in 28 boys and 22 girls, who were studied for having developed non-recognized syndromic phenotypes, with Valencian ancestor. The genomic array using SNPs/CNVs, CytoScan® HD Affymetrix, was applied. The obtained raw data, were analyzed with Chromosome Analysis Suite (Chas) software. The exact location of each CNV, was compared with overlapping variants, which were described in the CNVs data bases.

Results: 16 not described CNVs appeared. Their location overlapped with similar CNVs referred in ISCA as pathogenic. 7 patients, which result array was negative, carried one of these 7 CNVs (92 to 2 kbp); local origins were corroborated. The other 9 CNVs (16 to 4 kbp) are recurrently found in the series. Two patients carried the LOH fragments of 33.9 and 30.8 Mb, respectively.

Conclusions: The percentage of solved cases was similar to that proposed in the Consensus (20%). 7 of the 11 resolved cases (63.6%) carried cryptic causal alterations (<4 Mb). Building databases of CNVs with undetermined significance, from individuals of population level, was essential to the determination of its deleterious and informativeness capacity. Its existence repeatedly did not rule out its possible relationship with the clinical phenotype; wide association studies are essential for their proper assessment.

P18.028

Fine-scale genetic population structure and genetic risk for coronary artery disease in Finland

S. Kerminen¹, I. Surakka¹, A. Sarin¹, E. Tikkanen¹, G. Hellenthal², A. Havulinna², M. Perola³, V. Salomaa³, S. Ripatti¹, M. Pirinen¹;

¹Institute for Molecular Medicine Finland FIMM, University of Helsinki, Helsinki, Finland,

²University College London, London, United Kingdom, ³National Institute of Health and Welfare, Helsinki, Finland.

Introduction: Previous studies have reported genetic differences between South-West (SW) and North-East (NE) Finland and a similar division can be seen, e.g., in incidence of coronary artery disease (CAD). We refine the

current knowledge of the genetic structure in Finland and study whether it explains regional differences in incidence of CAD.

Material and Methods: We apply recent haplotype-based methods ChromoPainter and fineSTRUCTURE to 2376 such individuals from the FINRISK Study survey of 1997 for whom both parents were born close to each other. We generate two CAD genetic risk scores: (1) "Lead-SNP" score using 153 independent lead SNPs and (2) "Polygenic" score using 49,000 LD-pruned SNPs with P-value below 0.05 from CARDIoGRAMplusC4D Consortium.

Results: We show that the genetic borderline between NE and SW Finland follows closely the historic border from 1323 with relatively little uncertainty. Among the genetically identified subpopulations, incidence of CAD in the NE region of Kainuu is 1.82 times as high as in SW Finland and our "Lead-SNP" score for CAD yields an odds ratio of 1.11 ($p=0.025$) between Kainuu and SW Finland. The distribution of our "Polygenic" score shows relatively high risk for CAD in East and low risk in SW, which further reflects the known incidence of the disease.

Conclusions: Haplotype-based methods reveal new details describing Finnish population structure. Geographic distributions of genetic risk scores and incidence of CAD have similarities suggesting that some of the regional differences in risk of CAD are genetic.

Introduction: Recent genome-wide association studies have identified 56 loci associated with coronary artery disease (CAD) among predominantly European populations. However, their relevance to Asian populations is largely unknown.

Methods: We utilized GWAS data (1,147 CAD cases and 3,451 controls) from two Singaporean Chinese studies. Logistic regression analyses were carried out in each dataset and subsequently meta-analyzed. We further tested for involvement of known canonical pathways for loci that had significant associations in our study using Ingenuity Pathway Analysis.

Results: We detected associations at five index variants at the CDKN2A/2B, PHACTR1, BCAS3, ABO and VAMP5/VAMP8/GGCX loci (P-values 6.37×10^{-4} - 4.53×10^{-2}). At four additional loci (in or near LPL, REST/NOA1, COL4A1/2 and ZEB2 genes), we also detected modest associations (meta-analysis nominal P-values ranging from 8.65×10^{-3} - 4.46×10^{-2}) for regional SNPs that were in at least moderate LD with previously reported index SNPs ($r^2 > 0.4$ in 1000G ASN populations). Six pathways, including cell-cycle regulation pathways, glioma signaling and adipogenesis pathways (P-value 0.034 - 0.043) were identified.

Conclusions: We replicated the associations of at least 5 CAD-associated index SNPs among the Singaporean Chinese population. Chinese population has some common variants predisposing to CAD as Western population.

Sources of funding: This research was supported by the HUI-CREATE Programme of the National Research Foundation, Singapore (Project Number 370062002). The Singapore Chinese Health Study was supported by the U.S. National Institutes of Health Grant Numbers R01CA144034 and UM1 CA182876, and by the Singapore National Medical Research Council Grant Number 1270/2010.

Utility of genetic and non-genetic risk factors in predicting coronary heart disease in the Singaporean Chinese

X. Chang¹, R. Dorajoo², Y. Han¹, C. Khor², R. van Dam³, J. Yuan⁴, W. Koh^{2,5}, J. Liu^{2,2}, D. Goh¹, A. Salim⁶, Y. Friedlander⁷, C. Heng¹;

¹Department of Paediatrics, Yong Loo Lin School of Medicine, National University of Singapore; and Khoo Teck Puat - National University Children's Medical Institute,

National University Health System, Singapore, Singapore, ²Genome Institute of Singapore, Agency for Science, Technology and Research, Singapore, Singapore, ³Saw Swee Hock School of Public Health, National University of Singapore and National University Health System, Singapore, Singapore, ⁴Department of Epidemiology, Graduate School of Public Health; and University of Pittsburgh Cancer Institute, University of Pittsburgh, Pittsburgh, PA, United States, ⁵Duke-NUS Graduate Medical School Singapore, Singapore, Singapore, ⁶Department of Mathematics and Statistics, La Trobe University, Melbourne, Australia, ⁷School of Public Health and Community Medicine, Hebrew University of Jerusalem, Jerusalem, Israel.

Introduction: Although numerous phenotype based equations for predicting risk of 'hard' coronary heart disease (CHD) are available, limited data exist regarding the utility of genetic information for such risk prediction in the Singaporean Chinese.

Methods: We conducted a case-control study nested within the Singapore Chinese Health Study (SCHS). A total of 836 males (267 cases) and 470 females (128 cases) were included. All the SNPs included were previously reported in genome-wide association studies (GWAS) and were associated with CHD or its risk factors. Cox proportional hazards models with adjustments for age and gender were used to evaluate each SNP. Those associated with p values less than 0.10 were used to build the Genetic Risk Score (GRS). Three different base models were used - M1: Recalibrated Adult Treatment Panel III (ATPIII) Model; M2: Model built on traditional risk factors used in ATPIII with their coefficients estimated using SCHS data and M3: M2+hsCRP+creatinine.

Results: The GRS was significantly associated with CHD. The inclusion of GRS in the prediction models were shown to improve discrimination, with c-statistics reaching between 0.750-0.758 as compared to 0.662-0.697 obtained from base models for males and between 0.827-0.835 as compared to 0.773-0.780 for females. Higher accuracies were also observed in terms of overall net reclassification improvement (NRI) index across all three models (Male:19.0%-20.4%, $p < 0.001$; Females:14.0%-21.8%, $p < 0.001$). The best performing model is M3.

Conclusion: The GRS is an independent predictor for the risk of incident 'hard' CHD in addition to the conventional risk factors and new biomarkers.

Introduction: The aim of this study was to identify the profile of patients being referred for cytogenetic analysis in a Brazilian center and to determine the frequency and type of chromosomal abnormalities in our patients.

Materials and Methods: 2417 patients (newborns to 64 years-old) were referred for a clinical genetics evaluation followed by karyotype, when indicated, between 2005 and 2015 with variable phenotypes such as mental retardation, multiple congenital malformations, clinical features of Down syndrome (DS), Turner's syndrome (TS) and Klinefelter syndrome (KS), ambiguous genitalia, infertility, amenorrhea and recurrent miscarriage.

Results: We could obtain karyotype from 2376 cases (98.3%). 294 (12.4%) had an abnormal karyotype. Among these, the majority was 179 females (60.8%), and there was 1 male XX (0.3%). The median age was 9 years. 63 patients (21.4%) were newborns, 51 (17.3%) were between 1 month to 1 year-old and 59 (20%) were 18 years-old or older. The commonest abnormalities were DS (57 cases (19.4%), with 3.5% mosaic and 7% robertsonian translocations) and TS (51 cases (17.3%), with 58.8% mosaic cases). We also found 19 (6.4%) KS cases (26.3% mosaic); 67 (22.7%) unbalanced rearrangements; 29 (9.9%) apparently balanced translocations, being 10 (34.4%) relatives of index cases and 6 (2%) complex rearrangements.

Conclusions: We observed a lower rate of abnormalities than previous studies. Karyotyping is still an important tool for screening for malformations and developmental delay in developing countries and is also important for evaluating sexual aberrations and familial translocations.

A genome-wide association scan implicates the DCHS2, RUNX2, GLI3, PAX1 and EDAR gene regions in human facial diversity

M. Fuentes-Guajardo^{1,2}, K. Adhikari¹, C. Gallo³, M. Bortolini⁴, S. Canizales-Quinteros⁵, F. Rothhammer^{6,7}, G. Bedoya⁸, R. Gonzalez-José⁹, A. Ruiz-Linares⁵;

¹University College of London, London, United Kingdom, ²Universidad de Tarapaca, Arica, Chile, ³Universidad Peruana Cayetano Heredia, Lima, Peru, ⁴Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil, ⁵UNAM-Instituto Nacional de Medicina Genómica, Mexico City, Mexico, ⁶Universidad de Tarapacá, Arica, Chile, ⁷Universidad de Chile, Santiago, Chile, ⁸Universidad de Antioquia, Medellín, Colombia, ⁹Centro Nacional Patagónico, CONICET, Puerto Madryn, Argentina.

Introduction: Facial shape shows great variation in humans and is of considerable importance in biomedicine and forensics. Facial appearance has a strong genetic component and could have evolved to facilitate individual recognition. Although genes have been identified for various abnormal phenotypes and genome-wide studies in European populations have been conducted, the genetic basis of normal variation in human facial traits is poorly understood.

Materials and Methods: We conducted a Genome Wide Association Study (GWAS) using ~700,000 genome-wide markers from ~6,000 Latin American individuals. We considered fourteen ordinal facial traits examined in individual photographs. Nine of these traits were also examined in a sub-set of samples (~ 3,000) using landmarks to obtain quantitative data. Association tests used univariate linear regression with an additive genetic model considering age, sex, BMI and five genetic PCs as covariates.

Results and Discussion: SNPs situated in four gene regions (DCHS2, RUNX2, GLI3 and PAX1) showed associations with three ordinal traits related to nose morphology (wing breadth, root breadth, columella inclination). Quantitative analyses confirmed these associations and, in addition, detected an association of SNPs in EDAR with chin protrusion. Consistently, we characterized Edar mouse mutants and found alterations of mandible length. Finally, we replicated the reported association of nasion position with SNPs in PAX3. The genes identified have been implicated in craniofacial development, cartilage bone differentiation, malformations and the evolution of the face.

Conclusions: We demonstrate that human facial variation is influenced by DCHS2, RUNX2, GLI3, PAX1 and EDAR.

Grants:Leverhulme Trust (F/07 134/DF) and BBSRC (BB/I021213/1).

P18.033

LHFPL5 is the gene responsible for congenital hearing impairment in Reunion Island

L. Jonard¹, S. Marlin¹, J. Lerat¹, M. Jacquemont², F. Darce², J. Bonnefont¹, S. Gherbi¹, N. Loundon¹, I. Ben Aissa¹, F. Saint Jalmes Digeon¹;

¹Necker Hospital, APHP, Paris, France, ²Saint Pierre Reunion Hospital, Saint Pierre, France.

Located in the southern hemisphere, the Reunion island was isolated from the rest of the world until the first air transport. Its geography, consisting of two volcanic massifs is an obstacle to internal communications. The white Creoles, from the first core of settlers, represent 20% of the population of the island. Among them „Les PetitsBlancs“ settled in „les Hauts“ during the XIX century. It is in this population that we find the highest prevalence of congenital deafness: 1.6 / 1000 against 0.8 / 1000 in metropolitan France.

The genetic origins of congenital deafness are currently estimated to 80%. Two thirds of the prelingual deafness are isolated and over 40 genes implicated have been cloned to date. 90% of isolated congenital deafness are transmitted in an autosomal recessive mode. Since 2006, 20 children (from 16 families) originated from the Reunion island with bilateral profound deafness isolated received a cochlear implant in our service. 15 of them (from 12 families) presented with a similar phenotype: isolated congenital profound bilateral hearing loss, bilateral vestibular areflexia without cochleovestibular malformation nor retinal disease.

Thanks to NGS, we have involved LHFPL5 in 9/12 families. All patients carry the homozygous 185delT mutation except one family in which this deletion is combined with another variation false sense in trans. Through a study of birth records, we identified the common ancestor torque these 9 families. Alexis and Brigitte were born on the Bourbon island in 1693 and come from families arrived from the metropolitan France in 1665 and 1674.

Examining the type 2 diabetes and depression link using polygenic risk scores

C. Kan¹, N. Mullins¹, D. Mehta², J. Euesden¹, M. McCarthy³, G. Breen¹, Psychiatric Genetic Consortium Major Depressive Disorder Working Group, K. Ismail¹, C. M. Lewis¹;

¹Institute of Psychiatry, Psychology and Neuroscience, London, United Kingdom, ²The University of Queensland, Queensland, Australia, ³Wellcome Trust Centre for Human Genetics, Oxford, United Kingdom.

Background: A bidirectional association between type 2 diabetes (T2DM)

and depression has been consistently reported in epidemiological studies, suggesting that these disorders share common pathophysiological mechanisms. We examined whether polygenic risk scores for T2DM predicts depression status in the Psychiatric Genomics Consortium Major Depressive Disorder studies (PGC-MDD).

Method: T2DM-polygenic scores were constructed from the association summary statistics of Diabetes Genetic Replication And Meta-analysis Consortium (DIAGRAM: 34,840 cases and 114,981 controls), at nine association p-value thresholds (PT = 0.00005-0.5). Logistic regression was used to test for association between T2DM-polygenic scores and depression case/control status in 29 PGC-MDD studies (12,719 cases and 13,922 controls), adjusting for ancestry principal components and study. Cohorts included in DIAGRAM were excluded from PGC-MDD-29. Secondary analyses examined the interaction of T2DM-polygenic risk scores with i) sex and ii) Body Mass Index (BMI).

Results: T2DM-polygenic scores did not predict depression case status at any PT threshold, and no interaction between T2DM-polygenic scores and BMI was detected. A significant interaction between T2DM-polygenic scores and sex in predicting depression case status was found (p=0.00002, R2 explained=0.087% at PT=0.001), which exceeds the Bonferroni correction threshold for 9 PT thresholds and 5 analyses (p=0.001). Stratifying by sex showed that T2DM-polygenic scores predicted depression case status in males (p=0.017, R2 explained=0.067%, OR: 1.06 (1.01-1.10) at PT=0.001) but not in females (p=0.441).

Conclusion: This study provides the first evidence that the epidemiological association between T2DM and depression may have a genetic underpinning, particularly in males.

P18.035

The Irish DNA Atlas - a Study of Genetic Diversity in Ireland

E. H. Gilbert¹, S. O'Reilly², M. Merrigan², D. McGittigan², J. F. Wilson³, S. Ennis⁴, G. L. Cavalleri¹;

¹Royal College of Surgeons in Ireland, Dublin, Ireland, ²Genealogical Society of Ireland, Dún Laoghaire, Ireland, ³University of Edinburgh, Edinburgh, United Kingdom, ⁴University College Dublin, Dublin, Ireland.

Aims: The Irish DNA Atlas is a DNA collection being assembled with the aim of describing the fine-scale population structure in Ireland. Understanding such structure can inform on optimal design of clinical genetic studies as well as the history of the Irish population. We present an overview of, and the preliminary findings from, the study.

Methods: We are recruiting individuals with all eight great-grandparents born in Ireland, within 30 kilometres of each other. Participants are asked to complete a detailed birth-brief, which records place and date of birth of three generations of ancestors. DNA is extracted from a saliva sample. We have genotyped using an Illumina OmniExpress dense SNP genotyping platform. We present a number of analyses designed to visualise genetic structure, including; fineStructure, and ADMIXTURE analysis. We compare the Atlas Irish to European populations, and British individuals from the Peoples of the British Isles study.

Results: To date we have recruited 211 participants. An analysis of dense genotyping data from 142 participants shows that the Atlas participants present affinity with British individuals in ADMIXTURE analysis, but analysis at higher values of k resolves a component that appears enriched in Ireland, but also found in neighbouring counties. fineStructure analysis identifies geographically aligned genetic substructure within Ireland, and can clearly identify Irish with British 'Planter' ancestry.

Conclusion: The data and associated analysis presented here illustrates, for the first time via dense autosomal genotype data, clear resolution of genetic substructure in Ireland, and complements recent similar efforts in the British population.

P18.036

Genomic evidence for self-domestication in anatomically modern humans

C. Boeckx¹, C. Theofanopoulou²;

¹ICREA/Universitat de Barcelona, Barcelona, Spain, ²Universitat de Barcelona, Barcelona, Spain.

Introduction: The genomic revolution offers previously unavailable bodies of data to test hypotheses concerning the forces that shaped modern cognition. Here we adduce evidence from results in comparative genomics in favor of a role for self-domestication in modern humans.

Materials and Methods: We compared lists of genes showing strong signals of positive selection, especially lists of fixed mutations, in anatomically modern human vs. neanderthal (Paabo 2014, Cell), wolf vs. dog (Cagan and

Blass 2016, BMC Evol. Bio.), Large White vs. Tongcheng pig (Li et al. 2014, Animal Genetics), and lab-reared and wild-caught *Drosophila melanogaster* (Stanley and Kulathinal 2016, BMC Evol. Bio.).

Results: We find strong convergence, indeed common targets, in neurogenetic genes, as well as genes implicated in neural crest cells. Particularly in dogs and modern humans, we find genes influencing the velocity of axonal impulse conduction and hormonal changes leading to pro-social dispositions (oxytocin pathways).

Conclusion: The convergence observed suggests that self-domestication played a role in the emergence of cognitive and behavioral human modernity, and also provides partial support for the neural crest cell-based account of the domestication syndrome (Wilkins et al. 2014, Genetics).

P18.037

Genetic variants influencing epigenetic plasticity

M. Rask-Andersen, S. Enroth, U. Gyllenstein, Å. Johansson;
Uppsala university, Uppsala, Sweden.

Introduction: Variance or variation SNPs (vSNPs) are genetic variants associated with phenotypic variance heterogeneity, rather than mean phenotypic value. Such vSNPs could be advantageous for adaptation to new environments. It has been suggested that vSNPs can increase epigenetic plasticity, and thereby even explain part of the missing heritability behind complex diseases. In this study, we have identified vSNPs associated with unequal variances in DNA methylation.

Materials and Methods: DNA methylation levels at over 450,000 CpG sites and genotype data from over 10,000,000 SNPs were analyzed in 729 individuals. The variances for different genotypes were compared using an F test. Results: We could verify that three previously identified vSNPs (rs6936204, rs6936204, and rs3130320) are associated with unequal variance in DNA methylation ($P = 0.99$) with respective vSNP. We also identify 4797 novel vSNPs ($p < 9.4e-11$) of which a majority (96.7%) are due to additional linked SNPs that alter the mean methylation level of the CpG site. Only a small number of the vSNPs identified ($N=132$) did not appear to be explained by additionally linked SNPs.

Conclusions: Most vSNPs are not causing epigenetic plasticity, but are rather caused by linked genetic variants that are associated with the phenotypic mean. However, we have identified other potential vSNPs that might influence the variance in DNA methylation, possibly increasing the epigenetic plasticity and thus altering individuals' risk of environmentally induced diseases.

P18.038

Environmental effects on epigenetic variance in monozygotic twins

E. Carnero-Montoro¹, A. Visconti¹, C. Sacco², P. C. Tsai¹, T. D. Spector¹, J. T. Bell¹;
¹King's College London, London, United Kingdom, ²Department of Statistical Sciences, University of Bologna, Italy, Bologna, Italy.

It has been proposed that epigenetic modifications play a key role in mediating individuals' phenotypic responses to environmental changes. Recent epigenome-wide association studies (EWAS) have confirmed that environmental exposures, such as smoking, affect DNA methylation levels in human populations. Until now, EWAS have predominantly focused on finding mean differences in methylation levels between exposed and unexposed subjects. We hypothesize that environmental factors can increase epigenetic variability at functionally relevant genomic regions in individuals exposed to environmental stimuli, and that the increased epigenetic variance can trigger phenotypic plasticity in response to environmental exposures.

Monozygotic (MZ) twin studies are extremely valuable to detect environmentally-driven epigenetic changes, as MZ twins are matched for many factors, ruling out the possibility that associated epigenetic modifications are attributed to genetic variation. Here, we used an environment-concordance MZ twin study design to detect CpG sites showing differences in DNA methylation variance between twins exposed and unexposed to smoking, that we define as "environmentally-induced variable methylated sites" (eVMSs). To search for eVMS in a dataset of 490 female Caucasian from the TwinsUK registry, we calculated the difference of DNA methylation within each twin pair as a dispersion measure, and we applied the F-test to detect differences in dispersion values among smoking groups. We validated the genome-wide significant eVMSs using the Brown-Forsythe's test in a subset of 438 unrelated subjects. Furthermore, we explored the relationship between eVMSs and metabolic and healthy ageing traits to understand how risk factors, and the consequent environmental-induced epigenetic variability, may trigger disease-related phenotypic changes.

P18.039

A genome-wide association study for facial and scalp hair features in admixed Latin Americans

K. Adhikari¹, T. Fontani², S. Cañ², A. Ruiz-Linares¹;

¹University College London, London, United Kingdom, ²Universidad de Oviedo, Oviedo, Spain.

There is great diversity in primates including humans with regard to hair appearance, such as its distribution, shape and color. Hair plays a range of important functions, including thermal regulation, camouflage, sensory and social signaling, and the evolution of hair has been proposed to be influenced by both natural and sexual selection. Patterns of hair appearance are highly heritable, showing distinct differences across continents. Association studies, mostly in European and East Asian samples, have found loci corresponding to scalp hair color, shape and male pattern baldness.

In a genome-wide association study of admixed Latin Americans from five different countries, we identified eighteen genome-wide significant associations for features of scalp hair (shape, color, graying, balding) and facial hair (beard thickness, mono-brow, eyebrow thickness), including ten novel associations. These contain the first reported loci for hair graying, mono-brow, and eyebrow and beard thickness. A newly identified locus influencing hair shape includes a Q30R substitution in the Protease Serine S1 family member 53 (PRSS53). This enzyme appears to be highly expressed in the hair follicle, especially the inner root sheath, and that the Q30R substitution affects enzyme processing and secretion. The identified regions can have implications for both forensics and the cosmetics industry. Consistent with proposals regarding the evolution of human hair, the genomic regions associated with hair features are enriched for signals of selection.

High prevalence of monogenic familial hypercholesterolemia in a population based study needs deep genetic dissection

m. banikazemi^{1,2}, M. Daneshpour¹, S. Masjoodi¹, S. Zoroufchin¹, B. SedaghatiKhayat¹, K. Guity¹, F. Azizi²;

¹Cellular and Molecular Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran, Islamic Republic of; ²New York Medical College, Valhalla, NY, United States; ³Endocrine Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran, Islamic Republic of.

Introduction: Cardiovascular disorders are the most important health issues in most countries. Dyslipidemia are in high correlation with coronary cardiovascular disorders. In current study we aim to mark and determine prevalence of inherited forms of hypercholesterolemia in Tehran lipid and glucose study (TLGS) and select families for further studies of genetic pattern of this disorder.

Methods: Anthropometrics and biochemical measurements from 16,785 individuals older than 18 years enrolled in each five phases of TLGS were analyzed using Simon Broome criteria. Also individual with triglyceride more than 200 mg/dl were excluded as confounder. Each selected individual's full family pattern was drawn by Progeny software and reviewed in detail.

Results Overall prevalence of dyslipidemia in TLGS was determined to be around 13.9 % in subjects older than 18 years of age (58.2% females, 41.8% males). After reviewing all biochemical and demographic factors related with dyslipidemia, diabetes mellitus type II and obesity were ascertained as major contributing risk factors especially after 40 years old. The results also demonstrated increase in lipid lowering treatment rate along the study phases reaching around 40% during phase five of TLGS. Isolated familial hypercholesterolemia was seen only in 91 individuals (73 Families) with estimated prevalence of 0.005.

Conclusion:

Prevalence of dyslipidemia (elevated TC, LDL and TG) was relatively high in TLGS study cohort (13.86%) and in older age was associated with other comorbidity factors such as diabetes and obesity. However, inherited forms of isolated familial hypercholesterolemia prevalence were comparable to reported published data from other countries and communities.

Cancer surveillance program in young adult patients with Fanconi Anemia (FA)

E. Carrasco¹, N. Gadea², I. Esteban¹, S. Torres¹, C. Diaz³, D. Valcarcel⁴, C. Centeno⁵, M. Munill⁶, J. Lorente⁷, M. Pujol⁸, J. Surrallés⁹, J. Balmaña^{1,2};

¹Familial Cancer Program, Vall D'Hebron Institute of Oncology, Barcelona, Spain, ²Medical Oncology Department, University Hospital Vall d'Hebron, Barcelona, Spain, ³Pediatric Hematology and Oncology Department, University Hospital Vall d'Hebron, Barcelona, Spain, ⁴Hematology Department, University Hospital Vall d'Hebron, Barcelona, Spain, ⁵Gynecology Department, University Hospital Vall d'Hebron, Barcelona, Spain, ⁶Department of Oral and Maxillofacial Surgery, University Hospital Vall d'Hebron, Barcelona, Spain, ⁷Otorhinolaryngology Department, University Hospital Vall d'Hebron, Barcelona, Spain, ⁸Genome Instability and DNA Repair Group, Department of Genetics and Repair Group, Department of Genetics and Microbiology, Universitat Autònoma de Barcelona (UAB), Barcelona Spain and Centre for Biomedical Network Research on Rare Diseases (CIBERER), Barcelona, Spain.

Introduction: Young adult patients with FA face a high risk of solid malignancies. Efforts have been developed to promote follow-up programs for early cancer detection (Spanish guidelines from the *Red Nacional de Anemia de Fanconi, 2012*). Here we aim to describe our 6-year experience and the strategies developed to enhance compliance and reduce patient's cancer risk.

Materials and Methods: From 26 FA patients, 58% are male, median age 21 (17 -34y), 11 are current or former smokers. Patients undergo a full anamnesis and receive health education in the high risk clinics and are recommended a surveillance program that includes hematological, head and neck, oral cavity, and gynecologic (females) follow up every 6 months.

Results: All women have had HPV vaccination, and one premalignant cervical lesion was detected (CIN1). In two patients (8%) bone marrow aspirate yielded a diagnosis of myelodysplastic syndrome. Seven patients (27%) were diagnosed with a malignant tumor: In a biallelic *BRCA2* patient with a prior breast cancer, a secondary *in situ* breast cancer was detected in her prophylactic contralateral mastectomy. The other six patients had a tumor in the head and neck area (HNSCC). At maxillofacial follow-up, two *in situ* SCC in the oral cavity were diagnosed.

Conclusion: HNSCC are the most frequent neoplasm in young adults with FA. Intensive surveillance and preventive strategies are needed. Avoiding tobacco and counseling about healthy lifestyle habits are mandatory to minimize their risk of solid tumors. Increasing self-awareness of oral changes to seek medical evaluation are warranted for early detection.

Introduction:The prevalence of chronic diseases is increasing; thus large prospective cohorts studies are needed to increment the genetic and epidemiological knowledge of these conditions.

Materials&Methods:The Genomes for Life project develops a multi-purpose prospective cohort study that aims to identify genomic, epigenomic, environmental and lifestyle factors, as well as their interactions involved in the development of cancer and other diseases (i.e.cardiovascular, respiratory, metabolic). At recruitment, participants reported information on lifestyle/dietary habits, drug use, diseases diagnostics, family history of diseases, and medical interventions using questionnaires. Information on anthropometric measures, blood pressure, rate pulse, and blood sample were also collected for each participant. Started in the mid-2014 (still ongoing), the population is being recruited through the Blood and Tissue Bank network from Public Healthcare users, aged 40-65 years, and with current residence in the Catalan region. Participants will regularly update their exposure data and will be followed over time for the occurrence of events and mortality by linkage to personal clinical records from the Catalan Public Healthcare.

Results:In February-2016, the GCAT included 9.500 volunteers. The present analysis is based on a subset of 8.910 observations, of which 59% were women. 72% of the participants reported having a good self-perceived health, and according to the WHO classification, 54% were overweight. The

most common self-reported diseases were hypercholesterolemia, allergies, and hypertension (18%,17%,and 15% respectively), and 4% of participants had diabetes. Currently 3.500 blood samples have been genotyped for further analyses.

Conclusions:The GCAT project represents a platform for implementation of the genomic medicine on chronic disorders.

P18.043

Population genetic carrier screening tests : The Israeli national program experience

A. Singer¹, I. Grotto², P. Staffler³, C. Vinkler⁴;

¹Community Genetics, Public Health Services, Ministry of Health, Jerusalem, Israel, ²Public Health Services, Ministry of Health, Jerusalem, Israel, ³Cystic Fibrosis Center, Schneider Children's Medical Center of Israel, Petach Tikva, Israel, ⁴Inst Medical Genetic Wolfson Medical Center, Holon, Israel.

The Israeli population is combined of various ethnic groups which are quite conserved. These groups are Jewish (Ashkenazi and non-Ashkenazi) and arabs (Muslem, Christian, Druze). High frequency of genetic diseases is unique to the Israeli population as a result of its religious isolated small communities, and high rate of consanguinity. Founder mutations are known to be present in these communities and were identified over the years (e.g. Tay Sachs).

With the possibility to perform a molecular diagnosis of many genetic diseases, many disorders became candidates for screening. The Israeli Society of Medical Geneticists (ISMG) made recommendations to expand the carrier screening program and include all of the severe genetic diseases in which the carrier frequency has 1:60. The Israeli MOH accepted this recommendations and today 18 tests are offered free of charge to the general population. This program offers carrier screening for cystic fibrosis, fragile X, and spinal muscular atrophy for the general population and additional tests for severe diseases with high carrier frequency to specific ethnic groups according to founder mutation.

Methods: Tests are offered by the primary physician as part of preconception recommendations. Pretest information are given by trained professionals. Carriers are referred to genetic counseling for discussion of prenatal tests options.

Results: More than 400,000 tests were done during 2013-2014 for the above 18 traits. Of these 117,291 were CF carrier screening tests. The CF registry proves the impact of this program showing a marked reduction in CF birth rates with a shift towards milder mutations.

P18.044

A generalized multilevel adjusted latent class mixed modeling approach for genome-wide association study of blood pressure in a longitudinal pedigree framework

Ö. Karadag, S. Aktas;

Hacettepe University Department of Statistics, Ankara, Turkey.

Introduction: In order to find out the gene regions causing the disease of interest, association studies require a whole genome sequenced framework. Complex designs such as longitudinal measurements are useful tools to understand the behavior of the disease phenotype. In addition, family-based designs provide evidence about the heredity of the disease. In the presence of multiple correlated data, regarding the dependency between the observations may cause assumption violations. Hence, an advanced association model related the correlation structures should be use for testing the whole genome association in a longitudinal pedigree framework.

In this study we propose a generalized multilevel adjusted latent class mixed model for testing the association through the whole genome accounting both serial and the familial correlations by using a latent class structure for the heterogeneous longitudinal phenotype distribution.

Materials and Methods: Genetic Analysis Workshop data was used for the implementation of the proposed model. The longitudinal blood pressure trajectories are homogenized by using latent classes. Because of the computational restrictions, rare variants with MAF< 0,05 are excluded from the analysis. Familial aggregation was integrated into the model by calculating the kinship matrix.

Results: Odd numbered chromosomes were analyzed and the genome wide association results were displayed by using Manhattan plots. Parameter and the heritability estimates were calculated for remarkable gene regions.

Conclusions: The proposed model enables to analyze a considerable amount of SNPs by accounting both serial and familial correlations in the parameter estimations and according to results, provides a better fit rather than the classical models.

P18.045

Choosing the right genotyping array: more than just coverage

L. Broer¹, E. Clemens^{2,3}, O. Zolk⁴, A. Verkerk¹, A. am Zehnhoff-Dinnesen⁵, J. Hottenga⁶, C. Lanvers-Kaminsky⁷, T. Langer⁸, M. M. van den Heuvel-Eibink^{2,3}, A. G. Uitterlinden¹;

¹Department of Internal Medicine, Erasmus Medical Center, Rotterdam, Netherlands, ²Department of Pediatric Oncology, Erasmus Medical Center, Rotterdam, Netherlands, ³Department of Pediatric Oncology, Princess Maxima Center for Pediatric Oncology, Utrecht, Netherlands, ⁴Institute of Pharmacology of Natural Products and Clinical Pharmacology, Ulm University, Ulm, Germany, ⁵Clinic of Phoniatrics and Pedaudiology, University Hospital Münster, Münster, Germany, ⁶Department of Biological Psychology, VU University Amsterdam, Amsterdam, Netherlands, ⁷University Children's Hospital Muenster, Department of Pediatric Hematology & Oncology, University Hospital Muenster, Muenster, Germany, ⁸University Hospital for Children and Adolescents Lübeck, Department of Pediatric Oncology & Hematology, Lübeck, Germany.

Since the dawn of GWAS the number of genotyping arrays has exploded, which makes the choice of array challenging. We compared all currently available arrays on several array characteristics (coverage and imputation efficiency) and focused on several SNP categories such as pharmacogenetics, actionable genes and mtDNA.

SNP-manifest-files for all arrays were obtained from Illumina and Affymetrix. Calculations of coverage were based on the 1kG reference panel, which was divided in its separate ancestries. Imputations using HapMap samples were performed to 1kG. For pharmacogenetics 388 genes and for "actionable genes" 56 genes proposed by ACMG were considered. For mtDNA 71 mt-loci were evaluated.

Twenty-three arrays were included in the comparison. The coverage increased with the size (number of variants) of the array. Imputation quality also increased with the size of the array, indicating that coverage is a good predictor of imputation quality. For both pharmacogenetics and actionable genes a similar trend was observed. However, for pharmacogenetics the DrugDev array from Illumina had over double the number of variants in these genes compared to other arrays of similar size ($P < 0.0001$). Similarly, for actionable genes the Axiom_UKB had 7 times more variants than expected ($P < 0.0001$). No trend was observed for mtDNA, however 3 of the arrays had no mtDNA content, while the global array had a much larger mtDNA content than average ($P = 0.001$).

In conclusion, choosing the right genotyping array will depend on the questions to be answered. However, comparing the different arrays using objective criteria can help make this decision more manageable.

P18.046

Identification of a novel locus associated with skin color in African-admixed populations

N. Hernandez-Pacheco^{1,2}, E. G. Burchard^{3,4}, S. Alonso⁵, C. Eng³, S. Hunstman³, D. Hu³, C. Flores^{1,2,6}, M. Pino-Yanes^{1,6};

¹Research Unit, Hospital Universitario N.S. de Candelaria, Santa Cruz de Tenerife, Spain, ²Applied Genomics Group (GZA), Section of Genetics, Department of Biochemistry, Microbiology, Cell Biology and Genetics, Universidad de La Laguna, San Cristobal de La Laguna, Tenerife, Spain, ³Department of Medicine, University of California, San Francisco, CA, United States, ⁴Department of Biotechnology and Therapeutic Sciences, University of California, San Francisco, CA, United States, ⁵Department of Genetics, Physical Anthropology and Animal Physiology, University of the Basque Country UPV/EHU, Leioa, Bizkaia, Spain, ⁶CIBER de Enfermedades Respiratorias, Instituto de Salud Carlos III, Madrid, Spain.

Introduction: The identification of genetic variants involved in determining skin color has anthropological and forensic importance and could help to identify genetic factors involved in the susceptibility to skin cancer. Here we aimed to uncover genes associated with skin pigmentation in African-admixed populations.

Materials and Methods: We performed a genome-wide association study (GWAS) of melanin levels in 285 Puerto Ricans genotyped with the Axiom LAT1 array (Affymetrix). Imputation of genetic variants was performed using The Haplotype Reference Consortium data by means of the Michigan Imputation Server. A total of 11 million variants with minor allele frequency $\geq 1\%$ and $Rsq \geq 0.3$ were analyzed for association using EPACTS. Variants with $p \leq 1 \times 10^{-5}$ were followed up for replication in 373 African Americans genotyped with the same array.

Results: A total of 82 variants associated with melanin levels in Puerto Ricans at $p \leq 1 \times 10^{-5}$. Seventy-seven were accurately imputed in African Americans, 14 of which showed evidence of replication. A meta-analysis of the two samples identified nine genome-wide significant hits: seven of them located within two genes already known to be associated with skin color (*SLC24A5* [min p -value = 2.6×10^{-14}] and *SLC45A2* [min p -value = 9.7×10^{-10}]), and two variants located in an intergenic region between *BEND7* and *PRPF18* (min p -value = 4.6×10^{-9}), a locus associated with skin color for the first time.

Conclusions: Our GWAS in African-admixed populations confirmed the im-

portance of two loci identified by previous studies and revealed the contribution of a new locus in skin pigmentation.

P18.047

Exploring the ancestry of modern-day Tuscans

S. Anelli^{1,2}, C. Di Gaetano¹, S. Guarrera^{2,1}, G. Matullo^{1,2}, A. Piazza^{1,2};
¹University of Turin, Turin, Italy, ²HuGeF, Turin, Italy.

Background. Etruscan civilization flourished in central Italy from the eighth century BC to the first century AD. A theory of its origin was reported by Herodotus (484-425 BC), who guessed Etruscans came from Asia Minor. In Lemnos, an Aegean island, a stele with inscriptions similar to Etruscan language was found in 1885. Several genetic studies with conflicting pieces of evidence have been accumulated. We analysed the genetic relationships of modern Tuscans with other Aegean peoples by comparing 668,506 DNA SNPs in 122 unrelated individuals living since many generations where the historical Etruscans were settled (i.e. Murlo, Viterbo, Ferrara) and Lemnos island (n=16).

Results. Several identity-by-state (IBS) analyses pointed to a stratification of different genetic contributions to the Tuscan modern genome. Ancestry proportions computed using the ADMIXTURE code showed a predominance of Southern European and Middle Eastern components ($38.0\% \pm 2.8\%$ and $40.3\% \pm 3.8\%$, respectively). Principal component analysis highlighted the genetic relationship of Tuscans to Southern Europe in addition to that with Greek and Aegean individuals.

Conclusion. The high resolution analysis of the modern Tuscan genome exhibits a genetic signature broadly consistent with strata from Lemnos and Greece on a genetic background contributed by Middle Eastern and neighbouring Southern Italian individuals. Such results, to be corroborated by testing more and geographically better distributed individuals, are leading to a radical change of our paradigm of population genetic studies by rephrasing the often abused concept of population origin.

Highly differentiated variants in Africa: Genetic differentiation vs. migration

L. R. Botigué, B. M. Henn;

Stony Brook University, Stony Brook, NY, United States.

Introduction: An individual's genome is composed primarily of common variants, which are not uniformly distributed across all human populations. This uneven distribution is especially significant in Africa, characterized by a complex genetic structure, and where dramatic variation in allele frequencies is found across populations.

Materials and Methods: We analyze low coverage whole genomes from 3,400 Africans sampled from a dozen populations throughout the continent in order to quantify highly differentiated variants (HDVs). HDVs are variants common in one population but rare in another. We perform an enrichment analysis to test whether HDVs are enriched for specific biological functions, and we use population genetic theory to analytically predict the number of expected HDVs.

Results: We see little differentiation among Bantu-speaking populations, emphasizing the strong genetic footprint that the Bantu expansion left in sub-Saharan Africa. We find that HDVs are more affected by genetic drift than by time since divergence between populations, and we detect an exponential relationship between the number of HDVs and Fst. We identify some biological functions that are enriched in HDVs, though predictions of the number of HDVs do not deviate from observed HDVs.

Conclusions: Overall, we conclude that the number of HDVs found between populations is mainly due to demography rather than natural selection even though a large fraction of HDVs are likely to be functional.

Glycans are complex carbohydrates attached to the surface of the protein. With glycosylation being amongst the most abundant post-translational modification, glycans have important role in many physiological processes. Almost forty years ago they were first shown to be changed in patients with rheumatoid arthritis, and ever since the number of diseases associated with glycosylation has been growing.

We have performed genome-wide association studies of 77 immunoglobulin G (IgG) glycosylation traits on 8000 samples imputed to HapMap2 reference panel originating from four different European cohorts with replication in four additional European cohorts (n = 4500). Conditional and joint analyses have been performed using Genome-wide Complex Trait analysis software. Data-Driven Expression-Prioritized Integration for Complex Traits has been used to prioritise genes within associated loci.

More than a hundred novel hits mapping to more than thirty loci have been discovered, many of which were previously shown to be associated with various autoimmune diseases, implicating potential pleiotropy of IgG glycosylation and diseases such as Inflammatory Bowel Disease and Systemic Lupus Erythematosus. Gene sets and pathways enriched for association with glycosylation have been assessed, providing additional insights in the mechanisms of protein glycosylation.

With this study we expanded the network of genes known to be involved in glycosylation of immunoglobulin G providing us with further insights how these molecules could be involved in complex human diseases.

This research has been supported by FP7 grants MIMOmics (contract #305280), HighGlycan (#278535), IntegraLife (#315997), HTP-GlycoMet (contract #324400), PainOmics (contract #602736) and by Medical Research Council UK.

Association between INADL polymorphisms and ischemic stroke functional outcome through genome wide association meta-analysis. GDS Project

M. Mola-Caminal^{1,2}, C. Soriano-Tárraga¹, E. Giralte-Steinhauer¹, C. Carrera², R. Rabionet¹, I. Fernández-Cadenas³, C. Vives-Bauza⁴, X. Estivill⁵, J. Roquer⁶, J. Jiménez-Conde¹; ¹Hospital del Mar Medical Research Institute (IMIM), Barcelona, Spain, ²University of Barcelona (UB), Barcelona, Spain, ³Vall d'Hebron Research Institute (VHIR), Barcelona, Spain, ⁴Centre for Genomic Regulation (CRG), Barcelona, Spain, ⁵Fundació Docència i Recerca Mútua Terrassa, Terrassa, Spain, ⁶Fundació d'Investigació Sanitària de les Illes Balears (FISIB), Palma de Mallorca, Spain.

Cerebrovascular disease is one of the leading causes of disability in adults. Variability in functional outcome after ischemic stroke can be influenced by many factors. Irrespective of clinical factors such as age, stroke subtype, vascular stenosis, location of the injury and size of the affected area, inter-individual variation in neuronal recovery is considerable. A number of metabolic pathways are involved in the cerebral ischemic damage response and their activity may be modulated by variation in the genes that encode their various components. Our aim was to identify genetic variants and genes influencing the recovery process.

We conducted a meta-analysis of four different genome-wide association studies. We included 1193 anterior territorial ischemic stroke Spanish cases with modified Rankin functional Scale measures at 3 months after stroke. Peripheral blood cell DNA was genotyped using the Illumina HumanCore-Exome-24-BeadChip. Association analyses with outcome at 3 months after ischemic stroke were performed using SNPTEST and meta-analyzed with METAL. Data was adjusted for clinical severity at discharge measured by National Institute of Health Stroke Scale, hypertension, age, gender and principal components. Imputation was done using IMPUTE2.

We discovered three genetic variants associated with 3 months outcome after ischemic stroke located in the INADL gene (<5.3E-08).

We have identified a potential loci suggestive of being relevant for functional outcome and the recovery process after stroke. Follow-up studies are warranted to validate these findings in other populations and to establish whether INADL can be a novel therapeutic target for the rehabilitation strategies. Funding: Fundació la Marató de TV3

Improving the power of longevity GWAS by using disease candidates, also investigating pleiotropic effects on longevity via multiple diseases

A. F. McDaid¹, J. Murabito², Z. Kutalik¹;

¹Institute of Social and Preventive Medicine (IUMSP), Centre Hospitalier Universitaire Vaudois (CHUV), 1010 Lausanne, Switzerland, ²Boston University School of Medicine, Boston, MA, United States.

GWAS studies for longevity have found only two robustly replicating SNPs in and near APOE and FOXO3. Recent literature has improved power by looking at subsets of SNPs associated with specific diseases (Fortney et al, PLOS Genetics, Dec 2015). We improve on previous work in various aspects: (i) combined together the two largest longevity GWAS meta-analysis studies ; (ii) used a large panel (190 studies) of genome-wide association summary statistics and applied Mendelian Randomization to compute a causal estimate of various traits/diseases on longevity. For example, using the top 15 (independent) LDL-increasing SNPs we estimate that high LDL levels reduce the chance to live longer than 90 years (-0.24 log odds / LDL SD unit, with p<3e-15).

For each SNP we built priors for longevity effect by combining the SNP's effect on different diseases and the causal effect of these diseases on longevity. This way pleiotropic SNPs with even with small impact on individual traits can gain solid prior strength. We then calculated the Bayes factor for each marker and found that several loci gained genome-wide significance thanks to the informative prior. Furthermore, our approach allowed for dissecting longevity heritability to genetic factors that act through the examined diseases and those that do not. This analysis revealed that the genetic determinants of longevity strongly overlap with those that render us susceptible to diseases.

Genetic determinants of pigmentation in admixed Latin Americans

J. Mendoza-Revilla¹, K. Adhikari², V. Acuña-Alonso³, C. Gallo², G. Poletti², M. Bortolini³, F. Rothhammer⁴, G. Bedoya⁵, S. Canizales-Quinteros⁶, R. Gonzalez-José⁷, D. Balding⁸, A. Ruiz-Linares¹, CANDELA Consortium;

¹University College London, London, United Kingdom, ²Universidad Peruana Cayetano Heredia, Lima, Peru, ³Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil, ⁴Universidad de Tarapacá, Arica, Chile, ⁵Universidad de Antioquia, Medellín, Colombia, ⁶Universidad Nacional Autónoma de México, Mexico DF, Mexico, ⁷Centro Nacional Patagónico, CONICET, Puerto Madryn, Argentina, ⁸University of Melbourne, Melbourne, Australia.

Human pigmentation is a striking aspect of human variability, showing remarkable variation between individuals and populations. In recent years, association studies have identified a number of genes affecting common variation in pigmentation, highlighting the complex genetic architecture of this phenotype. The majority of these studies have been carried out in European-related populations. To better understand the genetic architecture of human pigmentation variation, and its evolution, analyses in a wider range of populations are needed.

We conducted a genome-wide association scan in over 6,000 Latin Americans for three pigmentation traits: skin, eye and hair color. Association testing used multivariate linear regression with an additive genetic model adjusting for: age, sex, and the first five principal components obtained from the SNP data.

Our analyses revealed eleven independent genome-wide significant signals of association with SNPs at 8 different genomic regions including a novel candidate region associated with skin pigmentation. We found that the associated SNP had a higher derived allele frequency in East Asians compared to Europeans and that it showed strong signals of positive selection in East Asians, consistent with the independent evolution of light skin in Eastern Eurasians. Ongoing functional analyses in skin melanocytes should help explain the biological basis of the association observed.

In conclusion, we identified a novel region impacting on human skin pigmentation, providing further insights into the genetics and evolution of this complex trait.

P18.053

Statistical tests for Hardy-Weinberg equilibrium for bi-allelic genetic markers at the X chromosome

J. Graffelman¹, B. S. Weir²;

¹Universitat Politècnica de Catalunya, Barcelona, Spain, ²University of Washington, Seattle, WA, United States.

Introduction: The X chromosome complicates much of genetic data analysis due to the fact that males carry only one copy. Even the most basic analysis, a test for Hardy-Weinberg equilibrium (HWE), is complicated by the hemizygous males. Hitherto, the standard approach for testing X-chromosomal markers has been to ignore the males. In this contribution we argue that males are relevant, because a difference in male and female allele frequency indicates that equilibrium does not hold.

Materials and Methods: We develop chi-square, likelihood-ratio, exact and permutation tests for bi-allelic markers at the X chromosome, assuming a multinomial distribution for the data considering all five genotype counts. We study the Type I error rate of the proposed tests, and compare this approach with the standard tests that exclude males. Empirical data from the GENEVA project on venous thromboembolism is used to assess the practical usefulness of the new methods.

Results: Our X chromosomal exact test (with mid p-value) is most promising because its rejection rate is most close to the nominal level under the HWE assumption. It shows better convergence to the nominal significance rate in comparison with the standard exact test which excludes males. The analysis of the GENEVA database reveals HWE test results can experience large changes in p-value when the males are included.

Conclusions: We have designed very basic statistical tools for the analysis of X-chromosomal genotype data. Our methods are omnibus procedures that verify Hardy-Weinberg proportions and equality of male and female allele frequencies in a single test.

P18.054

GWAS of rejection and mortality in heart transplant patients

J. van Setten¹, Y. R. Li², N. de Jonge³, M. V. Holmes², C. C. Baan³, O. C. Manintveld³, A. M. A. Peeters³, F. Dominguez⁴, P. Garcia-Pavia⁴, K. K. Khush⁵, J. W. Rossano², R. A. de Weger¹, B. Keating², F. W. Asselbergs¹;

¹University Medical Center Utrecht, Utrecht, Netherlands, ²University of Pennsylvania, Philadelphia, PA, United States, ³Erasmus Medical Center, Rotterdam, Netherlands, ⁴Puerta de Hierro University Hospital, Madrid, Spain, ⁵Stanford University, Stanford, CA, United States.

Introduction: Currently, donor/recipient (D-R) matching is suboptimal. Besides HLA, also other genetic factors play a role in graft rejection. We aim to identify genetic variation associated with rejection and mortality after heart transplantation.

Methods: iGeneTRAiN is a large-scale international consortium, which consist of over 11,500 solid organ D-R pairs, including over 1,000 heart transplant D-R pairs. We have conducted genome-wide association studies for rejection and for mortality one year after transplantation, testing over 13 million variants in 605 recipients of European descent. We aim to perform association testing in a larger sample of heart transplant recipients and also cross-organ including lung, liver, and kidney transplants, maximizing statistical power to identify novel genetic variants. Importantly, we have high-resolution data of the MHC region, including 4-digit HLA types.

Results: We did not identify novel loci for rejection and mortality after heart transplantation. Fourteen loci reached a suggestive P-value ($P < 1 \times 10^{-6}$).

Conclusions: We aim to identify variants associated with mortality and rejection after heart transplantation. While our current sample of 605 individuals did not yield novel loci, we will increase the sample size to over 1,000 patients from multiple ancestries. Possible sources of genetic variation underpinning rejection are homozygous deletion copy number variants spanning whole gene or exon regions and LoF variants ablating two copies of a given gene, resulting in incompatibility across the proteomes of donor and recipient. We ultimately aim to translate genetic data into clinical applications such as more optimal genomic compatibility matching of D-R pairs and immune suppression therapy dosing.

P18.055

Alpha globin gene mutations and rare variants in Antalya Province, Turkey

I. Keser¹, Y. Arıkan¹, T. Karaman¹, T. Bilgen², D. Canatan³, A. Kupesiz⁴;

¹Department of Medical Biology and Genetics, Medical Faculty, Antalya, Turkey,

²Department of NABİLTEM, Tekirdag, Turkey, ³Mediterranean Blood Diseases

Foundation, Antalya, Turkey, ⁴Department of Pediatric Hematology, Medical Faculty, Antalya, Turkey.

Haemoglobinopathies constitute entities that are generated by either an

abnormal haemoglobin or thalassaemias. Of these, Alpha thalassemia is a blood disorder which is characterized by absence or diminished production of alpha globin protein. Mostly deletions affects production of related protein differently. In this study, we performed investigate alpha globin gene mutations among 75 cases with alpha thalassemia in Antalya region, following reverse dot-blot hybridization and DNA sequencing for HBA1 ve HBA2 genes. We found 25 mutations out of 75 cases with alpha thalassemia trait phenotype and revealed that 2 out of 25 mutations were point mutation when 23 cases were found to be in deletional type mutation. Mutation negative cases on strip analyses in 2 different cases, HbG-Waimanalo and Hb-Fontainebleau were firstly discovered as two rare variants by DNA sequencing in Antalya. Deletional mutations were: 10 cases with MED, 5 cases with 20.5 kb, 8 cases with 3.7 kb gene deletion heterozygously and 2 cases with same deletion as homozygously. According to our results MED deletion is the most prevalent alpha thalassemia mutation in Antalya region. But, lastly, DNA sequencing method should be considered in cases with clinical background when there is no mutation on strip assay. Also, found the rare variants' origins should be investigated about geographical distribution. As a result, for identifying alpha-hemoglobinopathies and to give reliable genetic counselling, resolution power of the molecular tests are need to be well-evaluated.

P18.056

Trans-ethnic meta-analysis of Hirschsprung disease

C. S. TANG¹, H. Gui¹, S. S. Cherny¹, P. C. Sham¹, P. K. Tam¹, J. H. Kim², The International Hirschsprung Disease Consortium, M. M. Garcia-Barceló¹;

¹The University of Hong Kong, Hong Kong, Hong Kong, ²Sogang University, Seoul, Korea, Republic of.

Hirschsprung disease (HSCR), also known as aganglionic megacolon, is the most common cause of neonatal intestinal obstruction, occurring in 1 out of 5000 newborns. It is a congenital disorder characterized by an absence of ganglion cells in the nerve plexuses of the lower intestinal tract. Despite its high heritability, genetic factors predisposing to HSCR remain elusive. So far association of three disease-susceptibility loci—*RET*, *SEMA3* and *NRG1*—were detected from genome-wide association analyses (GWASs) in Europeans and Asians; however, much of the heritability remains unexplained. Here we present the largest trans-ethnic meta-analysis of HSCR (507 cases and 1191 controls), summarizing association results of all three published GWASs on the disease. By leveraging the trans-ethnic differences in linkage disequilibrium, we fine-mapped the three known loci and narrowed down the putatively causal variants to 99% credible sets. We observed no heterogeneity in effect for *RET* and *NRG1* across European and Asian ancestries but detected European-specific association of a low-frequency variant, rs80227144, in *SEMA3* locus (OR=5.2, $P=4.7 \times 10^{-10}$ in European GWAS). Conditional analysis on the lead SNPs further revealed a secondary association signal, corresponding to an Asian-specific, low-frequency missense variant encoding RET p.Asp489Asn (rs9282834, OR=20.3, conditional $P=4.1 \times 10^{-14}$ in Asian-specific meta-analysis). Effect of RET p.Asp489Asn appeared to be non-additive, with an increased risk of HSCR under a compound heterozygous state with the *RET* intron 1 enhancer. Overall, our study provides novel insights into the genetic architecture of HSCR and has profound implications for the future study design.

P18.058

Genetic network as post-GWAS analysis approach for correlated complex phenotypes: example on infectious diseases

A. Gelemanović¹, I. Patarčić¹, A. Relja¹, C. Hayward², I. Rudan³, I. Kolčić¹, O. Polašek¹;

¹School of Medicine, University of Split, Split, Croatia, ²Institute for Genetics and Molecular Medicine, University of Edinburgh, Edinburgh, United Kingdom, ³Usher Institute, University of Edinburgh, Edinburgh, United Kingdom.

Background: Due to the rigorous genome-wide significance threshold in GWA studies, causative common low-risk polymorphisms for complex phenotypes may be missed. We propose building a genetic network as post-GWAS approach to provide an insight into the role of host genetics in infectious disease pathogenesis from the 10,001 Dalmatians biobank.

Materials and methods: We included 1,998 participants representing isolated island populations and 1,012 participants from mainland population. GWAS with meta-analyses was performed for 11 infection-related phenotypes. Genotypic correlations between each phenotype-associated SNPs from GWAS were used for network construction and enrichment analysis. We also searched for the overlap between correlated infectious phenotypes to find shared core genes and pathways.

Results: Three genes reached a genome-wide significance threshold - HAPLN1 for meningitis in all cohorts, while IPMK for tuberculosis and TTC39B for hepatitis in island cohorts. Genetic network additionally revealed genes

DCN and CORIN to be marginally significant for tuberculosis, DMD for hepatitis and GALNT18 for systemic infections. Pathway analysis also revealed enrichment in genes outside of the immune system that may have plausible functions in various infection-related outcomes.

Conclusions: Network analysis can be a favourable post-GWAS approach, especially to elucidate shared genes among correlated complex phenotypes. Some variants in infectious diseases may be wide-spread, while others could be a result of genetic drift and isolation and possibly even local co-adaptation.

Mathematical modelling of NGS data for an alternative classification of paediatric inflammatory bowel disease

E. Mossotto, B. MacArthur, J. Brodzki, S. Ennis;
University of Southampton, Southampton, United Kingdom.

Introduction: Inflammatory bowel disease is a chronic condition typically classified into Crohn's disease, ulcerative colitis and IBD unclassified. Genetics plays an important aetiological role in paediatric disease. We hypothesise that patients with similar genetic mutation profiles may form distinct clusters in a machine learning model that can reflect or add to clinical information/management. We applied machine learning models to whole exome sequencing (WES) data and constructed an alternative classification model for young IBD patients.

Materials and methods: WES data from paediatric IBD cases (n=136) and controls (n=136) were used in model development and processed using customised scripts. Principal component analysis was used as an unsupervised machine learning model for data visualisation and classification.

Results: The inclusion of genomic variants in addition to clinical features in a machine learning model produced patient clusters distinct to those defined using clinical criteria only. Using KGGSeq scores and entropy calculations, we identified genes that discriminated paediatric IBD cases from controls. Furthermore, Jensen-Shannon divergence-based scoring system prioritises known causal genes and generates a restricted list of candidate genes that will be used to build a supervised model for further disease prediction and classification.

Discussion: Our customised gene selection algorithm demonstrates improved case/control discriminatory power above models based on clinical data only and will form the basis for a progressive supervised model.

This project is funded by the Hilary Marsden IfLS Scholarship.

International Breakpoint Mapping Consortium: the 25-year summary of Estonian results

L. Rohit¹, T. Mõlter-Vään², P. Ilisson¹, P. Tammur¹, K. Kuuse¹, T. Reimand^{1,3,4}, K. Öunap^{1,3};
¹Tartu University Hospital, United Laboratories, Department of Genetics, Tartu, Estonia,
²Tartu University Hospital, United Laboratories, Department of Genetics, Tallinn, Estonia,
³Department of Paediatrics, University of Tartu, Tartu, Estonia, Tartu, Estonia,
⁴Department of Biomedicine, Institute of Biomedicine and Translational Medicine, University of Tartu, Tartu, Estonia, Tartu, Estonia.

We are participating in International Breakpoint Mapping Consortium (IBMC) since 2015. The aim of this project is to map ~10,000 balanced chromosomal rearrangement breakpoints.

The aim of our study was to retrospectively analyse all cases with apparently balanced translocation or inversion and clinical phenotype since 1990 using the archives of our department (25 years). The collected data consists of clinical information, karyotype, results of chromosomal microarray analysis (CMA), DNA availability and the present status of a person (alive or dead). To all selected cases a request of informed consent was sent out, except dead persons. If the DNA sample was not available and/or CMA was not performed, the person was invited to counselling. We have an approval (244/T-11) from the Tartu University Committee of Ethics for this work.

All selected cases will be sent to Wilhelm Johannsen Centre for Functional Genome Research to be analyzed by Mate-Pair Sequencing to assess whether rearrangements predispose to disease by interrupting or otherwise affecting a specific gene.

We found 325 (2.7 % of all karyotypes from blood) diagnosed cases with apparently balanced translocation or inversion. Most of these investigated patients were clinically healthy, except infertility problems and therefore we did not include them. In 35 cases (10.8 % of diagnosed cases) clearly abnormal phenotype was noticed in addition to balanced aberration. Presently in 16 cases we have collected all needed information and material, which will

be investigated further.

In conclusion: abnormal phenotype and apparently balanced aberrations occur seldom in clinical practice in Estonia.

P18.061

Graphical tools for estimating family relationships

I. Galván-Femenía^{1,2}, J. Graffelman³, R. De Cid², C. Barceló-i-Vidal¹;
¹Department of Computer Science, Applied Mathematics and Statistics, Universitat de Girona, Girona, Spain, ²Diseases-GCAT lab group, Institute of Predictive and Personalized Medicine of Cancer (IMPPC) – Germans Trias Health Research Institute (IGTP), Can Ruti Campus Badalona, Barcelona, Spain, ³Department of Statistics and Operations Research, Universitat Politècnica de Catalunya, Barcelona, Spain.

Introduction: Estimating family relationships is a quality control step in Genome Wide Association Studies. Statistical methods as logistic regression require each individual to be independent. If there are any close relatives in the sample, the statistical models can generate misleading conclusions. Thus, identifying family relationships in genetic databases is recommended. Material and Methods: The GCAT-Genomes for Life Cohort Study of the Genomes of Catalonia Project is based on the study of the role of genomic and epigenomic factors in the development of cancer and chronic diseases in the Catalanian population. Currently 3500 blood samples have been genotyped by SNP-arrays methods for further analysis. In this contribution, we analyze these samples with the aim of identifying family relationships. Identity by state (IBS) and identity by descent (IBD) alleles are considered for this purpose. We summarize the most used graphical methods in relatedness research and present two additional tools from the field of compositional data analysis.

Results: Several related pairs are expected to be detected in the GCAT database by plotting the mean versus the standard deviation of IBS alleles and by plotting the proportions of sharing 0, 1 or 2 IBS alleles. Plotting the probabilities of sharing 0, 1 or 2 IBD alleles is used to confirm the supposed family relationships. The graphical tools used in compositional data analysis (ternary diagrams and the isometric logratio plots) mainly confirm the expected inferred relationships.

Conclusions: Graphics used in compositional data analysis such as ternary diagrams and logratio plots are useful in relatedness research.

⁴Applied Genomics Group (G2A), Section of Genetics, Department of Biochemistry, Microbiology, Cell Biology and Genetics, Universidad de La Laguna, Tenerife, Spain.

Introduction: Idiopathic pulmonary fibrosis (IPF) is a low incidence, devastating disease with unknown etiology and high mortality. Several studies, including one genome-wide association study (GWAS) completed by our group, have revealed common and rare variants in >15 genes that firmly associate with IPF susceptibility. In order to provide further delineation of the likely causal variants, here we performed a fine-mapping study of the three loci (11p15.5, 14q21.3, and 17q21.31) achieving significance in our GWAS. Materials and Methods: We used a custom-designed target capture SureSelect XT2 (Agilent) kit and the HiSeq2500 (Illumina) instrument in 181 European-Americans with IPF. Variant sites were identified using a custom GATK-based NGS analysis pipeline. Association testing was performed using unrelated European individuals (n=501) from The 1000 Genomes Project as controls.

Results and Conclusions: Approximately 10⁷ reads per sample were generated with an average of 100X depth coverage across the region of interest (1.7 Mb). A total of 16,253 variant sites were identified but association tests used genotypes from the 10,245 biallelic single nucleotide polymorphisms with call rates >95%, adjusting for five principal components to account for population stratification (lambda=1.001). Despite the reduced sample size, we identified 36 variants reaching genome-wide significance (p<5x10⁻⁸), including one previously identified in the promoter region of *MUC5B* gene (rs35705950), and several other novel susceptibility variants.

Improved imputation accuracy with population-specific SNP array and reference panel in Japanese population

Y. Kawai, T. Mimori, K. Kojima, F. Katsuoaka, J. Yasuda, M. Yamamoto, M. Nagasaki; Tohoku University, Sendai, Japan.

Introduction: Genotype imputation is a key step in genome-wide analysis in human genetics. Accuracy and coverage of imputed variants depend on the selection of SNP array for genotyping as well as the choice of the haplotype reference panel in imputation process.

We developed a new SNP array (Japonica array) optimized for Japanese population and evaluated the imputation accuracy of this array with various reference panels.

Materials and Methods: Whole-genome genotype imputation was conducted for the genotypes obtained from 131 individuals by Japonica array and other SNP arrays with cosmopolitan (international 1000 genomes) and population-specific (1070 whole genomes of Japanese individuals) panels. The imputation accuracy and coverage were computed by comparing the imputed genotype with genotypes obtained by whole genome sequencing.

Results: Better imputation performance was obtained for the Japonica array with the 1KJPN panel compared with other combinations of SNP array and reference panel. The genomic coverage of imputed genotypes ($r^2 > 0.8$) with the Japonica array reached around 97% and 67% for common ($MAF > 5\%$) and low-frequency SNPs ($0.5\% < MAF \leq 5\%$), respectively.

Conclusions: A combination of population-specific SNP array with dense haplotype collection improved both imputation accuracy and coverage.

Investigating the genetic control of kidney function of individuals in the Scottish population

R. F. Oppong¹, O. Devuyt², C. Hayward³, P. Navarro³, C. S. Haley^{3,4}, S. Knott¹;

¹IEB, SBS, University of Edinburgh, Edinburgh, United Kingdom, ²ZIHP, University of Zurich, Zurich, Switzerland, ³MRC IGMM, University of Edinburgh, Edinburgh, United Kingdom, ⁴The Roslin Institute and Royal (Dick) School of Veterinary Studies, Edinburgh, United Kingdom.

Measures of urine electrolytes provide useful information on kidney function in people and are used routinely by clinicians as biomarkers of kidney damage. Genome-wide association scans to identify significant loci associations in these traits will give some indication of the underlying genetics which potentially will provide useful insights into kidney disease aetiology. We therefore performed a mixed model GWAS on 2934 individuals which formed part of a larger cohort of individuals genotyped in the Generation Scotland: Scottish Family Health Study. We analysed 8 phenotypes consisting of measures of urine concentrations of sodium, potassium, chlorides, calcium, glucose, phosphorus, magnesium, and urine osmolarity. We further estimated whole genome and regional heritabilities for these phenotypes using GCTA and REACTA.

We report a GWAS significant SNP (rs4574243, p-value = 9.378709e-09) close to the RBMS3 gene on chromosome 3 associated with urine calcium concentration. The remaining traits had significant SNP associations at a suggestive level (p-value < 1e-06) but not reaching GWAS significance. The regional heritability results in most of the traits mirrored their GWAS results by showing significant estimates on chromosomes with GWAS hits. The heritability estimates were very low for all the traits suggesting that these traits are under modest genetic control.

The SNP hits identified for these traits lie within areas of the genome that have genes close by (<1Mb) which presents a useful avenue to be explored in future studies. There have been very sparse GWAS reports on these traits which make these findings uniquely important.

P18.066

Food and pathogen adaptations: tracing the spread of lactase persistence and human African trypanosomiasis resistance into southwestern Africa

J. C. Pinto¹, S. Oliveira^{1,2}, S. Teixeira¹, D. Martins³, A. M. Fehn^{1,4}, T. Aço⁵, M. Gayà-Vidal¹, J. Rocha^{1,2};

¹CIBIO/InBIO- Research Center in Biodiversity and Genetic Resources, Vairão, Porto, Portugal, ²Departamento de Biologia, Faculdade de Ciências, Universidade do Porto, Porto, Portugal, ³ISCED/Huila: Instituto Superior de Ciências da Educação, Lubango, Angola, ⁴Max Planck Institute for the Science of Human History, Jena, Germany, ⁵CEDO: Centro de Estudos do Deserto, Namibe, Angola.

Introduction: We investigated the frequency distribution and haplotype diversity of APOL1 and LCT variants associated with human African trypanosomiasis (HAT) resistance and lactase persistence (LP), respectively, in

populations from southern Angola to trace the spread of these genetic adaptations into southwestern Africa.

Materials and Methods: We resequenced two fragments of the LCT-enhancer and the APOL1 gene and genotyped flanking STRs in six groups from the Angolan Namib with different subsistence traditions, and in other populations from Africa and Europe for comparative purposes. The age and selection coefficient of these variants were estimated.

Results: LP in the Angolan Namib is represented by the -14010*C allele, which is associated with a predominant haplotype shared with other southern and eastern African populations. While LP was more frequent in foragers than in pastoralists, the frequencies of the two APOL1 variants (G1 and G2) did not differ between the two groups. The G1 allele is mostly associated with a single widespread haplotype. The G2 allele is linked to several haplotypes that are related to haplotypes found in African Bantu-speaking populations. The putatively archaic G3 variant displayed more intra-allelic diversity in Africa than in Europe.

Conclusions: The LP adaptation was carried to southern Africa from eastern Africa, probably by non-Bantu speaking pastoralists, although we could not confirm a direct link with groups speaking Khoe-Kwadi family languages. The presence of APOL1 variants G1 and G2 is linked to the Bantu expansions. Our results suggest that the G3 variant was retained in modern humans by incomplete lineage sorting.

GATA3 gene involvement in leprosy susceptibility in Brazilian population

A. P. Latini, P. Medeiros, K. B. Valezi, W. L. da Silva; Instituto Lauro de Souza Lima, Bauru, Brazil.

Leprosy is a disease caused by *Mycobacterium leprae*. The disease outcome is a complex trait and the host-pathogen-environment interaction defines the emergence of the disease. Human genetic risk factors are definitely associated to leprosy. The chromosomal region 10p13 was linked to leprosy and the GATA3 gene is a strong candidate to be part of this association. Therefore, we tested if SNPs at GATA3 are associated to leprosy risk.

The genotyping was made by allelic discrimination using TaqMan SNP assays (Applied Biosystems). All association analyses were conducted applying logistic regression model using R software.

We tested seven tag SNPs in a population from Mato Grosso State, Brazil (411 cases and 357 controls). The A allele of rs10905284 marker was associated with leprosy resistance for CA genotype (OR 0.65; 95%CI 0.47-0.90; p=0.0099) and for A allele carriers (OR 0.67; 95%CI 0.50-0.92; p=0.0117). Then, we tested this association in another Brazilian population from São Paulo State (511 cases and 380 controls). The association was confirmed for A allele carriers (OR 0.67; 95%CI 0.48-0.92; p=0.0151), heterozygous CA (OR 0.69; 95%CI 0.49-0.97; p=0.0344), and for homozygous AA (OR 0.61; 95%CI 0.40-0.93; p=0.0201). A significant association was also observed for the combined population for the CA (OR 0.67; 95%CI 0.53-0.85; p=0.0009) and AA (OR 0.67; 95%CI 0.50-0.89; p=0.0056) genotypes; A carriers (OR 0.67; 95%CI 0.53-0.84; p=0.0004), and for the A allele (OR 0.81; 95%CI 0.66-0.98; p=0.0341).

Thus, we demonstrated for the first time a GATA3 role in the genetic susceptibility for leprosy.

Age-related Macular Degeneration: an overview of the susceptibility genes in the Italian population

C. Strafella¹, G. Longo¹, R. Cascella^{1,2}, L. T. Marsella¹, P. Borgiani¹, F. Viola³, C. M. Eandi^{1,7}, F. Sangiulio¹, G. Novelli¹, A. Cusumano⁵, G. Staurenghi⁶, F. Ricci⁵, E. Giardina^{1,7};

¹University of Rome Tor Vergata, Rome, Italy, ²Emotest Laboratory, Pozzuoli, Italy, ³U.O. Oculist Foundation IRCCS "Cà Granda" Maggiore General Hospital, Milan University, Milan, Italy, ⁴Department of Clinical Physiopathology, Eye Clinic, University of Turin, Turin, Italy, ⁵UOSD Patologia retina Fondazione PTV "Policlinico Tor Vergata", Rome, Italy, ⁶Eye Clinic, Department of Clinical Science "Luigi Sacco", Sacco Hospital, University of Milan, Milan, Italy, ⁷Molecular Genetics Laboratory UILDM, Santa Lucia Foundation, Rome, Italy.

Age-related Macular Degeneration (AMD, OMIM #610149) is the progressive degeneration of the macula and is responsible of the low vision in people aged >55 years old. The disease leads to the gradual loss of central vision and the strong impairment of the ordinary activities.

AMD is a multifactorial disease that involves both environmental (age, smoking, diet, familiarity) and genetic factors (susceptibility loci). In particular, CFH (p=2.7*10⁻¹⁵), ARMS2 (p=9.9*10⁻¹³) and IL-8 (p=4.15*10⁻⁵) genes are the major contributors to the genetic susceptibility in the Italian population. GWASs conducted in European and Asian populations, identified 13 novel

genes (TIMP3, LIPC, APOE, VEGFA, IER3-DDR1, B3GALT1, TGFBR1, ADAM, COL10A1, CETP, RAD51B, SLC16A8, COL8A1) potentially involved in the development and progression of AMD. These genes have been analyzed in a cohort of 1512 Italian subjects (cases=712, controls=800), in order to set up a genetic risk panel representative of our population. The genotyping analysis was performed by TaqMan assay and 7500 Fast Real Time PCR device and pointed out the association of TIMP3 (rs5749482 C/G; $p=3.07823 \times 10^{-07}$ OR C=1.64, 95% CI:1.3-2.0), RAD51B (rs8017304 A/G; $p=0.031$ OR G=1.2, 95% CI:1.0-1.3), SLC16A8 (rs8135665 C/T; $p=4.59283 \times 10^{-6}$ OR T=1.4, 95% CI:1.2-1.7), COL8A1 (rs13081855 G/T; $p=1.73 \times 10^{-04}$ OR T=1.6, 95% CI:1.2-2.0), VEGFA (rs943080 C/T; $p=0.003$ OR T=1.2, 95% CI:1.0-1.3) with AMD in our cohort. These genes, together with CFH, ARMS2 and IL-8, represent a first overview of the genetic contribution to the disease susceptibility in Italian population. These results will be then combined with environmental factors to generate a population-specific "risk platform" for AMD.

Looking young for one's age has been a desire since time immemorial. This desire is attributable to the belief that appearance reflects health and fecundity. Indeed, perceived age predicts survival and associates with molecular markers of aging such as telomere length. Understanding the underlying molecular biology of perceived age is vital for identifying new aging therapies amongst other purposes, but studies are lacking thus far. As a first attempt, we performed genome-wide association studies (GWASs) of perceived facial age and wrinkling estimated from digital facial images by analyzing over 8 million single nucleotide polymorphisms (SNPs) in 2,693 elderly Dutch Europeans from the Rotterdam Study. The strongest genetic associations with perceived facial age were found for multiple SNPs in the *MC1R* gene ($p < 1 \times 10^{-7}$). This effect was enhanced for a compound heterozygosity marker constructed from four pre-selected functional *MC1R* SNPs ($p = 2.69 \times 10^{-12}$), which was replicated in 599 Dutch Europeans from the Leiden Longevity Study ($p = 0.042$) and in 1,173 Europeans of the TwinsUK Study ($p = 3 \times 10^{-3}$). Individuals carrying the homozygote *MC1R* risk haplotype looked on average up to two years older than non-carriers. This association was independent of age, sex, skin color, sun-damage (wrinkling, pigmented spots), and persisted through different sun-exposure levels. Hence, a role for *MC1R* in youthful looks independent of its known melanin synthesis function is suggested. Our study uncovers the first genetic evidence explaining why some people look older for their age, and provides new leads for further investigating the biological basis of how old or young people look.

Introduction: The melanocortin 1 receptor (*MC1R*) gene is a key regulator of skin and hair colour. Certain *MC1R* polymorphisms, which cause a loss

of protein function, have been associated with red hair colour (RHC) phenotype (red hair, fair skin and poor tanning response) and a higher risk of developing skin cancer. Although the *MC1R* protein is mainly expressed in melanocytes, it is also detected in neurons. We have observed that skin cells harbouring loss-of-function *MC1R* polymorphisms showed a deregulation of genes involved in pathways related to neurodegenerative diseases (Parkinson's disease (PD), Alzheimer's disease (AD) and Huntington's disease (HD)).

Material and Methods: We performed two case-control studies to elucidate the role of *MC1R* in PD and AD. We sequenced the *MC1R* gene in 870 PD patients, 525 AD patients and 736 controls from Spain. We assessed the role of *MC1R* as a modifier factor on age of onset (AOO) in HD, sequencing *MC1R* in 600 HD patients. We analyzed all non-synonymous *MC1R* variants with a minor allele frequency of at least 0.01.

Results: We found evidence that the loss-of-function p.R160W *MC1R* polymorphism is marginally associated with PD (OR=2.10; Bonferroni-corrected $P=0.063$) and that the p.V92M *MC1R* polymorphism increased risk of AD (OR: 1.97, $P=0.021$). Furthermore, another loss-of-function polymorphism (p.R151C) showed an effect on AOO in HD (Bonferroni-corrected $P=0.032$), which explains 1.42% of the variance in AOO that cannot be accounted for by the expanded HD allele.

Conclusion: Our results suggest that *MC1R* may play a role in neurodegenerative diseases.

Role of POT1 germline variants in familial melanoma in Spain

M. Potrony¹, M. Ribera-Sola¹, J. A. Puig-Butille^{2,3}, V. Iyer⁴, C. D. Robles-Espinoza⁴, C. Badenas^{2,3}, P. Aguilera^{1,3}, C. Carrera^{1,3}, J. Malvehy^{1,3}, D. J. Adams⁴, S. Puig^{1,2}

¹Dermatology Department, Melanoma Unit, Hospital Clinic of Barcelona and Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain, ²Biochemical and Molecular Genetics Service, Hospital Clinic of Barcelona and Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain, ³Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), Barcelona, Spain, ⁴Experimental Cancer Genetics Group, Wellcome Trust Sanger Institute, Hinxton, Cambridge, United Kingdom.

Introduction: Protection of telomeres 1 (POT1, NM_015450, 7q31) encodes a protein of the telomeric shelterin complex, which plays an important role in telomere maintenance. Two independent groups identified rare germline variants in POT1 that predispose to melanoma.

Material and Methods: POT1 was sequenced by next generation sequencing (NGS) in 183 probands from Spanish melanoma-prone families. Generated libraries, following Fluidigm unidirectional sequencing protocol, were sequenced on an Illumina MiSeq. Reads were aligned to the reference genome (GRCh37) using BWA mem. Variants were called with the GATK Haplotype-Caller and quality filters were set as standard. Variant effect was predicted with the Ensembl Variant Effect Predictor release 70. Missense variants or synonymous variants affecting splicing were sequenced by Sanger sequencing in the families detected for validation.

Results: We detected by NGS 11 candidate variants in 13 probands, from the 119 samples that passed the quality control. DNA from patients belonging to 11/13 families was available. We detected by Sanger sequencing 3/9 candidate variants that could be tested in 3 melanoma-prone families: p.Gly404Val (c.1211G>T, ENST00000357628, ExAC frequency=0.014) which is predicted to be probably benign, suggesting it is a polymorphism; p.Ile78Thr (c.233T>C, ENST00000357628, ExAC frequency=0), which was previously detected in a melanoma patient and is predicted to be pathogenic, and finally the p.Lys85Lys (c.255G>A, ENST00000357628, ExAC frequency=1e-05), which is located in a splicing site and furthermore cosegregates with melanoma within the family. Thus 2/119 (1.7%) families carry probably pathogenic variants in POT1.

Conclusion: POT1 germline variants play a role in familial melanoma susceptibility in Spain.

A comprehensive genome-wide analysis of melanoma Breslow thickness identifies interaction between CDC42 and SCIN genes

A. Vaysse^{1,2}, S. Fang³, M. Brossard^{1,2}, Q. Wei⁴, W. V. Chen³, H. Mohamdi^{1,2}, L. Vincent-Fetita⁵, P. Marguerite-Jeannin^{1,2}, N. Lavielle^{1,2}, E. Maubec^{1,6}, M. Lathrop⁷, M. Avril⁵, C. I. Amos⁸, J. E. Lee³, F. Demenais^{1,2}

¹INSERM U946, Paris, France, ²Université Paris Diderot, Paris, France, ³MD Anderson Cancer Center (MDACC), Houston, TX, United States, ⁴Duke University School of Medicine, Durham, NC, United States, ⁵Hôpital Cochin, Université Paris Descartes, Paris, France, ⁶Hôpital Avicenne et Université Paris 13, Bobigny, France, ⁷McGill University and Genome Quebec Innovation Centre, Montreal, QC, Canada, ⁸Geisel College of Medicine, Dartmouth College, Lebanon, NH, United States.

Breslow thickness (BT) is a major prognostic factor of cutaneous melanoma, the most fatal skin cancer. The genetic component of BT has only been explored by candidate gene studies with inconsistent results. Our objective

was to uncover the genetic factors underlying BT using a hypothesis-free genome-wide approach.

Our analysis strategy integrated a genome-wide association study (GWAS) for BT followed by pathway analysis of GWAS outcomes using the gene-set enrichment analysis (GSEA) method and epistasis analysis within BT-associated pathways. This strategy was applied to two large melanoma datasets with Hapmap3-imputed SNP data (~1 million SNPs): the French MELARISK study for discovery (966 cases) and the MD Anderson Cancer Center study (1,546 cases) for replication.

While no marginal effect of individual SNPs was revealed through GWAS, three pathways, defined by gene ontology (GO) categories were significantly enriched in genes associated with BT (False Discovery Rate $\leq 5\%$ in both studies): hormone activity, cytokine activity and myeloid cell differentiation. Epistasis analysis, within each significant pathway, identified a statistically significant interaction between *CDC42* and *SCIN* SNPs ($P_{\text{interaction}} = 2.2 \times 10^{-6}$, which met the overall multiple-testing corrected threshold of 2.5×10^{-6}). These two SNPs (and proxies) are strongly associated with *CDC42* and *SCIN* gene expression levels and map to regulatory elements in skin cells.

In conclusion, this study identified two novel genes influencing Breslow thickness. This finding has important biological relevance since *CDC42* and *SCIN* proteins have opposite effects in actin dynamics, a key mechanism underlying melanoma cell migration and invasion.

Association between depressive symptoms and insulin resistance is moderated by melatonin receptor 1B gene polymorphisms

K. Haljas¹, J. M. Lahti^{1,2,3}, T. Tuomi^{4,2,5}, L. H. Hakaste^{6,2,5}, B. Isomaa^{6,2}, J. G. Eriksson^{7,8,2}, L. C. Groop^{9,5}, K. Rääkkönen¹;

¹Institute of Behavioural Sciences, University of Helsinki, Helsinki, Finland, ²Folkhälsan Research Center, Helsinki, Finland, ³Collegium for Advanced Studies, University of Helsinki, Helsinki, Finland, ⁴Department of Endocrinology, Abdominal Centre, Helsinki University Hospital, Helsinki, Finland, ⁵Finnish Institute for Molecular Medicine, University of Helsinki, Helsinki, Finland, ⁶Department of Social Services and Health Care, Jakobstad, Finland, ⁷Department of General Practice and Primary Health Care, University of Helsinki and Helsinki University Hospital Helsinki, Helsinki, Finland, ⁸National Institute for Health and Welfare, Helsinki, Finland, ⁹Diabetes and Endocrinology, Department of Clinical Sciences, Lund University Diabetes Centre, Malmö, Sweden.

Background: Mechanisms for commonly shown association between depression and type 2 diabetes (T2D) are poorly understood. One possible explanation is disruption in circadian regulation placing melatonin signaling in key role. We set out to test if rs10830963 in *MTNR1B* gene - encoding for melatonin receptor 2 - that increases T2D risk moderates the association between depressive symptoms, insulin resistance and insulin secretion.

Methods: Participants of the PPP-Botnia (N=994) and Helsinki Birth Cohort Study (HBCS; N=1720) underwent oral glucose tolerance test (OGTT) and filled in Mental Health Index (MHI-5) of SF-36 questionnaire to study depressive symptoms at the mean age of 57.5 (SD: 10.7) and 61.5 (SD: 2.9), respectively. rs10830963 was directly genotyped in the PPP-Botnia and its proxy SNP rs1447352 (D': 1.0; r2: 0.4) in the HBCS. We used covariates-adjusted linear regression models to test the associations between the traits.

Results: In PPP-Botnia, rs10830963 moderated the association between depressive symptoms and fasting insulin, insulin area under curve (AUC), insulin resistance (HOMA-IR), and insulin sensitivity index (ISI) (p-value for interactions < .02). This pattern replicated in the HBCS. Depressive symptoms were significantly associated with higher fasting insulin levels, insulin AUC, HOMA-IR and lower ISI in homozygous individuals for risk allele but not in those who were homozygous for non-risk allele consistently in both cohorts. We did not find any significant interaction on glucose levels or CIR and DI. **Conclusions:** We show that those with depressive symptoms are in greater risk of developing insulin resistance if they carry risk genotype for diabetes in *MTNR1B*.

¹Eskişehir Osmangazi University Department of Medical Genetics, Eskişehir, Turkey, ²Eskişehir Osmangazi University Department of Romatology, Eskişehir, Turkey.

MEFV Mutations in Turkish Patients Suffering From Familial Mediterranean Fever

Familial Mediterranean fever (FMF) is an autosomal recessive disorder. Over 200 mutations have been identified in the MEFV gene responsible for

FMF. In the diagnosis of FMF the combination of; Tel-Hashomer Clinical Criteria (THCC) molecular methods can be used.

AIM: To identify distributions and frequencies of the MEFV gene mutations in patients.

PATIENTS-METHODS: The study was carried out on 3709 clinically diagnosed patients. Mutation screening of the MEFV gene was performed by pyrosequencing of exons 2, 3, 5 and 10 in 3709 patients.

RESULTS: The results of our study are summarized in the table.

CONCLUSION: Exon 10 is the most common site for FMF mutations whereas exon 2, 3 and 5 accounts for 32.13 % of the cases. The most common mutations among Turkish patients are M694V (A>G) and E148Q .

Genetic mitochondrial variation in the population of Transylvania revealed a different genetic diversity compared to the other regions of Romania: an influence of central Europe

F. Raicu^{1,2}, S. Schipor³, M. Hervella⁴, P. Cianga⁵, R. Popescu⁶, C. Banescu⁷, A. Martinescu⁸, M. Constantinescu², L. Bohiltea¹, R. Cocos^{1,9};

¹"Carola Davila" University of Medicine and Pharmacy, Bucharest, Romania, ²"Francisc I. Rainer" Anthropological Research Institute, Romanian Academy, Bucharest, Romania, ³National Institute of Endocrinology "C. I. Parhon", Bucharest, Romania, ⁴University of the Basque Country, Department of Genetics, Bizkaia, Spain, ⁵Grigore T. Popa University of Medicine and Pharmacy, Iasi, Romania, ⁶"Victor Babes" University of Medicine and Pharmacy, Timisoara, Romania, ⁷University of Medicine and Pharmacy Tg. Mures, Targu Mures, Romania, ⁸Ovidius University, Faculty of Medicine, Constanta, Romania, ⁹Genome Life Research Center, Bucharest, Romania.

Introduction: The aim of this study was to investigate if the population of Transylvania have a stronger Central European influence in comparison to the Romanian population located south east of the Carpathian Arch, considering its particular geography and various historical events such as different migration routes and colonisation events that could be reflected in the mitochondrial genetic diversity.

Materials and Methods: We analysed 714 samples originated from Wallachia (n= 226), Dobrudja (n=46), Moldavia (n=235) and Transylvania (n=207). The sequence of mtDNA control region for all samples was determined by sequencing the hypervariable segments HVS I and HVS II using two pair of primers.

Descriptive statistical indexes, the Tajima's D and Fu's FS neutrality tests based on control region sequences were calculated using Arlequin software. In order to visualize the relationships between population in Transylvania and other populations of Europe and Middle East, including the populations in of the other Romanian provinces, Principal Component analysis (PCA) and nonparametric multidimensional scaling (MDS) analyses were performed using SPSS software.

Results and Conclusions: Our findings revealed a genetic homogeneity across all Romanian regions with a lower genetic input from Slavic populations compared to neighbouring populations. A closer genetic affinity of population of Transylvania to Central Europe was indicated by both PCA and MDS analyses. Our data suggest that the geographical features of Romania territory probably had a differentiated impact on the shaping of genetic pool in the Romanian regions in the past.

The study was supported by CNCS-UEFISCDI grant PN-II-ID-PCCE 2011-2-0013.

lme4qtl: an efficient and flexible tool for QTL mapping in related individuals

A. Ziyatdinov¹, H. Brunel¹, M. Vázquez-Santiago², A. Martínez-Perez¹, J. Soria¹;
¹Unitat de Genomica de Malalties Complexes. Institut d'Investigació Biomèdica Sant Pau (IIB-Sant Pau), Barcelona, Spain, ²Unitat de Trombosis i Hemostasia. Hospital de la Santa Creu i Sant Pau, Barcelona, Spain.

Introduction: Mixed models have become a widely used method in quantitative genetics to study continuous and discrete traits. There are many existing tools available for mixed models, although they might lack flexibility when a more complex model is sought. The proposed lme4qtl R package is an extension of the lme4 R package, and allows an arbitrary number of correlated random effects with any correlation structure defined by a covariance matrix and/or grouping factors. A model of gene-environment interaction is shown for illustration.

Materials and Methods: Three main techniques were implemented. First, a correlated random effect, for example, defined via the double kinship matrix, was introduced into the model via the Cholesky decomposition of the covariance matrix and further update of the incidence matrix (method by Harville and Callanan). Second, the nearest positive definite of a real symmetric matrix was estimated for semidefinite covariance matrices (the al-

gorithm of Higham). Third, necessary constraints on the model parameters were incorporated in the framework of the lme4 package, mainly for the inference using the likelihood-ratio test (LRT) statistics.

Results: Sophisticated models for quantitative trait locus (QTL) mapping become available with the lme4qtl package. The following code shows an aging model, where the polygenic random effect interacts with the environmental factor (age).

```
relmatLmer(BMI ~ AGE + SEX + (1+AGE|ID) + (1+AGE|RID), dat, relmat = list(ID = kin2), weights = w, vcControl = c)
```

Conclusions: The lme4qtl R package allows (generalized) linear mixed models with correlated random effects for QTL mapping.

A piebald cladistic portray of mitochondrial DNA control region haplogroups in Khyber Pakhtunkhwa, Pakistan

S. Bhatti;

University of Health Sciences, Lahore, Pakistan.

Despite being situated at the crossroad of Asia, Pakistan has gained crucial importance because of its pivotal role in subsequent migratory events. To highlight the genetic footprints in an enigmatic picture of the relative population expansion pattern among four major Pashtun tribes in Khyber Pakhtunkhwa viz., Bangash, Khattak, Mahsuds and Orakzai, the complete mitochondrial control region of 100 Pashtun were analyzed. All Pashtun tribes studied here revealed high genetic diversity; that was comparable to the other Central Asian, Southeast Asian and European populations. The configuration of genetic variation and heterogeneity further unveiled through Multidimensional Scaling, Principal Component Analysis, and phylogenetic analysis. The results revealed that the Pashtun is a composite mosaic of West Eurasian ancestry of numerous geographic origin. They received substantial gene flow during different invasions and have a high element of the Western provenance. The most common haplogroups reported in this study are: South Asian haplogroup M (28%) and R (8%); whereas, West Asians haplogroups are present, albeit in high frequencies (67%) and widespread over all; HV (15%), U (17%), H (9%), J (8%), K (8%), W (4%), N (3%) and T (3%). Herein we linked the unexplored genetic connection between Ashkenazi Jews and Pashtun. The presence of specific haplotypes J1b (4%) and K1a1b1a (5%) point to a genetic connection of Jewish conglomeration with Khattak tribe. This was a result of an ancient genetic influx in the early Neolithic period that led to the formation of a diverse genetic substratum in present day Pashtun.

Novel association of bone metabolism genes with the susceptibility to Psoriatic Arthritis

R. Cascella^{1,2}, G. Longo¹, C. Strafella¹, M. Ragazzo¹, E. Galli³, L. Marsella¹, F. Sangiuolo¹, G. Novelli¹, A. Orlandi⁴, E. Giardina⁵;

Department of Biomedicine and Prevention, "Tor Vergata" University, Rome, Italy,

Rome, Italy, ⁵"Tor Vergata" University of Rome; Molecular Genetics Laboratory UILDM, Santa Lucia Foundation, Rome, Italy, Rome, Italy.

Psoriatic Arthritis (PsA, #607507) is a multifactorial inflammatory arthropathy. Although several inflammatory, immunologic and epidermal differentiating genes (HLA-Cw*0602, LCE3B, LCE3C, TRAF3IP2, ILs, RUNX3, TNF α , SLC22A5) are implicated in PsA etiopathology, the contribution of bone metabolism genes to the disease development is totally unknown. We therefore focused our attention to the 5q31 locus, which contains several PsA-associated genetic variants as well as a number of genes involved in the bone metabolism. On this subject, we studied the genomic variability of the 5q31 locus with a special focus to the region falling within 132,674,018-132,737,310 bp. From the in-silico study of the region, 4 SNPs (rs2227282, rs2285700, rs10062446, rs2897442) were genotyped in 1526 subjects (PsA=500, PsV=426, controls=600). The rs2227282 was localized in IL-4, while the rs2285700, rs10062446, rs2897442 were positioned in KIF3A. All of them resulted associated with PsA ($p=2.09601 \times 10^{-5}$, $p=3 \times 10^{-3}$, $p=5 \times 10^{-3}$, $p=1.2 \times 10^{-4}$, respectively) but not with PsV. The allele architecture analysis showed that the haplotype G-A-A-A was of risk, while the haplotype C-C-T-G was protective for PsA. We then extended our research to the KIF3A promoter, identifying other two PsA-associated SNPs (rs2277065, $p=0.001$ and rs2277066, $p=0.004$). Although the expression analysis was not possible, immunohistochemistry studies showed a strong signal of KIF3A in synovial and cartilaginous tissues. Interestingly, KIF3A and IL-4 are known to participate to osteogenic and remodelling bone activities. Our results pave

the path for the characterization of a cluster of PsA-associated genes within the 5q31 locus, in which immune/inflammatory and bone metabolism genes may interact into a unique etiopathogenetic pathway.

P18.079

Identifying genomic determinants and context dependencies of human germline mutation using very rare variants

S. Zoellner, J. Carlson, BRIDGES Consortium, J. Li;

University of Michigan, Ann Arbor, MI, United States.

Mutation is a fundamental biological process driving evolution and generating new disease mutations. Mutation rates depend on genomic context and adjacent nucleotides, but the exact effect of these predictors is unknown. Analyzing de novo variants provides an insufficient number of observations to obtain high-resolution estimates and estimates from species divergence are biased by selection and biased gene conversion. Here, we present a novel approach to comprehensively assess predictors of mutability.

We collect a dataset of over 36 million high quality singleton variants from 3765 whole-genome sequences. These singletons arose very recently in the population, and are thus largely unaffected by confounding evolutionary factors. Based on these variants, we develop statistical models to predict the effect of genomic context and adjacent nucleotides on the mutation density and mutation rates at a single-base resolution.

We find strong evidence for heterogeneity in the mutation rates of short sequence motifs up to 4bp upstream and downstream from the mutating site and estimate up to 60-fold difference between non-CpG motifs within a single mutation category. This heterogeneity provides insight into the biological processes creating germline mutations. The distribution of short motifs alone explains over 70% of variance in singleton density, implicating sequence context as a key determinant of mutability. The single-base mutation rate is further mediated by local genomic features, such as replication timing and histone marks. We also demonstrate that site-specific mutation rates can provide evidence for pathogenicity that is largely independent of existing measures.

Positive selection at ABCA12.

R. Sirica¹, M. Buonaiuto¹, D. Antonini², L. Sticco³, O. Guardiola¹, C. Missero², G. D'Angelo³, Q. Ayub⁴, C. Tyler-Smith⁴, V. Colonna¹;

¹National Research Council, Institute of Genetics and Biophysics, Napoli, Italy,

²University of Naples "Federico II", Napoli, Italy, ³National Research Council, Institute of Protein Biochemistry, Napoli, Italy, ⁴Wellcome Trust Sanger Institute, Hinxton, United Kingdom.

ABCA12 is a lipid carrier protein expressed in keratinocytes. It is essential for forming skin lipid barrier and is down regulated by UV radiation. Its mutations cause a rare recessive disorder characterized by accumulation of intracellular lipids, disruption of lipid barrier and formation of dry, scaly skin (ichthyosis). We found a signal of positive selection in non-Africans associated with the derived allele of an intronic variant (rs10180970) which is the most differentiated variant between Africans and non-Africans in this gene. To elucidate the environmental pressure responsible for this signal and investigate possible connections with ichthyosis, we analysed data obtained from 56 ancient hominins. The derived allele at rs10180970 is observed for the first time 45,000 years ago (ya) in a heterozygous state in one ancient DNA sample from Asia that shares a 27 kb haplotype with modern Eurasians and is homozygous in 90% Neolithic and Bronze age Eurasians. The high coverage archaic hominins (Neanderthal and Denisovan) older than 50,000 ya are homozygous for the ancestral allele. Preliminary data suggests an increase of ABCA12 expression between populations significantly associated with the T allele at rs10180970. Non expression condition of the gene is seen in Ichthyosis, therefore we are investigating its possible connection with rs10180970. Study of variability through time confirms signal of positive selection showing an increase in frequency for the derived T allele. We are, then, conducting cell assays to understand the role of this variant and to elucidate its part in disease onset.

P18.081

Young population profiling for NCDs risk assessment

A. Levitsky, G. Kurochkin;

State University of Medicine and Pharmacy Nicolae Testemitanu, Chisinau, Moldova, Republic of.

In presented research, non-communicable diseases in young population for diseases risk assessment are the aim. There were collected over 3000 samples of young people, with no disease related clinical evidences. About 1500

samples from young patients with established diagnoses as obesity, T2D, dyslipidemia and arterial hypertension are to be collected. It was created the database of patients inquirers, elaborated based on STEPS survey of NCDs in Moldova, comprising over 250 parameters from each of the participants. There was used the approach to identify SNPs related to the biochemical parameters and SNPs with established expression QTL association that potentially can be more informative biomarkers in disease risk assessment. In the first instance, SNPs related to Lipid parameters from GWAS Catalog were obtained. The results related to research of treatment effects, complications and non-European ancestry individuals were removed. There were determined 298 individual SNPs, separated in 3 groups, by reported genes: 1SNP - 1 trait, 1SNP - ≥ 2 traits, ≥ 2 SNPs - 1 trait. None of the SNPs located on chromosome 21, X and Y were identified. Also, only one SNP, located on chromosome 13, associated with BRCA2 gene was present. All selected SNPs were searched through eQTL Browser returning three results (rs10889353, rs2338104, rs646776, p-value < 10⁻⁵) associated with DOCK7, KCTD10 and CELSR2 genes, respectively. These SNPs will be used to evaluate their capacity of risk assessment at young people, by genotyping based on TaqMan technique.

The research was supported by two institutional grants, 11.817.09.21A and 15.817.04.42A (2011-2014, 2015-2018, respectively).

P18.082

Polymorphism in FTO, TP53 and Leptin Gene, Dietary Intake and Metabolic Biomarkers in Obese Malaysian Adults

P. Tan¹, F. Amini², S. R. Mitra³;

¹Nottingham University, Semenyih, Malaysia, ²UCSI University, Kuala Lumpur, Malaysia.

Introduction: Gene variation can explain individual differences in response to dietary interventions on weight management and might contribute to the success of interventions. This study aims to identify polymorphism of selected genes, metabolic biomarkers and dietary intake in obese Malaysian adults. **Method:** Malaysian adults with BMI>23, were genotyped for FTO (rs9939609), TP53 (rs1800371) and Leptin (rs7799039) using PCR-RFLP. Dietary recall was used to collect information on detailed habitual food intake. Biochemical parameters were analyzed by standard procedures. **Result:** Twenty three participants (17 females and 6 males) have been recruited so far. Average BMI was 31.4±6.7 kg/m². Mean age was 30.1±10. The average total blood cholesterol of 5.7±1.1mmol/L; blood triglycerides 1.4±1.2mmol/L; HDL cholesterol 1.6±0.5mmol/L and LDL cholesterol 3.3±1.4 mmol/L was observed. The average total calorie intake per day was 2013 ± 602 kcal. Fasting glucose level for GA carrier in rs7799039 was 5.6mmol/L, significantly higher than 4.6 mmol/L for GG (p=0.04). The same SNP, mean for dietary glucose intake was significantly higher in GA (70.8g) compared to GG (6.8g)(p=0.001). Systolic blood pressure was significantly higher in TT carriers in rs9939609 (124±14.8 mmHg) compared to TA (109±4.7 mmHg) (p=0.01). Currently the study participants are undergoing dietary and lifestyle changes in a multidisciplinary weight management programme. **Conclusion:** Our analysis showed hyper-lipaeamic blood in all subjects. *Lep* rs7799039 (GA) was associated with higher fasting glucose level and more intake of dietary glucose. *FTO* rs9939609 (TT) was associated with higher systolic blood pressure. The project is funded by UNMC and UCSI Universities.

P18.084

Polymorphisms in IRF6 and 17q22 loci are risk factors for nonsyndromic orofacial clefts in Slovak population

J. Salagovic¹, L. Klimcakova¹, M. Zabavnikova², J. Behunova^{3,4}, T. Hudakova¹, J. Fedeles⁵, A. Molnarova⁵, L. Podracka^{3,6};

¹Department of Medical Biology, Faculty of Medicine, P.J. Safarik University, Kosice, Slovakia, ²Department of Plastic, Reconstructive and Aesthetic Surgery, University Hospital, Kosice, Slovakia, ³1st Department of Pediatrics, Faculty of Medicine in P.J. Safarik University and Children's University Hospital, Kosice, Slovakia, ⁴Medizinische Universität Wien, Institut für Medizinische Genetik, Wien, Austria, ⁵Department of Plastic, Reconstructive and Aesthetic Surgery, Faculty of Medicine in Comenius University and University Hospital, Bratislava, Slovakia, ⁶1st Department of Pediatrics, Faculty of Medicine in Comenius University and Children's University Hospital, Bratislava, Slovakia.

Introduction: Nonsyndromic orofacial clefts are one of the most common birth defects, having multifactorial etiology involving both genetic and environmental factors. Linkage analyses and genome-wide association studies have identified several genomic susceptibility regions for this orofacial anomaly. Genetic predisposition to nonsyndromic orofacial clefts is ethnicity-dependent, and the genetic basis of susceptibility to this birth defect likely varies among populations.

In the present study 4 single nucleotide polymorphisms that have been pre-

viously identified by genome-wide association studies in other populations were analysed for an association with nonsyndromic orofacial clefts in a Slovak population.

Materials and Methods: Nucleotide variants rs642961 in IRF6, rs987525 in 8q24, rs7078160 in 10q25 and rs227731 in 17q22 were genotyped in 199 patients with nonsyndromic orofacial clefts and 157 unaffected controls. All variants of interest were analyzed by high-resolution melting analysis after the real-time PCR on Eco Real-Time PCR System.

Results: Significant associations with nonsyndromic orofacial cleft risk were observed for rs642961 and rs227731. Polymorphism rs642961 increased the risk when analyzed under a dominant model (GA + AA vs. GG: OR=1.66; 95% CI 1.06-2.60). Polymorphism rs227731 was significantly associated with an increased risk under a recessive model (CC vs. CA + AA: OR=1.71; 95% CI 1.03-2.83).

Conclusions: Our findings suggest that polymorphisms rs642961 in IRF6 and rs227731 in 17q22 are associated with an increased risk of nonsyndromic orofacial clefts and thus might act as a risk factor in Slovak population.

The study was supported by the grant VEGA 1/0312/14 of the Ministry of Education of Slovak Republic.

Coding variants in the MGP gene are involved in osteoarthritis of the hand

C. G. Boer¹, W. den Hollander², D. Hart³, M. S. Yau^{4,5}, Y. F. M. Ramos⁶, S. Metrustry³, L. Broer¹, J. Deelen¹, M. Beekman¹, L. A. Cupples⁷, F. Rivadeneira¹, M. Kloppenburg², M. Peters⁸, T. D. Spector⁹, A. Hofman¹, P. E. Slagboom², R. G. H. H. Nelissen¹, A. G. Uitterlinden¹, D. T. Felson^{4,7}, A. Valdes⁸, I. Meulenbelt², J. B. J. van Meurs¹;

¹Erasmus MC, Rotterdam, Netherlands, ²Leiden University Medical Center, Leiden, Netherlands, ³King's College London, London, United Kingdom, ⁴Boston University School of Medicine, Boston, MA, United States, ⁵Harvard Medical School, Boston, MA, United States, ⁶Boston University School of Public Health, Boston, MA, United States, ⁷University of Manchester, Manchester, United Kingdom, ⁸School of Medicine, University of Nottingham, Nottingham, United Kingdom.

Introduction: Osteoarthritis of the hand (OA) is to a large extent genetically determined. However only one locus has been found to be associated to hand OA. We aimed to identify novel genes and pathways involved in the aetiology of hand OA, by performing a genome-wide association study.

Materials and methods: We have performed a GWAS on 12,784 individuals (discovery:8743, replication:4011) using a quantitative bilateral hand OA phenotype, summing all KL-scores of the hand joints for both hands (min: 0, max: 120). RNA-sequencing of 96 human primary chondrocytes was used for allele specific expression analysis of GWAS top hits.

Results: After discovery, replication and joint-meta-analysis one SNP reached genome-wide significance (P=1.8*10⁻¹⁵). The risk allele of this variant associates with a higher KL-sum score (ΔKL-sum=8) compared to the reference. The variant is located near the Matrix-Gla protein (MGP) gene, which is a calcification inhibitor, and is in high (r²>0.8) linkage disequilibrium with a nonsynonymous and a 5'UTR variant in MGP. We found MGP to be highly expressed in human chondrocytes. Additionally these variants cause for allelic imbalance of MGP gene expression in human chondrocytes. The risk allele was consistently lower expressed compared to the reference allele (P<0.001).

Conclusions: We identified coding variants in MGP, which are genome-wide-associated to hand OA, and cause for decreased MGP expression. Carriers of the risk alleles seem more prone to develop articular cartilage calcification, a well described hallmark of OA. MGP function is dependent on vitamin-K, indicating vitamin K as a potential therapeutic target for OA.

P18.086

Identification of new genetic loci and environmental factors associated with parathyroid hormone levels

A. Boljat¹, I. Gunjača¹, N. Vidan¹, V. Torlak², D. Brdar², A. Punda², B. Lozić³, V. Boraska Perica¹, O. Polasek⁴, M. Baralić⁵, C. Hayward⁶, T. Zemunik⁷;

¹Department of Medical Biology, University of Split, School of Medicine, Split, Croatia, ²Department of Nuclear Medicine, University Hospital Split, Split, Croatia, ³Department of Pediatrics, University Hospital Split, Split, Croatia, ⁴Department of Public Health, University of Split, School of Medicine, Split, Croatia, ⁵Institute for Genetics and Molecular Medicine, Western General Hospital, University of Edinburgh, Edinburgh, United Kingdom.

Introduction: Parathyroid glands control calcium levels in blood through parathyroid hormone (PTH) regulation. Variations in PTH levels are under genetic control and influenced by environmental factors. The aim of this study was to identify genetic variants and environmental factors underlying parathyroid function by studying PTH levels in healthy individuals. To our knowledge, this is the first study that examines PTH using genome-wide

data.

Methods: PTH was measured in blood plasma of 1012 participants from Split, Croatia (aged 18-85). To identify variants associated with PTH, genome-wide association study was performed using linear regression analysis and an additive model, with adjustments for age, gender and relatedness. To assess the influence of various environmental factors on PTH, nonparametric tests were used due to non-normal distribution of PTH levels.

Results: We identified two potentially associated loci: rs28524851 on chromosome 22 in FAM19A5 gene ($p=5.06 \times 10^{-7}, \beta=-0.33, SE=0.06$) and rs6688219 on chromosome 1 in CASZ1 gene ($p=7.96 \times 10^{-7}, \beta=-0.94, SE=0.19$). Among females, PTH showed positive association with BMI and systolic blood pressure while smoking and alcohol consumption were negatively associated. Diastolic blood pressure was positively associated with PTH among males. Serum calcium levels and bone density showed negative association with PTH.

Conclusions: We found two potentially associated loci that need to be confirmed in a replication study. One of those is located in CASZ1 gene which is known to be associated with cardiac phenotypes. These results also indicate that environmental factors have influence on parathyroid function.

P18.087

NMR metabolites association analysis to determine parent of origin effects

N. Pervjakova^{1,2}, T. Haller¹, S. Kasela^{1,2}, R. Mägi¹;

¹Estonian Genome Center University of Tartu, Tartu, Estonia, ²Department of Biotechnology, Institute of Molecular and Cell Biology, Tartu, Estonia.

Parent-of-origin effect (POE) occurs when the allelic effect on phenotype depends on whether the allele is inherited from mother or father. POE can be mediated through several mechanisms, such as genomic imprinting, trans-generational effects, in utero effects and the maternal environment. The aim of this study was to identify POE of common variants in NMR metabolites.

We considered 5,853 individuals from Estonian Biobank (EGCUT) for 82 NMR metabolites. Individuals were imputed to the 1000 Genomes Project reference panel (March 2012 release). POE analysis was performed using POE method in QUICKTEST using markers with MAF $\geq 1\%$, info ≥ 0.8 . We observed evidence of POE for 7 metabolites ($p < 5 \times 10^{-8}$) and are replicating these findings in an independent dataset. Identified variants are associated with lipids and lipoproteins.

Two of the found variants (rs1330350; rs189194743) located in TNC and PTPRD genes, which are associated with signaling molecules regulating a variety of cellular processes, such as neuronal regeneration, mitotic cycle, cell growth, neurons and axons migration during development. These regulatory features provide normal embryonic growth and therefore it suggests that identified POE may be mediated through genomic imprinting. This idea motivated us to perform further steps, such as allele-specific expression analysis, epigenome-wide association analysis with further replication in an independent cohort and methylation QTL to investigate mechanisms underlying POE and its association with genomic imprinting. We believe our results will contribute to uncovering complex relations between genetic variants and common traits and help to reveal some of the hidden heritability. Grants: EU30020; EU48695; SP1GVARENG.

P18.088

Individual-level pathway polygenic score method for identifying heterogeneous genetic bases of complex diseases

Y. Ruan, G. Breen, P. F. O'Reilly;

MRC Social, Genetic and Developmental Psychiatry Centre, IoPPN, King's College London, London, United Kingdom.

GWAS-based pathway analyses aim to identify biological pathways involved in the pathogenetic mechanisms of complex diseases. So far, these methods have generally focused on summary statistic results and identified the pathways that have causal effects at the whole sample level. Although existing approaches can highlight the involvement of causal pathways, they could not reveal the heterogeneous pathogenetic mechanisms across cases for a disease. Here, we develop a new method that utilizes individual-level genotype data to test for heterogeneity in the enrichment of risk alleles across different pathways for each individual - it does this by calculating polygenic risk scores specific to different pathways for each case individual. Our method aims to identify heterogeneity in the genetic basis of complex diseases, as well as potentially increase the overall power to identify causal pathways. Here we test this method on simulated case-control data in which the cases have heterogeneous causal pathways to assess its power to detect heterogeneity in pathway aetiology, and also compare its power for

overall pathway detection with existing summary statistic based methods. We exemplify the performance of our method to identify heterogeneity in pathways for several complex diseases, including schizophrenia and BMI, and compare our results with those from several well-established pathway analysis methods.

Demographic inference of the Lithuanian population

A. Urnikytė, A. Molytė, E. Pranckevičienė, V. Kučinskas;

Department of Human and Medical Genetics, Faculty of Medicine, Vilnius University, Vilnius, Lithuania.

The effective population size (N_e) is one of the most important natural population parameters providing an insight into ancient structures of modern human populations. We estimated N_e and divergence time by analysing patterns of Linkage disequilibrium between autosomal single nucleotide polymorphisms (SNPs). We aimed to reconstruct past events of separation between Lithuanian ethnolinguistic groups Aukštaičiai and Žemaičiai, since these groups over a long time period might have developed as two independent Baltic tribes.

We used Illumina 770K HumanOmniExpress-12v1.0 array data of 295 unrelated individuals of six ethnolinguistic groups of Lithuanian population (South Aukštaičiai (SA), East Aukštaičiai (EA), West Aukštaičiai (WA), South Žemaičiai (SŽ), West Žemaičiai (WŽ), North Žemaičiai (NŽ)). *NeON* R package was used to estimate N_e and divergence time.

Estimated N_e ranged from 4940 in the WŽ group to 5314 in the WA group. According to divergence time, the WŽ was earliest diverging group. The longest divergence time was observed between the WŽ and SA (9950 ya), and between the WŽ and EA (9650 ya), whereas the most recent separation occurred between the NŽ and SŽ groups (4775 ya).

It is ascertained that the overall effective population size of Žemaičiai is less in comparison with the overall of Aukštaičiai. More recent separations happened in ethnolinguistic groups residing in the same geographical area.

Our results support the hypothesis that Lithuanians originated from two Baltic ethnicities - Western Žemaičiai and South Aukštaičiai.

Investigating probable Turkish ancestry of Hungarians and Romani people on a genome-wide basis

Z. Bánfai^{1,2}, A. Szabó^{1,2}, B. L. Bálint³, B. I. Melegh^{1,2}, K. Hadzsiev^{1,2}, B. Melegh^{1,2};

¹University of Pécs, Department of Medical Genetics, Pécs, Hungary, ²University of Pécs, Szentágotthai Research Centre, Pécs, Hungary, ³University of Debrecen, Department of Biochemistry and Molecular Biology, Debrecen, Hungary.

History of Hungarians, Roma and Turkic groups could have overlapped several times during their demographic activities. Ancestors of Hungarians, migrating from the Ural region to the Carpathian basin, were in contact with nomadic Turkic tribes. It is also known that significant part of recent Hungary fell to Ottoman control between the 16th Century for 150 years. Migration of Roma included also the Anatolian Island. Roma arrived to Hungary in the 15th century, fleeing from the conquering campaigns of the Ottoman Empire. Roma were a notable ethnic group of the Kingdom of Hungary in the 16th Century already.

According to these historical events, relationship of Hungarians and Roma with Turks was investigated based on genome-wide single nucleotide polymorphism (SNP) data. Clustering software, utilizing algorithmic and model-based approaches, formal tests of admixture, and identity-by-descent (IBD) segment analyzes were carried out attempting to shed light to the conclusion of these demographic events in a genome-wide basis. We attempted also to measure the impact of the Ottoman rule in East-Central Europe.

We confirmed that admixture of Roma and Turks during the Ottoman rule is also significant, and our estimation shows a proportion of 66% of total Turkic ancestry in Roma, compared to their Northwestern Indian ancestry. We estimate that Hungarians have an average IBD share length of 0.69Mb with Turks, which is significant, compared to other populations under Ottoman rule.

Our analyses confirmed that Ottoman occupation leaved detectable impact in East-Central Europe including Hungarians, and also shaped the ancestry of the Romani people.

Nationwide genomic study in Denmark reveals remarkable population homogeneity

G. Athanasiadis¹, J. Cheng¹, B. J. Vilhjálmsson¹, F. G. Jørgensen², T. D. Als¹, S. Le Hellard², T. Espeseth⁴, P. F. Sullivan⁵, C. M. Hultman⁵, P. C. Kjærgaard¹, M. H. Schierup¹, T. Mailund¹;
¹Aarhus University, Aarhus, Denmark, ²Jørring Gymnasium, Aarhus, Denmark, ³University of Bergen, Bergen, Norway, ⁴University of Oslo, Oslo, Norway, ⁵Karolinska Institutet, Stockholm, Sweden.

Denmark's genetic history has never been studied in detail. In this work, we analysed genetic and anthropometrical data from ~800 Danish students as part of an outreach activity promoting genomic literacy in secondary education. DNA analysis revealed remarkable homogeneity of the Danish population after discounting contributions from recent immigration. This homogeneity was reflected in PCA and AMOVA, but also in more sophisticated LD-based methods for estimating admixture. Notwithstanding Denmark's homogeneity, we observed a clear signal of Polish admixture in the East of the country, coinciding with historical Polish settlements in the region before the Middle Ages. In addition, Denmark has a substantially smaller effective population size compared to Sweden and Norway, possibly reflecting further lack of strong population structure. None of these three Scandinavian countries seems to have suffered a depression due to the Black Death in the Middle Ages. Finally, we used the students' genetic data to predict their adult height after training a novel prediction algorithm on public summary statistics from large GWAS. We validated our prediction using the students' self-reported height and found that we could predict height with a remarkable ~64% accuracy.

Background: The genetic structure of human populations varies throughout the world, being influenced by migration, admixture, natural selection and genetic drift. Human population structure has first been investigated at broad scales, between and within continents. Currently researchers focus on finer scales, examining genetic structure within countries or regions. Characterising such genetic variation is of interest as it provides insight into demographical history and informs research on disease association studies, especially the ones focusing on rare variants.

Results: We genotyped 456 individuals from Western France Atlantic Coast, from Finistère to Vendée, with at least three of their grandparents born within a 15 kilometres distance using Axiom CEU Chip. Principal Components analysis revealed that individuals from the same departments form clusters and we observed a high correlation between geographical position and components (p-value < 2e-16). The main geographical barrier in the region is Loire River. Many independent methods support the hypothesis that Loire River is also a genetic barrier. The two groups of individuals, from north or south of Loire, are well differentiated along PC1 axis. ADMIXTURE estimated different ancestry proportions for the two groups. The first split of hierarchical clustering returned by fineSTRUCTURE, and the one based on normalized counts of identity-by-descent segments is between north and south of Loire.

Conclusion: We here report both evidence for isolation by distance and existence of a genetic barrier, the Loire River. The discovered fine-scale population structure may have consequences in association analyses, especially for rare variants which tend to be geographically clustered.

P18.093

Association analysis between quantitative traits and genetic marker for longitudinal data

M. Lin¹, J. Chien¹, S. Lin¹, W. Y. Wu¹, L. Chen², A. M. Yen³, T. Liu⁴, H. Chen⁵;

¹Institute of Public Health, National Yang-Ming University, Taipei, Taiwan, ²School of Oral Hygiene, College of Oral Medicine, Taipei Medical University, Taipei, Taiwan, ³School of Oral Hygiene, College of Oral Medicine, Taipei Medical University, Taipei, Taiwan, ⁴Lienchiang County Government, Matsu, Lienchiang County, Taiwan, ⁵Institute of Epidemiology and Preventative Medicine, College of Public Health, National Taiwan University, Taipei, Taiwan.

Introduction: Quantitative traits are generally changed with time. Longitudinal genetic studies with multiple measurements offer a valuable resource to examine how genetic and environmental factors that may affect complex

traits over time. However, most of genetic studies of quantitative traits using longitudinal data did not take into account genetic effects that may interact with age. Fan et al. (2012) develop penalized spline-based mixed model to estimate the temporal trend of mean effects and genetic effects. Nevertheless, their simulation study did not consider gene-time interaction.

Methods: We conducted a simulation study to investigate the performance of spline-based mixed model and three parametric mixed models on the settings of gene-time interactive effects as well as gene-time invariant effects. This spline-based mixed model was also applied to analyze the association between the Matsu Community-Based Integrated Screening (MA-CIS) program longitudinal blood pressure data and six single nucleotide polymorphisms in the *KLOTTHO* gene.

Results: Our simulation study showed that spline-based mixed model had better power and less bias square than other parametric mixed models for both gene-time invariant effect and gene-time interactive effect. For the MA-CIS data, we found the haplotype GGACTA was associated with blood pressure and the SNP rs1207568 and haplotype AGCCCA had gene-time interactive effects with blood pressures. Conclusion: Our study demonstrated that the spline-based mixed model is more flexible than the parametric mixed models as it could conveniently capture the pattern of relationship between quantitative traits and genetic markers.

Boosting the power of the sequence kernel association test (SKAT) by properly estimating its null distribution

K. Wang;

University of Iowa, Iowa City, IA, United States.

The sequence kernel association test (SKAT) is probably the most popular statistical test used in rare-variant association studies. Its null distribution involves unknown parameters that need to be estimated. The current estimation method has valid type I error rate but the power is compromised as all subjects are used for estimation. We develop a novel estimation method that uses only „control“ subjects. Named SKAT+, this new method uses the same test statistic as SKAT but differs in the way the null distribution is estimated. It is more powerful than SKAT almost surely as sample size increases. Extensive simulation studies and an application to a Genetic Analysis Workshop 17 data demonstrate its overall superior power performance over SKAT while maintain control over type I error rate. The proposed approach is easily applicable to existing numerous variations of SKAT in the literature.

Introduction: Low or excessive sleep duration has been associated with multiple health outcomes, however the biology behind these associations remains elusive. Specifically, genetic studies in children are scarce. In this study, we aimed to: (1) estimate the proportion of genetic variance of sleep duration in children attributed to single nucleotide polymorphisms (SNPs),

(2) identify novel SNPs associated with sleep duration, and (3) investigate the genetic overlap of sleep duration and metabolic and psychiatric outcomes.

Material and methods: 10,554 European children aged 2-11y from cohorts participating in the Early Genetics and Life course Epidemiology (EAGLE) Consortium were included in the study. Sleep duration was assessed through questionnaires. Fixed-effects meta-analyses were performed on 1000G imputed GWAS data using METAL. Heritability was estimated with GCTA and LD score regression. LD score regression was also used to test genetic correlations.

Results: We found evidence of significant, but modest SNP heritability of sleep duration in children (SNP h^2 0.14, 95% CI 0.05, 0.23). A novel region at chromosome 11q13.4 (rs74506765, minor allele frequency=0.1, $p=2.27e-08$) was associated with sleep duration, but it was not replicated in an independent sample of children ($N=1,250$). Significant genetic overlap ($r_G=.23$, $p=.05$) between sleep duration in children and type 2 diabetes (T2D) in adults was detected, while no correlation was observed with other metabolic or psychiatric outcomes.

Conclusions: The significant SNP heritability of sleep duration in children, and the genetic overlap with T2D support the continuation of studies investigating the genetic mechanisms linking sleep duration to health outcomes.

P18.096

Devising a SNP-based panel for human identification in Indian populations

A. Sarkar, M. R. Nandineni;

Centre for DNA Fingerprinting and Diagnostics, Hyderabad, India.

Background and aim: Currently, forensic DNA profiling comprise of amplifying a battery of 14-16 short tandem repeat (STR) loci which often fails when the DNA is highly degraded. Single nucleotide polymorphism (SNP) has been proposed and studied as an alternative for human identification (HID), but for Indian populations, SNP-based panel has not been explored. The current study aims towards building a SNP-based panel for Indian populations for forensic HID.

Methods: A bioinformatic approach was utilized to shortlist SNPs from public databases which were subsequently genotyped from the salivary DNA of ~460 unrelated adult volunteers in Indian populations using GoldenGate® Genotyping Assay (Illumina, Inc. USA). Based upon the distribution of the alleles in the tested populations (grouped as North, East, West and South India) the SNPs with most desired characteristics were accepted.

Results: Screening public databases from worldwide populations led us to shortlist a panel of 270 SNPs which were genotyped in Indian populations and finally, 2-4 SNPs from each autosome were selected to devise a panel of 70 SNPs. Random match probability (RMP) of the panel was $\sim 10^{-29}$ for all the regions which was higher than panels currently available for forensic DNA profiling.

Discussion and conclusion: Considering several factors, a SNP-based panel for India has been devised which is highly efficient, is expected to ensure conclusive results even in challenging forensic samples and can be considered for other world populations as well.

The study was funded from the core grant of Centre for DNA Fingerprinting and Diagnostics (CDFD).

P18.097

A population-level analysis of mutations affecting splicing

P. Puigdevall, R. Castelo;

Universitat Pompeu Fabra, Barcelona, Spain.

Wild-type processing of RNA transcripts by the splicing machinery is a fundamental step in the gene expression pathway. Mutations affecting this step can produce aberrant splicing with deleterious effects that ultimately lead to disease. Mutation databases curating the scientific literature store an increasing number of single nucleotide variants (SNVs) inducing aberrant splicing involved in disease. Yet, this increase is far below the current growth rate of genetically profiled diseased individuals. This results in many SNVs of unknown effect. In this context, understanding the deleterious effects of SNVs on splicing becomes extremely important to attempt a sensible prioritization of such SNVs. Population-level allele frequencies constitute a valuable resource to gather understanding of mutation processes. We have used the last release of the 1000 Genomes and the ExAC catalogs of human variation to characterize mutations that affect splicing and attempt a sensible prioritization of such SNVs.

High-order epistasis explains majority of still-missing heritability for human height and BMI

R. de Vlaming, C. A. Rietveld;

Erasmus University Rotterdam Institute for Behavior and Biology, Rotterdam, Netherlands.

Narrow-sense heritability (h^2) estimates for complex traits based on common SNPs are generally substantially lower than estimates obtained from the classical twin-design, a disparity referred to as the 'still-missing heritability'. By estimating the variance components of a SNP-based ACE model in a sample of monozygotic and dizygotic twins, we show that imperfect tagging of genetic variation by common SNPs does not fully account for the large difference between SNP-based and classical twin-study h^2 estimates for human height and BMI. However, a SNP-based model that accounts for high-order epistatic effects provides h^2 estimates for human height and BMI that agree with previously reported SNP-based estimates; 47% for height (SE=4%) and 28% for BMI (SE=5%). Moreover, the difference between h^2 estimates from the epistatic model and the classical twin-design coincide with the theoretically expected bias in twin-study estimates under a high-order epistatic model. Given that the twin-study assumption of equal environment for monozygotic and dizygotic twins holds, these results provide evidence that twin study h^2 estimates are biased upwards due to the misattribution of epistatic effects to additive effects in the classical ACE model. The bias due to epistasis is able to explain the majority of the still-missing heritability for human height and BMI.

P18.099

Increasing power to infer relatedness and ancestry by using haplotype information

G. Hellenthal;

University College London, London, United Kingdom.

Understanding and correctly modelling the genetic structure of individuals sampled world-wide is essential for both designing and interpreting genotype-phenotype association studies. As both the number of individuals and number of genetic markers increase with the onslaught of new e.g. large-scale sequencing studies, more subtle -- and likely regional -- genetic variation patterns will be captured, enabling the elucidation of (and necessitating accounting for) genetic differences at increasingly finer geographic scales. I demonstrate how using haplotype information, which exploits correlation patterns among neighbouring Single-Nucleotide-Polymorphisms (SNPs) or other variants, increases precision to infer genetic relatedness and ancestry over the far more commonly-used programs that ignore this information. In particular I highlight how incorporating haplotype information identifies genetic patterns at fine geographic scales, e.g. within a country, where standard approaches fail. I describe new statistical methodology that infers the ancestry and relatedness of individuals by comparing haplotype patterns among an arbitrarily large number of world-wide groups, while accounting for sampling artefacts such as unequal group sample sizes and readily accommodating DNA samples from ancient human remains. I apply this model to individuals from geographically localized regions of Africa and Europe to elucidate population sub-structure, infer haplotype sharing patterns among groups, discover and date past interbreeding events (i.e. admixture) and identify regions of the genome affected by selection events.

Identification of genetic markers associated with high density lipoprotein cholesterol by genome-wide screening in Tehran cardio-metabolic genetic study (TCGS)

M. S. Daneshpour¹, M. Fallah¹, B. Sedaghatkhatay¹, K. Guity¹, F. Azizi²;

¹Cellular and Molecular Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran, Islamic Republic of,

²Endocrine Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran, Islamic Republic of.

Introduction: Genome-wide association studies (GWAS) have become an important strategy for genetic examination of human complex diseases. Present study is the first GWAS in Middle East and tried to investigate and replicate the association between HDL-C concentration and candidate loci in Tehran cardio-metabolic genetic (TCGS) participants.

Materials and methods: In TCGS, 8296 subjects analyzed for 623393 quality-checked SNPs (HumanOmniExpress-24-v1-0 bead at deCODE genetics). Serum HDL level was used as the main phenotype indicator with normal distribution and outlier data ($\pm 4SD$) were excluded. Efficient Bayesian mixed-model analysis with the help of Bolt-LMM v2.1 was used for association analysis in total population, male and female separately.

Results: At the genome-wide level ($p < 10^{-7}$), 45 SNPs were statistically associated with circulating HDL-cholesterol concentrations in total population that distributed in 8p21.3, 8p23.1, 11q23.3, 15q21.3, 16q13 genomic regions. Most of these SNPs were confirmed in male and female separately.

Conclusion: In this study we discovered 5 loci with 6 protein coding gene (ALDH1A2, APOA5, CETP, LPL, PIEZO2, SLC12A3); ncRNA (LOC157273); Novel miRNA (AC012181.1) related to HDL variation. We provide genetic analysis in relation to HDL in Iranian population with high prevalence of low HDL. This study is the first GWAS in Iran and Understanding the molecular, cellular and clinical consequences of the newly identified loci may inform therapy and clinical care.

P18.103

Genome-wide survival analysis of skin cancer in a Celtic renal transplant population

C. P. Stapleton¹, P. B. Mark², P. J. Phelan³, P. J. Conlon⁴, G. L. Cavalleri¹;

¹Department of Molecular and Cellular Therapeutics, Royal College of Surgeons Ireland, Dublin, Ireland, ²Institute of Cardiovascular and Medical Sciences, University of Glasgow, Glasgow, United Kingdom, ³Department of Nephrology, Royal Infirmary of Edinburgh, NHS Lothian, United Kingdom, ⁴Beaumont Hospital Kidney Centre, Dublin, Ireland.

Renal-transplant recipients have a 33-fold increased risk of developing non-melanoma skin cancer relative to age-matched non-transplanted individuals. Some of this risk can be attributed to factors including type of immunosuppressant treatment, however much of the risk remains unaccounted for. A mega-analysis of dense gene-chip data was conducted between datasets from Dublin and Glasgow to map germline genetic variations influencing time to onset of skin cancer post-transplantation.

Genotyping was carried out using the Illumina Human610-Quad BeadChip. Genome-wide survival analysis was conducted using a Cox proportional hazards model. Recipient age, recipient gender and the first 4 principal components were used as covariates. A genome-wide significance threshold of 5×10^{-8} was used.

In the Dublin dataset (n cases=94; n controls=231), a significant novel association ($p = 4 \times 10^{-8}$) was found between time to developing skin cancer post-transplantation and the variant, rs12519378, in SPOCK1. Heterozygote individuals developed skin cancer 7 times faster than wild-type homozygotes. The significance ($p = 2 \times 10^{-5}$) of rs12519378 fell in the mega-analysis when the Glasgow cohort (n cases=5; n controls=64) was added. No other SNPs achieved the threshold of significance.

SPOCK1 expression activates the PI3K/AKT pathway thus inhibiting apoptosis and promoting oncogenesis. The results presented here hint at a potential role of SPOCK1 in the development of post-transplant skin cancer. However, further data is required to determine the robustness of the SPOCK1 signal and identify other signals of association. We are currently seeking to extend this analysis to additional patient cohorts.

This work was funded by the Irish Research Council and PuncHESTOWN Kidney Research Fund.

Stop variants identified by exome-sequencing in patients and controls for Type 2 Diabetes Mellitus (T2DM) from Spanish population

V. Lendinez-Tortajada¹, I. Galán-Chilet¹, D. Pérez-Gil¹, A. Sanchis-Juan¹, P. Marín-García¹, A. B. García-García^{1,2}, F. J. Chaves^{1,2};

¹Genotyping and Genetic Diagnosis Unit, Biomedical Research Institute-INCLIVA, Valencia, Spain, ²CIBER of Diabetes and Associated Metabolic Diseases (CIBERDEM), Barcelona, Spain.

Introduction: Type 2 Diabetes (T2DM) explains the 90-95% of diagnosed cases with Diabetes Mellitus. It is a multifactorial disease affected by ambient and genetic factors. The genetic component appears to be very high and T2DM inheritability is around the 70%. Up to now, the studies have only proved the 10-15% of this component. The aim of our study is the identification of rare variants that can explain a part of genetic component of T2DM. Material and Methods: We performed a study in the Spanish population, of 200 healthy controls and 200 patients with T2DM from 40-65 years, sequencing their exome with the System HiScanSQ of Illumina®. By bioinformatics data analyses, we identified rare variants with theoretically functional impact on the phenotype, detected in cases or controls but do not found in both. From these variants we selected the gained/loss stop mutations and were verified by Sanger sequencing.

Results: We have identified 102 gained/loss stop variants in the control group and 50 gained/loss stop variants in the diabetic group.

Conclusion: We have described new variants with a possible related functional effect with diabetes and protection against its development; some of them are in genes not previously associated with the disease. Further studies are needed in order to establish specific associations between variants and T2DM.

Actionable mutations in the whole-genome sequenced gene donors of Estonian Genome Center

N. Tõnisson^{1,2}, T. Nikopensus¹, K. Vaiküll¹, L. Leitsalu¹, M. Kals¹, P. Padrik³, T. Esko^{1,4}, A. Metspalu^{1,5};

¹Estonian Genome Center, University of Tartu, Tartu, Estonia, ²Dept. of Genetics, Tartu University Hospital, Tartu, Estonia, ³Oncology Clinic, Tartu University Hospital, Tartu, Estonia, ⁴Broad Institute, Cambridge, MA, United States, ⁵Institute of Molecular and Cell Biology, University of Tartu, Tartu, Estonia.

Introduction: In 2013, American College of Medical Geneticists (ACMG) has issued a minimal list of 24 actionable conditions and 56 related genes of medical utility if incidentally found mutated in clinical whole genome and whole exome sequencing. The data were suggested to be reported back to sequenced individuals irrespective of their gender and age.

Aims, materials and methods: In Estonian Genome Center, we have performed whole genome sequencing of over 2200 individuals selected to be a representative subset of Estonian population with approximately 30x mean coverage. The data is meant to be used for a variety of further population and health-related studies. As one of the aims of our biobank is to provide feedback to the gene donors related to their health risks, we were searching the sequencing data for known and expected pathogenic mutations, starting from the ACMG gene list as the first priority.

Results: Based on initial filtering, database and literature search, we were able to detect 33 variants in 20 genes related to 13 clinical conditions in the ACMG list mentioned above. 45 individuals (2% of the sequenced cohort) carry the variants. One of the surprises was that 16 individuals with known and expected BRCA1 and BRCA2 pathogenic mutations (0.7% of total) were detected in the sequencing cohort.

Perspectives: The sequencing data will be further validated and used as to set up a health-related feedback routine in our biobank, together with the required professional counselling. The confirmed cases will get any further required specialist medical support.

P19.02

Towards and beyond the Eureka! The role of disease advocacy groups in diagnostic odyssey and benefits of collaborating with them more frequently

V. Okur¹, M. E. Schwartz², F. J. D. Smith²;

¹Haydarparisa Numune Research & Education Hospital, Istanbul, Turkey, ²Pachyonychia Congenita Project, Salt Lake City, UT, United States.

Background: Diagnosing a rare disease is very important for geneticists so much so that we can describe it as eureka moment for us. Correspondingly, geneticists usually know the general rare disease statistics such as total number of rare diseases and percentage of affected population worldwide very well. Unfortunately, most of us are not aware of how many rare disease advocacy groups there are, what their struggles are and how they can also change the patients' journey towards diagnosis.

Patients: Two first cousins with congenital nail dystrophies were referred with a differential diagnosis of pachyonychia congenita. Due to technical and economic limitations we contacted disease advocacy group, Pachyonychia Congenita Project, to seek help for molecular studies. After reviewing the cases the genetics team associated with the advocacy group proposed to screen another recently defined rare entity, "autosomal recessive nail dysplasia", and found a new mutation in a causative gene, FZD6, within 2 months.

Discussion: The role of patient advocacy groups in human genetics is undeniable. Apart from providing support for patients, their determination may have saved 5-10 years in treatment discoveries of some rare diseases. Nowadays, with the advance of genetic technologies we often forget them except for some devoted physicians and scientists. However, patient advocacy groups are experts in their rare disorder and can play a crucial role, as in our cases in determining a correct diagnosis and preventing unnecessary tests and/or treatment. Therefore, it can be beneficial to consult with disease advocacy groups at early stages of diagnostic odysseys.

P19.03

Array Comparative Genomic Hybridisation result communication: navigating uncertainty in the Genetics Clinic.

S. Aziz^{1*}, L. Bennett^{1*}, S. Hewitt², M. Ahmed³, K. Prescott³, *Contributed equally;
¹School of Medicine, University of Leeds, Leeds, United Kingdom, ²Leeds Genetics Laboratory, Ashley Wing, St James's Hospital, Leeds, United Kingdom, ³Yorkshire Regional Genetics Service, Clinical Genetics Department, Chapel Allerton Hospital, Leeds, United Kingdom.

Introduction: Array Comparative Genomic Hybridisation (aCGH) allows whole genome analysis at a higher resolution than was previously possible by karyotyping alone. This has resulted in the increasing detection of ambiguous results, termed 'Variants of Uncertain Significance' (VOUS). VOUS results pose communication challenges to clinicians and families. Currently there are no universal guidelines for aCGH result communication. This study evaluates the counselling practice of aCGH results of differing pathogenicities.

Methods: This observational study included 75 paediatric patients who had aCGH testing at the Yorkshire Regional Genetics Service, UK. Cases were randomly selected from three result categories; Clinically Significant (n=24), VOUS Likely Benign (n=25) and VOUS Uncertain (n=26). Data regarding the communication of results was collected from patient records. Descriptive statistics and Fisher's Exact test were applied to the data.

Results: Pre-test counselling regarding the possibility of a VOUS result was documented in 5.3% of cases. There was a significant difference in the mode of result disclosure between categories (p=0.001). 75.0% of Clinically Significant results were disclosed via face-to-face consultation and letter, whereas 74.5% of VOUS results were disclosed via letter only. 23.5% of those receiving VOUS results were advised to re-contact genetics services in the future.

Conclusions: Communication of aCGH results varies according to their pathogenicity. To standardise practice, all patients should be counselled about the possibility of a VOUS result. The effect of mode of disclosure on result comprehension should be studied further. Patients receiving VOUS results should be advised to re-contact genetics services to seek new information.

P19.04

The evolution of an annual information model for BRCA1/2 gene fault carriers

A. Wijesinghe, D. Petrie;
Genetic Alliance Australia, Darlinghurst, Australia.

Introduction: Individuals with BRCA1/2 gene faults are a unique group with specific support needs. Genetic Alliance Australia (GA), a peak umbrella organisation, was approached by a consumer and a genetic counsellor in 2001, seeking support for BRCA1/2 gene fault carriers. The outcome was an annual BRCA1/2 information day hosted by GA for 15 years, an alternative to traditional support group models. GA documented how this unique model evolved with patients' support needs over time.

Method: Qualitative and quantitative data was collected and analysed from completed evaluations over 15 years. Patients' perspectives and suggestions for improvements/topics for the day were recorded and logistical elements analysed.

Results: Evaluation results showed on average 73% of annual attendees were new. GA continually reevaluated and modified the format based on feedback, catering to new and repeat attendees. Participants consistently responded positively to the diversity of information presented and appreciated opportunities to ask health professionals questions in a non-clinical setting. Participants appreciated hearing personal stories and embraced the opportunity to communicate and share their experiences with others who were at different points in their journey with BRCA1/2 gene faults. Life changing decisions and challenges were openly shared. Partnership with familial cancer genetic counsellors and consumers has grown from a consultative group into a cohesive and integrated partnership.

Conclusion: The BRCA1/2 Information Day provides a non-clinical, face-to-face approach focusing on mutual aid amongst participants. It has evolved into a unique hybrid of support group and information day models, driven by consumers' needs, demonstrating its portability.

BRCA population screening in unaffected Ashkenazi Jewish women. A Randomized Controlled Trial of different pre-test strategies

S. Lieberman^{1,2}, A. Tomer¹, A. Ben-Chetrit^{1,2}, O. Olsha³, S. Levin⁴, R. Beer¹, A. Raz⁵, A. Lahad⁶, E. Levy-Lahad^{1,2};
¹Medical Genetics Institute, Shaare Zedek Medical Center, Jerusalem, Israel, ²Faculty of Medicine, Hebrew University of Jerusalem, Jerusalem, Israel, ³Surgical Department, Shaare Zedek Medical Center, Jerusalem, Israel, ⁴Family Medicine, Clalit Health Services,

Shoham, Israel, ⁵Ben-Gurion University of the Negev, Beer Sheva, Israel, ⁶Department of Family Medicine, Clalit Health Services, Jerusalem, Israel.

Approximately half of BRCA1/BRCA2 carriers lack significant family history, and would only be identified through screening. Ashkenazi Jewish (AJ) population is a model for screening, given high prevalence (1/40) and testing sensitivity (>95%) of three common mutations. Towards implementation, we aim to examine the impact of excluding pre-test genetic counseling (GC) in the population screening setting.

Healthy AJ women age ≥ 25 years are randomized to two pre-test arms: written information only (WI) vs. GC. Post-testing, GC is provided to high-risk non-carriers and to all carriers. Psychosocial outcomes (satisfaction, stress, personal perceived control (PPC), knowledge) are assessed one week (Q1) and 6 months (Q2) post-testing.

Among the first 749 participants (mean age 46 years), we identified 11 carriers (1.5%). Only 3/11 carriers had significant family history. Post-testing, 95% of GC and 94% of WI participants report being satisfied with testing. Stress (IES) scores were similar in both groups. At Q1, PPC scores and knowledge were higher in GC (p=.005; p=.0001), At Q2, only PPC scores remained higher in GC: 1.39 vs. 1.25 in WI (p=.02). Carriers had higher PPC and knowledge than non-carriers. At Q2, carriers' stress level was higher (14.9 vs. 5.3, p=.0006), as expected.

Screening would identify substantially more carriers (regardless of family history). Compared to WI, pre-test GC provides a mild, temporary, increase in knowledge, accompanied by a greater sense of control. Forgoing pre-test GC may be an alternative for screening, particularly if alternative methods for imparting knowledge are explored.

Variant Reclassification in Cancer Genetic Testing: Are Genetic Counselors Prepared? A Review of Current Practices

N. White¹, B. White², C. Radford³, K. Brooks⁴;
¹Wessex Clinical Genetics Service, University Hospital Southampton NHS Foundation Trust, Southampton, United Kingdom, ²Levine Cancer Institute, Carolinas Medical Centre, Charlotte, NC, United States, ³Invitae, San Francisco, CA, United States, ⁴South Carolina Oncology Associates, Columbia, SC, United States.

Cancer genetics is a critical specialty that is continuously advancing; genetic counsellors must be in sync with these advancements. Currently, multi-gene testing is being adapted into the genetic counselling setting. The 'hot topic' of an increased likelihood of variant results has been explored previously. However, research surrounding VUS reclassification is lacking. This study aimed to identify current practices of cancer genetic counsellors with regard to variant reclassification.

Method: This study utilised an online survey. SAS 9.4 was employed for quantitative data, qualitative data was analysed for themes.

Results: We determined that cancer genetic counsellors handle the reclassification of VUS results in a unified manner. 95% of respondents (n = 209) discuss reclassification with their patients upon receiving a VUS result. Similarly, 95% of respondents (n = 209) will sometimes or always make a plan to communicate VUS reclassifications should they arise in the future. The majority (97%) (n = 183) indicated that the protocol for re-contacting patients with a VUS reclassification wouldn't be different from what they had used for single-gene analysis. Varying opinions existed on whether practice guidelines are necessary, a number expressed concerns surrounding liability issues and the feasibility of implementing recommendations across different institutions.

Conclusions: Study findings indicate most genetic counsellors are utilising unified practices when handling variant reclassifications. A proportion felt guidance for certain areas relating to variant reclassifications are necessary. Given the coming wave of reclassifications from multiple collaborative efforts to reclassify VUS results future research must explore in-depth the issues identified in this project.

Improving referral criteria for cancer risk assessment from primary care centers and community hospitals in the era of new indications for genetic testing.

A. Solanes¹, E. Grau¹, A. Velasco², E. Darder², A. López², M. Salinas³, S. Iglesias³, À. Teulé³, A. Izquierdo³, C. Lázaro³, G. Capellà³, J. Brunet³, M. Navarro¹;
¹Hereditary Cancer Program, Catalan Institute of Oncology, Badalona, Spain, ²Hereditary Cancer Program, Catalan Institute of Oncology, Girona, Spain, ³Hereditary Cancer Program, Catalan Institute of Oncology, L'Hospitalet, Spain.

Identify the patient/families with inherited cancer (IC) improves the prevention, treatment and survival.

The increasing demand of genetic assessment collapsed our cancer genetic counselling unit (CGCU) in 2015. Covered by a genetic counsellor and an oncologist specialized in IC, we increased from 142 first visits in 2008 up to 570 on 2014. It became necessary to review the activities and resources to optimize it all. One of the improvements was to provide the professionals that collaborate with us with tools to filter the suitable cases. Goals: to confirm the attention of non appropriate cases in order to solve it, to explain last guides, to provide feedback between specialists and CGCU. In January 2015 we reviewed 99 first visits of 2014. We classified them on the risk level of IC, 47,5% of high risk, 25,25% of moderate risk and 27,25% of non risk. We wrote the project and didactic material. We contacted the contributor centers to set up the training sessions and did workshops. In January 2016, we reviewed the last 93 first visits and classified them too, 71% of high risk, 17,2% of moderate risk and 11,8% of non risk. (80w)
After the project, the patient referral criteria has improved 23%. The didactic material is available (intranet). There's a new contacts network, and a new online access to final report of CGCU.
We have to adapt ourselves to the increasing usage of cancer genetics with current resources. Our results confirm that increasing the knowledge improves the quality of the service.

Introduction: In 1996, the Cystic Fibrosis (CF) Network organized the first large international external quality assessment (EQA) scheme for CFTR genetic testing. The scheme evolved from a paper-based six-sample EQA to automated electronic data-collection for three samples. Originally, EQA forms were distributed by fax and post, later by e-mail. Since 2004, an online submission system and database have revolutionized the workflow.

Materials and Methods: Participants receive purified DNA samples, since 1999 accompanied by mock clinical cases. Written reports as would be sent to the requesting clinician have to be submitted. Hence the entire analytical process is evaluated, including genotyping, report content, clinical interpretation and the correct use of HGVS nomenclature. Genotype and report results are scored against predefined criteria by a group of expert assessors. Persistent poor performers (unsuccessful in the current year and at least once in the two previous years) are notified and expert support for corrective actions is offered.

Results: In 1996, 35% of laboratories made genotyping errors. Within four years, this number decreased to 10%, and by 2015 it was down to 3%. The percentage of interpretation errors or risk calculation errors varies depending on the complexity of the cases. Longitudinal analysis shows that repeated participation improves clinical interpretation.

Conclusions: Continued EQA participation is advised to further improve testing quality. Interpretation and risk calculation are still prone to errors in more challenging cases. Consequences for poor performance are lacking and are suggested to be implemented by the government to ensure patient safety.

P19.09

Results from a survey of UK patients at risk of bowel cancer, their experiences and information preferences

S. M. A. Goodman, H. Skirton, R. Jones;
Plymouth University, Plymouth, United Kingdom.

Individuals at increased risk of familial bowel cancer are advised to have regular colonoscopy and to discuss the implications of their diagnosis with relatives. However, only a minority of relatives access screening or genetic testing, which is partly due to lack of knowledge about their personal risk. We are studying information preferences to develop ways for patients to

share information online.

Using a cross-sectional survey design, we have collected data on patient preferences via an online questionnaire. We are recruiting patients via charity websites, genetics clinics and colorectal clinics. Quantitative data were analysed using descriptive statistics and qualitative data from free text responses were analysed for recurrent themes. Preliminary results indicate that most (47/60) would like information in other ways; via email, websites or social media, but also through follow-up appointments (33/55). Respondents wanted more information about genetic testing (31/59), healthy lifestyle (24/59) and talking to children (20/59). Initial data illustrate a diverse experience of families' access to appropriate advice and screening. There is an appetite for more comprehensive information and a recurring theme of "having to fight for screening all the time". Updated results will be given. Results indicate a pragmatic approach is needed to help relatives share information. Building on these data, telephone interviews of a purposive sample of respondents will guide development of a website. We propose to use and evaluate digital technology to enhance support to patients and facilitate information sharing within families. The results may be applicable for genetic conditions beyond cancer.

P19.10

Genetic counselling in a family with Cri du Chat syndrome: beware of cryptic chromosomal rearrangements and family risks

E. Haquet, J. Puechberty, P. Blanchet, L. Pinson, M. Willems, G. Lefort, F. Pellestor, A. Schneider, S. Taviaux, D. Genevieve, C. Coubes;
Hôpital Arnaud de Villeneuve, Montpellier, France.

A 31-year-old woman was seen for genetic counselling in our Genetics Centre. She had questions concerning her risk of having children with Cri du Chat Syndrome (CdCS). Her older brother had been diagnosed with Cri-du Chat syndrome, confirmed on a 46,XY,del5p karyotype done 30 years ago.

CdCS is characterized by a high-pitched monochromatic cry, microcephaly, mainly severe psychomotor deficiency and other variable clinical features. The incidence is about 1:30,000 live-born infants. CdCS is usually due to de novo 5p deletion. For the brother, the diagnosis was clinically suggested by the paediatrician soon after birth and then confirmed on a standard karyotype.

Genetic counselling seemed straightforward but we nonetheless ordered chromosome studies in the patient, including FISH with a 5p subtelomeric probe. FISH analysis revealed 5p duplication / 4q deletion in our patient who has a normal phenotype.

This result led us to reconsider the information originally given to the family. We ordered parental karyotype analysis which revealed an apparently balanced t(4;5)(q35;p15.5) translocation in the mother.

CdCS patients with an inherited unbalanced chromosomal rearrangement have been reported and represent about 5% of CdCS patients. Generally speaking and especially in CdCS, when the index case's karyotype was done more than 20 years ago or when the parents have not had chromosome studies including FISH, repeat chromosome studies in the index case and parental chromosome studies are recommended.

P19.11

Deciphering variants of unknown significance in the CFTR gene

M. Poulou, I. Fylaktou, S. Kitsiou-Tzeli, M. Tzetis;
Department of Medical Genetics, Athens, Greece.

Cystic Fibrosis is one of the most common autosomal recessive disorders affecting Caucasians. To date, more than 2000 changes in the CFTR gene have been reported (<http://www.genet.sickkids.on.ca/>) with the clinical consequences of some still being unproven. In an attempt to provide with better genotype-phenotype correlations CFTR2 database (<http://www.cftr2.org/>) has been created. CFTR2 database provides information about what is currently known about the clinical signs and symptoms associated with specific CFTR mutations. In some cases where there is not enough clinical information the mutation is described as having varying clinical consequences. This creates confusion especially for family planning of carrier couples.

In this study we are reporting data from the Department of Medical Genetics, University of Athens, regarding the pathological consequences of the following mutations: p.Phe1052Val, c.483+3A>G, p.Met348Lys, p.Ser737Phe, p.Val920Leu, p.Arg74Trp, p.Asp1152His, p.Phe305Val and p.Tyr301Cys. These data are derived after full CFTR gene screening of 19,000 general population individuals and 800 patients.

It is evident that in the era of next generation sequencing and whole genome sequencing, unless you accumulate enough data from a big number of patients, conclusions are hard to be drawn even for a monogenic disorder.

P19.13

Mutation detection in custom-designed gene panel NGS is more accurate compared to whole exome sequencing (WES)

R. van den Bogaard, R. J. Florijn, M. Alders, E. J. W. Redeker, H. Bikker, R. H. Lekanndit-Deprez, P. Lombardi, S. van Koningsbruggen, M. M. Motazacker, F. van Ruissen, M. A. Haagmans, O. R. F. Mook, M. M. A. M. Mannens;
Clinical Genetics, AMC, Amsterdam, Netherlands.

Introduction: Inherited diseases are usually associated with specific disease associated gene-sets. Targeted resequencing of such gene-sets can be applied by custom designed gene panels or by WES, the latter in combination with software selection of the genes of interest. Custom panel sequencing has the advantage that the coverage for all genes can be easily optimized. **Materials and Methods:** We have evaluated both sequencing strategies for gene coverage, mutation calling accuracy, false positive rate and copy number variation(CNV) determination for several diseases such as lymphedema, cardiac disease, metabolic disease, dementia, eye diseases and others, each with different numbers of genes. CNV detection of 1 exon deletions were evaluated using the "hidden Markov model".

Results: Custom sequence captures optimized for evenly distributed coverage of genes of interest easily cover over 99% of the genes of interest with at least 30 unique reads. In comparison WES reaches a maximum of 95%. Furthermore, 1 exon deletions and duplications could be reliably identified in custom sequence captures, but not in WES. Novel identified mutations for different selected diseases will be presented.

Conclusions: We show that for defined set of genes, custom panel sequencing is preferred over exome sequencing because of optimal coverage, calling accuracy, lower false positive rate, less unclassified variants and secondary findings and CNV detection. In conclusion, custom panel sequencing of selected sets of genes is recommended for DNA diagnostics where highly reliable results are crucial. These custom gene panel tests can be performed at considerably lower costs.

P19.14

Is One Diagnosis the Whole Story? Patients with Double Diagnoses

A. Kurolap¹, N. Orenstein², I. Kedar³, M. Weisz Hubshman², D. Tiosano⁴, D. Tiosano^{4,5}, A. Mory¹, Z. Levi^{6,7}, D. Marom^{8,7}, L. Cohen³, N. Ekhilevich¹, W. Tan⁹, H. N. Baris^{1,5};
¹The Genetics Institute, Rambam Health Care Campus, Haifa, Israel, ²Genetics Unit, Schneider Children Medical Center, Petah Tikva, Israel, ³The Raphael Recanati Genetics Institute, Rabin Medical Center, Beilinson Hospital, Petah Tikva, Israel, ⁴Pediatric Endocrinology, Ruth Rappaport Children's Hospital, Rambam Health Care Campus, Haifa, Israel, ⁵The Ruth and Bruce Rappaport Faculty of Medicine, Technion-Institute of Technology, Haifa, Israel, ⁶The Early Detection and High Risk GI Cancer Service, Gastroenterology Division, Rabin Medical Center, Petah Tikva, Israel, ⁷Sackler School of Medicine, Tel Aviv University, Tel Aviv, Israel, ⁸Pediatric A, Schneider Children Medical Center, Petah Tikva, Israel, ⁹Division of Genetics and Genomics, Boston Children's Hospital; Harvard Medical School, Boston, MA, United States.

Background. Evaluating a patient in the genetics clinic aims at finding a diagnosis that would explain their full clinical presentation. In some cases the patient's diagnosis remains undefined; in others it does not explain all the patient's findings. As clinicians are often bound by a „single disorder“ paradigm, diagnosing multiple genetic conditions requires a heightened sense of awareness. We aim to raise awareness to the „double diagnosis“ phenomenon and to share our experience.

Procedure. Patients (n=14) were seen over the last decade at The Genetics Institutes at Rambam Health Care Campus, Haifa, Israel, Beilinson hospital and Schneider Children's Medical Center, Petah Tikva, Israel, and Boston Children's Hospital, Boston, MA, USA. All patients were clinically evaluated by their geneticists, and underwent diagnostic genetic analyses (Table 1).

Conclusions. With most patients, the primary physician is the pivotal figure that facilitates their care; he is best acquainted with the patient and should be the first to question a diagnosis that doesn't explain the patient's full clinical picture. The phenomenon of double diagnosis is bound to expand in the era of next generation sequencing, as it continues to grow in clinical, rather than just research, settings. We recommend physicians to question every diagnosis and see whether it indeed explains all of the patients' symptoms, or should they continue the evaluation for a more accurate and complete diagnosis or diagnoses.

Table 1: Genetic diagnoses of patients in our case series.

Case	Aneuploidy	Microdeletion / Microduplication	Imprinting disorder	Monogenic / Molecular disorder

Preconception carrier screening for multiple disorders: evaluation of a screening offer in a Dutch founder population

I. B. Mathijssen¹, K. C. A. Holtkamp^{2,3}, C. P. E. Ottenheim¹, J. M. C. van Eeten-Nijman¹, P. Lakeman¹, H. Meijers-Heijboer^{1,2}, M. C. van Maarle¹, L. Henneman^{2,3};
¹Department of Clinical Genetics, Academic Medical Center, Amsterdam, Netherlands, ²Department of Clinical Genetics, VU University Medical Center, Amsterdam, Netherlands, ³EMGO Institute for Health and Care Research, VU University Medical Center, Amsterdam, Netherlands.

Introduction: Although preconception carrier screening for multiple disorders is becoming more widely available, only few studies have been done to evaluate such kind of screening. This study assessed experiences with carrier screening in a Dutch founder population in which four severe recessive disorders frequently occur.

Methods: In a special outpatient clinic, individuals from the founder population were offered screening for the four disorders simultaneously. Those who attended between September 2012 and June 2014 were asked to participate in our evaluation study. Questionnaire(s) were completed by 182 counselees before and after counselling, and after receiving test-results.

Results: Although knowledge after counselling increased (p<0.001), still 10% (compared to 34% before counselling) mistakenly thought that there is an increased risk of having an affected child if both parents are carrier of different disorders. Most participants (97%) could recall their test-results correctly. 63% Felt worried waiting for their results, but anxiety levels returned to normal afterwards. 4% (2/52) Of the carriers felt less healthy after knowing their results. Participants did not regret testing (97%) and would recommend screening to others (97%). Eight carrier couples were identified who all made reproductive decisions based on their test-results. **Conclusion:** Individuals from the Dutch founder population who were offered screening were very satisfied. Although familiarity with genetic diseases is high in this population, knowledge is still not optimal. No adverse psychological effects were demonstrated. Our experiences provide lessons for the implementation of expanded carrier screening panels in the general population.

Grant: The Netherlands Organization for Health Research and Development.

P19.17

How to improve parents' and children's experience of predictive testing for Familial Hypercholesterolaemia

K. Forrest Keenan, L. McKee, Z. Miedzybrodzka;
University of Aberdeen, Aberdeen, United Kingdom.

Background: Genetic testing is recommended in children at risk of Familial Hypercholesterolaemia (FH) to allow early treatment with statins. In Scotland a system of cascade screening was introduced in 2008. Whilst 13% of the at-risk population have been identified to date, the majority remain untested and undiagnosed, with uptake rates for children a concern. **Methods:** A qualitative study of 17 parents whose children were offered FH genetic testing and treatment.

Results: Key points for clinical practice were: (1) Consider if parent(s) need time to discuss how/when to share information with their child about FH, and offer separate appointment before meeting child if necessary; (2) Provide age appropriate and engaging information for parents about FH to use with children. Signpost to resources such as <http://heartuk.org.uk/FHchildrenresources>; (3) Explore any parental concerns and emotions e.g. grief, loss, guilt, fear, threat. (4) Offer referral elsewhere for additional support if necessary e.g. more experienced team members, psychology or FH nurse; (5) Explore parents and children's views about genetic testing and statin treatment - aim for joint decision making; (6) Use a multidisciplinary approach and joint clinics where possible and (7) If family is at risk of disengaging aim to maintain a good relationship and advise that your 'door is always open.' **Conclusion:** Attention to these issues in genetic counselling/ paediatric genetics could improve parents and children's experiences of

predictive testing and care pathways for FH. KFK was funded by a CSO Fellowship, Scottish Government.

P19.18

Filling the Void: a support initiative for families affected with a rare condition living in rural/remote Australia.

D. T. Ranaivoharison, D. Petrie;
Genetic Alliance Australia, Sydney, Australia.

Background: Living with a rare genetic condition and/or caring for someone with a rare genetic condition is associated with significant social and emotional impacts. These are even more pronounced for families in rural/remote areas with added difficulties of geographic isolation, limited access to services and lack of appropriate community support. Genetic Alliance Australia was created in 1988 to provide a national umbrella group for information dissemination and representation of those impacted by rare genetic conditions.

Method: Filling the Void (FTV) uses a collaborative approach between carers/ families and professionals to respond to the various needs of those living in isolation affected by rare genetic conditions. Individuals / families are referred by professionals, friends, family or self-referral and contact is made via phone, email, web or social media inquiry. The outreach program is delivered through a series of rural seminars, sibling workshops, networking events and tele-counselling groups.

Results: FTV has been running for over 10 years. Evaluation and monitoring of the program has shown a persistent positive feedback from participants. As a response to the changing environment where information is more easily accessible, the program is looking for innovative ways to meet consumers' need. Communication with health professionals underlined the necessity to engage with early educators and allied health professionals to ensure that families' needs are met.

Conclusion: Rural/ remote outreach support in Australia is strongly needed. Strong collaboration is necessary to keep up with its constant evolution and its expansion to professionals.

P19.19

A forum for French-speaking patients with developmental diseases with no diagnosis or an ultra rare genetic diagnosis

T. Heuyer¹, C. Vicard¹, A. Lapointe², L. Demougeot², D. Lacombe², N. Bahi-Buisson², S. Sigaudy², C. Thauvin-Robinet², L. Faivre²;

¹Maladies Rares Info Services, Paris, France, ²Filière de Santé AnDDI-Rares, Dijon, France.

A diagnosis can be classically reached in 50% of patients with developmental diseases. This figure is tending to fall since the arrival of next generation sequencing, which sometimes make it possible to identify extremely rare diseases. In these two situations, patients and/or their families are very keen to share their experience with other patients confronted with the same problems. Two organizations from different horizons have joined forces to propose a solution to these patients to help them escape from their isolation. Maladies Rares Info Services (MRIS) is the reference information and support service for rare diseases in France. It offers a complete range of services (telephone, mail, ch@t, Forum...) so that families can be listened to, find support and ask questions about rare diseases or share their experience. The AnDDI-Rares network brings together reference centres, genetics laboratories and patients support groups involved in genetic developmental diseases. It is developing particular actions around the diagnosis, the management of patients, research and training/information. The patients concerned by this new offer will be informed during genetic consultations in the AnDDI-Rares network. They can visit the site of MRIS where they will find a section called forum for patients/families without diagnosis, or contact Maladies Rares Info Services if they wish to create a new forum for an extremely rare disease. A team of professionals is on hand to provide assistance and moderate. Even though international initiatives are being set up, it is important to create national initiatives to improve access for all.

P19.20

Developmental abnormalities and intellectual disability: an original French organisation in two national networks, AnDDI-Rares and DéfiScience

Verloes⁵, C. Vernin¹¹, DéfiScience Competence Centres, AnDDI-Rares co-coordinators, V. des Portes³, D. Héron⁷;

¹AnDDI-Rares, Dijon, France, ²AnDDI-Rares, DéfiScience, Dijon, France, ³DéfiScience, Lyon, France, ⁴AnDDI-Rares, Paris, France, ⁵DéfiScience, Paris, France, ⁶AnDDI-Rares, Angers, France, ⁷AnDDI-Rares, DéfiScience, Paris, France, ⁸AnDDI-Rares, DéfiScience, Strasbourg, France, ⁹AnDDI-Rares, DéfiScience, Reims, France, ¹⁰DéfiScience, Toulouse, France, ¹¹AnDDI-Rares, Lyon, France, ¹²AnDDI-Rares, Clermont-Ferrand, France, ¹³AnDDI-Rares, Montpellier, France, ¹⁴AnDDI-Rares, Bordeaux, France, ¹⁵AnDDI-Rares, Lille, France, ¹⁶AnDDI-Rares, DéfiScience, Rennes, France, ¹⁷AnDDI-Rares, DéfiScience, Marseille, France, ¹⁸AnDDI-Rares, DéfiScience, Lyon, France, ¹⁹AnDDI-Rares, DéfiScience, Montpellier, France, ²⁰AnDDI-Rares, DéfiScience, Tours, France, ²¹DéfiScience, Lille, France.

Developmental abnormalities (DA) and (ID) are both extremely heterogeneous groups of disorders comprising over 3,000 distinct clinical entities. Although individually rare, they affect from 1.5 to 3% of the population, corresponding to around 1.8 million French people. DA/ID, lead to chronic life-long physical, cognitive and adaptive disability, and represents a major public health problem leading to medical and scientific challenges: diagnosis of the underlying etiology (about half of the patients remain undiagnosed), early multidisciplinary follow-up and care, substantial familial support and qualified research in various fields such as molecular biology, neurobiology, cognitive science, pharmacology, education and social science.

After the certification of reference and competence centres for rare diseases by the first "French National Plan for Rare Diseases", launched in 2005 by the French Ministry of Health, 23 national networks for rare diseases were certified in 2014 through the second plan. For DA/ID, two networks have been certified, AnDDI-Rares and DéfiScience, devoted to AD and ID, respectively. These networks gather 13 reference and 15 competence centres, all genetic diagnosis labs devoted to DA/ID, more than 40 research teams, 12 learned societies and more than 50 patients' support associations.

Taking advantage of complementary fields of expertise, AnDDI-Rares and DéfiScience work together to facilitate patients' access to functional and molecular diagnosis, implement national registries, write detailed care and follow-up recommendations, coordinate medico-social actions, teach professionals, apply communication strategies to spread knowledge and develop interactions, promote clinical and translational research, and increase international visibility and collaborations.

P19.21

The role of the genetic counselor in the decision by pregnant women with the risk of chromosomal abnormalities in the fetus regarding invasive diagnostics

V. L. Izhevskaya¹, L. A. Zhuchenko²;

¹Research centre for medical genetics, Moscow, Russian Federation, ²Russian Medical Academy of Postgraduate Education Studies, Moscow, Russian Federation.

The effect of different demographic and social factors on the consent of pregnant women for invasive prenatal diagnosis or rejection of it was analyzed. Pregnant women from the Moscow region were examined in the period from 12.12.2012 till 30.10.2014. 1580 pregnant women were at the risk of chromosomal abnormalities in the fetus of 1: 100 and above. All of them have received genetic counseling. Invasive procedure was carried out in 1164 (73.7%) of them, 416 (26.3%) rejected it. Data on age, place of residence, social status, presence or absence of children, children's health, the presence or absence of spontaneous abortions have been received. Statistically significant differences between the two analyzed groups of women in these parameters were not obtained. The proportion of women who refused invasive procedure, significantly differed from two genetic counselors ($\chi^2 = 7.8$; $p = 0.0055$). First counselor's patients significantly more frequently indicated that they feared complications of invasive procedures (63.8% vs 31%), or they could not formulate reasons for the refusal of it (83.3% vs 16.7%). Second counselor's patients significantly more frequently pointed to the decision to have a child, regardless of his health (70% vs 30%). About 13% of patients of both doctors refused the procedure because they were sure that their baby is healthy. Perhaps we need additional training geneticists involved in the program of early prenatal screening. This work was supported by the Russian Foundation for Humanities, project 15-03-00822.

P19.22

Genetic Counselling Service in Korea

H. J. Kim;

Korean Foundation for Rare Disease, Seoul, Korea, Republic of.

Genetic Counseling Service(GCS) is considered as an integral part of medical service for pts. with genetic disease in most of developed countries. Howe-

ver, GCS is yet to be established in Korea where National Health Care System covered by the uniform national insurance policy.

Korean Governmental Health policy for pts. with Rare disease includes special discount health care fees and benefits, but genetic counseling is not recognized as a health service yet. Therefore many pt. and family with genetic disease look for help and requested aids for GCS to KFRD, an advocate for rare disease.

In May 2012 KFRD started funding for GCS to aid pts. and family members at high risk, in order to provide GCS including genetic testing and for the evaluation of effectiveness of GCS, survey questionnaire was administered to 496 individuals of pts & family members participated.

Among 118 respondents to the survey, 109(92%) responded „overall satisfaction“ on GCS, 108(91.5%) “helpful in understanding the diagnosis and natural history of the disease affected“, 103(87.2%) „helpful in understanding accurate medical and genetic information“ and 98(83%) „helpful in management of disease and make decision on reproductive options“.

111(94%) acknowledged financial aids allow them to receive GCS and expressed strong desire of the aid program to be continued.

These findings strongly support that GCS should be provided to pts. and family with genetic disease for the better management and prevention of incurable and disabling rare hereditary disease, as an integral part of health care policy in Korea.

P19.23

Examining the genetics nursing lesson's situation in nursing curriculum in Turkey

Y. Erdem, A. Güneş, N. Bora Güneş;
Kirikkale University, Kirikkale, Turkey.

Background: Genetics nurses help people at risk for or affected by diseases with a genetic component achieve and maintain health. So it is important to all university to integrate genetic nursing courses into the curriculum. In Turkey, genetic diseases are high because of consequences married.

Aim: To explore the nursing curriculum about genetics nursing courses in Turkey

Methods: In this descriptive research, 133 bachelor degree nursing schools were explored via e-mails and telephone interview.

Results: In this research, we found that % 2.25 (3 nursing school) of all nursing school are given separately to genetics courses into their curriculum. Two of them are included as Medical Genetic and Biology in the first year as mandatory. Also, all of them are included as Genetics Nursing courses in the 3rd years as optional. In Turkey most of bachelor degree nursing schools integrated genetics into different courses like pediatric nursing, obstetrics and gynecology nursing or medical nursing. In our country, most of nursing students taught that the courses is insufficient.

Discussion: With major advances in genetics and genomics, nurses need to develop their knowledge and understanding of the topic and know how to integrate this into practice.

Conclusion: In Turkey genetic nursing course curriculum is insufficient in the nursing bachelor's degree and should be empowered

P19.24

Predicted and reported response to genetic risk information among hypertension patients

L. Leitsalu^{1,2}, K. Läll^{1,3}, Ü. Meren^{4,5}, H. Alavere¹, M. Tammaru⁵, K. Fischer¹, P. C. Ng^{1,6}, A. Metspalu¹;

¹Estonian Genome Center, University of Tartu, Tartu, Estonia, ²Institute of Molecular and Cell Biology, University of Tartu, Tartu, Estonia, ³Institute of Mathematical Statistics, University of Tartu, Tartu, Estonia, ⁴Department of Pharmacy, University of Tartu, Tartu, Estonia, ⁵East Tallinn Central Hospital, Tallinn, Estonia, ⁶Genome Institute of Singapore, Singapore, Singapore.

Introduction: The feasibility and utility of incorporating genetic risk prediction for common chronic diseases in primary care practice are largely unknown. We examine whether genetic information elicits health behaviour changes in those at risk for chronic diseases, and compare predicted and reported effects.

Methods: We conducted a study in multiple Estonian medical centres. 240 men with newly diagnosed primary hypertension visited a medical centre five times over one year. In addition to the standard cardiovascular disease risk evaluation participants received genetic risk information for hypertension-related diseases. Participants filled in surveys about the expected effect of genetic risk information (predicted), about the immediate reaction to receiving genetic information, and at the end of the study to examine the long-term effects (reported).

Results: At the start of the study the participants had a positive attitude and

optimistic expectations towards the impact of genetic risk predictions on their medication adherence (88%) and health behaviour (92%). A majority (95%) thought sufficient amount of information was included in the report and considered the information received understandable (98%) and informative (92%). The preliminary results show that at the end of the study, 67% reported positive changes in their everyday habits.

Conclusions: The results remain to be analysed relative to the specific risk information received. However, the participants predicted response to genetic risk information is more optimistic than the reported response.

Grant reference: This research has been supported by EU Regional Development Fund through Archimedes Foundation, grant No. 3.2.1001.11-0033.

P19.25

The influence of perceived and actual risk on use of cancer genetic services in women at risk for hereditary breast cancer

C. Ming, C. Nikolaidis, M. Katapodi;

Institute of Nursing Science, Faculty of Medicine, University of Basel, Basel, Switzerland.

Background: Cancer genetic services (counselling and testing) are recommended for women with family history of early onset breast cancer (≤ 50 years old). The Gail model can differentiate women with high susceptibility to the disease from those at average/population risk. Perceived risk has significant effects on health behaviors, yet, it is unknown whether it influences use of cancer genetic services. The study explores associations between perceived breast cancer risk and Gail risk scores with use of cancer genetic services.

Methods: We recruited 430 female relatives of women diagnosed with breast cancer ≤ 45 years old. Perceived risk was measured with one item assessing perceived chances of getting breast cancer. We calculated 5-year and lifetime Gail scores, and evaluated barriers to using genetic services.

Results: Participants were 43.4 (± 11.9) years old; 80% self-identified as White/Other and 20% as Black. The average 5-year and lifetime Gail scores were 1.55% and 16.42%, respectively. Average perceived risk was 4.67 (± 1.99), meaning “save as average.” From 334 participants with lifetime Gail risk $>$ average 81.1% underestimated their risk; from 74 participants with lifetime Gail risk \leq average 5.4% overestimated their risk. Only 33 women had genetic services and 13 had testing. Lifetime Gail scores were higher for those who had genetic services ($p=0.0043$). Logistic regression modeling will explore predictors of using cancer genetic services.

Conclusion: Women with family history of early onset breast cancer have \geq average risk for the disease. Our study adds weight to understanding use of cancer genetic services and improving risk communication and management strategies.

P19.26

Gen-Equip: Equipping European Primary Care Health Professionals to Deal with Genetics

V. Curtisova¹, E. Houwink², L. Jackson³, P. Lunt³, M. Paneque⁴, V. Stefansdottir⁵, D.

Turchetti⁶, M. Campos⁷, M. Corne⁸, M. Macek⁹, A. Kent⁷, H. Skirton, PL4 BAA³;

¹Charles University, Prague, Czech Republic, ²VU University Medical Centre, Amsterdam, Netherlands, ³Faculty of Health and Human Sciences, Plymouth, United Kingdom, ⁴IBMC, University of Porto, Porto, Portugal, ⁵Landspitali Hospital, Reykjavik, Iceland, ⁶Università di Bologna, Bologna, Italy, ⁷Genetic Alliance UK, London, United Kingdom.

With expansion of genetics and genomics, primary care professionals are increasingly expected to help deliver genetic services in daily patient care. This requires appropriate skills and knowledge to deliver care that addresses patient needs and maximises use of health resources. The aim of the Gen-Equip project is to improve primary care of patients with genetic/genomic conditions. Via a partnership between expert patients and specialists in adult education, primary care and genetics, we are implementing free, online education in genomic healthcare for European primary care practitioners.

To date, we have undertaken a systematic review of genetic education for primary care and developed an educational curriculum for European professionals. Expert advice indicated that an approach based on questions asked by patients in primary care was likely to be perceived as relevant to the target learner group. Ten case-based modules set in primary care have been prepared, these can be accessed online (<https://www.primarycaregenetics.org/>) by any health professional and include pre and post-test module tests. Topics include familial cancer, familial hypercholesterolaemia, inherited cardiac conditions, developmental delay and reproductive issues. A series of online webinars are also available on core topics such as ‘Genetic/genomic test results: what they mean for your patient’. All educational content will be available in six European languages and accredited by national professional organisations.

Assessment of educational tools relating to changes in knowledge, skills and practice is important and we will investigate short and long-term changes. Examples of learning tools and initial assessments will be given. Co-funded by the EU: 2014-1-UK01-KA204-000065.

P19.27

Building capacity and capability in the NHS for Genomic Medicine: a national strategic approach to the underpinning educational framework

A. Seller¹, M. Bishop¹, N. Latham¹, S. L. Hill², E. V. Davison¹;
¹Health Education England, Birmingham, United Kingdom, ²NHS England, London, United Kingdom.

England's 100,000 Genomes project aims to establish a new genomic medicine service for the National Health Service (NHS) through transformation of patient and diagnostic care pathways, improving diagnosis in patients with Rare disease and Cancer, and in time realising the potential for new and effective treatments.

This ambitious project affords a unique opportunity to implement a co-ordinated approach to workforce education and development, upskilling the existing workforce and ensuring a lasting legacy of genomics embedded in mainstream clinical practise. To address this need a £20M programme of resource, capacity and capability development has been established by Health Education England's Genomics Education Programme.

To underpin the multiprofessional education and training needs of the current workforce to deliver the 100,000 Genomes Project we undertook a gap analysis, identifying nine resources to support the project pipeline. These include a range of e-learning resources including: obtaining project consent, DNA extraction and sample processing, validation and clinical reporting of the results and an online tumour assessment tool. Our MOOC on whole genome sequencing aims to reach a wider audience. Capability and capacity is being addressed through implementation and funding of new postgraduate scientist training curricula, a new NHS specialism of Clinical Bioinformatics, and a national Genomic Medicine Master's programme for NHS staff. To date we have funded 57 postgraduate trainees, approved 240 MSc applications and >2700 learners have registered for our online courses. We will present our strategy together with data on course engagement, and evaluation of the programme's impact on workforce transformation.

P19.28

Hereditary breast and ovarian cancer: Report of a case of double heterozygosity, concurrent pathogenic variants in germline BRCA1 and BRCA2

S. B. Margarit¹, F. Benavidez¹, K. Espinoza¹, P. Raimilla², F. Cádiz², G. Repetto²;
¹Clinica Alemana Universidad del Desarrollo, SANTIAGO, Chile, ²Clinica Alemana de Santiago, SANTIAGO, Chile.

Introduction: Cases of double heterozygosity caused by the presence of mutations in the BRCA1 and BRCA2 genes are unusual. To date, the vast majority of reported cases are of Ashkenazi Jewish descent being rare in other populations. Clinical presentation of double heterozygotes individuals is varied and has a similar phenotype and age of onset as carriers of a single mutation. We report a case of double heterozygosity in the Chilean population with early age of onset compared to members of the same family carriers of a single mutation.

General Description: Pretest genetic counseling and commercial high-risk breast cancer panel was offered in view of proband's personal history of breast and ovarian cancer and family history of cancer. Mutations in BRCA1 and BRCA2 were identified in enriched targeted genes. Post-test genetic counseling and single site mutation testing was offered to high risk family members at our laboratory in Santiago, Chile.

Results: Double heterozygosity was identified in the proband. In BRCA1 c.3331_3334delCAAG (rs80357903) also known as c.3450del4 recognized as pathogenic. This mutation is a common cause of hereditary breast and ovarian cancer in Colombian ancestry. In BRCA2 c.4889C>G (rs80358711) also known as c.5117C>G is a truncating variant that creates a premature translational stop signal. Single site mutation testing was offered to 7 family members, 3 were BRCA2 carriers, 2 BRCA1 carriers and 2 family members obtained negative results for both mutations.

Conclusion: Detection of double heterozygosity in germline BRCA1 and BRCA2 has implications for genetic counseling and clinical management of carriers identified.

P19.30

Audit of the testing strategy for inherited bowel cancer predisposition genes in the Clinical Genetics Department and Liverpool Women's Hospital

K. A. Eggleton;
 Liverpool Women's Hospital, Liverpool, United Kingdom.

Genetic testing for families who are at an increased risk of developing bowel cancer due to a genetic predisposition can be time consuming, expensive and complex. Testing can be carried out by two methods: Directly sequencing mismatch repair (MMR) genes or indirectly using immunohistochemistry (IHC) and microsatellite instability (MSI) testing on tumour tissue. At the Liverpool Women's Hospital (LWH), an individual must fit the modified Amsterdam Criteria to qualify for direct genetic testing. Alternatively, individuals that meet a less stringent criterion (Cairns *et al* guidelines) or departmental criteria may be sent for IHC/MSI testing.

Through a clinical audit of this strategy, it was established that IHC/MSI testing had a very low pick-up rate (4%) and a 6-12 month turnaround time. In addition, this testing was found to cost a minimum of £460 per sample plus £138 for methylation tests should an abnormal result be discovered. This gave a cost per positive of £7406 in 2014. In 2015, the LWH genetics department implemented a Multiplicom HNPCC-related gene panel which reduced the cost of direct gene testing to approximately £500 per sample and reduced analysis time to 6 days. Given the number of patients tested in 2014, this test would have a cost per positive of £3500.

As a result of the audit, new departmental guidelines have now been developed. Direct gene testing has now been expanded to individuals who fall within a new departmental criteria, IHC testing has been significantly restricted and MSI testing has been removed from standard practice.

P19.31

„The result is a little more complicated than we expected“: Incidental findings in predictive testing

R. F. Pope-Couston¹, K. K. Gamet², P. Dryland²;
¹Genetic Health Service NZ, Auckland, New Zealand, ²Labplus Auckland District Health Board, Auckland, New Zealand.

Introduction: Often, genetic counselling for predictive testing may not focus on the possibility of incidental or unexpected findings due to the perception that the narrow focus of genetic testing for known mutations would make those types of findings highly unlikely. In this case, due to the nature of the test platform being used, it was found that while the consultand did not carry the maternal familial BRCA1 deletion, he did carry a pathogenic duplication. This incidental finding was a novel experience for both the genetic counsellors and laboratory staff involved and required management of a number of complex issues.

Methods: Laboratory staff liaised with the genetics unit to develop a report which accurately reflected how the finding had been detected. Counsellors involved considered a number of ethical issues in preparation for providing the result to the consultand and working with his family. These included planning how, or if, to raise the possibility of non-paternity given the low de novo rate for BRCA mutations and the absence of a reported paternal family history of cancer.

Outcome: Collaborative communication between the laboratory and genetic counselling staff and between genetic counsellors and family members was the key to effectively managing this incidental finding and the flow-on effects within the family. Successful communication and support has resulted in a number of at-risk relatives coming forward for predictive testing. This case also highlighted the importance of comprehensive pre- and post-test counselling particularly as the resolution and complexity of genetic testing platforms continues to increase.

P19.32

Detection of tissue mosaicism in Klinefelter and Klinefelter-like patients by using FISH and its clinical importance

A. M. Hassan, A. A. B. Shahin, I. Mazen, M. M. Eid, O. M. Eid, H. T. El-Bassyouni;
 National research center, Cairo, Egypt.

Introduction: Klinefelter syndrome (47,XXY) is the most chromosomal abnormality that repeatedly registered in infertile men with an incidence of 9-11% in azoospermic individuals. However there are no fixed predictive factors for testicular sperm extraction success has been established. Detection of mosaicism could be important for the clinical evaluation. In this study we have assessed the degree of mosaicism in peripheral blood and buccal mucosal cells. The fluorescence in situ hybridization (FISH) using centromere X,Y probe was applied on the peripheral blood and buccal cells as a sensitive technique for the detection of mosaicism.

Materials and Methods: 20 Patients are classified into 12 Klinefelter syndrome patients (group I) and 8 Klinefelter syndrome-like patients (group II) according to karyotype and clinical appearance. Karyotype for each patient was done and FISH analysis for cells from peripheral blood and buccal swap was recorded.

Results: Out of the 12 klinefelter syndrome patients (group I), 5(41.6%) were found to have mosaic cell lines. The mosaic Klinefelter syndrome patients were 47,XXY/46,XY. Testicular volumes in patients of group II were larger when compared to those in group I. One patient in group II has no azoospermia.

Conclusions: The mosaicism level in testicular tissue, not only concerning germ cells but also for somatic cells, could be of relevance to the final outcome of spermatogenesis in patients with Klinefelter syndrome. So the complete evaluation should include cells from the peripheral blood and another tissue. Mucosal cells can be of help for better estimate of the sertoli cell mosaicism.

P19.33

Management of emergency care for patients with FBN1 gene mutation: epidemiological study

L. Boidron, A. Charpin, R. Tjiffha, E. Gautier, C. Binquet, H. Devilliers, A. Soudry, A. Mosca-Boidron, N. Jean, B. Mangola, J. Eicher, L. Faivre;
Dijon University Hospital, Dijon, France.

Introduction: Marfan syndrome (MFS) is characterized by a variable combination of cardiovascular, skeletal or eye events. In emergencies situations, the knowledge of this history is crucial to ensure quality of care. When calling to Emergency Medical Call Center (EMCC), the patient has an interview with a medical dispatcher that adjusts the response given the gravity of the situation and the patient's history.

Materials and Methods: In this study we sought to evaluate the frequency, cause, and the quality of care for patients with FBN1 gene mutation calling to EMCC. Between April 2008 and October 2015, we collected all calls of the 37 mutated patients known. We analyzed the number, recurrence and reasons of call as well as the knowledge of the history of MFS by the dispatcher. **Results:** Among the 37 patients known as MFS carrier, 16 have called 25 times to EMCC during 7 years. More than half of calls (60%) had a potential link with the MFS (10 calls for chest pain, 5 for dyspnea 5). Trauma represents 5 calls. The notion of MFS was known in two calls (8%). Dispatcher's decision was appropriate in 40% of cases.

Conclusion: Half of patients with FBN1 mutation have used the EMCC mostly for reasons related to their condition. The notion of MFS was known only in 8% of calls that probably reduce quality and safety of healthcare. A registration of MFS patients on a special list for the EMCC should improve the quality of management.

P19.35

MedGen: Development of medical genetics education through curriculum reforms and establishment of training programs

D. Babikyan^{1,2}, H. Skirton³, Z. Sedlacek⁴, M. Ser⁵, K. Sargsyan⁶, A. Hovnanian⁷, S. Allon Shalev⁸, E. Shalev⁹, L. Basel⁹, M. Berkenstet⁹, K. B. Avraham⁹, K. Hovhannesian¹⁰, G. Shahsuvaryan¹⁰, S. Midyan¹⁰, H. Hayrapetyan¹, A. Hovhannisyanyan¹, T. Sarkisian¹²;
¹Yerevan State Medical University after Mkhitar Heratsi, Yerevan, Armenia, ²Center of Medical Genetics and Primary Health Care, Yerevan, Armenia, ³University of Plymouth, Plymouth, United Kingdom, ⁴Charles University in Prague, Prague, Czech Republic, ⁵Alma Mater Studiorum Università di Bologna, Bologna, Italy, ⁶Medical University of Graz, Graz, Austria, ⁷Université Paris Descartes, Paris, France, ⁸Technion-Israel Institute of Technology, Haifa, Israel, ⁹Tel Aviv University, Tel Aviv, Israel, ¹⁰Russian-Armenian University, Yerevan, Armenia.

Despite increasing awareness of public health officials and medical professionals about the role of genetic factors in health and diseases in Armenia and Israel, the development and implementation of effective medical genetic interventions is critically constrained by a lack of professional workforce capacity. For this reason, MedGen project has been launched where the wider objective is the development and implementation of education programs of Medical Genetics (MG) corresponding to EU recommendations of educational and professional standards in MG and reinforcement of international cooperation capacity. Four different education programs are being developed in four universities of Armenia and Israel in Genetic Counselling and Clinical Genetics. National consultations with presentation of policy briefs for MG to stakeholders provided better opportunity to develop graduate profiles and content of education programs with blended teaching and learning platform. The faculty training provided by five outstanding European universities upgrade the teaching capacity of Armenian and Israeli teaching staff to deliver the MG courses corresponding to EU standards. Accreditation and delivery of developing programs are expected by the end of 2016

with the development of cooperation between the partners and European universities as strong indicators of the project's sustainability. The harmonized education in MG will serve as a hub for international education and research programs and will contribute to the overall quality of healthcare in Armenia and Israel.

Introduction: CDKN2A is the main high-risk melanoma-susceptibility gene, but has been poorly assessed in Latin America. We analyzed CDKN2A and MC1R in patients from Latin America with familial and sporadic multiple primary melanoma (SMP) and compare the data with those for patients from Spain to establish bases for melanoma genetic counseling in Latin America.

Material and Methods: CDKN2A and MC1R were sequenced in 186 patients from Argentina, Brazil, Chile, Mexico, and Uruguay, and in 904 Spanish patients. Clinical and phenotypic data were obtained.

Results: Overall, 24 and 14% of melanoma-prone families in Latin America and Spain, respectively, had mutations in CDKN2A. Latin American families had CDKN2A mutations more frequently (P = 0.014) than Spanish ones. Of patients with SMP, 10% of those from Latin America and 8.5% of those from Spain had mutations in CDKN2A. Latin American patients had fairer hair and skin and a higher prevalence of MC1R variants compared with Spanish patients.

Conclusion: The inclusion criteria for genetic counseling of melanoma in Latin America may be the same criteria used in Spain, as suggested in areas with low to medium incidence, SMP with at least two melanomas, or families with at least two cases among first- or second-degree relatives.

Funding was provided by GenoMEL (LSHC-CT-2006-018702) and the National Cancer Institute US NIH (CA83115). Research in Barcelona was funded by grants 03/0019, 05/0302, 06/0265, 09/1393, 12/00840 from FISS; by CIBERER of ISCIII; by AGAUR 2014_SGR_603 and by the European Commission under the 6th Framework Programme.

P19.37

Molecular genetics for the patients - prioritization criteria in the face of limited resources

M. Puu^{1,2}, N. Andrescu¹, S. Farcas¹, C. Zimbru³, A. Chirita-Emandi³;

¹University of Medicine & Pharmacy Victor Babes, Genetics Department, Center of Genomic Medicine, Timisoara, Romania, ²Regional Center of Medical Genetics Timis, Emergency Hospital for Children "Louis Turcanu", Timisoara, Romania, ³Department of Automation and Applied Informatics, Faculty of Automation and Computers, Politehnica University, Timisoara, Romania.

Background: The technology for genomic studies has expanded tremendously in the last decade. Although the price of molecular genetic tests has gradually decreased, the burden of costs is considerable even for highly developed European countries. Romania is a developing country where even though appropriate laboratory equipment now exists in some genetic centres, the cost for consumables needs to be well planned. We aimed to define an approach for prioritizing the allocation of molecular genetics tests at national level.

Methods: The norms for allocating resources need to account for clinical usefulness of a test (treatment/prevention strategies); and treating people equally. With limited resources, the degree of an individual's need for medical intervention may be the most important criterion. Nonetheless, it is imperative to offer genetic tests non-discriminatively to all people in need, regardless of their economical/social/ethnic status.

Results: Romanian Society of Medical Genetics together with the Ministry of Health, Romanian National Alliance for Rare Diseases (RoNARD) and other stakeholders are developing a national strategy for allocating resources, based on epidemiological data on genetic conditions in Romania. In accordance with needs, healthcare expertise and existing infrastructure, prioritization criteria are being developed to optimize patient access to genetic tests. Coordination between regional centres of medical genetics is crucial for improved efficiency.

Conclusion: Further work is needed to determine the criteria necessary in decision making, in order to respect equality but also clinical need within a limited budget.

Acknowledgements: Development of existing infrastructure and creation of new infrastructure. POSCCE-A2-02.2.1-2013-1, Center of Genomic Medicine University of Medicine and Pharmacy "Victor Babes" Timisoara.

P19.38

Using MOOCs to increase exposure to genomics in an undergraduate medical curriculum

L. Marks, M. Jackson, S. Meek;

University of Glasgow, Glasgow, United Kingdom.

Introduction: We have recently found that 'Student Selected Component' (SSC) provision in our Medical School undergraduate curriculum needed to be expanded to exemplify the diversity of modern medicine, particularly in the area of genomics. Simultaneously we have also run a MOOC 'Cancer in the 21st Century: The Genomic Revolution' and as educators and course designers we were frustrated by the seeming redundancy facing an excellent example of course design and implementation.

Methods: Earlier this year we re-purposed the MOOC, using a blended learning approach, in order to offer a Cancer Genomics SSC to a wider group of students than previously possible. To evaluate its success we used a combination of a questionnaire and thematic analysis of student reflective diaries as well as staff evaluations.

Results: Analysis of the questionnaires and reflective diaries highlighted a number of key themes. The overall level of enjoyment of the SSC was high but a number of issues deserve further investigation. In particular we will discuss knowledge versus skill acquisition, pacing of the content, interaction with fellow students and educators and the concept of learning along side 'non-experts'.

Discussion: Genomics is a key area for the next generation of medical students to have a secure understanding of, but the ever crammed undergraduate curriculum as well as the reliance on 'in house' expertise may limit the exposure to this exponentially expanding area. We propose that the use of MOOCs may be a novel and effective way to combat this challenge.

P19.39

Innovative Strategy for Achieving Optimal Care and Significant Cost Savings for Critically Ill Neonates

V. Ortega, G. V. N. Velagaleti;

University of Texas Health Science Center, San Antonio, TX, United States.

Among the yearly 4 million newborns in the US, 15% are premature accounting for 75% of NICU admissions while the remaining 25% term babies ad-

mitted have varying pathology including developmental delay/intellectual disability (DD/ID). Establishing underlying genetic etiology early helps with diagnosis, prognosis and comorbidity information. According to American Academy of Pediatrics chromosome analysis (CA) is required for evaluation of children with DD/ID. Yet CA and FISH are sub-optimal in identifying the etiology of DD/ID. American Academy of Neurology, Child Neurology Society, and American College of Medical Genetics recommend that chromosomal microarray analysis (CMA) be the first-line genetic test. However, the average turnaround time for CMA is 21 days and the daily NICU cost exceeds \$3,500 per infant. With test utilization and costs significantly impacting healthcare institutions, we developed a novel approach to perform CA with reflex testing to CMA on pediatric blood samples. A CA preliminary result is reported within 24 hours. If positive for trisomy, final result is reported within 48-72 hours. If negative, CMA is reflexed based on practice guidelines. Clients are only charged either CA or CMA. Since inception in January 2015, clients requested reflex testing on 43 patients, of which 6 resulted in a positive preliminary requiring no further testing. With our approach, we estimate a cost savings of ~\$63,000 per infant by reducing the NICU stay by ~16-18 days. Reflex testing to CMA after a 24 hour CA preliminary study shows potential for extensive cost savings while maintaining optimal care for NICU patients.

P19.40

The Italian "Telethon Undiagnosed Diseases Program"

R. Castello¹, A. Torella^{2,3}, F. Musacchia⁴, M. Mutarelli⁵, M. Dionisi¹, G. Oliva^{1,3}, M. Pizzo¹, F. Radio⁴, M. Dentici⁴, A. Bartuli⁴, M. Digilio⁴, A. Cioffi⁴, S. Pizzi⁴, A. Bruselles⁵, V. Caputo⁶, G. Mancano⁷, S. Maitz⁷, G. Sgroi⁷, G. Cappuccio^{8,9}, M. Pinelli¹, E. Rizzi⁸, G. Parenti^{8,1}, S. Banfi^{8,1}, M. Tartaglia⁴, A. Selicorni⁷, N. Brunetti-Pierri^{8,1}, B. Dallapiccola⁴, L. Monaco⁹, V. Nigro^{2,1};

¹Telethon Institute of Genetics and Medicine (TIGEM), Pozzuoli (NA), Italy, ²Seconda Università di Napoli, Napoli, Italy, ³ICAR-CNR, Napoli, Italy, ⁴Ospedale Pediatrico Bambino Gesù - IRCCS, Roma, Italy, ⁵Istituto Superiore di Sanità, Roma, Italy, ⁶Università di Roma "La Sapienza", Roma, Italy, ⁷MBBM Foundation- AO San Gerardo, Monza, Italy, ⁸Università di Napoli Federico II, Napoli, Italy, ⁹Fondazione Telethon, Milano, Italy.

Undiagnosed genetic disorders represent a significant burden for affected children and their families. The lack of diagnosis precludes the development of specific therapies and genetic counselling. The mission of Italian Telethon requires aggregating all available resources for the benefit of genetic patients. To this purpose, the Telethon Undiagnosed Diseases Program has been launched in February 2016.

The Program has two major aims: 1) to establish a shared and standardized clinical selection of undiagnosed children through comprehensive phenotyping; 2) to identify genetic causes of undiagnosed genetic diseases by using NGS.

The Program started in February 2016 as a three-year pilot plan. From April 2016, Italian physicians will be able to submit potential cases of undiagnosed disorders through a specifically developed web tool. The program is centered at the Telethon Institute of Genetics and Medicine (Pozzuoli) where NGS activities will be converged. It will rely on a core network of three clinical centers: Ospedale Pediatrico Bambino Gesù (Rome), Ospedale San Gerardo-Fondazione MBBM (Monza) and AOU Federico II (Naples). These centers will be working together for phenotyping and selecting the cases. Family members will be analyzed by high-coverage whole exome sequencing. Results will be shared and compared with those from similar international sequencing projects to identify additional patients with the disease/molecular defect. Within a time-frame of three years, we will sequence 350-400 families (1200-1500 individuals). A particular effort will be made in order to standardize all patients' related information by adopting internationally standard tools such as Phenotips and Phenome Central.

P19.41

Genetic counselling for NIPT - a South African perspective

M. Schoeman¹, M. F. Urban¹, S. Morris²;

¹Stellenbosch University/Tygerberg Hospital, Cape Town, South Africa, ²Fetal Assessment Centre, Cape Town, South Africa.

Introduction: Non-invasive Prenatal Testing (NIPT) using cell-free fetal DNA was offered in South Africa for the first time by our unit in July 2013. We describe the first 2 years of our experience with implementing NIPT in a clinical, private practice setting, specifically focusing on the genetic counselling considerations. **Materials and Methods:** A record review was performed for data pertaining to women who received genetic counselling for NIPT during the period July 2013 - June 2015 for common autosomal and/or sex chromosome aneuploidies and/or gender. Data was collected on rate of uptake of NIPT, indications and motivations for testing, characteristics of patients and test results. **Results:** During this period, 385 women received genetic counselling about NIPT and 354 (91%) accepted the test. Of wo-

men tested, 79% were at high risk for Down syndrome, because of advanced maternal age (60%) or positive screening tests (21%). Mean maternal age was 38 years and tests were mostly performed between 12-13 weeks gestation. Eight (2.3%) NIPT screen positive results were obtained: seven for Trisomy 21 and one for Trisomy 18, seven ended in termination of pregnancy. Conclusions: In South Africa, NIPT is a relatively expensive screening test, currently only available in the private sector to a select group who can afford it. Whilst most women requested NIPT for a high risk of Down syndrome, other reasons included additional reassurance or general concerns about Down syndrome/disability. Pre-test counselling is important- NIPT is declined in 9% of cases, often because the indications for NIPT are misunderstood.

P19.42

Implementing non-invasive prenatal testing for aneuploidy in a national healthcare system: global challenges and national solutions

R. V. Van Schendel^{1,2}, C. G. Van El^{1,2}, E. Pajkrt³, L. Henneman^{1,2}, M. C. Cornel^{1,2},
¹VU University Medical Center, Amsterdam, Netherlands, ²EMGO Institute for Health and Care Research, Amsterdam, Netherlands, ³Academic Medical Centre, Amsterdam, Netherlands.

Background: Since the introduction of non-invasive prenatal testing (NIPT) in 2011, mainly by commercial companies, a growing demand for NIPT from the public and healthcare professionals has put pressure on healthcare systems of various countries. This study identifies the challenges of establishing a responsible implementation of NIPT for aneuploidy in prenatal healthcare, by looking at the Netherlands.

Materials and methods: We used a mixed methods approach involving 13 stakeholder interviews (laboratory specialists, gynecologists, clinical geneticists, midwives, patient organization representatives, health-insurance advisor and prenatal screening experts), document analysis and (participatory) observations of the Dutch NIPT consortium meetings. The Diffusion of Innovation Theory and a Network of Actors model were used to interpret the findings.

Results: Implementation of NIPT was facilitated by several factors. The set-up of a national NIPT Consortium enabled discussion and collaboration between stakeholders. Moreover, it led to the plan to offer NIPT through a nationwide research setting (TRIDENT study; Trial by Dutch laboratories for Evaluation of Non-Invasive Prenatal Testing), which created a learning phase for careful implementation. The Dutch legal context was perceived as a delaying factor, but eventually gave room for the stakeholders involved to organise themselves and their practices.

Conclusions: This study shows that implementing advanced technologies with profound effects on prenatal care benefit from a learning phase that allows time to carefully evaluate the technical performance and women's experiences and to enable public debate. Such a coordinated learning phase, involving all stakeholders, will stimulate the process of responsible and sustainable implementation.

P19.43

A systematic review of interventions to provide genetics education for primary care

M. Paneque¹, D. Turchetti², L. Jackson³, P. Lunt⁴, E. Houwink⁵, H. Skirton³;
¹IS, Instituto de Inovação e Investigação em Saúde, Porto, Portugal, ²Department of Medical and Surgical Sciences, Unit of Medical Genetics, University of Bologna, Bologna, Italy, ³Faculty of Health and Human Sciences, Plymouth University, PL4 8AA, Plymouth, United Kingdom, ⁴Faculty of Health and Human Sciences, Plymouth University, PL4 8AA, Plymouth, United Kingdom, ⁵Department of Clinical Genetics, Section Community Genetics, EMGO Institute for Health and Care Research, VU University Medical Center, Amsterdam, Netherlands.

At least 10% of patients seen in primary care have a condition with a genetic component. Previous studies indicate that primary care practitioners lack practical knowledge of genetics and genetic testing and lack confidence in providing services related to genetic conditions. There is therefore strong potential for professionals to fail to recognise patients who are at risk of genetic disease, resulting in inadequately management or referral to specialist services. The aim of this systematic review was to evaluate genetics educational interventions in the context of primary care.

We used the process for systematic reviews developed by the Centre for Reviews and Dissemination and conducted a search of five relevant electronic databases. Primary research papers were eligible for inclusion if they included data on outcomes of educational interventions for primary care professionals focussed on genetics. The results from each paper were coded and presented in narrative form.

Eleven studies were included in the review. The five major themes identified were: prior experience, changes in confidence, changes in knowledge, chan-

ges in practice, satisfaction and feedback. In five studies, knowledge of practitioners improved following the educational programmes, while practitioner confidence improved in six studies. There was little apparent change to practice, where this was investigated.

The objective of educational programmes is to enhance patient care, but more effort is needed to measure resulting changes in practice. We also suggest that, in addition to educational programmes, provision of resources to supply 'just in time' information and accessible clinical tools may contribute to improving care.

P19.44

Challenging the Cancer Genetic Counselling Units (CGCU) with the Treatment Focused Genetic Testing (TFGT) for Ovarian Cancer (OC) patients: the ICO network experience

A. Teulé¹, A. López², L. Feliubadaló¹, H. Ahmed³, E. Darder², A. Izquierdo², A. Solanes⁴, E. Tornero¹, M. Navarro⁴, M. Menendez¹, E. Grau⁴, S. Iglesias¹, M. Salinas¹, A. Velasco², G. Capellà¹, C. Lázaro¹, P. Barretina³, J. Brunet^{1,4};

¹Hereditary Cancer Program, Catalan Institute of Oncology, L'Hospitalet de Llobregat, Spain, ²Hereditary Cancer Program, Catalan Institute of Oncology, Girona, Spain,

³Medical Oncology Department, Catalan Institute of Oncology, Girona, Spain, ⁴Hereditary Cancer Program, Catalan Institute of Oncology, Badalona, Spain.

Since the approval of the PARP inhibitor olaparib, the TFGT indications for OC have increased. Furthermore, several guidelines include genetic testing for all non-mucinous OC patients irrespectively of age and family history. All these new indications challenged our CGCU and Molecular Diagnosis Laboratory (MDL).

In December 2014, the Gyne Oncologists Team (GOT), CGCU members and the MDL established a consensus protocol on indications for risk assessment (RA) and TFGT. An express track for RA at CGCU/CFU (0-10 days) and test results delivery (<35 days) was defined for patients whose germline BRCA1/2 test results were needed to tailor their treatment.

Between January 1st and November 30th, 115 new OC patients were seen at the CGCU/CFU. 27 (23 %) followed the express track. Median time from the referral date to test results for standard GC was 77 days (36-98) and 27 days (18-65) for express GC. Median age was 59 (23-80) and 63% had not family history of cancer. BRCA1/2 results were available for 100 patients. Deleterious mutations and USV were identified in 22%(15% in the group without family history of cancer) and 9% of patients respectively.

The development of an express GC track for OC patients with a potential olaparib indication allowed us to offer RA and TFGT through our CGCU thus avoiding direct testing from the GOT. Time to first appointment for RA and test results was optimal. The relatively high frequency of BRCA1/2 mutations could be explained by the bias selection of patients with platinum sensitive relapse.

P19.45

Clinical features associated with pericentric inversion of chromosome 9 [inv(9)(p12q13)]

G. C. Cozaru, M. Aschie, A. Mitroi, D. Capatina, C. Brinzan;
 „Sf. Apostol Andrei” Constanta County Emergency Clinical Hospital, CONSTANTIA, Romania.

Introduction: This paper presents a detailed study of inversion in chromosome 9 and its correlation with phenotype features. The inv(9)(p12q13) has been reported in various human diseases such as couples with repeated spontaneous abortions, bad obstetric history, infertility and congenital anomalies.

Aim: In this study we aimed to evaluate the clinical impact of inversion by presenting three case studies: 2 children diagnosed with dysmorphic features and congenital anomalies and one couple with infertility. So, first case (5 days/F) has: facial dysmorphism, macrocephaly, cleft lip palate, low set ears, limb shortening, right pulmonary hypoplasie; second case (2 days/F) present: short stature, dysmorphic features, hypertelorism, low set ears, short neck, mild hypotonia; and the third case is a couple (F = 37 yrs / M = 39 yrs) with two pregnancies stopped (in the first trimester) and without a family history of reproductive disorders.

Materials and Methods: In this respect, we made karyotyping analysis using GTG-banding for each proband and also for their parents.

Results: Parental origin of inv(9)(p12q13) was detected in maternal (in the second case) in one children and in the other two cases was *de novo* origin (first case and the female).

Conclusion: Our investigation revealed that all three cases with inv(9)(p12q13) had various clinical features and we appreciate that inv(9) may have a role in the abnormal phenotype development. The parental chromosomal analysis is essential for appropriate genetic counseling.

P19.46

Nurses and midwives attitude toward pre-conception carrier screening (PCS) in Japan

A. Kondo¹, D. Nakaoku¹, M. Murakami¹, K. Mori¹, M. Morine¹, K. Hinokio¹, T. Iwai¹, K. Takahashi², S. Izumi², K. Maeda¹;

¹Shikoku Medical Center for Children and Adults, NHO, Zentsuji, Japan, ²Tokai University School of Medicine, Isehara, Japan.

Introduction: It is known that identifying carriers of recessive disorders before pregnancy has the potential to benefit couples. In Japan, PCS has not been introduced yet. However, a number of commercial companies are offering PCS directly-to-consumers, recently. In this study, we would like to find out the view of the health care providers on PCS in Japan

Materials and Methods: A total of 24 nurses under an adult female ward (AF) and 38 nurses/midwives under a prenatal maternity ward (PM) at a tertiary hospital responded to the questionnaire based on both the Likert scale method and free writing. Average age of nurses/midwives were 32.9(AF)/ 32.9(PM) year old respectively and all of them were female.

Results: 65% of the participants answered genetics is difficult and 16% answered genetics is scary. 68% of the participant had a wish to have PCS for themselves. There were no significant difference between the ward (AF/PM) and their specialty. However, unmarried group tended to wish having PCS for themselves and their partners compared to married group (p<0.005). As their free comment, they showed the manner to respect a person's willingness. Some people mentioned a concern about discriminations for the carrier.

Conclusion: Surprisingly, Japanese nurses and midwives are positive for PCS. It could be related to recent science reports and media regarding genetic therapy or possible preventions. Some participants pointed out concerns and issues around PCS in the future. It would be important to discuss on these issues before future introduction of PCS in Japan.

P19.47

Public involvement in policy making for newborn screening: goals, definitions, mechanisms, levels, and evaluation

M. E. Jansen^{1,2}, C. G. van EF, M. C. Cornef¹;

¹Institute for Public Health Genomics, School for Oncology and Developmental Biology (GROW), Faculty of Health, Medicine, and Life Sciences, Maastricht University, Maastricht, Netherlands, ²Department of Clinical Genetics, Section Community Genetics and EMGO Institute for Health and Care Research, VU University Medical Center, Amsterdam, Netherlands.

Technological developments have influenced newborn bloodspot screening (NBS) in the past and will probably influence the purpose of programs now and in the future. A shift in the purpose of NBS has implications for the public. However, the public is not structurally involved in NBS policy decisions. In light of current discussions about expanding NBS via Next Generation Sequencing (NGS), an approach to involve the public is needed for meaningful and successful public health policy development.

To summarize different key elements for public involvement in policy making for NBS, a rapid review of literature was performed. Search terms included: newborn, screening, public involvement, genetics, and decision making. Furthermore, a snowball method was applied where the references of resultant key articles were checked for additional relevant articles.

Five key topics were summarized from literature: the goals of public involvement, how to define 'public', which mechanisms exist for public involvement, on what levels it can prove to be valuable, and relevant indicators to evaluate the outcome. Most literature focused on public involvement in general, and the literature discussing NBS illustrated that the involvement is often through patient representatives, takes place *ad hoc*, and focuses on informing rather than deliberating.

Public involvement does not take place in a structured or transparent manner in current NBS policy making. It is relevant to shape such involvement and develop a model to include relevant views from the public, and also debate whether expanding NBS is the right mechanism to implement possibilities from NGS.

P19.48

Families in which the rare disease is not rare - 3 case reports

R. Gaillyová^{1,2}, I. Valášková^{1,2}, J. Němečková¹, R. Beharka¹, H. Bučková², A. Holčíková², J. Blatný³, L. Foretová⁴;

¹University Hospital, Dept. of Medical Genetics, Brno, Czech Republic, ²Faculty of Medicine, Masaryk University, Brno, Czech Republic, ³University Hospital, Pediatric Clinic, Brno, Czech Republic, ⁴University Hospital, Clinic of Pediatric Infectious Diseases, Brno, Czech Republic, ⁵University Hospital, Department of Children Hematology, Brno, Czech Republic, ⁶Masaryk Memorial Cancer Institute, Dept. of epidemiology and tumor genetics, Brno, Czech Republic.

The Department of medical Genetics of University Hospital in Brno (Czech Republic) is closely involved in the National Strategy for rare diseases in the country. We actively cooperate with the Coordinating center for rare diseases in the Czech Republic at the University Hospital Prague Motol and we are also members of teams of medical professionals for patients with Epidermolysis bullosa congenita (EB Centre) and for patients with Cystic fibrosis (CF Centre) at the University Hospital in Brno. We introduce three cases of families, where the patient combine several rare diseases. As a part of the CF center, we have a patient in our care, who is treated simultaneously for Cystic fibrosis and Hemophilia A. Together with the EB Center at the University Hospital Brno, we take care about the family with recurring Epidermolysis bullosa and Marfan syndrome. Our patient, who suffers from Huntington's Chorea is also a carrier of the BRCA gene mutations. She underwent cancer treatment and is also a carrier of Duchenne muscular dystrophy (DMD). Her two sons died prematurely as a result of DMD. Molecular genetic testing, genetic counseling and genetic prevention in these families are an important part of health care.

P19.49

A new model to represent medical laboratories in Orphanet adapted to genomic developments in a changing international context

M. Arles, V. Lanneau, B. Belloir, Q. Laurent, S. Gérard, M. Hanauer, A. Rath; Inserm, US14 - Orphanet, Paris, France.

For patients affected by a rare disease, obtaining a timely and accurate diagnosis is key to accessing the appropriate medical expertise. Orphanet, the reference database for rare diseases and orphan drugs, offers a range of freely accessible services, including a directory of medical laboratories and diagnostic tests. In order to respond to the evolution of genetic testing techniques and to provide useful information for the identification of laboratories across Europe in the framework of the European Cross-Border Healthcare Directive, Orphanet has further developed its medical laboratories and clinical tests database. New information has been associated with the tests, with each test assigned at least one purpose (e.g. prenatal, postnatal, preimplantation), one specialty (e.g. molecular genetics, cytogenetics), one objective (e.g. targeted mutation analysis, sequence analysis of the entire coding region, methylation analysis), and one technique (e.g. Sanger sequencing, NGS sequencing, MLPA based techniques). This new model allows for a more precise and user-friendly search for a test or laboratory via the Orphanet website. One significant improvement is that results can be filtered using this newly registered data, as well as by the country of the laboratory and/or data concerning the quality management (accreditation and participation to EQAs). This new model also allows panels of genes used in tests performed by NGS to be included. In Orphanet, these evolutions concern around 40,000 clinical tests, available for 3,500 rare diseases in 39 countries.

P19.50

Undiagnosed Diseases Network International (UDNI): an international initiative to foster the translation of research into medical practice

D. Taruscio¹, S. C. Groff², H. Cederroth³, B. Melegh⁴, P. Lasko⁵, K. Kosaki⁶, G. Baynam⁷, A. McCray⁸, G. Florida¹, M. Salvatore¹, W. A. Gahl⁹;

¹Centro Nazionale Malattie Rare, Istituto Superiore di Sanità, Roma, Italy, ²National Institutes of Health, United States, Bethesda, MD, United States, ³Wilhelm Foundation, Brotthj, Sweden, ⁴Department of Medical Genetics, University of Pecs, Pecs, Hungary, ⁵McGill University, Montreal, QC, Canada, ⁶Keio University School of Medicine, Tokyo, Japan, ⁷Princess Margaret and King Edward Memorial Hospitals, Perth, Australia, ⁸Harvard Medical School, Boston, MA, United States, ⁹National Institutes of Health, Bethesda, MD, United States.

Undiagnosed diseases are a global health issue, calling for an international scientific and healthcare effort. In 2008, the National Institutes of Health's (NIH) Undiagnosed Diseases Program (UDP) was initiated to provide diagnoses for individuals who had long sought one without success. Moreover, as a result of two international conferences (Rome 2014 and Budapest 2015), the Undiagnosed Diseases Network International (UDNI) was established, modeled in part after the NIH UDP and the recently formed US-wide Undiagnosed Diseases Network (UDN). The UDNI has published a consensus framework of principles, best practices and governance; the Board of Directors reflects its international character, as it includes experts from Australia, Canada, Hungary, Italy, Japan and the USA. The UDNI involves centers with internationally recognized expertise, and its scientific resources and know-how aim to fill the knowledge gaps that impede diagnosis. Consequently, the UDNI fosters the translation of research into medical practice. Active patient involvement is critical; the Patient Advisory Group is expected to play an increasing role in UDNI activities. After the UDNI launch (2015), several countries have activated national networks (e.g., Australia, Italy, Au-

stria, Japan) operating in the framework of UDNI and in collaboration with other UDNI members, who convened in Vienna in February of 2016 to plan for data sharing. All information for physicians and patients is available at the UDNI website(<http://www.udninternational.org>)

P19.51

Telephone Genetic Counselling: A service evaluation of patient and clinician experiences and impact on service delivery in cancer genetics

R. K. Jassi, C. Patch, A. Srinivas, A. Shaw, A. Kulkarni, D. Ruddy, L. Izatt, V. Tripathi; Guy's Hospital, London, United Kingdom.

Introduction: The Guy's cancer genetics service covers a population of 5 million. There has been a steady increase in referrals, clinical queries from secondary care and a demand to increase patient accessibility in our peripheral locations. This prompted us to revisit our current service delivery model. In order to service this need, a model of weekly telephone clinics was initiated as part of a pilot project at Guy's Hospital. Prior to this pilot, all cancer referrals were offered face-to-face clinic appointments. A total of 125 telephone clinic appointments were conducted with patients referred to our cancer service over a six month period.

Aims: The aims of the telephone clinics were:

- Manage service demand
- Increase capacity for appointments within same resources
- Increase patient accessibility in wide geographical areas
- Reassure families not at increased familial cancer risk
- Collect and clarify further information required to complete the cancer risk assessment
- Provide fast access to information and advice for those not requiring face to face appointments

Methods: Feedback questionnaires were sent to the Cancer Genetics clinicians and patients that participated in each telephone appointment. Reasons for offering or choosing a telephone appointment, ease of understanding and delivering information, and clinician and patient satisfaction were measured and correlated.

Results and Conclusion: The findings of this service evaluation as well as its impact on patient and clinician satisfaction will be presented. This evaluation will inform the appropriate use of telephone clinics as an integrated part of the Cancer Genetics Service.

P19.52

Why is the teratological counseling necessary?

M. Seven¹, S. Dasedmir¹, H. Ulucan¹, M. B. Duz¹, E. Kirat¹, U. Gumus¹, M. Demir²; ¹Istanbul University, Cerrahpasa Faculty of Medicine, Department of Medical Genetics, Istanbul, Turkey, ²Istanbul University, Cerrahpasa Faculty of Medicine, Department of Nuclear Medicine, Istanbul, Turkey.

Women exposed radiation without awareness during their pregnancies have often deep concern about possibility of having baby with the congenital anomalies. This situation leads families to make the decision for termination. In this study, the risk of the congenital anomalies due to radiation exposure was calculated and the importance of „teratological counseling“ was demonstrated to avoid unnecessary terminations. 252 pregnant women with the history of radiation exposure enrolled in the study (mean age \pm S.D.: 31.40 \pm 5.70 years, age range: 19-47), gestational ages at admission to the clinic were 4.7-25.2 weeks (10.0 \pm 3.96), radiation exposure weeks were 0.3-22.6 weeks (4.58 \pm 3.10) and fetal absorbed radiation dose ranged from 0.01 to 10.30 rad (0.72 \pm 1.45). 228 of 252 (% 90.47) pregnancies gave birth to healthy children. 3 were terminated for medical purposes while 8 were resulted as spontaneous abortion. We could not reach 6 women. 141 of 252 (% 55.95) pregnant women were suggested to terminate their pregnancy before teratological counseling. After teratological counseling, only 8 of those women preferred to terminate their pregnancy, whereas remaining 132 pregnancies decided to continue the pregnancy and delivered healthy children. Therefore, teratological counseling has provided % 94.3 success of pregnant women who had the decision termination thanks to change their mind to continue their pregnancy after teratological counseling. In conclusion, we suggest that teratological counseling is necessary to reduce the anxiety of families and it is the most effective method to prevent unnecessary pregnancy terminations.

P19.53

Training the next generation of clinical scientists

M. Cornell¹, J. Taylor², A. Davies¹, A. Brass¹; ¹University of Manchester, Manchester, United Kingdom, ²HMDS, Leeds Cancer Centre, Leeds, United Kingdom.

Next generation sequencing (NGS) techniques have the potential to revo-

lutionise diagnostic techniques across healthcare. Along with the development of new whole genome and whole exome analysis for germline variants, stratified treatments for cancers and new preimplantation screening strategies are becoming possible.

In order to translate these advances into real patient benefit, analysis of NGS data needs to be undertaken by highly trained clinical bioinformaticians, of which currently there are acute global shortages.

In the UK, the National Health Service launched Modernising Scientific Careers and has begun the Scientist Training Programme (STP), recruiting students into training programs with specialisms including Clinical Bioinformatics for Genomics, Health Informatics and Physical Sciences.

The University of Manchester has been involved in delivering bioinformatics training to clinical scientists. This has included the development of NGS analysis pipelines and tools for interpreting the effects of genetic variants as well as programming and database development. The course is in its third year and the first cohort of students are approaching graduation.

In this presentation we discuss the development and delivery of training materials, the response of students and mechanisms for delivering further training beyond the UK health service.

P20 Psychological/Ethical/legal issues

P20.01

Direct-to-consumer advertising of genetic tests: legitimate or not?

L. Kalokairinou¹, H. C. Howard², P. Borry¹; ¹KU Leuven, Leuven, Belgium, ²Uppsala University, Uppsala, Sweden.

During the past decade, the advertising of direct-to-consumer (DTC) genetic tests (GT) has provoked criticism over its potential adverse impact to public health. In October 2013, the European Parliament suggested in its proposal for Regulation of in vitro diagnostic medical devices that DTC advertising of GT with both direct and indirect medical purpose should be banned. While the proposed Regulation is currently under discussion among the European institutions, this work aims to evaluate the proportionality of forbidding DTC advertising for a broad range of GT. To this end, an overview is provided of the various ways genetic tests have been advertised over the past years and the different ethical issues that have arisen from advertisements. Subsequently, this work examines the laws currently regulating the advertising of GT both at the EU and at the Member States level. Finally, the proportionality of the ban is discussed, drawing a parallel with the discussion regarding the ban on DTC advertising of prescription drugs in Europe. As a conclusion, it is argued that it might be more proportionate to only implement a ban on DTC advertising of GT that may have a direct impact on consumers' health, and impose rigorous rules on DTC advertising for the rest of health-related genetic tests. Such regulation should ensure that promotional claims are substantiated and the benefits, risks and limitations, as well as the target audience of GT are clearly presented.

P20.02

Obstetricians' views on ethics of amniocentesis and its implications on NIPT: discourse analysis from 1969 to 1978 in Japan

M. Sato, K. Muto; the University of Tokyo, Tokyo, Japan.

[Background] Abortion is prohibited by Japanese criminal law but is legally justifiable when maternal health is threatened. In the 1970s, amniocentesis was introduced across Japan, but was harshly criticized owing to its eugenic and paternalistic implications. The medical society is believed to have changed its outlook towards amniocentesis since that time, placing greater importance on „parental autonomy.“ However, this view has not been verified from a bioethical perspective. We aimed to determine the origin of Japanese „autonomy“ with respect to amniocentesis by analyzing obstetricians' discourses.

[Methods] The authors surveyed three representative journals of obstetrics and selected articles that mention ethical issues pertaining to amniocentesis. Thirty-two articles were selected and categorized based on their ethical references. Next, we discussed the implications of the noninvasive prenatal testing (NIPT) guidelines drawn by the Japan Society of Obstetrics and Gynecology (JSOG).

[Results] Since 1975, reports criticizing selective abortions owing to amniocentesis increased, corresponding with the social attack on the implementation of the prenatal test. Simultaneously, instances emphasizing parental autonomy have increased as well. However, amniocentesis was generally viewed as an inadequate screening test.

[Discussion] Our work suggests that Japanese „autonomy“ with respect to amniocentesis was first discussed by professionals defending amniocentesis against social criticism, which considered it paternalistic. Since its introduction, doctors have observed that amniocentesis should not be applied to all pregnant women. The JSOG guidelines on NIPT succeeded to this approach and additionally guarantee genetic counseling. Therefore, the criticisms regarding the link between amniocentesis and disability discrimination remain to be appropriately answered.

P20.04

Living at-Risk for Hereditary Breast and Ovarian Cancer: A Qualitative Study of Concerns and Fears of Genetic Discrimination in Flanders

A. Wauters, I. Van Hoyweghen;
KU Leuven, Leuven, Belgium.

The idea of differential treatment based on personal genetic information has caused a great deal of concern in society and the threat of 'genetic discrimination' has led to the development of regulations to protect against this in many countries. However, despite these regulatory efforts, people still seem to hold concerns about becoming victims of genetic discrimination. This study aimed to explore whether concerns relating to genetic discrimination are present in Flanders, the origins of these fears, and which coping strategies people employ.

Semi-structured interviews were conducted with 30 carriers of a BRCA1 or BRCA2 mutation, recruited through a Flemish BRCA self-help group.

Many participants did not express concerns about genetic discrimination, believing that being at risk for breast- and ovarian cancer would not be considered as a valid basis for discrimination. These participants had never experienced it personally, nor seen it happening to others. However, other participants did hold concerns about either direct or indirect genetic discrimination. They mentioned a range of different contexts in which they felt discrimination could occur, such as insurance and employment, where their concerns originated from seeing others experience discrimination, although genetic information was not the basis for this. They also discussed discrimination in relationships, holding concerns that new partners would not cope with a future overshadowed by the risk of having cancer.

These findings show that despite Belgium's legislative effort to prohibit the use of genetic information, some BRCA mutation carriers are still concerned to become the victim of discrimination.

P20.05

Physicians' messages to unaffected women with BRCA1 and BRCA2 mutations about risk management behaviour. A Swiss qualitative study of patients' experiences

M. Caiata-Zufferey¹, V. Cina², O. Pagani³, V. Membrez⁴, M. Taborelli⁵, S. Unger², A. Murphy⁶, C. Monnerat⁶, P. Chappuis⁷;

¹University of applied sciences of Southern Switzerland, Lugano-Manno, Switzerland,

²Service of Medical Genetics, Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland,

³Oncogenetics and Breast Unit, Institute of Oncology of Southern Switzerland, Lugano-Viganello, Switzerland,

⁴Division of Medical Genetics, Institut Central, Hôpital du Valais, Sion, Switzerland,

⁵Oncogenetics and Cancer Prevention Unit, Division of Oncology, University Hospitals of Geneva, Genève, Switzerland,

⁶Service of Oncology, Hôpital du Jura, Delémont, Switzerland,

⁷Division of Genetic Medicine, University Hospitals of Geneva, Genève, Switzerland.

Introduction: Women with BRCA1 and BRCA2 mutations are at increased risk of breast and ovarian cancer. Managing this risk requires a multidisciplinary approach. However, the literature suggests that healthcare professionals do not always have similar views of genetic risk and its management. This paper explores the messages that physicians convey, consciously or unconsciously, to unaffected genetically at-risk women and the consequences of these messages, based on the experience of the women themselves.

Material and methods: Using a grounded theory design, retrospective biographical interviews were conducted with 32 unaffected women with BRCA1 and BRCA2 mutations, who had presymptomatic testing at least three years previously. Data were analyzed with the constant comparative method using ATLAS.ti software.

Results: Physicians convey three different messages during the consultation: a normative message (at-risk women are required to take responsibility for their health and to adopt risk-management behaviour); a self-confronting message (at-risk women are invited to question what is essential to them and to act accordingly); a minimizing message (at-risk women are considered as "second-class patients" compared to patients who have presented cancer). Being simultaneously exposed to these conflicting messages, genetically at-risk women experience a strong sense of disorientation and find it difficult to know how to act regarding their risk.

Conclusions: There is an urgent need to make physicians aware of the messages they convey to unaffected genetically at-risk women and to promote a shared representation of this condition among healthcare professionals. Study supported by the Swiss National Science Foundation (grant number PZ00P1_132633 / 1)

P20.06

The role and functioning of data access committees: Opinions and experiences of data access committee members and experts

M. Shabani, P. Borry;
KU Leuven, Leuven, Belgium.

Purpose: Genomic researchers benefit from broad access to large and information-rich datasets. Data Access Committees (DACs) are established as a governance mechanism to assess data access requests for the purpose of approval or disapproval. This paper explores the perspectives of DAC members and experts on components of access review and functionality of DACs in handling data access requests in accord with the genomic data sharing goals.

Methods: Semi-structured interviews were conducted with 16 DAC members and 4 experts in the field, from a diverse international and professional background. Data was analyzed using content analysis methodologies.

Results: The interviewees indicated the access review mainly comprises of assessing the ethical footings and the scientific merits of the proposed uses. However, they were ambivalent about the scope and rigor of such review by DACs and the adequacy of available tools and mechanisms to achieve the goals of review. In addition, qualification of the users was subject to scrutiny of DACs. Given the fragmented or poorly delineated qualification criteria at times, the interviewees underscored the significance of adopting standard ways in order to streamline the procedure.

Discussion and Conclusion: DACs would benefit from international and institutional policies and guidelines delineating various aspects of access review, including the user's qualification criteria and the sanctions against the violations of policies. Furthermore, the current components of access review should be revisited to reassure the complexity of the access review corresponds to the concerns associated with data sharing and facilitates responsible data use.

P20.07

Ethical considerations in sharing genomic data of patients' relatives in cancer research

K. Takashima¹, S. Mori², H. Mano¹, T. Noda², K. Muto¹;

¹The University of Tokyo, Tokyo, Japan, ²The Cancer Institute of the Japanese Foundation of Cancer Research, Tokyo, Japan.

Background: Sharing study data with other researchers in repositories or databases will promote scientific progress. In cancer genomic research, not only family history information, but also germline sequence data, including genomic data from patients' relatives, is essential. Sharing these relatives' data requires careful ethical consideration, because future studies may reveal that they present with known or unknown pathogenic variants. Moreover, when the total number of families is small in a given study, the risk of re-identifying family members increases. However, to date, there is no regulation especially for sharing relatives' data.

Methods: We investigated the editorial and publishing policies of major scientific journals and the International Committee of Medical Journal Editors on availability of data and protection of research participants. After reviewing all policies, we developed a proactive policy for protection of participants on what researchers should do when they publicly deposit and share relatives' data in their study.

Results: Policies on data availability are classified in two categories; submission to a community-endorsed public repository is mandatory and the accession numbers must be provided in the paper, or deposition of sequence data in a repository is encouraged but not required. While most policies have provisions for patient/participant consent and privacy protection, there is no specific rule for relatives' data.

Conclusions: We propose recommendations for researchers on how to share genomic data of patients' relatives.

Grants: This study was supported by Japan Agency for Medical Research and Development's Project for Development of Innovative Research on Cancer Therapeutics (P-DIRECT).

P20.08

Secondary findings on diagnostic exome sequencing: Patient preferences and detection rates based on 1500 DES samples tested at a single clinical laboratory in the United States

C. M. Osborne, L. Shahmirzadi, Z. Powis, C. L. Alamillo, K. F. Hagman, S. Tang; Ambry Genetics, Aliso Viejo, CA, United States.

Introduction: Diagnostic exome sequencing (DES) involves the simultaneous analysis of virtually all exonic and flanking intronic sequences. Consequently, DES may result in the identification of secondary findings (SF), which are incidental deleterious variants unrelated to the testing indication. In 2013, the American College of Medical Genetics and Genomics (ACMG) issued recommendations pertaining to the reporting of disease-causing mutations within 56 genes identified incidentally during exome or genome analysis.

Methods: We examined the evolution of SF test offerings within a single clinical laboratory in the United States from 2011 to 2015. We also performed a retrospective analysis of the patient preferences and positive rates of SF from the ACMG recommended 56 and/or expanded gene lists among the first 1500 patients who underwent DES through our clinical laboratory.

Results: Of 1500 DES cases, 437 (29.1%) were ordered before ACMG published recommendations, and 1063 (70.9%) were issued after. Overall, 1361 of 1500 (90.7%) patients requested at least some SF results, and 451 (30.1%) of these cases requested results from more than the ACMG recommended gene list. The majority of cases (1214/1361; 89.2%) had no reported SF, and 47 (3.45%) of patients had at least one reported SF from among the ACMG recommended list of 56 genes.

Conclusions: Based on our experience, most patients proceeding with DES elected to receive at least some SF results. Almost 90% of these cases were negative. A continued evolution in the reporting of SF is anticipated as DES becomes increasingly utilized, and as disease-gene relationships are better elucidated.

P20.09

Current state and ELSI of DTC genetic testing in minors or fetuses in Japan

N. Ohashi;

Osaka University, Suita, Japan.

Introduction: In addition to uses of genetic testing in clinical and research settings in Japan, direct-to-consumer (DTC) genetic testing services are becoming more common due to the spread on the internet. However, genetic information has Ethical, Legal and Social Issues (ELSI) because of its particularity. Some of those issues occur or become more complicated when the subjects are minors or fetuses who have no or insufficient competency for giving consent. In this presentation I would like to discuss the current state of these ELSI in Japan and consider some solutions.

Methods: Investigation and analysis of various research papers, guidelines, and legal regulations at home and abroad

Results: While ethical guidelines formulated by related academic societies have no legally enforceable powers, these guidelines have a certain degree of binding effect on their members in the research and clinical fields. However, the industry sector of DTC genetic testing services relies on self-regulation, which is largely ineffective. As a result, there is a great deal of variation in the quality of companies' tests, as well as the ethical standards under which these companies operate.

Conclusions: In cases where minors or fetuses are subjects, especially in DNA paternity tests without consent from minors or their mothers and prenatal DNA paternity tests, these tests can seriously harm minors and fetuses—sometimes even causing abortion in the case of fetuses. Regulations—including legal ones—should be made in accordance with the type of genetic testing being conducted.

This work was supported by JSPS KAKENHI Grant Number 15K08550.

P20.10

Medical staff approach towards undergoing deep genome sequencing as part of their medical training

A. Harari-shaham¹, H. Doron², G. Larom-Khan¹, A. Peleg¹;

¹Carmel medical center, Haifa, Israel, ²Tel hai College, Upper Galilee, Israel.

Introduction: Clinical use of new genetic technologies such as Exome/genome sequencing technologies (E/GST) introduces the medical staff to dilemmas regarding professional, ethical and emotional issues. E/GST might provide information regarding cureless diseases, late onset diseases, risk factors for various medical conditions and variants of unknown significance. Furthermore, such information may affect not only the patient, but also his immediate and extended family. As the use of these technologies expands,

clinicians should be familiar with these professional and psychological issues. A questionnaire survey was conducted among medical staff, examining their approaches and attitudes towards undergoing self-wide genome sequencing as part of routine medical training.

Materials and methods: Socioeconomic, cognitive dimension (positions and perceptions), and personality traits questionnaire. Population study: Medical Doctors, nurses, genetic counsellors and medical students. Statistical analysis: T-test, Pearson and regression analysis with SPSS software.

Results: Medical Doctors and genetic counsellors significantly preferred to receive only information regarding preventable or curable medical conditions.

Medical doctors and genetic counsellors' approaches were that self E/GST does not improve their clinical skills. The Genetic counsellors' approach differs from the other groups. In their opinion, self E/GST will not provide a better understanding of the ramifications on the patients' emotions.

Conclusions: The results of this study provide a more thorough understanding of the approaches of medical staff from different fields towards the use of self E/GST. A better understanding could provide practical implications, for developing professional training programs in regards to the rapidly expanding clinical use of these technologies.

P20.11

Guidance to families of children with disabilities as a result of birth defects: contribution of Family Quality of Life Model in Colombia (South America)

D. M. Ortiz¹, Y. J. Ariza-Araujo¹, A. F. Ramírez-Botero¹, H. Pachajoa^{1,2};

¹Universidad Icesi, Cali, Colombia, ²Fundación Clínica Valle del Lili, Cali, Colombia.

Introduction: This study sought to determine the status of family quality of life in children and youth with disability associated to birth defects, who attended the clinical genetics outpatient consultation at a reference center in southwestern Colombia.

Materials and Methods: The Family Quality of Life models proposed by the University of Kansas, and The Family Quality of Life Scale (FQOL) adapted for Colombia, were used to evaluate indicators and scale factors. Each factor was rated in terms of importance and satisfaction according to the caretaker. The Map Family Quality of Life (MFQOL) was configured and shows two areas (critical and strong). The information was saved and processed with the Excel software.

Results: The MFQOL showed that most of the indicators were located the strong area of the map, with the exception of some related with family resources and support of persons with disabilities (PWD), which were located in the critical area. Through design strategies it was generated a graphic form to summarize the results and present them clearly to families.

Conclusions: information about the needs that families PWD regarding the environment in which they operate, is a first step in developing action plans to define a better care and contribute to the social inclusion of people with disabilities.

P20.12

Genetic information disclosure to kin: patients' organizations points of view and roles consequences of a new legal framework in France

D. d'Audiffret¹, S. de Montgolfier^{2,3};

¹Lipha Université Paris-Est Marne-la-Vallée, Marne la Vallée, France, ²IRIS (Ehess/ Inserm), Paris cedex 13, France, ³UPEC, Creteil, France.

In case of serious genetic anomaly, the disclosure of this information, when prevention measures or treatments exist, can be relevant for other family members. In an interdisciplinary research project exploring the consequences of the evolution of the legal framework in France: we assess the impact on the healthcare professionals' practices, patients' reactions and related ethical issues. At the ESHG 2015, we presented the results from an online quantitative research survey dedicated to healthcare professionals. Our aim, now is to get a clearer picture of the challenges arising from this issue regarding patients' associations and to ask them: What is the relevance of transmitting this information to families? What are their needs and expectations? What impact on patients' associations roles?

To explore these questions in a context of numerous genetic diseases, we have organised semi-structured interviews (11/2 hour) with ten patients' organization representatives of different genetic diseases. Thus, we have studied if the patients' perception regarding the genetic information disclosure to family members is impacted by the level of expressivity, age of onset, impacts on the quality of life, access to treatment, or access to genetic counselling. We discussed the online survey completed by healthcare professionals with them in order to identify their point of views.

This study allows us to elaborate recommendations to accompany each sta-

keholder in his role to improve care of patients and families.
 Research project financed by INCa and Canceropole Ile-de- France: "Family disclosure in human genetics" (subvention 2013-130).

P20.13

Return of research results in a large-scale birth cohort study involving children in Japan

I. Ri, K. Muto;
 University of Tokyo, Tokyo, Japan.

Background: The Ministry of the Environment in Japan funded the "Japan Environmental Children's Study" (JECS) in 2011 to follow up on about 100,000 sets of parents, and children from the fetal stage to 13 years of age. As JECS has not determined a detailed plan for genome sequencing, it remains an issue as to how to obtain consent from parent participants and assent from child participants. Moreover, return of the individual results of biomonitoring and environmental exposures has been recommended for the community's benefit [Brody et al. 2014]. However, recommendations about the individual results of genome sequencing in pediatric research require a careful consultation process to ensure the best interests of the children are preserved [Sénécal et al. 2015]. The purpose of our research is to consider the conflicts in both perspectives and to clarify future agendas that will be faced by birth cohort studies.

Methods: We carried out a literature review, that included consent forms and relevant documents published by JECS and ethical guidelines.

Results: The points of controversy were classified mainly into six categories. Some of the recommendations should be assessed at both the individual and community levels: (1) the balance of risk/burdens and benefits, (2) confidentiality and autonomy, (3) risk communications concerning the pertinent results and incidental/secondary findings, (4) informed assent/dissent and consent, (5) uncertainty, and (6) actionability (not only concerning clinical implications but also life more generally).

Discussions: It is necessary to investigate participant and community attitudes toward genome sequencing, and how results are communicated.

P20.14

Professionals' reactions on indirect disclosure of genetic information to kin: first lessons of the French experience

B. Derbez¹, S. de Montgolfier^{1,2};
¹IRIS (Ehess/Inserm), Paris cedex 13, France, ²Université Paris Est Créteil, Creteil, France.

French bioethics law of 2011 has had the opportunity to create an original device to face issues of genetic information to kin. According to the law, people who undergo a genetic test have the legal duty to inform their family members in case of serious illness for which measures of care, prevention or genetic counselling are available. In case of difficulty, professionals can directly contact the patient's relatives to inform them about a potential genetic risk. To do it, the professionals need to acquire the consent of the index case and to preserve his/her anonymity. However, how have they grasped this new device? How is the "indirect way" practiced in the daily activity of genetic services?

To answer these questions, we propose to explore data of a one-year qualitative fieldwork (observations and interviews) in genetic wards of two hospitals in France. The first was specialized in genetic predispositions to cancers (breast and ovarian mainly) and the second in genetic diseases of red blood cells (sickle cell disease and hemochromatosis in particular).

Firstly, in this presentation, we propose to analyse few cases where "indirect way" has been set up at the request of patients by asking each other how the procedure was negotiated between the social actors. Secondly, this will lead us to question the relationship of professionals with a device that seems to be at odds with some medical action standards.

Research project financed by INCa and the Canceropole Ile-de- France. "Family disclosure in human genetics" (subvention 2013-130)

P20.15

Quality of life in adults with Neurofibromatosis 1 in Brazil

D. G. Melo, N. P. Bicudo, B. F. Menezes Neto, L. R. S. de Avó, C. M. R. Germano;
 Department of Medicine, Federal University of São Carlos, São Carlos, São Paulo, Brazil.

Introduction: Neurofibromatosis type 1 (NF1) is a neurocutaneous genetic disorder that can be associated with severe complications, and it may shorten patients' lifespan and affect their quality of life negatively. This study aimed to examine quality of life constructs among adults with NF1 in Brazil. Methods: It is an exploratory, descriptive and cross-sectional study consisting of two stages, involving thirteen adult patients with NF1, who have a

wide range of severity and visibility of the disease. The first stage was developed using a quantitative methodology, namely the WHO Quality of Life-100 questionnaire; responses for the patients were compared to a matched control group. The second stage comprised clinical-qualitative research whereby patients took part in a semi-structured interview; these data were analyzed using the categorical thematic analysis technique.

Results: There were no statistically significant differences in the questionnaire domains between the NF1 patients and the control subjects. Eighteen main themes were extracted from the interviews, showing interference of the NF1 visibility principally in psychological aspects and social relationships. Patients mentioned curiosity about NF1 and confusion about the distinctions between NF1 and contagious diseases, which lead to prejudice. They were concerned about the future and how the disease would develop in themselves and their offspring, and emphasized difficulties acquiring proper healthcare.

Conclusions: These findings may help in planning healthcare for Brazilian NF1 patients and improving their quality of life.

This survey was supported by the São Paulo Research Foundation (FAPESP, grant 13/25330-3).

P20.16

Boosting medical research innovations at European level thanks to a wider dissemination of patents

F. Le Corre¹, G. Chassang², M. Roques¹, E. Rial-Sebbag³;
¹Inserm, Toulouse, France, ²JuristeConsult, Toulouse, France, ³Inserm, University Toulouse III Paul Sabatier, Toulouse, France.

Patents confer the right to exclude others from making, using, or selling a claimed invention, for a period of 20 years from its filing date. The paradox raised by patents is that they ensure a monopoly to the patent holder on his invention while it might be considered as a brake on innovation because when a patent owner exploits his patent, no-one else can use the technology without asking for a license. Then, if a researcher wants to use several patented technologies for his own project, he will need to negotiate with all patent holders which is considered as time consuming and expensive. A wider dissemination of inventions can be offered while preserving the patent-owners' rights, through a collaborative process known as "patent pool" or "clearing houses" mechanisms.

In this system, a specific scientific domain can be targeted by stakeholders who can decide to propose global governance for the intellectual property rights and for the access to their patents. This collaborative licensing model already exist (e.g. for AIDS), it makes patented technology landscape more transparent and it leads to an easier access to patents and to a significant reduction of transactions costs.

A collaborative model at a European infrastructure level (BBMRI-LPC) could be proposed to favor the transfer of technology for medical research at large. It might be considered as a solution to the roadblocks in accessing to essential technologies by researchers who want to use inventions within their specific area of expertise.

BBMRI-LPC : FP7 Grant Agreement N°313010

P20.17

The offer of expanded preconception carrier screening to couples: are there differences in views within couples and do views change after discussion?

M. Plantinga¹, J. Voorwinden², J. Schuurmans¹, A. Lucassen³, A. Buitenhuis¹, E. Boersma¹, E. Birnie¹, M. Verkerk⁴, I. van Langen¹, A. Ranchor²;
¹UMCG, Department of Genetics, Groningen, Netherlands, ²UMCG, Health Psychology, Groningen, Netherlands, ³Faculty of Medicine, Clinical Ethics and Law (CELS), Southampton, United Kingdom, ⁴UMCG, Department of Internal Medicine, Groningen, Netherlands.

Introduction: Technological developments in genome sequencing allow for rapid and cheap testing of many autosomal recessive diseases concurrently. The University Medical Center Groningen (UMCG) developed a preconception screening (PCS) test which covers 50 serious, early onset, untreatable autosomal recessive diseases. The test is offered and analysed per couple. Results are communicated as 'couple has increased (1:4) risk of having a child with disease X' or 'no increased risk detected for this couple'. We think this is ethically, technically and economically justifiable. However, views of eligible couples, and specifically the extent to which they agree with each other, are not known yet.

Materials and Methods: By means of an online survey we explored how couples view the offer of a couple-based PCS test. We examined discrepancies within and between couples (n=117) and before and after (n=84) discussion of test-information.

Results: Views differ between couples: 45% of the couples are positive about PCS testing, 10% are negative and 45% are neutral. Of all couples, 30% intend to test, 20% do not and 50% are neutral. Within couples there is large agreement: in 70% of the couples both partners display the same level of attitude and intention. Views change after discussion of test-information. After discussion, respondents displayed a significantly more positive attitude towards PCS testing. Intention also increased, but only in couples with low relation satisfaction.

Conclusions: Eligible couples are positive about the offer of a couple-based PCS-test. Views differ between but not within couples and become more positive after discussion of test-information.

P20.19

Analysis of a new national initiative for the implementation of genome medicine in Japan

J. Minari¹, K. Kato^{1,2};

¹Department of Biomedical Ethics and Public Policy, Graduate School of Medicine, Osaka University, Osaka, Japan, ²Institute for Integrated Cell-Material Sciences, Kyoto University, Kyoto, Japan.

Recently, leading programs such as the Precision Medicine Initiative in the US and Genomics England in the UK have promoted the implementation of genome medicine. These national-level initiatives aim to demonstrate the complex relationship between genetic, lifestyle and environmental factors regarding the development of disease, foreseeing individualized diagnosis, prevention or treatment of disease.

In Japan, a new policy movement to implement genome medicine has recently started. In 2012, Japan established the Headquarters of Healthcare Policy (HHP) to promote healthcare innovation. The committee charge of 'genome medicine', positioned under the HHP, has released a new policy for the achievement of genome medicine, and showed the approach of research development as well as of improving the environment for genome medicine. In addition to these movements, the Act on the Protection of Personal Information was revised in 2015, so that the ethical and legal regulation regarding genome information are currently being reviewed.

In this study, we have examined the current policy movements, including ethical considerations, related to genome medicine in Japan. We have clarified the drafting process and major points of the new policy, and suggested some of the main challenges and opportunities in its implementation. One of the main findings is that the latest policy has significantly emphasized role-sharing arrangements and organic co-operation primarily between cabinet secretariat, ministries and funding agencies. This study represents a valuable opportunity to share an experience regarding policy developments in Japan with other countries and to explore and develop new methods of policy making.

P20.21

Rights and responsibility in genomic decision-making: a systematic review of qualitative and quantitative studies exploring stakeholder views on secondary findings in genomic sequencing

M. P. Mackley, B. Fletcher, M. Parker, H. Watkins, E. Ormondroyd; University of Oxford, Oxford, United Kingdom.

Purpose: The return of secondary findings (SF) in whole-genome and -exome sequencing (WGS/WES) is a subject of much debate. As WGS/WES moves into routine clinical practice, it is timely to review data that might inform this debate in the development of policies that maximize benefit for participants.

Methods: We systematically searched 6 electronic databases for qualitative and quantitative studies that explored stakeholder views on SF in WGS/WES, in clinical and research settings. Framework analysis was undertaken to identify major themes, and assess the extent to which there was sufficient evidence base for informing policy on SF in WGS/WES.

Results: Thirty-two articles reporting views of over 11,000 stakeholders were found to meet inclusion/exclusion criteria. Stakeholders were broadly supportive of returning life-threatening and treatable SF, but varied in views on other types of SF. Largely, views of sequencing providers focused on the idea of 'responsibility' and non-providers focused on 'rights.'

Conclusions: Stakeholders agreed on importance of patient autonomy and generally supported a model of shared responsibility in SF management. Professionals, therefore, need to balance their responsibility to care for participants with sharing decision-making. To do so, professionals need to help participants exercise their rights in an informed manner. This has implications for pre-test discussions and informed consent, as technical knowledge was not found to lead to more informed decision-making. Further research into what best informs decisions around SF is, therefore, essential. As 70% of the included studies were American, it is crucial that research gathering European and other international perspectives be conducted.

P20.22

Disclosing genetic information to family members: a comparative-law study of the legal regimes applicable to patients' and health professionals' liability

C. Farnos¹, L. Battistuzzi², Á. Mendes^{3,4}, P. Borry⁵, H. Nys⁶, M. Rothstein⁶, C. Mitchell⁷, P. Nicolas⁸, D. Sprumont⁹, E. Rial-Sebbag¹;

¹Inserm UMR 1027, University of Toulouse III – Paul Sabatier, Faculty of medicine, Toulouse, France, ²Dept. of Internal Medicine and Medical Specialties, University of Genoa, Genoa, Italy, ³IS – Instituto de Investigação e Inovação em Saúde, Univ. Porto, Porto, Portugal, ⁴UnIGENE and Centre for Predictive and Preventive Genetics (CGPP), IBMC – Institute for Molecular and Cell Biology, Univ. Porto, Porto, Portugal, ⁵Centre for Biomedical Ethics and Law, University of Leuven, Leuven, Belgium, ⁶Institute for Bioethics, Health Policy and Law, University of Louisville School of Medicine, Louisville, KY, United States, ⁷HeLEX - Centre for Health, Law and Emerging Technologies, University of Oxford, Oxford, United Kingdom, ⁸Interuniversity Chair in Law and The Human Genome, University of the Basque Country, Bilbao, Spain, ⁹Institut de droit de la santé, Université de Neuchâtel, Neuchâtel, Switzerland.

Genetic information is often considered as 'exceptional' health information because of its personal, predictive and familial dimension. Indeed, the diagnosis of a serious genetic anomaly in a patient can be clinically relevant for other family members when preventive measures or treatment exists. However, the transmission of such confidential medical information to at-risk relatives questions some fundamental principles of health law, such as medical secrecy, the right to privacy, the right to health information, or the right not to know.

In France, the legislator introduced a specific system for disclosing genetic information to family members in 2004, revised in 2011 by the last Bioethics law. The patient has now a legal duty to inform his relatives about genetic risks when it is relevant for their health. This information can be delivered directly by the patient, or indirectly through a specific procedure involving the prescribing medical doctor. Although the French legislator tried to conciliate the various rights raised, the patient and the prescribing doctor are in charge of many procedural obligations, which have significant implications in terms of liability. Indeed, if the patient does not inform his relatives, he could be held liable under civil law.

A comparative study of eight countries (Italy, Portugal, Belgium, USA, UK, Spain, Switzerland and France) on the disclosure of genetic information to family members will be carried out, with a focus on the liability regimes applicable to patients and health professionals, and on their judicial consequences.

P20.23

Citizen's Health through public-private Initiatives: Public health, Market and Ethical perspectives

P. Borry¹, I. Budin Ljøsne², H. Beate Bentzen³, O. Feeney⁴, H. Howard⁴, M. Loi⁵, D.

Mascalzoni⁶, S. Nordal⁶, H. Skirton⁷, S. Sterckx⁸, E. Stupka⁹, H. Felzmann¹⁰;

¹University of Leuven, Leuven, Belgium, ²University of Oslo, Oslo, Norway, ³National University of Ireland, Galway, Ireland, ⁴University of Uppsala, Uppsala, Sweden, ⁵ETH Zurich, Zurich, Switzerland, ⁶University of Iceland, Reykjavik, Iceland, ⁷University of Plymouth, Plymouth, United Kingdom, ⁸Ghent University, Ghent, Belgium, ⁹Boehringer Ingelheim, Neu-Ulm, Germany.

Rapid advances in sequencing technologies are accelerating the integration and use of genomic information in research setting and clinical practice. Moreover, citizens are being confronted with an expansion of genetic testing services available through the internet. Engaging with the generation and interpretation of genetic data represents a tremendous opportunity but also poses new challenges for researchers, healthcare providers, policy makers and society. Existing ethical and regulatory frameworks may not be suitable in dealing with this increasing availability of genomic information. In 2014, the COST Action CHIPME, comprised of members from 27 European countries, began its work to address the need of interdisciplinary reflection on these developments in the European context. CHIPME focuses on the following objectives: (1) Advancing the study of the ethical, legal and social implications of new developments in genetics by building a strong network of early stage and experienced researchers from a wide range of disciplinary backgrounds. (2) Achieving communication between a diverse group of European stakeholders in the field of human genetics, including social science and bioethics experts, genetic researchers, public institutions and companies. (3) Building capacity by facilitating new connections between stakeholders and connecting established scholars with early stage researchers. The Action addresses ethical and regulatory issues with regard to innovations in biobanking, DTC genetic testing, large scale sequencing projects, personalized medicine and participant-led initiatives, and is developing a White Paper addressed to policy makers.

P20.24

Transparency and clinical trials in Europe: case study on the incidents in France

G. Chassang¹, F. Taboulet^{2,3};

¹Juriste Consult Ethique et Santé, Toulouse, France, ²INSERM UMR 1027, Toulouse, France, ³Université Paul Sabatier Toulouse III, Toulouse, France.

Background: Clinical trials are essential activities for scientific and medical progress that involve interventions on human beings which voluntarily participate to biomedical research projects for testing new drugs, medical devices or methods. Biomedical research protocols intrinsically involve some risks for the participants which have to be outweighed by the health/scientific benefits and controlled by researchers and public authorities. Participants are entitled to know about these risks before consenting to the trial and their interests should always prevail on scientific interest.

EU law and bioethical guidelines promote transparency and data sharing principles as obligations for research sponsor/promoters and investigators. Allowing independent assessment and public oversight of the activities, transparency mechanisms are supporting fairness, safety, precaution, social responsibility and research integrity in innovation. Transparency should find concrete applications through projects' designs and be particularly respected where security problems arise and engage the health of the participants. This poster summarises the key points of transparency implementation, as required by law and good clinical practices and illustrate the needs for transparency in the rare context of risk realization.

Discussion: In the light of the inquiry on the drama that occurred in January 2016 with the phase 1 BIOTRIAL clinical trial (EudraCT n° 2015-001799-24) conducted in France that caused the death of a healthy participant and emergency hospitalization of 5 other volunteers, this poster tends to inform and question crisis management from an ethical point of view while the EU Clinical Trial Regulation of 2014 is going to be enforced in the coming years.

P20.25

Parent Perspectives on Whole Genome Sequencing for Autism Spectrum Disorder

M. J. Szego^{1,2}, J. A. Anderson¹, N. Hoang², P. Szatmari^{1,2}, S. W. Scherer^{1,2};

¹University of Toronto, Toronto, ON, Canada, ²The Hospital for Sick Children, Toronto, ON, Canada.

Autism spectrum disorder (ASD) is a group of neurodevelopmental conditions that have a complex genetic etiology. Whole genome sequencing (WGS) is a powerful ASD research tool since it can assay many types of genetic variation in a single test. In recent years, there has been a lot of debate around return of results following genetic testing; however, there is a paucity of empirical data on research subject's experience with WGS, in particular. To elicit and analyze participants' experiences with WGS, we invited parents (and capable children) who were enrolled in an ASD genomic study to participate in semi-structured interviews at two times during the WGS testing cycle: 1) following informed consent, and 2) following return of results. To date, we have interviewed 19 parents at time 1 and 8 parents at time 2. Emerging themes from time 1 interviews include, hope for a genetic diagnosis, hope for treatment, and altruism. Parents also hoped for findings that they could use for planning and prevention purposes, although they expressed concerns over inflicted insight and insurance discrimination. Following return of results at time 2, emerging themes include, the value of learning genetic information, the resolution of blame between biological parents, and disappointment at not receiving treatment-guiding information. Our findings suggest that participants may have different motivations/concerns before and after testing; whereas many begin with altruistic motivations, their desire for actionable results weighs heavily post testing. Though our analysis is provisional, these results suggest that novel strategies for education and informed consent are necessary.

Outcome of aneuploidy screen positive test based on amniocentesis results in 100 Iranian pregnant women

S. Mesghali, M. Fatahi, F. Harrazizadeh-e-yazdi;
Yazd Genetic, Yazd, Iran, Islamic Republic of.

Background: About half of spontaneous abortions are caused by chromo-

somal abnormalities. Furthermore, diagnosis of chromosomal abnormalities during first and second trimesters of pregnancy can lead to detection of many infirmities and treated abortion.

Method: We analyzed 100 pregnant women with evidence of chromosomal aberrations. Among them 83% had positive in screening serum test, 3% with abnormal sonographical soft markers, and 6% with both of serum screening and sonographical soft marker, 7% with past history of chromosomal abnormal child, 1% with maternal chromosomal abnormality. Amniocytes were cultured and then the fetus karyotypes were cytogenetically analyzed.

Results: Normal karyotyping was in 80% of fetuses (39% male and 41% female). Minimal change and major chromosomal aberrations were seen in 20% of fetuses, consisting of: 9qh+ (6), 22ps+(1), 21ps+ (1), translocation(5,9)(1 case), inversion 9 (2), Down syndrome (47,XX+21)(1 case), Down syndrome with Robertsonian translocation (1), mosaic Turner syndrome(1).

Conclusion: Due to diagnosis of many chromosomal abnormalities by non-invasive screening test we can confirm that these screening methods are really useful and highly recommended in prenatal diagnosis.

E-P01.04

Evaluation of amniocentesis decision-making: 4447 patients from a tertiary reference center

K. M. Erdogan¹, O. Kandemir², S. Yalvac², S. Esin², F. Alpaslan Pinarlı³, A. Tukun⁴;

¹Etlik Zübeyde Hanım Gynecology and Obstetrics Training and Research Hospital Department of Medical Genetics, Ankara, Turkey, ²Etlik Zübeyde Hanım Gynecology and Obstetrics Training and Research Hospital Department of Perinatology, Ankara, Turkey, ³Diskapi Yıldırım Beyazıt Training and Research Hospital Stem and Genetic Diagnosis Center, Ankara, Turkey, ⁴Ankara University Medical School Department of Medical Genetics-Duzen Laboratories Group, Medical Genetics Division, Ankara, Turkey.

Detection of trisomies especially trisomy 21 in the fetus is the major goal of amniocentesis. As this procedure is invasive and has a small risk of miscarriage amniocentesis is usually offered to women with high risk. For the risk estimation of pregnant women, it is important to know the frequency of chromosomal abnormalities according to the different clinical indications. We analyzed retrospectively the cytogenetic results of 4447 amniotic fluid samples referred to our hospital from 2008 to 2012. Chromosome abnormalities were detected in 2.6%. Classical autosomal trisomies were the most frequent ones (45,2%). Positive prenatal screening and advanced maternal age (AMA) were the most common referral reasons with 56.1% and 38.9%. Positive predictive value of ultrasound abnormalities was highest with 5,8% and for increased triple test screening risk and AMA it was 2,3% and 2,7%, respectively. When the karyotype analysis results of amniocentesis according to abnormal and normal karyotype results performed for AMA and increased triple test compared, the difference was statistically not significant (p>0.05).

E-P01.05

Aneuploidy findings on two different pregnancy loss materials from the same mother

I. Buran¹, E. M. Ay¹, G. Dogru¹, O. Izci Ay¹, U. Karakas¹, K. Cevik¹, D. Yuksek¹, U. Dilek², E. M. Erdal¹;

¹Mersin University, Faculty of Medicine, Department of Medical Biology, Mersin, Turkey, ²Acibadem University, Faculty of Medicine, Department of Gynecology and Obstetrics, Istanbul, Turkey.

Introduction: Early miscarriages are the most common complications of pregnancies and frequency of such cases is about 10-15% of all pregnancies. Endocrinological and anatomical causes, infectious diseases, environmental factors, immunological defects, genetic factors including numerical and structural chromosomal aberrations are the main causes for early miscarriages. The most common karyotypic anomaly in early miscarriages is autosomal trisomy. Chromosomal aberrations play an important role in the etiology of early miscarriages.

Materials and Methods: 37 years old pregnant female patient who has a healthy daughter was admitted to Polyclinic of Gynecology and Obstetrics at Faculty of Medicine in Mersin University for the missed abortion. Abortion materials from two separate pregnancies were sent to laboratory at different times. Samples from the first fetus from the 8th week of the pregnancy and the samples from the second fetus from the 9th week of pregnancy were cultured and metaphase plates are obtained using GTG banding technique. 15 metaphase plates from the first fetus and 20 from the second fetus were cytogenetically examined.

Results: As the result of cytogenetic analysis, 15 cells obtained from the fetal tissue of the first pregnancy showed 47,XX+12 karyotype and 20 cells from the second pregnancy showed 48,XY+16,+22 karyotype.

Conclusions: Aneuploidy is the primary cause of the first trimester miscarriages. Cytogenetic studies showed that aneuploidy level can be at 50-80% in certain populations. While autosomal trisomy is the most common karyotypic anomaly among these, polyploidy, sex chromosome anomalies and structural rearrangement can also be found at high rates in spontaneous miscarriages.

E-P01.06

Usefulness of array-CGH technique for genetic counseling regarding Y;autosome translocations in prenatal diagnosis

A. Pavel^{1,2}, L. Dimos¹, M. Necula¹, I. Pavel¹, F. Nedelea^{1,3}, V. Plaiasu^{1,4}, R. M. Simion¹, D. Stambouli¹;

¹Cytogenomic Medical Laboratory, Bucharest, Romania, ²"Stefan S. Nicolau" Institute of Virology, Romanian Academy, Bucharest, Romania, ³Filantropia Hospital, Bucharest, Romania, ⁴Mother and Child Care Institute "Alfred Rusescu", Bucharest, Romania.

Introduction: Structural chromosomal abnormalities, balanced or unbalanced, may be inherited from a carrier parent or may occur as de novo rearrangements. When the abnormality occurs as a de novo event, the risk for genetic disease is increased, even when the rearrangement appears balanced. This may result from either submicroscopic deletions or duplications at the breakpoints. Like any other chromosome, Y chromosome can be translocated onto an autosome, in a balanced or unbalanced way, with a low incidence.

Materials and methods: We report two prenatal cases with a de novo Y;autosome translocation resulting in submicroscopic deletions. The cases were analysed by conventional karyotype using standard chromosome preparation technique. The investigation continued with targeted array-CGH technique, using BAC clones for the identification of potential submicroscopic imbalances. All results were confirmed by FISH analysis using specific probes.

Results: Conventional karyotype revealed abnormal karyotypes for both cases with 45 chromosomes and a translocation of the entire Y, (or at least the entire long arm) to an acrocentric autosome, chromosome 13 and chromosome 15 respectively. Array-CGH detected genomic imbalances, more precisely, a deletion of 305.6Kb on Yp of the SRY gene for the first case and a deletion of 6.5Mb on chromosome 15q of the Prader Willi/Angelman region for the second case. Both array-CGH results were confirmed by FISH.

Conclusions: Array-CGH method increases the detection of chromosomal abnormalities for high risk pregnancies and allows for more accurate genetic counseling, recurrent risk assessment and for more informed reproductive decision making.

E-P01.12

Mutation analysis of Tudor Domain in TDRD5 gene and association study of rs508485(HIWI2) and rs11703684(HIWI3) polymorphisms in Iranian azoospermic men

Z. Kamalian, R. Mirfakhraie, S. Pooryamanesh;

Shahid Beheshti University of Medical Sciences, Tehran, Iran, Islamic Republic of.

Introduction: Azoospermia, the most common reason for male infertility, is caused by spermatogenetic failure. Recently, the role of piRNA pathway has been approved in spermatogenesis. The purpose of the present study was to mutation analysis of the Tudor domain in TDRD5 gene and also association study of rs508485(T>C) in HIWI2 and rs11703684(C>T) in HIWI3 genes in Iranian men with idiopathic non-obstructive azoospermia.

Materials and methods: Genomic DNA was extracted from blood samples obtained from 108 azoospermia samples and 100 healthy controls. Probable mutations in exons 9 and 10 of TDRD5 gene were screened using multi-temperature single strand conformation polymorphism (MSSCP) technique. Genotyping was performed using Tetra-ARMS-PCR for rs508485(T>C) and rs11703684(C>T) polymorphisms.

Results: Significant difference in distribution of rs508485 genotypes was found in azoospermia cases in comparison to controls, with P-value of 0.035 and odds ratio equal to 2.00 (95% CI: 1.04-3.86). No mutation was detected in Tudor domain of the TDRD5 gene in the patients.

Conclusion: We provide, for the first time, evidence for association between genetic variation the genes involved in the piRNA pathway and azoospermia in Iranian patients. Therefore, piRNA genes variants can be considered as risk factors for male infertility. Further studies will be required to validate the significance of the studied genetic variation in diverse ethnic populations.

E-P01.13

A novel TAZ gene mutation detected prenatally in a family with Barth syndrome

E. Benušienė^{1,2}, M. Rachlevičiūtė¹, A. Morkūnienė^{1,2}, L. Ambrozaitytė^{1,2}, A. Utkus^{1,2};

¹Department of Human and Medical Genetics, Faculty of Medicine, Vilnius University, Vilnius, Lithuania, ²Centre for Medical Genetics, Vilnius University Hospital Santariškių Klinikos, Vilnius, Lithuania.

Barth syndrome (OMIM 302060) is a rare X-linked disease characterized by dilated cardiomyopathy, proximal skeletal myopathy and cyclic neutropenia. Barth syndrome is caused by various mutations in the tafazzin (TAZ) gene which causes abnormalities of cardiolipin, an essential mitochondrial phospholipid.

A 22-year-old woman, G1 P0, was referred to our unit at 13 weeks of gestation for genetic counselling because of familial history of cardiomyopathy. Her first brother died at 6 months of age due to cardiac failure. The second brother on the 10th day of his life was diagnosed with cardiac insufficiency. At 1 year and 4 months of age the boy was diagnosed with growth retardation, hypotonia, cardiac insufficiency, hypoglycemia and neutropenia. Biochemical findings were excess of 3-methylglutaric and 3-methylglutaconic acid in urine and low free carnitine in blood. Barth syndrome was admitted based on clinical, biochemical findings and family history. The boy died of cardiopulmonary insufficiency at 11 years of age.

The first trimester ultrasound scan determined the male fetus and chorionic villus sampling was performed. DNA testing revealed a novel TAZ gene mutation c.285-1G>C. The same heterozygous mutation was detected in the woman - carrier status was confirmed. Other members of the family were also tested. Results of the mutational analysis offers the possibility of prenatal genetic counselling and preimplantation genetic diagnosis for the family.

E-P01.16

Assisted reproductive technologies for infertile couples with chromosome abnormalities - 6-years' experience results of "Center of Reproductive Medicine"

S. Zhukovskaya¹, N. Rumiantseva¹, S. J. Zhukovskaya²;

¹Center of Reproductive Medicine, Minsk, Belarus, ²Belarusian State Medical University, Minsk, Belarus.

Introduction: Chromosome abnormalities cause infertility, reproductive failures, birth of affected offsprings. Materials and methods: We present cytogenetic data and ART results of infertile patients that underwent treatment in 2010-2015. Results: 87 patients (1.5%, 60 males, 27 females) with chromosome abnormalities found among 5846 examined people. Balanced rearrangements diagnosed in 51 cases (58.6%): 22 (43.1%) reciprocal translocations (including X;autosome), 9 (17.6%) Robertsonian translocations, 18 (35.2%) inversions (including 4 paracentric), 2 (3.9%) insertions. Carriers showed normal gender determination, mental, growth development. Men presented spermatogenesis impairment, testicular hypoplasia, varicocele/cysts. Females presented hormonal imbalance, menstrual dysfunction, ovarian cysts, endometriosis. 36 patients (41.4%) presented unbalanced karyotype including mosaic forms. Among 26 males 20 patients presented numerical gonosome abnormalities, 4 - structural Y-chromosome aberrations; one case 46,XY,r(21)(p11.2;q22.3) and heteromorphisms 46,Y,15q11.2var. Females presented 6 cases of numerical aberrations (monosomy X; trisomy X), 3 cases 47,XX,+mar, one case 46,XX,del(X)(q26). Patients displayed normal mental health, no malformations.

Polysomy X males presented azoospermia, testicular hypoplasia, hormonal imbalance. Monosomy X females had primary amenorrhea. Mosaic or structural gonosome's abnormalities carriers displayed hypogonitalism of various severity. 48 balanced rearrangements carriers (17 females; 31 males) underwent ART (27 IVF, 21 IVF+ICSI). Pregnancy occurred in 23 cases (47.9%). 6 pregnancies resulted in miscarriage, 11 - term delivery, 5 pregnancies are continuing. 13 unbalanced carriers used ART (6 IVF; 7 IVF+ICSI). Pregnancy occurred in 3 cases (23%): 2 miscarriages, 1 continuing pregnancy. 91% pregnant women underwent invasive diagnostics; no fetuses with unbalanced karyotype were detected. Conclusion: cytogenetic screening must be recommended to all couples undergoing infertility treatment.

E-P01.18

Copan human DNA free FLOQSwabs™ stored in eNAT medium are a good buccal collection device for genetic investigations

A. Squassina, S. Castriciano;

Copan Italia, Brescia, Italy.

Introduction: Genetic diagnostic has increased in the last decade. Buccal swabs are considered an alternative to blood for collecting genetic material,

since are not invasive, well accepted by donor and cost effective. Copan is producing a human DNAfree FLOQSwabs™ line, available dry or associated to a tube of eNAT™, a molecular medium that preserves DNA at RT and inhibits bacterial flora and allows the possibility to perform multiple tests from the same donor. The objective of this study was to evaluate short and long term storage stability of human DNA from buccal swab collected with hDNA free FLOQSwabs™ stored in eNAT medium.

Methods: Buccal swabs replicates were collected with FLOQSwabs™ and stored in eNAT medium from 30 donors. Swabs were stored at room and refrigerated temperature for 1, 4, 8 and 12 months. 200 ul of each eNAT sample was used to extract Human DNA at each time point using PrepSEQ Express and AutoMate Express, quantified using Quantifiler Trio onto 7500 Real Time PCR machine, and profiled using Identifier Plus (Life technologies).

Results: The buccal swabs in eNAT medium gave an average of 10 ng/ul and good quality DNA. Minimal loss of DNA was observed after 1 and 4 months at room and refrigerated temperature. Longer stability is ongoing.

Conclusions: Copan hDNA free FLOQSwabs™ stored in eNAT medium are a good device for buccal swabs collection for human DNA genetic investigations, HLA testing for donor screening, paternity testing, cancer markers, and a diagnostic tool for infectious or hereditary diseases.

E-P01.19

Comparative Genomic Hybridization for genetic evaluation of early fetal losses

Z. G. Markova, E. V. Musatova, Y. O. Kozlova, N. V. Shilova;
Federal state budgetary institution «Research centre for medical genetics», Moscow, Russian Federation.

Introduction: Spontaneous abortion is one of the most frequent problem of pregnancy.

More than 50% of all spontaneous abortions have abnormal karyotype. Comparative genomic hybridization (CGH) can detect chromosomal abnormalities associated with spontaneous abortions while avoiding the technical problems associated with tissue culture.

Materials and Methods: A total of 76 spontaneous abortions of the first trimesters (4 -12 weeks of gestation) were studied by CGH. The additional aneuploidies detected by CGH were all confirmed by targeting FISH with corresponding DNA probes. All samples shown to be chromosomally balanced in CGH underwent interphase FISH to determine ploidy with DNA probes for chromosomes 18, X and Y.

Results: The overall rate of detected numerical chromosomal abnormalities was 57%. Trisomies of autosomes were the predominant chromosomal aberrations (58 %) followed by triploidy (23%) and monosomy X (12%). An unbalanced structural rearrangement was found in one (2,3%) case. In two cases complex aneuploidies were identified: monosomy X simultaneously with trisomy 22, monosomy X with partial trisomy 6q. Most frequently involved in trisomies were chromosomes 16 and 22 (16% each), 4, 5, 15 and 21 (4, 7 % each). Trisomies of 2,10, and 13 chromosomes was found in one (2,3 %) cases each.

Conclusions: We concluded that FISH analysis, followed by CGH is a suitable technique for the detection of chromosomal abnormalities in spontaneous abortion. Future the results of molecular cytogenetic analysis of noncultured cells will provide additional insight and may even change our knowledge on the frequencies of chromosomal abnormalities in spontaneous abortions.

E-P01.21

Genetic and epigenetic factors of decreased ovarian reserve in patients from Ukraine

G. Livshyts^{1,2}, O. Kotenko³, N. Hryshchenko¹, K. Khazhlyenko², L. Livshyts¹;
¹Institute of Molecular Biology and Genetics NAS Of Ukraine, Kyiv, Ukraine, ²“ISIDA-IVF” clinic, Kyiv, Ukraine, ³Taras Shevchenko National University of Ukraine, Kyiv, Ukraine.

Today more and more women delay the childbearing. Such a social shift results in increased number of women who get interested in having regular cycles and giving a birth at a later age but who are subfertile due to their diminished ovarian reserve. A search of genetic markers and X-chromosome (XCI) patterns are in great demand as it might help on the one hand, in identifying of women at a ovarian failure risk and, on the other, women who can benefit from advanced fertility preservation technologies applied prior to oocyte loss. The aim of our work was to study the association between phenotype and INHα, FMR1, FSHR, ESR1 genotypes and XCI-status in women with ovarian dysfunction and those with “poor response” to FSH ovarian stimulation in IVF cycles. It was shown that the frequencies of 769G>A in INHα variant and -397T PvuII variant in ESR1 gene heterozygous carriers, polymorphic haplotype Ala307-Ser680 heterozygous carriers, and “high

risk” alleles of FMR1 gene (40-47 CGG-repeats) heterozygous carriers were significantly higher in both ovarian dysfunction and “poor responders” groups comparing to control groups. According to analyses of XCI patterns in peripheral blood DNA samples of “poor responders” and control groups the frequency of skewed X-inactivation women are significantly higher in the “poor responders” group than in group of “good responders”. Obtained results showed that the analyzed allelic variants in INHα, FMR1, FSHR, ESR1 genotypes and XCI-patterns can be used in genetic diagnostic of ovarian dysfunction and “poor” response to FSH stimulation in IVF-cycles.

E-P01.23

Vacuoles in sperm head are associated with DNA damage

E. Komarova¹, M. Mazilina², I. Fedorova¹, A. Gzgyan¹;
¹The Research Institute of Obstetrics, Gynecology and Reproductology named after D.O. Ott, Saint-Petersburg, Russian Federation, ²St. Petersburg State University, Saint-Petersburg, Russian Federation.

Sperm DNA quality plays a major role in male fertility. But the parameters of the conventional semen analysis do not reliably predict it. The integrity of the sperm DNA is essential for the accurate transmission of genetic information. Large sperm nuclear vacuoles are thought to be related to sperm DNA damage such as DNA fragmentation.

The purpose of this study was to know if the sperm morphology reflects its DNA fragmentation which thought to be associated with reduced embryo quality, implantation and live birth rates.

In the present study we evaluated the sperm DNA fragmentation measured by the deoxynucleotidyl transferase-mediated dUTP nick end labeling assay (TUNEL) in 10 male patients with subfertility. For each patient two types of motile spermatozoa were selected under the high magnification by the same trained operator as follows: with large nuclear vacuoles and normal. We included patients with various sperm characteristics (various proportions of ‘normal’ and ‘vacuolated’ spermatozoa in ejaculate, various motility profiles and various sperm concentration).

A total of 429 ‘vacuolated’ and 197 ‘normal’ spermatozoa were analysed. The threshold for statistical significance was set to P≤0,05. Among sperm with large nuclear vacuoles DNA fragmentation rate was extremely higher compare to the control: 12,6% vs. 1,5% (p<0,001).

The DNA fragmentation rate appeared to be correlated with the presence of large sperm-head vacuoles. Such a relationship might help to select spermatozoa with intact DNA to improve fertilization efficiency and embryo quality when assisted reproductive technologies are used.

E-P01.26

Analysis of maternal polymorphisms of MTHFR gene and risk of Down syndrome offspring

N. Keser, A. Pazarbaşı, L. Özpak, H. Lüleypak, H. Pazarbaşı, F. Özgünen;
Çukurova University Faculty of Medicine Department of medical Biology, Adana, Turkey.

BACKGROUND: Down syndrome (DS) is the most common trisomy in live born with a prevalence of 1 in 1000 to 1 in 1100. Well-studied etiologies were maternal age and genetic polymorphism of folate metabolic pathway. Folate metabolism is governed by multiple enzymes. One of them methylenetetrahydrofolate reductase (MTHFR) converts 5,10-methylenetetrahydrofolate to 5-methylenetetrahydrofolate. Polymorphisms in gene encoding the folate metabolizing methylenetetrahydrofolate reductase (MTHFR C677T and A1298C) have been linked to the etiology of Down syndrome. We examined the prevalence of these variant genotypes in mothers who had given birth to a child with Down syndrome and in control mothers.

MATERIALS AND METHODS: Two common variants C677T and A1298C of the MTHFR gene were screened in mothers with DS children (n = 67 for C677T polymorphism; n=65 for A1298C polymorphism) and control mothers without DS children (n = 53 for C677T polymorphism; n=51 for A1298C polymorphism) from Çukurova region of Turkey. The MTHFR genotypes were studied by RFLP analysis of PCR-amplified products.

RESULTS: AA and AC genotypes for A1298C polymorphism are not associated with the risk of DS pregnancy while C677T polymorphism is significantly associated with the risk of DS pregnancy. The CC genotype was at higher rate at cases than controls for A1298C polymorphism (p<0.05). The CC genotype was higher in the controls than cases for C677T polymorphism (p<0.05).

CONCLUSION: Our study suggests that C677T polymorphism is significantly associated with the risk of DS pregnancy. CC genotype for A1298C polymorphism is also associated with the risk of DS pregnancy.

E-P01.30

Heterochromatin polymorphism does not appear to alter spermatogenesis in infertile men

A. Urbano^{1,2}, I. Ochando^{1,2}, M. Sánchez^{1,2}, E. Montoya^{1,2}, A. Segura^{4,2}, J. J. López-Gálvez^{4,2}, M. Lloret^{4,2}, J. Rueda^{3,1,2};

¹Unidad de Genética. Clínica Vistahermosa, Alicante, Spain, ²Cátedra de Biomedicina Reproductiva Vistahermosa. UMH, Alicante, Spain, ³Departamento Histología. Universidad Miguel Hernández, Sant Joan d'Alacant, Spain, ⁴Unidad de Reproducción. Clínica Vistahermosa, Alicante, Spain.

The number of infertile men is increasing in recent years. Heterochromatin polymorphism (HP) is a normal cyogenetic variant that is more frequent in infertile men. It has been suggested a relationship between HP and infertility, although not a possible mechanism. The HP could be related to the existence of meiotic alterations that can be detected by Fluorescent in situ hybridization (FISH) analysis in decondensed sperm. In the present work, we study blood karyotype and FISH on spermatozoa of infertile men, to evaluate the relation between heterochromatic variants and meiotic alterations. Blood karyotype and sperm aneuploidy (disomy and diploidy) rates for chromosomes 13, 18, 21, X and Y were evaluated in 251 infertile men with karyotype without structural rearrangement.

A total of 84 patients showed alterations in the FISH (33.5%) and 167 were normal. From the 251 patients, 52 patients (20.7%) showed HP. 22.6% of the patients with HP showed altered FISH in contrast to 19.7% of the patients with HP an normal sperm FISH. The most frequently observed polymorphism was 9qh+ (11%).

There were no significant differences in abnormal sperm FISH analysis between individuals with chromosomal polymorphisms and with normal karyotype (36.5% vs 32.7%; $p > 0.05$).

Our data reveals that HP is not related to FISH alteration. Infertile men with HP have not more meiotic alteration than infertile men with normal karyotype, suggesting that alteration of spermatogenesis is not the origin of infertility in men with HP

E-P01.31

The influence of gene-gene interactions and fibrinogen level on ART results in women with primary infertility

N. Medvedieva¹, Z. Rossokha¹, S. Kyryachenko², I. Gyulmamedova³, V. Sirenko³, N. Gorovenko²;

¹State Institution "Reference-centre for molecular diagnostic of Public Health Ministry of Ukraine", Kyiv, Ukraine, ²Shupyc National Medical Academy of Postgraduate Education, Kyiv, Ukraine, ³The Institute for Reproductive Medicine, Kyiv, Ukraine.

Introduction: Unsuccessful ART procedure is associated with coagulation genes polymorphism. Fibrinogen is one of the most important factors in the coagulation cascade. Increased fibrinogen level can be influenced adversely on ART result.

Materials and methods: We analyzed past histories of 97 women with primary infertility after ART. The analysis included FV (G1691A), FII (G20210A), PAI-I (675 5G/4G), MTHFR (C677T, A1298C), MTRR (A66G), MTR1 (A2756G), FGB (C148T, G-455A), ESR1 (A-351G, T-397C) genes polymorphism and fibrinogen level investigations. MDR 2.0 and SPSS 17.0 programs were used for statistical analysis.

Results: 45 women had successful treatment of infertility during ART procedures (Group 1). No embryo implantation was in 52 women (Group 2). Fibrinogen levels were measured in women of both groups during 5-7 days after embryos transfer. The average level of fibrinogen in comparison groups did not differ. We have found two predictive model of ineffective ART procedure: MTHFR (677CT)/PAI-I (675 5G/4G)/FGB (C148T) and FGB / PAI-I(675 5G/4G)/fibrinogen level. Cut-off for unfavorable mean fibrinogen level was 3,9 g/l. Patients in Group 2 had significantly higher prevalence of 148 CT and 148 TT genotypes in FGB gene and fibrinogen levels more than defined cut-off. But we found no correlation between FGB polymorphism and fibrinogen.

Conclusions: The risk of ineffective ART procedure in women with primary infertility is significantly increased in case of combined influences of patients FGB (C148T) genotypes and higher fibrinogen level. Further investigations of gene-gene and gene- factors interactions are necessary to find group risk of unfavorable ART outcome.

E-P01.32

Ascertainment of chromosomal imbalances origin: utility of parental chromosome and FISH analysis for genetic and reproductive counselling

E. Margarit^{1,2,3}, M. A. Vallecillos¹, A. Sánchez^{1,2,3}, A. Soler^{1,2,3};

¹Biochemistry and Molecular Genetics and IDIBAPS, Hospital Clínic, Barcelona, Spain, ²CIBER de Enfermedades Raras (CIBERER), Barcelona, Spain, ³IDIBAPS: Institut d'Investigacions Biomèdiques August Pi i Sunyer, Barcelona, Spain.

INTRODUCTION: The finding of a genomic imbalance provides an initial genetic diagnosis for a patient/fetus. The extension and composition of deleted/duplicated region determines his possible pathogenicity. The risk of associated abnormalities is higher when the alteration is de novo, an issue especially important in prenatal diagnosis. When the chromosomal imbalance has been originated by a parental balanced rearrangement, the recurrence risk for next pregnancies is significantly increased, particularly in complex alterations, insertions and some type of inversions.

METHODS: After reviewing our series of cytogenetic parental studies following chromosome imbalance detection, we report, among all the ascertained abnormalities, those particular cases demonstrating the importance of additional chromosome and FISH analyses in patients and parents to characterize and locate the unbalanced rearrangement.

RESULTS: In the following cases, additional investigations using conventional cytogenetic and FISH analysis resulted in a more accurate genetic diagnosis for affected individuals and risk assessment for future gestations, substantially increasing the quality of genetic counselling: $ins(18;2)mat-t(8;13;12)-double\ t(14;15)(14';21)-rec\ inv(4)pat-rec\ inv(14)mat-rare\ segregation\ 3:1\ for\ t(3;5)pat-del(Xp)mat-t(Y;autosome)$.

CONCLUSIONS: The finding of a genomic imbalance in a patient/fetus should be followed by additional studies to precise and locate the chromosomal rearrangement, in special when deletion or duplication has been identified using a quantitative analysis as array-CGH, qPCR or MLPA. Also, parental study is always required to investigate the aberration origin, very important not only for genetic prognosis but also for reproductive counselling.

This work was partially supported by grant PI11/01841 from FIS-Spanish Ministerio de Sanidad y Consumo.

E-P01.35

A genetic association study of AGT and AGTR1 gene polymorphisms in idiopathic spontaneous abortion in Iranian Patients

M. Sheikholeslami¹, M. yavari^{1,2}, M. Heidari¹, M. Seyed Hasan², M. Khatami¹;

¹Department of Biology, Faculty of Science, Yazd University, yazd, Iran, Islamic Republic of, ²Dr. Seyed Hasani medical Genetic Center, Yazd, Iran, Islamic Republic of.

Introduction: Recurrent spontaneous abortion is a multifactorial disease. At least 50 percent of abortions have no specific reason and are considered idiopathic. The renin-angiotensin system plays a considerable role in growth and differentiation in very early human development and in organogenesis. We sought to investigate whether exists any relationship between AGT M235T and AGTR1 A1166C with recurrent spontaneous abortion in Iranian patients.

Methods: The Frequency of AGT M235T and AGTR1 A1166C polymorphisms in 110 idiopathic recurrent spontaneous abortion women were compared to 105 females with no abortion history, employing tetra-primer ARMS-PCR. The validity of mentioned experiments were evaluated through sequencing procedure. The amino acid change was analyzed with tools like "UCL-CS", "EXPASY", "SIFT" and "Polyphen2".

Results: The frequency of A1166C in patients was AA (% 70), AC (% 28) and CC (% 1/8). The A1166C frequency of controls was AA (% 84/7), AC (% 15/2) and CC (% 0) ($P=0.008$) and the frequency of M235T in patients was TT (% 38.18), TC (% 61.8) and CC (% 0). The M235T frequency of control cases was TT (% 83.8), TC (% 16.2) and CC (% 0) ($P=0.001$).

Conclusion: Our results show significant relationship between the AGT M235T and the AGTR1 A1166C polymorphisms with idiopathic recurrent spontaneous abortion in Iranian women.

So these polymorphisms can serve as appropriate options for investigation of other populations and it may contribute to the understanding the one of the genetic etiology of idiopathic recurrent spontaneous abortion.

E-P01.38

The possible role of chromosome 9q11.1-1.2 duplication resulting with infertility and recurrent pregnancy loss

O. Ozdemir¹, O. Yildiz¹, B. Kuru¹, B. Paksoy¹, D. Uysal¹, F. Silan¹;

¹Faculty of Medicine, Canakkale, Turkey.

Aim: Pericentric heterochromatic variation of chromosome 9 is frequently encountered in karyotyping analysis. However, 9q11.1-11.2 duplications ra-

rely reported in reproductive failure.

Method:220 RPL and 145 infertility couples and 24 healthy reproductive controls (2 or more healthy children and none of miscarriage) were enrolled in the current results. Cytogenetic and molecular analyses using GTG-C banding and FISH were performed for the target chromosome 9q11.1-11.2 profiling.

First trimester fetal tissues of miscarriages analysed with QF-PCR and 13 aneuploid, 1 triploidy, 1 tetraploidy and 1 paternal-uniparental-isodisomy detected. Parents of abnormal fetuses analysed with GTG-C banding.

Results:128 infertile/RPL patients(69 male-59 female) and only 1 healthy reproductive control's banded analysis and FISH results showed the homozygous (8/6.3%) or heterozygous (120/93.7%) 9q11.1-11.2 duplication and 1 case has 9q11.1-11.2 triplication with concordance in the current patient-control cohort with reproduction problems. 46, XY,9qh11.1-11.2 triplication case's wife has two pregnancy loss, first with trisomy 15 and second with monosomy X; third pregnancy resulted with healthy girl.

9q11.1-11.2 duplication related to high risk of infertility/RPL (OddsRatio=4.89, p=0.1219)

All trisomy21(6 fetus), trisomy18(2), monosomyX and monosomy X+trisomy 21,triploidy(1), paternal-uniparental-isodisomy(1) fetuses has one or two 9qh+ parents; only trisomy 13(2) and tetraploidy(1) fetuses has parents without 9qh duplication. 9q11.1-11.2 duplication related to high risk of abnormal QF_PCR resulted fetuses (OddsRatio=23.00, p=0.0038)

Conclusion:Current results are the first report of 9qh+ variation in cases with RPL/infertility quantitative analysed with FISH and statistics compared to healthy reproductive cases. Results show the dup9q11.1-11.2 may cause the chromosomal abnormal fetuses because of interchromosomal effect and resulted as reproduction failure.

E-P01.40

Structural chromosome aberrations in couples with fertility problems

A. Kybartiene, Z. Zemeckiene, J. Peculaitiene, D. Medelinskiene, V. Asmoniene; Department of Genetics and Molecular Medicine, The Hospital of Lithuanian University of Health Sciences, Kaunas, Lithuania.

Introduction. Infertility is important health problem, there are about 10-15% of infertile couples in the world. Structural chromosome aberrations may be one of the infertility reasons. The aim of this study was to evaluate structural chromosome aberrations in couples with fertility problems in Lithuania.

Materials and Methods. 187 couples with fertility problems (187 male (age 34,6±6,38 yrs) and 187 female (average age 32,0±5,51 yrs)), who underwent genetic counseling in The Hospital of Lithuanian University of Health Sciences Kauno Klinikos in 2013-2015y, were involved in this study.

Karyotype analysis on peripheral blood lymphocytes was performed for all couples by the standard laboratory protocol. Chromosome preparations were stained with trypsin-Giemsa to obtain G-banding. C-banding was also performed when necessary.

Results. Normal karyotype was found in 165 (88,2%) and chromosomes with structural aberrations in 22 (11,8%) of all tested couples. 14 (63,64%) of chromosome aberrations in couples were heteromorphic structural changes. We found 3 (1,60%) couples with chromosome alterations in both partners. Complete results are presented in table.

Conclusions. In this study we found that structural chromosome aberrations could influence infertility in only 11% of couples with fertility problems in Lithuania.

Double and triple hetero and homozygous forms of FVL/PTH/MTHFR mutations as a high risk factor of pregnancy complications in Georgian population

N. Pirtskhelani¹, N. Kochiashvili¹, K. Kartvelishvili¹, L. Makhaldiani², N. Pargalava³; ¹National Forensics Bureau/Forensic Biology (DNA) Department, Tbilisi, Georgia, ²Hemophilia and Thrombosis Center, K. Eristavi Experimental and Clinical Surgery National Center, Tbilisi, Georgia, ³Georgian Centre of Angiology and Vascular Surgery, Tbilisi, Georgia.

Introduction: Inherited thrombophilia, caused by the gene mutations of Factor V Leiden (FVL), Prothrombin (PTH G20210A) and Methylenetetrahydrofolate reductase (MTHFR C677T), is often associated not only with thromboembolism, but also with pregnancy complications, but we don't have detailed information about correlations between double and triple hetero and homozygous forms of FVL/PTH/MTHFR mutations and pregnancy complications (Spontaneous abortions, stillbirths, premature placental abruption, fetal development delay, preeclampsia, thromboembolism). Purpose of the study was to detect presence of different combinations of above mentioned mutations as a high risk factor for pregnancy complications.

Materials and Methods: 350 Patients with pregnancy complications and 100 healthy individuals (aged 20-45 years), were genotyped by PCR analyses.

Results: Different combinations of double and triple hetero and homozygous forms of FVL/PTH/MTHFR mutations (50 cases) were found in patients (27 (7,71%) cases of FVL/MTHFR heterozygous, 9 (2,57) - PTH/MTHFR heterozygous, 6 (1,71%) - FVL-hetero/MTHFR-homozygous, 3 (0,86%) - FVL/PTH/MTHFR heterozygous, 2 (0,57%) - PTH-hetero/MTHFR-homozygous, 2 (0,57%) - FVL/PTH heterozygous, 1 (0,29%) - FVL homozygous mutations) and only one case with double PTH/MTHFR mutations in control group. There was a strong correlation between combinations of these mutations and development of thromboembolism, together with other complications, during pregnancy and postpartum.

Conclusions: Existence of these double and triple mutations indicates high distribution of inherited thrombophilia in Georgian population. Therefore we confirm a significant role of inherited thrombophilia, especially combined forms of mutations in development of pregnancy complications with severe thromboembolism during pregnancy and postpartum.

Lethal Gaucher Disease: a resolution for a challenging family history of intrauterine fetal deaths

N. Ekhilevitch^{1,2}, A. Kurolap¹, A. Mory¹, T. Hershkovitz¹, H. N. Baris-Feldman^{1,2}; ¹Rambam health care campus, Haifa, Israel, ²Rappaport School of Medicine, Technion - Israel Institute of Technology, Haifa, Israel.

Introduction. We describe a young couple with a history of four in-utero fetal deaths at 7-23 weeks of gestation. All fetuses presented with severe IUGR, multiple congenital anomalies and fetal hydrops. The parents are first-degree cousins of Muslim-Arab origin from Northern Israel. They have two healthy daughters. Recurrent in-utero fetal deaths with severe fetal malformations have a wide differential diagnosis. Family history and consanguinity directed toward autosomal recessive inheritance; therefore, whole-exome sequencing was utilized.

Methods. Following parental informed consent, whole-exome sequencing was conducted on a fetus and both parents' genomic DNA using Illumina's NextSeq platform. Variant analysis focused on rare pathogenic homozygous changes, followed by Sanger validation and co-segregation analysis.

Results. Exome analysis revealed a homozygous missense mutation in the GBA gene, NM_000157.3: c.820G>A (p.Glu274Lys).

Discussion. Gaucher disease is an autosomal recessive disorder with genetic and phenotypic heterogeneity caused by deficiency of glucocerebrosidase. The lethal type is typically depicted in-utero or during the neonatal period as hydrops and/or congenital ichthyosis with severe progressive neurological symptoms. The p.Glu274Lys mutation has previously been described as disease-causing in conjunction with another deleterious variant, showing a 100% decrease of GBA enzymatic activity; our family describes the first occurrence of this variant in a homozygous manner.

Lethal Gaucher disease is rarely diagnosed due to the clinical difficulty of recognizing it in-utero. Our family emphasizes that lysosomal storage diseases should be suspected in recurrent in-utero fetal deaths with severe fetal malformations and hydrops fetalis.

Inversion 4 Carrier with Infertility

M. S. Yildirim, M. N. Somuncu, A. G. Zaman;

Department of Medical Genetics, Meram Medical Faculty, Necmettin Erbakan University, KONYA, Turkey.

Inversion is one of the rearrangements result when a chromosome segment excises and reintegrates oriented 180° from the original orientation. There are two types of this chromosomal anomalies according to centromere position thus if the inversion segment includes centromere is called pericentric so break points are in each arm or thus if doesn't include centromere so both breaks occur in one arm is called paracentric inversion types. This chromosomal aberration usually may not cause any phenotypically effects on carriers as if the inversion segment is balanced but when the rearrangement is unbalanced with extra or missing DNA may due to miscarriage and infertility.

In our case, a 25 years old female represented by pericentric inversion on chromosome 4 applied of prediagnostic infertility also our case had been ivf pregnancy but resulted abortion. The patient peripheral blood was analyzed by classic cytogenetic technique as added to FISH method for detecting the orientation of the inverted segment. FISH probe was amount of the 4p(16.3) and 4q(ter) region but we didn't observed any inversion signal with fluorescently microscopy. At the end of cytogenetic analysis the karyotype was detected 46,XX,inv(4)(p16.2;q1,12).

Inversions are no loss of the genetic material however the gene sequences can be changed thus if crossing over occurs including inverted segments can cause the unbalanced gametes. In this case the patient karyotype can lead to an increased risk of miscarriage and infertility. So that family may be offered genetic counseling and comprehensive genetic examination.

Prenatal diagnosis and outcomes of congenital lower urinary tract obstruction (LUTO) in a South African hospital

H. Bezuidenhout¹, L. Geerts², M. Urban³;

¹Division of Molecular Biology and Human Genetics, Stellenbosch University, Cape Town, South Africa, ²Department of Obstetrics and Gynaecology, Stellenbosch University, Cape Town, South Africa, ³Division of Molecular Biology and Human Genetics, University of Stellenbosch, Cape Town, South Africa.

Introduction: To determine the frequency, etiology, survival and morbidity of prenatal Lower Urinary Tract Obstruction (LUTO) in a low-resource country.

Methods: Retrospective record review of prenatal LUTO cases at Tygerberg Hospital, South Africa, between January 2003 and June 2014.

Results: 75 prenatal LUTO cases were detected in 12 years, with a frequency of 1.2 per 10,000 births calculated over 3 years. The median gestation at diagnosis was 22.4 weeks. Prenatally 39 (52%) were classified as 'Isolated', 16 (21%) as 'Isolated with marker' and 20 (27%) as 'Complex'. Gender difference observed with predominance of males (60/68) (88%), male:female ratio 7.5:1. Males had predominantly 'Isolated LUTO' (n=36, 60%), and females 'Complex LUTO' (n=5, 63%). Survival outcomes included: TOP 26 (35%), IUD 1 (1%), Stillbirths 8 (11%), NND 12 (16%), Infant deaths 4 (5%), alive >1 year 16 (21%), Lost to follow-up/Unknown 8 (11%). The most common etiology was PUV (51%). Chromosomal aneuploidy was found in 9.3% (7/75), all in males, with Trisomy 21 the most common anomaly (4/7) (57%). Prenatal findings shown to be significantly associated with a 'Poor outcome' are bilateral renal cortex echogenic/cystic changes (p=0.029), anhydramnios (p=0.011) and pulmonary hypoplasia (p=0.003). Morbidity measures showed survivors beyond 1 year of age (n=16) had renal impairment (n=6, 37%), bladder dysfunction (n=4, 25%), recurrent UTIs (n=9, 56%).

Conclusions: Novel data on the burden of congenital LUTO in a developing country confirms high mortality and significant morbidity and supports the predictive value of specific ultrasound findings. The overall poor prognosis makes extensive counselling essential.

E-P01.48

Rare case of male infertility due to monosomy X and structural rearrangement of chromosome Y

D. Brazdziunaite¹, B. Burnyte², V. Sliuzas², A. Utkus²;

¹Faculty of Medicine, Vilnius University, Vilnius, Lithuania, ²Department of Human and Medical Genetics, Faculty of Medicine, Vilnius University, Vilnius, Lithuania.

Objective: To present a male with primary infertility due to mosaic karyotype with monosomy X and structural rearrangement of chromosome Y.

Inspection and Investigation: Here we present data from 34-year-old patient complaining about his inability to have children with his partner. There

were no significant health problems in childhood. Urological examination revealed testicular hypoplasia and his spermogram showed azoospermia. Phenotypically patient has short stature and eunuchoid voice. Screening of the AZFa, AZFb, and AZFc regions did not detect any chromosome Y microdeletions. Cytogenetic analysis of 50 metaphase spreads from peripheral blood lymphocyte cultures revealed mosaic karyotype: 45,X[44]/46,X,idi(Y)(p11.3)[16]. One cell line had monosomy X, while other had isodicentric chromosome Y, which was composed of two chromosomes Y fused at terminal segments of p arms. According to literature, this karyotype determines various male fertility disorders. Isodicentric chromosomes are the most commonly reported aberrations of the chromosome Y. Phenotypes of mosaic karyotype may vary from male to abnormal female or individual with ambiguous genitalia.

Conclusion: Although our patient has mosaic karyotype without normal karyotype cell line, he lives a normal life without physical symptoms or other complaints about health, except for primary infertility. It is well known that phenotypes depend on the location of chromosome breakpoints as well as on the proportion of each cell line and degree of mosaicism in various tissues.

E-P01.53

MiRNA regulation of uterine fibroids pathogenesis.

M. S. Matevosyan, I. O. Pokudina, D. E. Romanov, E. V. Butenko; Southern Federal University, Rostov-on-Don, Russian Federation.

Introduction: Uterine fibroids are the one of the most common neoplasms in women of reproductive age. The accumulated data and functional model experiments confirm the concept of the impact of microRNAs on disease development. MiRNAs regulate genes by binding to their transcripts, while the coefficient of miRNA binding is directly proportional to its regulatory capacity. Current study is to predict miRNA that regulate genes included in pathobiology of uterine fibroids.

Materials and methods. We analyzed the intergene spaces located in surroundings of 35 genes of the pathogenesis. Full sequences were obtained from NCBI data base using E-utilities API. miRNA sequences were taken from the miRBase release 21. Binding sites search was carried out with MiRanda and GLAM2Scan program combination. The results were filtered to yield only those matches with 95% identical nucleotides.

Results: The entire set of non-coding DNA sequences around 35 genes contains 164 miRNA binding sites of miR-619, miR-5096, miR-1273(g,h,f,e), miR-8485, miR-1273e, miR-5585, miR-548d -2, miR-1285-1 and miR-545. The maximum number of binding sites (13-20) was identified for HMG A2 (16), ICAM1 (20), TGFB1 (17), MMP16 (20), KIT (13). MiR-619 regulates 22 genes from the study group, miR-5096 -18 genes, miR-1273g -13 genes, the rest miRNAs to regulate 1-3 genes studied.

Conclusion. The results suggest an important role that detected miRNAs play in uterine fibroids pathogenesis. Further research may provide the basis for future use of miRNAs as biomarkers and therapeutic targets.

This research was supported assignment of the Ministry of Education and Science of Russia № 1878

E-P01.54

Prenatal cytogenetic analysis on amniocytes fails to detect low grade mosaic trisomy 9

A. Zagorac¹, K. Writzl², A. Golub¹, Z. Kanic³, N. Kokalj Vokac^{1,4};

¹Laboratory of Medical Genetics, University Medical Centre Maribor, Maribor, Slovenia,

²Institute of Medical Genetics, University Medical Centre Ljubljana, Ljubljana, Slovenia,

³Division of Paediatrics, University Medical Centre Maribor, Maribor, Slovenia, ⁴Medical Faculty Maribor, University Maribor, Maribor, Slovenia.

The aim of prenatal diagnosis is to correctly establish and interpret the karyotype of the fetus. Detection of low-grade mosaicism involves many factors, like the type and number of tissues analyzed, the number of cells studied and the sensitivity of the techniques applied.

We describe a case of cytogenetic analysis after amniocentesis in which a normal male karyotype was obtained. Postnatal molecular cytogenetic tests on peripheral blood revealed a low level trisomy 9 mosaicism.

Amniocentesis requested for advanced maternal age gave a normal male karyotype. Because of poor fetal growth and the pathological CTG emergency cesarean section at 32nd week of gestation was done. At the age of 10 month the propositus was presenting some abnormalities: hypotonia, delayed motor development, mild micrognathia, deeper palmar and plantar creases, left eye strabismus, bilateral cryptorchidism and bilateral inguinal hernia. Ultrasound examination revealed ASD secundum, dilatation of the left ventricle, and bilateral mild pyelectasia.

These findings led us to perform postnatal molecular cytogenetic testing. Array-CGH on peripheral blood indicated mosaic trisomy 9. FISH on cultured peripheral blood lymphocytes using 9q subtelomeric DNA probe in com-

binar with CEP 9 centromeric DNA probe confirmed presence of cell line with trisomy 9 in 2% of metaphases and in 7% of interphase cells. Postnatal genetic tests results and boy's phenotype suggested that this is a case of low grade trisomy 9 mosaicism. We have compared the clinical findings of our patients with those previously reported and some thinkings about pitfalls in prenatal diagnosis will be discussed.

E-P01.56

Prenatal diagnosis of Pallister-Killian syndrome

D. Raskova¹, V. Frisova², D. Smetanova¹, B. Prosova², J. Hodacova¹, M. Trkova¹, V. Becvarova¹, L. Dohnalova¹, M. Koudova¹, D. Stejskal¹;

¹Centre for Medical Genetics and Reproductive Medicine GENNET, Prague 7, Czech Republic, ²Profema-Fetal Medicine Centre, Prague 2, Czech Republic, ³Dept. of Radiology 2nd Faculty of Medicine, Charles University and Motol University Hospital, Prague 5, Czech Republic.

Pallister-Killian syndrome is a rare chromosomal disorder characterized by a tissue-limited mosaicism of tetrasomy of the short arm of chromosome 12, caused by extra metacentric chromosome - isochromosome i(12)(p10). Mosaicism is present only in fibroblasts, the karyotype of lymphocytes is normal. Clinical features include intellectual disability, seizures, streaks of hypo- or hyperpigmentation, prominent forehead, flat occiput, hypertelorism, short nose with anteverted nostrils, flat nasal bridge, short neck, polyhydramnion, rhizomelic micromelia and diaphragmatic hernia.

Chorionic villi sampling (CVS) was performed at 28-year old G2/P0 woman due to nuchal translucency (NT) 3,5 mm/1,99 MoM and normal first trimester biochemistry. Karyotype and microarray investigation of the fetus were normal, screening for deletion of exons 7 and 8 of the SMN1 gene and mutations of the FGFR3 gene were negative.

The ultrasound investigation in 20th week proved mild ventriculomegaly, hydronephrosis bil., short long bones (under 5.percentile), high NSF, wide insertion of the umbilical cord with herniation of the liver tip, subcutaneous edema of face, skull and neck, edema of the nasal bridge, wide flat nose, flat profile, high forehead, hypertelorism, convulsive movements. Echocardiographic investigation and magnetic resonance were in accordance with ultrasound findings.

Differential diagnosis considerations included Pallister-Killian syndrome and repeated targeted prenatal diagnosis by amniocentesis was offered. The diagnosis of Pallister-Killian syndrome was conformed by finding of 80% mosaicism of tetrasomy 12p by FISH investigation (isochromosome of the short arm of chromosome 12).

The pregnancy was terminated in accordance with the decision of the family.

E-P01.62

Investigation of relationship between Interleukine-2 promoter polymorphism and preeclampsia

G. Ay, Ö. Turgut, U. Luleyap, M. A. Erkoç, P. Pazarcı, D. Alptekin, F. T. Özgünen; Cukurova University Faculty of Medicine, Adana, Turkey.

Introduction: Pregnancy, which results in a healthy gestation period and birth depends on well-functioning immune system of mother. Interleukine-2 (IL-2) is one of the most important cytokine which is produced by active T-lymphocytes and determines the cellular or humoral response along with macrophages during infection. Preeclampsia is a disease which generally occur during first pregnancy and its potential reasons are considered to be genetic and immunologic factors.

Materials and Methods: In this study, we aimed to investigate the relationship between preeclampsia and polymorphisms at -384 position in the promoter region of IL-2 gene. For this purpose, blood samples are taken from patients with stable preeclampsia and from healthy people as control. Potential polymorphisms related to the -384 promoter region of IL-2 gene are investigated by using Restriction Fragment Length Polymorphism technique.

Results: In 89 preeclamptic women involved in study, 38, 36 and 15 of them are found to have TT, GT and GG polymorphisms respectively. In 57 pregnant women (control), 28, 22 and 7 of them are found to have TT, GT and GG polymorphisms respectively.

Conclusions: Allele frequencies and genotype distributions at -384 promoter region of IL-2 gene is analyzed by Chi-square test and no statistically significant difference between patient and control group is found. Since factors such as abnormal immunological tolerance in pregnant women during pregnancy, HLA discrepancy between father and mother, and imprinting are important in preeclampsia, we consider that genetic based comprehensive researches involving all negative factors effective in placenta formation will be useful.

E-P01.63

Investigation of Methylenetetrahydrofolate reductase (MTHFR) gene A1298C Polymorphism and Distribution of Genotypes in Preeclampsia and Normal Pregnancies

L. Özpak, A. Pazarbaşı, N. Keser, N. Ilgaz, F. Özgünen; Çukurova University, ADANA, Turkey.

Introduction: Methylenetetrahydrofolate reductase (MTHFR) gene polymorphism in the development of preeclampsia in pregnant woman might be thought to play an active role. Therefore, we assessed whether MTHFR gene A1298C polymorphism increase the risk of preeclampsia.

Method: In this study, 98 pre-eclamptic and 78 normotensive pregnant women were genotyped for MTHFR A1298C polymorphism by RFLP (restriction fragment length polymorphism) analysis and the distribution of genotype and allele frequencies belonging to this polymorphism in pre-eclamptic patients and controls were also evaluated.

Results: Among controls, the genotypes of A/A, A/C, and C/C were observed in 42%, 43%, and 15% , respectively, whereas the A/A, A/C, and C/C genotypes were observed in 46%, 50%, and 4% of case patients, respectively for MTHFR A1298C polymorphism. The C/C genotype of the MTHFR gene were associated significantly with the risk of developing preeclampsia. Prevalence of the CC mutant genotype (%15) for the A1298C polymorphism was higher among PE women. There was a significant difference in terms of these genotypes between preeclamptic and normotensive pregnant women ($p=0.044$). There was significant difference in term of frequency of A allele ($p<0.05$) while there was not significant difference for frequency of C allele.

Conclusion: There was differences in genotype frequencies between preeclamptic patients and controls, but there was difference only in frequency of A allele between preeclamptic patients and controls, for MTHFR A1298C polymorphism.

E-P01.64

Association between P-Selectin polymorphism and preeclampsia

S. Sezer¹, O. Ates¹, F. Demirturk², N. Bozkurt¹, E. Ensari¹;

¹Department of Medical Biology, Medical Faculty, Gaziosmanpaşa University, Tokat, Turkey, ²Department of Obstetrics and Gynecology, Medical Faculty, Gaziosmanpaşa University, Tokat, Turkey.

Introduction: Preeclampsia is a pregnancy-specific disorder characterized by new-onset hypertension and proteinuria. It is reported that the affecting 2-10% of all pregnancies. The disease develop after 20 weeks of gestation and the exact etiology is unknown.

However, the occurrence of the disease may be associated with apoptosis, early vascular and endothelial cell dysfunction. In the proposed another mechanism, changes in the immune system of pregnant as a result of increased inflammatory response is lead to faulty placentation. P-selectin is a cell adhesion molecule and it is increases in many inflammatory conditions including preeclampsia. Therefore, it may be important to study the selectin polymorphisms in preeclampsia patients. In this study, our aim was to research the possible association between P selectin (Thr715Pro) polymorphism and preeclampsia.

Materials and methods: The study group consisted of 101 preeclampsia patients and 113 woman controls. P-Selectin polymorphism were analyzed by using Polymerase Chain Reaction (PCR) -Restriction Fragment Length Polymorphisms (RFLP) method.

Results: Statistical evaluation of the data results showed a significant association for genotypic and allelic frequency distribution between P-Selectin polymorphism and preeclampsia ($p=0.0027$; $p= 0.004$, OR: 4.03, 95% CI: 1.40 -14.12).

Conclusions: Our study results suggest that P-Selectin polymorphism may be one of the many genetic factors for preeclampsia susceptibility.

This work was supported by Gaziosmanpaşa University Scientific Research Projects Fund

Allelic and genotypic distributions of the studied polymorphism

E-P01.65

The endothelial protein C receptor haplotypes are not associated with increased risk of recurrent pregnancy loss or repeated implantation failure

I. Joksic¹, S. Zivanovic², G. Joksic²;

¹Clinic of Gynecology and Obstetrics, Belgrade, Serbia, ²Institute of Nuclear Sciences, Vinca, Belgrade, Serbia.

The endothelial protein C receptor (EPCR) is a key component of the protein C anticoagulant pathway. Four common haplotypes of PROCR have been reported (H1, H2, H3, H4). The A6936G allele (H3) is associated with lower EPCR densities on trophoblasts, but data are lacking for its effect on the risk of pregnancy loss in humans. In PROCR knockout mice, fibrin deposition in trophoblast cells results in thrombosis at the maternal-embryonic interface and pregnancy loss. Also, low EPCR density on trophoblast cells may influence implantation of the blastocyst and thus lead to implantation failure. We examined the frequencies of EPCR haplotypes in women experiencing recurrent pregnancy loss (RPL) and repeated implantation failure (RIF) and fertile controls.

The study included 50 women with history of at least three repeated IVF failures, 86 women with history of at least three pregnancies loss and 30 fertile controls. We investigated frequencies of EPCR gene haplotypes using reverse PCR Vienna lab CVD StrippAssays.

Our results showed no statistically significant difference in frequencies of EPCR haplotypes in three investigated groups (chi 2,003 p=0,8948). The most prevalent genotype is h1h2 in all studies groups, while h3h3 genotype has lowest frequency in our study population.

Although animal studies strongly suggested a link between EPCR haplotype and successful pregnancy outcome, our study did not confirm these findings. Further investigations on larger number of pregnant women as well as their partners is needed in order to evaluate if carrying a homozygous child is associated with increased risk of pregnancy loss

E-P01.66

Cytokine and folate cycle genes additive effect study in pregnancy loss

E. Mashkina, K. Kovalenko, E. Butenko;

Research Institute of Biology, Southern Federal University, Rostov-on-Don, Russian Federation.

When there are several gene products which are involved in one function and process, minor but multiple changes have additive effect and cause the disturbance of whole metabolic pathway. Here we investigate the additive effect of pro-inflammatory cytokines and folate cycle enzymes allele variants in pregnancy loss. 151 women with early pregnancy loss (ERL) and 134 women with normally progressing pregnancies were studied. Polymorphisms -31C-T (rs1143627) IL-1 β , -174G-C (rs1800795) IL-6, C677T (rs1801133) MTHFR, A66G (rs1801394) MTRR were detected by allele-specific PCR. We analyzed gene-gene interactions among 4 polymorphisms using the multifactor dimensionality reduction (MDR) method. Two high risk genotypes were detected. 6,4% of women with EPL had genotype -31CT IL-1 β / -174GG IL-6 / 677CT MTHFR / 66GG MTRR, whereas in control group this genotype wasn't detected. Described allele variants combination is a high-risk factor for the first trimester pregnancy loss (OR = 17,3 p = 0,01). 9,9% of women with EPL had genotype -31CC IL-1 β / -174GC IL-6 / CT677 MTHFR / 66AG MTRR that is 3,9 fold higher rate than in control group (OR = 4,3 p = 0,03). Shift in inflammatory reactions intensity, including that caused by cytokines gene variants, is a risk factor for pregnancy. Pro-inflammatory cytokines can act as a mediators between inflammation and hypercoagulation. Hyperhomocysteinemia can cause the development of numerous pathologies through pro-inflammatory cytokines expression up-regulation, oxidative stress induction, apoptosis activation and methylation processes dysregulation. This study was supported by the federal assignment № 6.98.2014/K from Russian Ministry of Science and Education.

Small Supernumerary Marker Chromosome 15 identified in prenatal diagnosis due to advanced maternal age

S. Teofilova¹, O. Miljanovic¹, T. Ostojić¹, M. Bulatović¹, T. Liehr²;

¹Clinical Center of Montenegro, Podgorica, Montenegro, ²Institute of Human Genetics, Jena, Germany, Jena, Germany.

Introduction: Small supernumerary marker chromosomes are defined as extra and abnormal chromosomes whose derivation and content can't be typically determined by G banding techniques. Approximately 70% of SMCs are de novo and 30% are inherited.

Materials and Method: Here, we report a case of sSMC identified in prenatal diagnosis. A 36-year-old pregnant woman was monitored due to advanced

maternal age. The amniocentesis was performed at 17 weeks of gestation. The fetal karyotype was obtained from an amniotic fluid cells.

Results: Conventional cytogenetics analysis revealed an abnormal karyotype 47,XY,+mar detected in all metaphases. Both parents had normal karyotypes. Molecular investigation by FISH were carried out in the Jena, Institute for Human Genetics. The additional marker chromosome could be characterized after the application of the probes mentioned above as a del (15) (q11.2). Molecular-cytogenetic result 47,XY,15p++mat,+ del (15) (q11.2) (100%). After a complete genetics analysis, the parents were informed that there are several cases small SMC(15)s described in the literature which did not show any clinical abnormalities regardless inherited or de novo, and those cases were not directly associated with an abnormal phenotype. After this information and ultrasound findings, the parents decided to continue with the pregnancy and keep the baby. In week 40 of the gestation a boy was born, now 3 years old, phenotypically healthy and with normal intelligence level.

Conclusions: In such cases it is necessary to do molecular investigation by FISH in order to exclude the presence of critical region of Prader Willi and Angelman syndromes.

E-P01.70

Screening of high-risk pregnancies for chromosomal aneuploidies

D. Medelinskiene¹, Z. Zemeckiene¹, A. Kybartiene¹, G. Stremaityte², V. Asmoniene¹;

¹Department of Genetics and Molecular Medicine, The Hospital of Lithuanian University of Health Sciences, Kaunas, Lithuania, ²Department of Genetics and Molecular Medicine, Lithuanian University of Health Sciences, Kaunas, Lithuania.

Introduction. The aim of this study was to evaluate numerical and structural chromosome aberrations in amniotic fluid cells of different maternal age groups.

Materials and methods. This retrospective study involved 1163 pregnant women (age 16-51 years, average 35.5±5.63 yrs), who underwent prenatal genetic counseling in The Hospital of Lithuanian University of Health Sciences Kauno Klinikos in 2012-2015. All women had high risk for aneuploidy according to double, triple biochemical tests or ultrasound examination.

Amniotic fluid for prenatal analysis was obtained by transabdominal amniocentesis between 16-22 weeks gestation. Interphase fluorescence *in situ* hybridization for aneuploidy screening was performed on non-cultivated cells with Kreatech Poseidon probes according to manufacturers protocol. Preparation of chromosome slides G-banding using trypsin-Giemsa staining were performed according to standard laboratory methods.

Results. We found aneuploidies in 89 cases (7,65%) and heteromorphic structural aberrations in 18 (1,55%). Results in different age groups are presented in table.

Conclusions. Most of chromosome aneuploidies and structural aberrations were found in women over 35 years. The most common aneuploidy was 21 chromosome trisomy.

Table. Chromosome aneuploidies and structural aberrations in different maternal age groups.

Maternal age groups	Chromosome aneuploidies and structural changes, n(percentages from all abnormalities)						Total
	13 chromosome trisomy	18 chromosome trisomy	21 chromosome trisomy	Sex chromosome aneuploidies	Triploidies	Chromosome structural aberrations

Cytogenetics study of 468 sample of products of conception

I. Tkach¹, N. Huleyuk¹, D. Zastavna¹, A. Weise², N. Kosyakova², T. Liehr², E. Ciszkowicz³;

¹Institute of Hereditary Pathology, NAMS of Ukraine, Lviv, Ukraine, ²Jena University Hospital, Friedrich Schiller University, Institute of Human Genetics, Jena, Germany, ³Department of Biotechnology and Bioinformatics, Faculty of Chemistry, Rzeszow University of Technology, Rzeszow, Poland.

Introduction: The karyotype of a spontaneously aborted conceptus provides valuable clinical information. Chromosomal abnormalities (mostly aneuploidy) account for ~50% of fetal losses in the first 8-15 weeks of gestation. For later (15-24 weeks) losses the frequency is approximately 20 %. Most of

them are numerical aberrations such as polyploidy, trisomy, or monosomy X. Materials and Methods: Cytogenetic study of 468 samples products of conception was performed. G-banding cytogenetic results were obtainable in 153 cases. For the analysis of products of conception where banding analysis was not possible due to absence of metaphases mFISH analysis was performed. Interphase mFISH with the probe panel for chromosomes 13, 14, 15, 16, 17, 18, 21, 22, X and Y was performed on 315 uncultured cell suspensions from spontaneous abortions samples.

Results: G-banding and molecular-cytogenetic karyotyping of products of conception identified numerical chromosomal abnormalities in 34.4% of cases with prevalence of autosomal trisomy – 15.0%, polyploidy – 9.8% and monosomy X – 8.1%, especially in pure form (7.6%). Among the autosomal trisomy abnormalities of chromosomes 16 (5.3%), 21 (2.8%) and 18 (2.4%) were the most prevalent.

Karyotype	G-banding results	mFISH results	Total results	
	n	n	n	%
Normal XY	67	87	154	32.9
Normal XX	36	117	153	32.7

Parental microRNA polymorphism and recurrent pregnancy loss: an association study in Iranian population

m. amin-beidokhti¹, r. mirfakhraie¹, s. zare-karizi², f. karamoddin³,

¹Shahid Beheshti University of Medical Sciences, Tehran, Iran, Islamic Republic of,

²Islamic Azad University Varamin Pishva Branch, Varamin, Iran, Islamic Republic of,

³Shafa Hospital, semnan, Iran, Islamic Republic of.

Introduction: Recurrent pregnancy loss (RPL) is defined as two or more pregnancy losses prior to 20 weeks from the last menstrual period. The medical evaluation of RPL is mainly focused on the maternal factors. However, paternally expressed genes may also play role in implantation and placenta quality. In addition, recent studies have revealed the role of miRNAs in RPL. The aim of the present study was to investigate the possible association between parental miR-499aT>C (rs3746444) polymorphism and RPL in Iranian couples.

Materials and methods: We conducted a case-control study of 366 Iranian people consisted of 166 couples with at least two unexplained consecutive pregnancy losses, 100 healthy men and 100 healthy women with at least one live birth and no history of pregnancy loss. Genotyping was performed using PCR-RFLP. Significant difference in distribution of miR-499a genotypes was found only in males from RPL cases in comparison to controls, with P-value of 0.0005 and odds ratio equal to 2.91 (95% CI: 1.58-5.33).

Conclusions: We provide evidence for association between genetic variation in paternal miR499aT>C polymorphism and recurrent pregnancy loss. Further studies will be required to validate the significance of the studied genetic variation in diverse ethnic populations.

E-P01.74

Frequency of sexually transmitted bacterial infections with *Neisseria gonorrhoeae*, *Ureaplasma urealyticum*, *Ureaplasma parvum* and *Gardnerella vaginalis* in spontaneous abortions

K. Slavova^{1,2}, T. Stoycheva², A. Alexeev¹, A. Todorova^{1,2}, V. Mitev¹,

¹Medical University Sofia, Sofia, Bulgaria, ²Genetic Medico-Diagnostic Laboratory Genica, Sofia, Bulgaria.

Gonorrhoeae, *Ureaplasma* and *Gardnerella* are among the most common sexually transmitted bacterial infections which lead to spontaneous abortion. The aim of our research was to monitor the frequency of these infections among spontaneous abortions in Bulgarian population.

For this reason we examined endometrial tissue derived from 100 patients using PCR technique. Patients were divided into two groups - 1) control group of 40 patients with voluntarily interrupted pregnancy and 2) target group of 60 patients with spontaneous abortion for unspecified reasons.

In one of spontaneous abortion cases (1.7%) we found *Ureaplasma parvum*. *Gardnerella vaginalis* was found in five of the patients with spontaneous abortion (8%) and eleven of the control group patients (27.5%). *Neisseria gonorrhoeae* and *Ureaplasma urealyticum* infections were not found. Current results demonstrate high frequency (10%) of several sexually transmitted bacterial infections in spontaneous abortion. More profound analysis of these results is needed by comparing with additional control group patients with successfully completed pregnancy, because of the high possibility of genital infections in this examined control group patients with voluntarily interrupted pregnancy.

The study of association between spontaneous abortions and sexually transmitted bacterial infections will help spontaneous abortion prevention using adequate treatment.

The financial support of Medical University Sofia, Bulgaria, Grant №5/2014 is gratefully acknowledged.

⁴Department of Pathology, Aalborg University Hospital, Aalborg, Denmark,

⁵Department of Gynecology and Obstetrics, Aalborg University Hospital, Aalborg, Denmark.

Introduction: Opitz syndrome was first described in 1969 and is characterized by a variable expression of midline defects. In 2015 the causative gene SPECC1L (22q11.2) of the autosomal dominant form of the condition was described. We report a novel missense mutation in SPECC1L in a family with ocular hypertelorism, bicornuate uterus and diaphragmatic hernia.

Material and Methods: The proband, a 28-year-old woman, presented with prominent ocular hypertelorism at birth. Chromosome analysis revealed a normal 46,XX karyotype. She developed normally and was not genetically nor clinically diagnosed until she was referred to genetic counselling after having undergone termination of pregnancy due to fetal diaphragmatic hernia. Additionally, the fetus had a bicornuate uterus; a feature that was also reported in the proband herself. Before the diagnosis was established, the proband was pregnant again. Ultrasound examination and subsequent fetal autopsy revealed a phenotype similar to that of the first fetus. Chromosomal microarray and sequencing of MID1 (X-linked Opitz syndrome) was performed as SPECC1L analysis was not offered in a clinical setting. Further diagnostics proceeded with hotspot Sanger sequencing of SPECC1L on a research basis.

Results: A novel de novo missense mutation in SPECC1L, c.1258G>A, was found in the proband and subsequently in the two fetuses.

Conclusion: This case demonstrates that a clinical diagnosis is paramount in the prenatal setting reducing turnaround time as a targeted analysis strategy can be applied. The bicornuate uterus and diaphragmatic hernia reported in this family broaden the spectrum of phenotypic features in Opitz and SPECC1L hypertelorism syndromes.

E-P01.76

The study of STAG3 gene mutations and Y chromosome microdeletions in Iranian patients with non-obstructive azoospermia

S. Pouriamanesh, Z. Kamalian, M. Amin-Beidokhti, R. Mirfakhraie;

Shahid Beheshti University of Medical Sciences, Tehran, Iran, Islamic Republic of.

Introduction: Azoospermia is defined as complete absence of sperm from ejaculate and approximately occurs in 10-15 percent of infertile men with abnormal semen analysis. Genetic factors including microdeletions in the Y chromosome and single gene mutations are contributed to non-obstructive azoospermia. Recently, genome-wide association studies have identified the STAG3 gene as a strong candidate gene for human male infertility. The aim of this study was to investigate the incidence of AZF deletions and mutation analysis of the Stag3 gene among Iranian infertile men with idiopathic non-obstructive azoospermia.

Materials and methods: A total of 122 Iranian azoospermic infertile men were selected. The presence of 11 sequence tagged site (STS) markers from

AZF region including sY81, sY84 and sY86 for AZFa; sY121, sY124, sY127 and sY134 for AZFb; and sY242, sY239, sY254 and sY255 for AZFc were investigated using multiplex polymerase chain reaction (M-PCR). Existence of possible mutations in exon 7 of Stag3 gene was also investigated using multitemperature single strand conformation polymorphism (MSSCP) method. One hundred fertile men were also studied as control group.

Results: Thirteen (10.66%) patients showed Y chromosome microdeletions and among these, deletion in AZFc region was the most frequent. However, no mutation was detected in the Stag domain coded by exon 7 of the STAG3 gene.

Conclusion: According to the results, in the studied population, the main causing factor in developing azoospermia was Y chromosome microdeletions. Therefore, we did not suggest STAG3 gene as a strong candidate gene in non-obstructive azoospermia.

The case of der(5)t(5;14)mat caused by adjacent I meiotic segregation in prenatal diagnosis

D. Yuksele¹, O. Izci Ay¹, E. M. Ay¹, O. Tezoz², G. Dogru¹, K. Cevik¹, U. Karakas¹, F. Cayan³, I. Buran¹, E. M. Erdal¹;

¹Mersin University, Faculty of Medicine, Department of Medical Biology, Mersin, Turkey, ²Mersin University, Faculty of Medicine, Pediatrics Clinic, Mersin, Turkey, ³Mersin University, Faculty of Medicine, Department of Gynecology and Obstetrics, Mersin, Turkey.

Introduction: Genetic material exchange between homologous chromosomes occurs in somatic and germ cells. This type of exchanges in certain cases may occur in non-allelic chromosomal regions resulting in structural chromosomal anomalies in form of translocations. Translocations are categorized in two general types namely balanced and unbalanced. Balanced reciprocal translocations can risk the pregnancy as it may produce unbalanced gametes.

Materials and Methods: The amniotic fluid (20ml) belonged to a 27 years old female patient in 18th week of her pregnancy who was admitted to the Polyclinic of Gynecology and Obstetrics at Faculty of Medicine in Mersin University was sent to laboratory for cytogenetic analysis. Parents were not consanguinity. Amniotic material was processed using the in-situ culture method and GTG banding technique. 39 metaphase plates (20 colonies) were obtained and cytogenetic analyses performed on these plates.

Results: As a result of the cytogenetic analysis, the fetus was determined to be 46,XX,der(5)t(5;14)(p13;p11)mat karyotype. The cytogenetic analysis that was performed on peripheral blood samples taken from the parents showed that the finding was not de novo but of maternal origin.

Conclusions: Incidence of reciprocal translocations in the amniocentesis is 0.06%. Balanced reciprocal translocations do not change the amount of chromosomes and genetic materials. However they may cause unbalanced chromosomal rearrangement in the gametes of these carriers. Although the reciprocal translocation in our case is unbalanced. Upon family's request, the pregnancy was sustained. The 28-month case with Cri du Chat symptoms are being monitored by the Department of Pediatrics, Mersin University Faculty of Medicine.

Novel mutation in the CHST6 gene causes macular corneal dystrophy in a black South African family

N. Carstens¹, S. Williams², T. Carmichael², M. Cheung³, S. Büchmann-Møller², M. Sultan², F. Staedtler², C. Zou⁴, P. Swart⁵, D. S. Rice⁵, A. Lacoste⁵, K. Paes⁵, M. Ramsay¹;

¹Sydney Brenner Institute for Molecular Bioscience, University of the Witwatersrand, Johannesburg, South Africa, ²Division of Ophthalmology, Department of Neurosciences, University of the Witwatersrand, Johannesburg, South Africa, ³Biomarker Development, Novartis Institutes for BioMedical Research, Basel, Switzerland, ⁴Center for Proteomic Chemistry, Novartis Institutes for BioMedical Research, Basel, Switzerland, ⁵Novartis Institutes for Biomedical Research, Cambridge, MA, United States.

Macular corneal dystrophy (MCD) is a rare autosomal recessive disorder that is characterized by progressive corneal opacity that starts in early childhood and ultimately progresses to blindness in early adulthood. The aim of this study was to identify the cause of type I MCD in a black South African Sotho-speaking family with two affected sisters using whole exome sequencing. Variant filtering to identify the MCD-causal mutation included the inheritance pattern, variant minor allele frequency and potential functional impact. Ophthalmologic evaluation of the cases revealed a typical MCD phenotype and none of the other family members were affected. Variant filtering identified a homozygous E71Q mutation in CHST6, a previously identified MCD-causing gene encoding corneal N-acetyl glucosamine-6-O-

sulfotransferase, as the MCD-causal mutation in this family. This E71Q mutation results in a non-conservative amino acid change in a highly conserved functional domain of the human CHST6 that is essential for enzyme activity. This is the first description of MCD in a black Sub-Saharan African family and therefore contributes valuable insights into the genetic aetiology of this disease, while improving genetic counselling for this and potentially other MCD families.

E-P02.02

A novel FOXC1 mutation in an Axenfeld-Rieger patient with childhood glaucoma

S. Carmona^{1,2}, M. Freitas³, H. Froufe¹, M. Simões¹, M. Sampaio⁴, E. Silva⁵, C. Egas^{1,6};
¹Next-Gen Sequencing Unit, UC-Biotech, Cantanhede, Portugal, ²Faculty of Medicine, University of Coimbra, Coimbra, Portugal, ³Department of Ophthalmology, Hospital da Arrábida, Porto, Portugal, ⁴Department of Paediatric, Hospital CUF, Porto, Portugal, ⁵Vision Psychophysiology Unit, Faculty of Medicine, University of Coimbra, Coimbra, Portugal, ⁶Center for Neuroscience and Cell Biology, University of Coimbra, Coimbra, Portugal.

Axenfeld-Rieger syndrome (ARS) is a rare dominant, autosomal developmental disorder characterized by anterior segment abnormalities of the eye. Posterior embryotoxon with iridocorneal adhesions are always present and iris stromal thinning or atrophy, corectopia, iris holes and iris ectropion are common. Approximately half of the ARS patients develop glaucoma. Systemic anomalies like craniofacial anomalies and cardiovascular can also be present. Mutations and CNV in FOXC1 and PITX2 have been previously reported in ARS patients.

A DNA sample of a 14-month-old male with bilateral glaucoma, posterior embryotoxon with extension of the peripheral iris to Schwalbe's line, short stature, hypertelorism, frontal prominence, broad flat nasal root, maxillary hypoplasia and unilateral testicular atrophy was sequenced for the whole exome with the Ion Proton sequencer. Rare variants with functional impact were selected to identify the disease-causing variant. Sanger sequencing was performed to validate the mutation in the patient and to study the parents.

A novel heterozygous nonsense variant Y64X (c.192 C>G) was found in the FOXC1 gene. This de novo mutation leads to the loss of 88.6% of the protein, including the functional FHD domain.

The presence of de novo FOXC1 mutation confirms the ARS diagnosis. This result is consonant with previous studies that report a positive association between FOXC1 mutations and ARS patients with glaucoma. Further studies will be needed to understand the pathogenic mechanism of this mutation.

S. Carmona was supported by a doctoral fellowship from Fundação para a Ciência e Tecnologia (SFRH/BD/90445/2012), Programa Operacional Potencial Humano / Fundo Social Europeu (POPH/FSE).

Novel BMP4 mutation causing coloboma in a Jewish Ashkenazi kindred

Y. Yogeve¹, O. Wormser¹, D. Halperin¹, Y. Perez¹, M. Volordarsky¹, L. Gradstein², O. S. Birk^{2,1};
¹Morris Kahn Laboratory of Human Genetics, National Institute for Biotechnology in the Negev (NIBN), Ben-Gurion University of the Negev, Be'er Sheva, Israel, ²Department of Ophthalmology, Soroka University Medical Center, Be'er Sheva, Israel, ³Institute of Genetics, Soroka University Medical Center, Be'er Sheva, Israel.

An Israeli family of Jewish Ashkenazi descent presented with a phenotype of bilateral coloboma affecting several generations in an apparent dominant mode of inheritance. Whole exome sequencing data of an affected individual were analyzed and filtered for known benign variants using our in-house databases along with open access databases (1000 genomes, NHLBI ESP, ExAC etc.). The analysis yielded several candidate variants in genes which were previously associated with various ocular disorders. Candidate variants were further analyzed using Sanger sequencing and restriction analysis. Only a single heterozygous c.392A>G missense mutation in BMP4, resulting in a p.H121R substitution, showed full segregation within the family and was not found in 100 healthy Ashkenazi controls. In-silico analysis of the novel p.H121R variant showed that it is likely to have a deleterious effect on the mature protein. Mutations in BMP4 were previously described as causative for various conditions such as anophthalmia-microphthalmia, coloboma, retinal dystrophy, myopia, cleft lip, cleft palate and brain-digital abnormalities. Our data suggest that the novel BMP4 heterozygous mutation is the cause for the dominantly inherited isolated coloboma in this kindred, possibly through a dominant negative effect, in line with the known function of BMP4 as a homodimer.

Whole exome sequencing of the Yakut family from Eastern Siberia with congenital autosomal-recessive cataract: the novel nonsense mutation in the FYCO1 gene

N. A. Barashkov^{1,2}, F. A. Konovalov^{3,4}, F. M. Teryutin^{1,2}, A. V. Solovyev^{1,2}, V. G. Pshennikova^{1,2}, G. P. Romanov^{1,2}, N. N. Gotovtsev¹, I. V. Morozov^{5,6}, A. A. Bondar⁵, L. U. Dzhemileva^{7,8}, E. K. Khusnutdinova^{7,9}, A. N. Alexeev¹⁰, M. I. Tomsky⁴, O. L. Posukh^{6,11}, S. A. Fedorova^{2,1};

¹Yakut Scientific Centre of Complex Medical Problems, Siberian Branch of the Russian Academy of Medical Sciences, Yakutsk, Russian Federation, ²M.K. Ammosov North-Eastern Federal University, Yakutsk, Russian Federation, ³Federal State Budgetary Institution „Research Centre for Medical Genetics“, Moscow, Russian Federation, ⁴Genomed Ltd., Moscow, Russian Federation, ⁵Institute of Chemical Biology and Fundamental Medicine of Siberian Branch of the Russian Academy of Sciences, Novosibirsk, Russian Federation, ⁶Novosibirsk State University, Novosibirsk, Russian Federation, ⁷Institute of Biochemistry and Genetics of Ufa Scientific Centre, Ufa, Russian Federation, ⁸Bashkir State Medical University, Ufa, Russian Federation, ⁹Bashkir State University, Ufa, Russian Federation, ¹⁰Institute of Humanitarian Research and Indigenous Peoples of the North, Siberian Branch of the Russian Academy of Sciences, Yakutsk, Russian Federation, ¹¹Federal Research Center Institute of Cytology and Genetics, Novosibirsk, Russian Federation.

Congenital cataracts are a major cause of vision loss in children worldwide. Autosomal -recessive congenital cataracts form a clinically diverse and genetically heterogeneous group of the crystalline lens - disorders. To identify the genetic cause of congenital nuclear cataract in Yakut family with three affected siblings from isolate Yakut population in Eastern Siberia (Sakha Republic, Russia) we performed whole exome sequencing on Illumina NextSeq 500 in one proband. For the first time, we have revealed homozygous c.1621C>T (chr3:46009205G>A) transition in previously known in association with congenital cataract gene FYCO1 (3p21.31). Detected mutation is not reported in the „1000 Genomes“, the ESP6500, and the ExAC projects. The c.1621C>T transition leads to premature stop-codon formation (p.Gln541Ter, NM_024513.3) in exon 8 of FYCO1 gene. The c.1621C>T (p.Gln541Ter) mutation was found in homozygous state in one patient with congenital cataract (CTRCT18, OMIM: 610019) from family with three affected siblings whose mother and father have a normal vision. This finding confirms autosomal recessive pattern of cataract inheritance in examined Yakut family. Hence, by analogy of founder effect in prevalence of rare orphaned diseases described in Yakut population isolate such as SCA1 (OMIM 164400), methemoglobinemia (OMIM 250800), DM1 (OMIM 160900), three M syndrome 3 (OMIM 273750), OPMD (OMIM 164300) and DFNB1A (OMIM 220290) we suggest that this mutation in homozygous state is one of the major causes of congenital cataract in patients from Eastern Siberia. Study was supported by Ministry of Education and Science of the Russian Federation #6.656.2014/K and Sakha Republic Government project “Yakutian history”.

E-P02.05

Whole exome sequencing detects a probable novel mutation in the cluster of crystallin genes in a Mexican family with autosomal dominant congenital cataract

O. Messina-Baas¹, L. Gonzalez-Huerta², J. Toral-Lopez², S. Cuevas-Covarrubias⁴; ¹Oftalmologia, Hospital General de Mexico, Mexico DF, Mexico, ²Genetica, Hospital General de Mexico, Mexico DF, Mexico, ³Ecatepec Medical Center, Edomex, Mexico, ⁴Genetica, Facultad de Medicina, Hospital General de Mexico, Universidad Nacional Autonoma de Mexico, Mexico DF, Mexico.

Introduction: Autosomal dominant congenital cataract (ADCC) is a clinically and genetically heterogeneous disease with high penetrance. ADCC represents around 10% of a treatable cause of childhood blindness. More than 30 loci have been associated to ADCC. Gamma crystallin genes are a family of 6 genes (4 CRYBA and 2 CRYBB) located on several chromosomes, this family of genes is associated to congenital cataract. The aim of the present study is to describe a Mexican family affected with ADCC and clinical diversity in three generations through whole exome sequencing (WES). Material and methods: Genomic DNA was analyzed through WES and DNA sequencing. Results: we detected a dominant CRYGA gene defect in exon 2 that produced the p.N18I change. This transversion mutation (c.53A>T) only co-segregated in the affected members of the family and was not found in non-affected members and in 100 normal controls. Bioinformatic analysis detected this mutation as deleterious. This missense mutation has not been previously reported; nevertheless more studies are necessary to confirm this type of mutations as deleterious. This is the first Mexican family ADCC with this mutation. WES is a powerful tool for the detection of genetic origins of cataracts due to genetic and clinical heterogeneity in this type of disease. Grant DGA-PA/PAPIIT/UNAM Proyect IN204114-2.

E-P02.07

Identification of a digenic inheritance in three Mexican families with hearing impairment using whole exome sequencing

M. Martinez-Saucedo¹, M. Rivera-Vega¹, L. Gonzalez-Huerta¹, H. Urueta-Cuellar¹, P. Berruecos-Vilalobos², M. Arenas-Sordo³, S. Cuevas-Covarrubias⁴; ¹Genetica, Hospital General de Mexico, Mexico DF, Mexico, ²Audiologia y Foniatria, Hospital General de Mexico, Mexico DF, Mexico, ³Genetica, Instituto Nacional de Rehabilitación, Mexico DF, Mexico, ⁴Genetica, Facultad de Medicina, Hospital General de Mexico, Universidad Nacional Autonoma de Mexico, Mexico DF, Mexico.

Background: Sensorineural hearing loss (SNHL) is a clinically and genetically heterogeneous disease. In some populations, mutations in the GJB2 gene represents the most frequent cause of hereditary SNHL. The great diversity of mutations in the GJB2 gene worldwide highlights the participation of ethnic background in SNHL. It is considered that 200 to 250 genes are involved in SNHL. Recently, more than 80 genes, around 1000 mutations, and 140 loci have been associated with SNHL (<http://hereditaryhearingloss.org/>). Improvement of the technology plays an important role in the diagnosis of different pathologies, whole exome sequencing (WES) represents an important tool in the identification of the genetic etiology in individuals with SNHL. Objective: To describe the presence of digenic inheritance in three families with SNHL involving the GJB2, MYO1C, OTOA and OTOG genes in a Mexican family with SNHL. Materials and methods: Three Mexican families with SNHL were included in the study. Analysis through WES and DNA direct sequencing analysis in all members of the family and in 100 normal controls Results: Affected sibs showed the digenic inheritance involving OTOA (p.E787X), GJB2 (c.365delG), MYO1C p.E831K and OTOG (p.T1235P) genes. Parents and non-affected members of the families were heterozygous for the molecular defect, all of them with normal audition. Conclusion: We describe three families through WES analysis with SNHL due to digenic inheritance; this enriches the mutational spectrum in Mexican population in patients with SNHL. Grant DGAPA/PAPIIT/UNAM Proyect IN204114-2.

Fuchs endothelial corneal dystrophy: strong association with rs613872 not paralleled by changes in corneal endothelial TCF4 mRNA level

D. Ozieblo¹, E. Ruszkowska¹, M. Udziela², E. Binczyk², A. Scieczynska³, R. Ploski⁴, J. P. Szaflik¹, M. Oldak^{1,3};

¹Department of Genetics, Institute of Physiology and Pathology of Hearing, Warsaw, Poland, ²Department of Ophthalmology, Medical University of Warsaw, Warsaw, Poland, ³Department of Histology and Embryology, Medical University of Warsaw, Warsaw, Poland, ⁴Department of Medical Genetics, Medical University of Warsaw, Warsaw, Poland.

Fuchs endothelial corneal dystrophy (FECD) is a common corneal endotheliopathy with a complex and heterogeneous genetic background. Different variants in the TCF4 gene have been strongly associated with the development of FECD. TCF4 encodes the E2-2 transcription factor but the link between the strong susceptibility locus and disease mechanism remains elusive. Here, we confirm a strong positive association between TCF4 single nucleotide polymorphism rs613872 and FECD in Polish patients (OR = 12.95, 95% CI: 8.63-19.42, $\chi^2 = 189.5$, $p < 0.0001$). We show that TCF4 expression at the mRNA level in corneal endothelium (n = 63) does not differ significantly between individuals with a particular TCF4 genotype. It is also not altered in FECD patients as compared to control samples. The data suggest that changes in the transcript level containing constitutive TCF4 exon encoding the amino-terminal part of the protein seem not to contribute to disease pathogenesis. However, considering the strong association of TCF4 allelic variants with FECD, genotyping of TCF4 risk alleles may be important in the clinical practice.

This work was supported by the Medical University of Warsaw Grants 1M15/NM4/2011, 1M15/N/2015, and 2WF/N/2015 and the project entitled “Integrated System of Tools Designed for Diagnostics and Telerehabilitation of the Sense Organs Disorders (Hearing, Vision, Speech, Balance, Taste, Smell)” INNOSENSE, cofinanced by the National Centre for Research and Development within the STRATEGMED Program.

Genetic analysis of rare non-syndromic prelingual hearing disorders

R. Birkenhäger, C. Heinemann, S. Arndt, A. Aschendorff, R. Laszig; Department of Otorhinolaryngology, Head and Neck Surgery, University Medical Center Freiburg, Freiburg, Germany.

Introduction: Approximately 1-3 / 1000 newborns are affected at birth or in the first two years of a profound hearing impairment, 60% of these cases are due to genetic causes. So far, 103 loci and 59 genes have been identified for this type of hearing loss. Genetic alterations in DFNB1 locus in which the genes GJB2 (connexin 26) and GJB6 (connexin 30) are located, are the main

cause of prelingual non-syndromic hearing loss. Objective of the project is to analyze, which other genes are involved in prelingual hearing disorders, in addition to the genes GJB2 and GJB6.

Material and Methods: In this project, so far 155 patients were included; a serious non-syndromic hearing impairment was diagnosed until the age of 2 years, also there were demonstrably no inner ear malformations and no alterations in the DFNB1 locus. The detection of genetic changes was carried out by bi-directional sanger sequencing of the coding exons, and intron transitions.

Results: First, the genes GRXCR1 and TPRN were in this patient population analyzed, and additionally the genes ESRRB, CIB2 and ILDR1. By DNA sequencing 3 novel mutations, 8 unknown polymorphisms and 22 known variations were detected.

Conclusions: The genetic analysis illustrated a few functionally relevant mutations in the genes GRXCR1 and TPRN, and additionally some unknown polymorphisms, an accumulation of changes in the analyzed genes is not present. Therefore further studies are required for the characterization of the etiology of rare genetic hearing disorders.

E-P02.16

Genetics of ion homeostasis in Ménière's Disease

L. Zagato¹, S. Delli Carpini², C. Lanzani¹, N. Casamassima¹, C. Cassandro², R. Albera², M. Bussi¹, P. Manunta^{3,4}, R. Teggi¹;

¹San Raffaele Scientific Institute, Milano, Italy, ²Surgical Sciences Department, University of Torino, Torino, Italy, ³Università Vita-Salute San Raffaele, Milano, Italy.

Background and aims: Ménière's Disease (MD) is an inner ear disorder characterized by episodic vertigo, fluctuating sensorineural hearing loss and aural fullness. It may arise from the interplay of genetic and environmental factors. To date the genetic investigation didn't produce conclusive results. Our previous work suggested a role for alpha-Adducin, a cytoskeletal protein regulating the Na⁺-K⁺ pump activity, in MD patients. Since ionic homeostasis in the inner ear is crucial for the maintenance of endocochlear potential, in this work we studied the variants of genes involved in the regulation of ionic transport.

Materials and methods: 155 patients with definite MD were enrolled and accurately phenotyped. 137 control subjects without a lifetime history of vertigo were included. 36 SNPs located in 25 genes involved in ionic transport have been selected from a panel of polymorphisms associated to essential hypertension. Correction for multiple comparison tests has been performed applying a false discovery rate of 10%. Logistic regression analysis has been implemented to compute odds ratio, genetic interactions and genetic score effect.

Results: Four SNPs in 3 genes (SLC8A1, CYP11B2 and SIK1) displayed a significant difference in allelic and genotypic frequency ($p=0.01/0.006$; $p=0.028/0.009$; $p=0.009/0.016$ and $p=0.024/0.01$) in MD patients compared to controls. The presence of all four risk variants increases by 5 times the odds of developing MD. CYP11B interacts with SIK1 ($p=0.002$, OR=1.87).

Conclusions: genetic alterations of ionic transporters may act as a predisposing factor to develop MD. Further studies on other cohorts may validate these new candidate genes for MD.

E-P02.17

Ophthalmological phenotype associated with homozygous null mutation in the NEUROD1 gene

O. Orosz¹, M. Czeglédi², I. Kántor², I. Balogh³, A. Vajás¹, L. Takács¹, A. Berta¹, G. Losonczy¹;

¹Department of Ophthalmology, University of Debrecen, Debrecen, Hungary,

²Department of Ophthalmology, Jósza András Hospital, Nyíregyháza, Hungary, ³Division of Clinical Genetics, University of Debrecen, Debrecen, Hungary.

Introduction: NEUROD1 is a basic helix-loop-helix protein involved in the development and maintenance of the endocrine pancreas and neuronal elements. Loss of NEUROD1 causes ataxia, cerebellar hypoplasia, sensorineural deafness and retinal dystrophy in mice. Heterozygous loss-of-function mutations in NEUROD1 have previously been described as a cause of maturity-onset diabetes of the young (MODY). Homozygous NEUROD1 mutations have only been detected in three patients causing permanent neonatal diabetes, neurological defects, including visual impairment. Our aim was to characterize the ophthalmological phenotype associating to the previously reported homozygous c.427_428delCT NEUROD1 mutation.

Materials and Methods: The female patient was investigated on multiple occasions for 6 years, including visual acuity testing, automated perimetry, funduscopy, anterior-segment imaging, optical-coherence tomography of the posterior pole, standard full-field electroretinography, and fundus-autofluorescence imaging.

Results: The patient suffered from nyctalopia, blurry vision, visual-field con-

striction from childhood. Her best corrected visual acuity ranged between 20/25 and 15/25. Perimetry showed concentric constriction in both eyes. Optical-coherence tomography revealed total absence of the photoreceptor layer of the retina outside the fovea, where a discoid remnant of cone photoreceptors could be detected. The standard full-field electroretinography could not detect electrical response from the retina. Color fundus photos presented peripheral chorioretinal atrophy and central RPE mottling. A hyperreflective parafoveal ring was detected on fundus autofluorescent photos.

Conclusions: Loss of NEUROD1 has similar functional and anatomical consequences in the human retina as are described in mice. The present description can help the diagnosis of future cases and provide clues on the rate of disease progression.

E-P02.18

Population frequencies of 35delG mutation in GJB2 gene in main ethnic groups of Karachay-Cherkess Republic

N. E. Petrina¹, A. K. Makaov², N. V. Petrova¹, T. A. Vasilyeva¹, A. N. Petrin^{3,4}, E. K. Ginter¹, R. A. Zinchenko^{1,4};

¹Federal state scientific budgetary Institution «Research Centre for Medical Genetics», Moscow, Russian Federation, ²Municipal Budgetary Health Care setting „Habezkaya central district hospital“, Chabez, Russian Federation, ³Moscow State University of Medicine and Dentistry, Moscow, Russian Federation, ⁴Pirogov Russian National Research Medical University, Moscow, Russian Federation.

Introduction: Hearing loss is one of the most common human diseases. The frequency of hearing loss is 1:1000-2000 newborns. About 50% of congenital deafness is caused by hereditary factors. More than 100 loci associated with hereditary nonsyndromic deafness (HND) have been mapped, among which the most has AR type of inheritance. More than half of all cases of early-onset HND in European populations is due to a 35delG mutation in the GJB2 gene. However, 35delG frequency varies in populations and ethnic groups.

Materials and Methods: 766 healthy individuals of the main ethnic groups of Karachay-Cherkessia were screened for 35delG mutation in the GJB2 gene (Karachays (N = 370), Cherkessians (N = 102), Russians (N = 35), Abazyns (N = 137), Nogays (N = 122)).

Results: Population frequencies of 35delG mutation in Russians is 0.0143 (heterozygous carrier rate 1:35), in Karachays - 0.00135 (1:370), in Cherkessians - 0.0098 (1:51), in Abaza - 0.0145 (1:34), in Nogays - 0.0041 (1:122).

Conclusion: These differences result from origins and ethnogenesis of the peoples. Karachays belong to Caucasian anthropological type of the Balkan-Caucasian race. They speak Karachai-Balkar language of Kipchak group of Turkic family. Nogays are much younger, time of its formation refers to the end of the XIV century. They are Turkified tribes of Mongol branch; speak one of the Turkic languages. Circassians and Abaza are Abkhaz-Adyghe peoples; speaking Adyghe languages of Abkhaz-Adyghe language group. This work was partially funded by RFBR grants 14-04-00525, 15-04-01859.

Oculocerebrorenal syndrome in children

O. Marginean^{1,2}, T. Marcovici^{1,2}, D. Nicoara², G. Brad^{1,2}, O. Belei^{1,2}, N. Mang¹, S. Maruntelu², M. Puiu^{1,2};

¹University of Medicine and Pharmacy „Victor Babes“, Timisoara, Romania, ²„Louis Turcanu“ Children's Emergency Hospital, Timisoara, Romania.

Introduction: Oculocerebrorenal syndrome (Lowe syndrome) is caused by mutations in the OCRL-1 gene. It is a rare recessive X-linked disorder (1:500,000 people) characterized by eye, kidney and neurological impairment. Males are mostly affected. Cataracts and glaucoma are characteristic ocular findings in these patients and visual acuity may be impaired. Children with Lowe syndrome have delayed development, behavioral problems, feeding difficulties. The progressive kidney dysfunction can lead to chronic renal failure. Polyuria, dehydration, metabolic acidosis, electrolyte imbalance and osteopenia are present.

Material and Methods: We present a five years old boy with delayed development, protein-energy malnutrition, severe vitamin D deficiency and femur fracture. The case was evaluated by means of anamnesis, physical examination, paraclinical tests (imaging, functional, biology) and interdisciplinary check-ups.

Results: The patient exhibits typical facial appearance (elongated face, deep-set small eyes, frontal bossing), failure to thrive (BMI =12, below the 5th percentile for age and sex), congenital cataracts, corneal keloids, delayed motor and mental development, weak muscle tone, and self-injurious behavior. Proteinuria, aminoaciduria and albuminuria reveal renal tubular damage. Diagnosis of osteopenia was set by the presence of femoral fracture, severe vitamin D deficiency and confirmed through osteodensitometry.

Conclusions. The diagnosis was based on the particular phenotype association with biological abnormalities characteristic of the Lowe syndrome. Interdisciplinary management of the case is mandatory. Vital prognosis depends on the preservation of renal function.

E-P02.21

Technically difficult, diagnostically important - exon ORF15 of the RPGR gene in retinitis pigmentosa

M. Oldak¹, E. Ruszkowska¹, S. Siwiec², A. Pollak¹, P. Stawiński¹, K. Szulborski², J. P. Szaflik²,
¹Department of Genetics, Institute of Physiology and Pathology of Hearing, Warsaw, Poland, ²Department of Histology and Embryology, Medical University of Warsaw, Warsaw, Poland, Warsaw, Poland, ³Department of Ophthalmology, Medical University of Warsaw, Warsaw, Poland, Warsaw, Poland.

The aim of the study was to identify the genetic background of retinitis pigmentosa (RP) in a Polish family with previously excluded involvement of the majority of known RP genes except for the ORF15 exon in the RPGR gene (Xp21.1). ORF15 is a highly repetitive, purine-rich DNA region with a number of different polymorphic variants and thus difficult to study. Genomic DNA was isolated from peripheral blood of the family members (n = 9). Exon ORF15 was amplified in a long-range polymerase chain reaction (PCR) and sequenced using the new generation method (NGS). Presence of the identified variant was confirmed by direct Sanger sequencing of the amplicon encompassing the mutation. In the ORF15 region NM_001034853:c.2899delG (p.E967Kfs*122) mutation was detected. It completely segregated with the disease in the studied family. The identified change is pathogenic and has already been found to cause RP. It is estimated that more than a half of RPGR mutations is located in the ORF15 region. In families with a suspected X-linked inheritance of RP and in males with a negative family history of RP genetic tests should begin with analysis of ORF15.

This work was supported by the Medical University of Warsaw Grant 1M15/N/2015 and the project entitled "Integrated System of Tools Designed for Diagnostics and Telerehabilitation of the Sense Organs Disorders (Hearing, Vision, Speech, Balance, Taste, Smell)" INNOSENSE, cofinanced by the National Centre for Research and Development within the STRATEG-MED Program.

E-P02.22

GJB2 susceptibility mutations in a group of Romanian children with non-syndromic hearing loss

C. Strugaru¹, A. Brinzan², R. Ursu¹, C. Popa², R. Bohiltea³, L. Bohiltea⁴,
¹Department of Genetics, Bucharest, Romania, ²Department of Pediatrics, Bucharest, Romania, ³"Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania, ⁴Department of Genetics, "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania.

Background and aims: Sensorineural hearing loss (SNHL) is a multifaceted condition with profound medical, social, and cultural ramifications. For children born with moderate to profound hearing impairment, particularly in families in which there is no previous history of deafness, the diagnosis has a major impact on that family.

Objectives: Testing for mutations in GJB2, the gene for connexin 26 (Cx26), can account for up to 60% of prelingual nonsyndromic hearing impairment, is commercially available, and many more deafness-related genetic tests undoubtedly will follow in the near future.

Methods: In our study, we performed mutation screening for GJB2 in 42 non-syndromic hearing loss families, including those with cases of sporadic deafness. Peripheral blood lymphocyte DNA was used to amplify by polymerase chain reaction the Cx26 coding region, followed by 35delG mutation detection screening and complete sequencing. For DNA extraction we used QIAamp DNA Blood (QIAGEN), and PCR fragments were sequenced using the forward primer and the ABI BigDye Terminator v3.1 Cycle Sequencing Kit.

Results: The most frequent mutation was 35delG, followed by 167delT. In our study, we identified other mutations such: R32C, I20T, S19T and a compound heterozygous mutation 35delG/ R127H. However, a large fraction - 68% have only one mutant allele.

Conclusions: The high frequency of the 35delG mutation indicated its screening, regardless severity of hearing impairment or familial history. On the other hand, these results highlight the usefulness of 35delG mutation screening for genetic counseling and suggest the importance of entire sequencing of the gene responsible for DNFB1.

E-P02.23

Identification by next generation sequencing of novel compound heterozygous mutations in the CDH23 gene

F. Cesca¹, E. Bettella¹, R. Polli¹, E. Leonard¹, B. Sicilian², D. Croatto², A. Murgia¹,
¹Laboratory of Molecular Genetics of Neurodevelopment, Department of Women's and Children's Health, University of Padova, Padova, Italy, ²Medical Center of Phoniatrics, Casa di Cura Trieste, Padua, Italy, Padova, Italy.

Hereditary sensorineural Non-Syndromic Hearing Loss (NSHL) is characterized by clinically indistinguishable phenotypes and genetic heterogeneity that up until recently have hampered effective early aetiological diagnosis. Next Generation Sequencing (NGS) technologies offer unprecedented diagnostic capacities and hold the promise of a significant expansion in knowledge on the pathogenic role of many disease-genes.

The CDH23 gene (NM_022124) encodes a calcium dependent cell-cell adhesion glycoprotein, involved in stereocilia organization and hair bundle formation; its mutations, initially described as associated with Usher syndrome type 1D, are also responsible of autosomal recessive non-syndromic hearing loss.

By NGS strategy on Ion Torrent PGM platform, we have developed a multigenic NSHL panel which is integral in our NSHL molecular diagnostic pipeline. This NGS approach has led to the identification of two CDH23 mutations in two sisters, aged 16 and 11, affected with congenital profound sensorineural non-syndromic hearing loss. No retinal alterations are present. The two girls had previously been found to carry a pathogenic GJB2 sequence variant.

The novel CDH23 variants: a missense mutation, c.6530C>A (p.P2177H), predicted as damaging by consent of in silico tools, and a splice-site mutation c.8966-1G>C, were both Sanger validated. Compound heterozygosity in the sisters was confirmed by mutation analysis in the normal hearing parents, who were found to be heterozygotes.

Our report, which describes two novel CDH23 mutations, provides evidence of the fact that truncating mutations of this gene, frequently found in Usher syndrome patients, may also be associated with non-syndromic sensorineural deafness.

E-P02.26

Targeted next generation sequencing identified a novel mutation in MYO7A causing Usher syndrome in an Iranian consanguineous pedigree

D. Kooshavar¹, M. Razipour¹, M. Entezam¹, A. Karamzade¹, M. Saberi¹, M. Keramatipour¹,
 Tehran University of Medical Sciences, Tehran, Iran, Islamic Republic of.

Introduction: Usher syndrome is mostly characterized by hearing impairment (HI) and adolescent-onset retinitis pigmentosa. It is categorized into two major types.

Materials and Methods: In this study a pedigree with two affected members were investigated. A 16 years old male with profound HI, rod-cone degeneration, and clinical diagnosis of Usher syndrome, result of a consanguineous marriage, was referred for genetic counseling/analysis. The proband had a one year old cousin, also result of a consanguineous marriage, with profound HI. Target region capturing of 13 Usher syndrome-related genes (CDH23, DFNB31, GPR98, MYO7A, PCDH15, USH1C, USH1G, USH2A, CLRN1, HARS, PDZD7, CIB2, and ABHD12) was performed followed by next generation sequencing (NGS).

Results: A novel homozygous variant in MYO7A gene was detected in the proband as NM_000260:c.4513G>T (p.Glu1505*). It was detected in homozygous state in the other affected member of the pedigree by Sanger sequencing. Segregation analysis was consistent with the AR pattern of inheritance. This variant was absent in population (1000G, ExAC, dbSNP) and disease-specific (ClinVar, OMIM, HGMD) databases, predicted to be disease-causing by multiple *in silico* predictive tools (mutation taster, SIFT, PolyPhen, CADD), and the substituted nucleotide was evolutionally well conserved (ConSurf, phyloP, phastCons).

Conclusions: Based on the ACMG standards and guidelines for interpretation of sequence variants, it is classified as a pathogenic variant. Although MYO7A is the most common gene causing Usher syndrome type1, NGS was able to detect this novel mutation. Therefore applying NGS in less investigated populations can still detect novel variants, even in well-studied genes for different disorders.

E-P03.01

Severe stage IV kidney disease in a child with ARID1B mutation : is there a link?

K. Dahan¹, S. Boulanger¹, X. Lolin², K. Ismaili², A. Destré¹;
¹Centre de Génétique IPG, Gosselies, Belgium, ²Service de Néphrologie Pédiatrique, HUYDERF, Bruxelles, Belgium.

Segmental renal infarction is a rare condition in children, resulting from small arteries occlusion and responsible for renovascular hypertension. We report an unusual case of stage IV chronic kidney disease (CKD) with arterial hypertension in a 13-year-old boy with non-syndromic intellectual disability and a splice-site mutation in ARID1B. Nonenhanced CT shows multiple small (and larger) areas of renal parenchymal scarring, coexisting with normal appearing kidney. The renal sonography was normal at age 3.5. The cause of CKD remains unknown but multiple arteries occlusions and chronic ischemia are suspected. In absence of hypercoagulable factors or renal artery injury, this unusual presentation raises the hypothesis of a relationship between ARID1b and segmental renal infarction. Note the ARID1B gene was first identified in 2001 as an overexpressed transcription factor in vascular smooth muscle cells in response to kidney vascular injury.

E-P03.09

Analysis of CYP21A2 gene mutations in patients from Ukraine with congenital adrenal hyperplasia

S. Chernushyn, L. Livshits;
 Institute of Molecular Biology and Genetics, Kiev, Ukraine.

Congenital adrenal hyperplasia (CAH) refers to a group of disorders that arise from defective steroidogenesis. CAH is an autosomal recessive disorder with an incidence about 1:15,000. Using the long-range PCR, RFLP and ARMS methods, we have studied, deletion/conversion of CYP21A2, 8 bp deletion in exon 3 and eight CYP21A2 point mutations in 33 Ukrainian patients with different clinical signs of CAH. Mutations P30L, cluster exon 6 were not found. The analyzed mutations were detected in 32 from 33 CAH patients. The most prevalent mutation was deletion/conversion of CYP21A2, determined in 25 mutant alleles (37.9%), IVS2-13 A/C>G in 10 mutant alleles (15.2%), Q318X in 6 mutant alleles (9.1%), V281L in 6 mutant alleles (9.1%), R356W in 2 mutant alleles (3.0%) and I172N in 2 mutant alleles (3.0%), E110Vfs in 2 mutant alleles (3.0%). In rest 13 alleles (19.7%) analyzed mutations were not detected. Interestingly, we observed higher Q318X frequency and lower I172N frequency in our population compared to the other European populations.

E-P03.10

Significant phenotype variability of congenital central hypoventilation syndrome (CCHS) in three-generation family with polyalanine expansion mutation of PHOX2b gene

E. Klásková¹, M. Prochazka², J. Drábek³, V. Curtisová², J. Hyjánek², V. Smolka¹;
¹Dpt. of Pediatrics, University Hospital and Medical Faculty of Palacky University, Olomouc, Czech Republic, ²Dpt. of Medical Genetics, University Hospital and Medical Faculty of Palacky University, Olomouc, Czech Republic, ³Institute of Molecular and Translational Medicine, University Hospital and Medical Faculty of Palacky University, Olomouc, Czech Republic.

Introduction: CCHS belongs to rare genetic disorders. It is characterized by hypoventilation secondary to absent responses to both hypercapnia and hypoxia being most pronounced during the sleep. CCHS has been shown to result from mutations in the PHOX2B gene located on chromosome 4p12.3. **Materials and Methods:** A rare familial case of CCHS caused by polyalanine expansion mutation of PHOX2B gene with significant phenotype variability in three generations. **Case 1:** A girl firstly admitted to the hospital with a history of severe cyanosis and respiratory failure related to pneumonia at six weeks of the age. Until four years of age, she was five times hospitalized because of respiratory failure in connection with respiratory tract infection. **Case 2:** a seemingly asymptomatic patient's father. Retrospectively we learned that he suffered from a severe headache and excessive daytime sleepiness. Both daughter and her father require overnight mechanical ventilatory support now. **Case 3:** Patient's grandmother who died after general anaesthesia at fifty years of age.

Results: Genetic testing revealed that the patient and her father are heterozygous for a polyalanine repeat expansion mutation of the PHOX2B gene (casual mutation c.741_755dup15 in exon 3 of PHOX2B). Considering

grandmother's history, she is highly suspected of having CCHS as well. **Conclusion:** Although most CCHS PHOX2B mutations occur de novo, autosomal dominant inheritance with incomplete penetrance has been proposed. The increased attention should be paid to seemingly asymptomatic relatives as they are at increased risk of complications associated with respiratory infections, general anaesthesia, and drugs known to depress ventilation.

E-P03.11

Characterization of inflammatory and apoptotic molecular markers of active Crohn's disease

B. Stankovic¹, N. Kotur¹, B. Zukic¹, S. Srzentic¹, K. Klaassen¹, S. Dragasevic², D. Popovic^{2,3}, A. Sokic-Milutinovic^{2,3}, S. Lukic^{2,3}, T. Alempijevic^{2,3}, T. Milosavljevic^{2,3}, G. Nikcevic¹, S. Pavlovic¹;
¹Institute of Molecular Genetics and Genetic Engineering, University of Belgrade, Belgrade, Serbia, ²Clinic for Gastroenterology and Hepatology, Clinical Center of Serbia, Belgrade, Serbia, ³Medical faculty, University of Belgrade, Belgrade, Serbia.

Intestinal mucosal damage in Crohn's disease (CD) patients occurs as a result of deregulation of inflammatory and apoptotic processes. Transcriptional factor NF-κB has a key role in transcription of genes that mediate these events. The aim of this study was to elucidate molecular patterns that underlie these processes.

We analyzed expression levels of proinflammatory *IL-6* and *TNF-α*, and apoptotic *Bcl-2*, *Bax*, *Fas* and *FasL* genes in intestinal mucosa and peripheral blood mononuclear cells (PBMC) of 24 patients with active CD and 21 controls, using qRT-PCR methodology. Among these participants, we selected 10 CD patients and 5 controls in order to conduct EMSA analysis of the DNA binding activity of NF-κB from the nuclear extracts of donors' intestinal mucosal samples.

Results showed that expression levels of *IL-6* and *TNF-α* were significantly increased, while expression level of *Bcl-2* was significantly decreased in ileal inflamed mucosa of CD patients. Our results also revealed that the expression level of *FasL* in PBMC of male CD patients was significantly decreased. The analysis of the DNA binding activity of NF-κB revealed an association of decreased level of NF-κB binding activity and increased expression level of *TNF-α* with intestinal mucosal fragility.

Our results demonstrated that expression profiles of selected proinflammatory and apoptotic genes, as well as the DNA binding activity status of NF-κB could be considered as molecular markers of active CD.

This work was funded by the Ministry of Education, Science and Technological Development, Republic of Serbia (grant no. III 41004) and by European Commission, EU-FP7-REGPOT-316088.

E-P03.12

Cys282Tyr, His63Asp and Ser65Cys mutations in the diagnosis of hereditary hemochromatosis type 1

S. Turyk, M. Sakurai, S. Bonsergent, M. Notaris, O. Rabinovich, N. Fernandez, J. Benavidez, K. Smith;
 Hospital Britanico de Buenos Aires, Buenos Aires, Argentina.

Hereditary hemochromatosis type 1 (HH) is an autosomal recessive disorder of iron metabolism. It is characterized by progressive iron overload and caused by mutation in the HFE gene on chromosome 6. The predominant feature of HH is excessive absorption of dietary iron and its deposition in parenchymal tissues and results in cirrhosis, diabetes, skin pigmentation and testicular failure. Prevalence is estimated at 1 in 200 to 1 in 2000.

26 HH patients (9 females and 17 males) and 72 healthy controls were screened for the Cys282Tyr, His63Asp and Ser65Cys, using polymerase chain reaction amplification of genomic DNA, followed by digestion with Rsa I and Bel-1. All patients had the following parameters: iron studies including serum Fe, ferritin and transferrin saturation, serology for hepatitis B and C, liver function tests and abdominal echography.

The mean age at genotype diagnosis was 55 years in males and 52.8 years in females. 23 from 26 (88.46%) HH patients were homozygous for Cys 282Tyr mutation. Two (7.7%) were compound heterozygous for Cys 282Tyr/His63Asp and one (3.84%) was for Cys282Tyr/Ser65Cys. Five (6.9%) of our controls were heterozygous for Cys282Tyr and one (1.3%) was heterozygous for His63Asp.

Hereditary hemochromatosis type 1 is an underdiagnosed disorder. The most frequent form is associated with homozygosity of the Cys282Tyr mutation. Because of the late manifestation of HH, it should be considered in any patient with dysfunction of parenchymal tissues.

E-P03.14

The spectrum of the most common CFTR gene mutations at Hospital of Lithuanian University of Health Sciences Kaunas Clinics during the years 2003-2015

I. Pocevičienė, I. Valanciūtė, B. Sabaniene, V. Asmoniene;
Hospital of Lithuanian University of Health Sciences Kaunas Clinics, Kaunas, Lithuania.

Introduction: This study aims at reviewing the patients tested for CFTR gene mutations at Hospital of Lithuanian University of Health Sciences Kaunas Clinics and to find most common CFTR gene mutations of the patients tested.

Materials, methods: 355 patients were tested for CFTR gene mutations in the period of 2003-2015 in the laboratory of Genetics and Molecular Medicine at Hospital of Lithuanian University of Health Sciences Kaunas Clinics. CFTR gene mutations were tested using commercial INNO-LiPA CFTR19 (Innogenetics, Belgium) hybridisation kit from 2003 till 2010, xTAG® Cystic Fibrosis 39 Kit v2 (Luminex) from 2011 till 2013 and xTAG® Cystic Fibrosis 71 Kit v2 (Luminex) for the 71 CFTR mutations from 2013 till 2015.

Results: The CFTR gene mutations were found in 17,5% of all analyzed cases. The most common mutation, as expected, was F508del with a incidence of 63,86 % out of all mutations detected. As far as F508del is concerned, 14 patients were diagnosed to be homozygotes (508del/508del) and 25 heterozygotes. 9 patients were diagnosed to have CFTRdele2,3 (21kb) mutation that accounts for 10,84% of all detected. R553X mutation showed the incidence of 10,84% (9 patient). 6 patients were diagnosed with G542X mutation (7,23%), 2 patients with R117H mutation (2,41%), 3 patients with 3849+10kb C>T mutation (3,61%). 1 patient with R1066C mutation (1,20%). 10 patients were diagnosed to have compound heterozygote genotypes: R553X/CFTRdele2,3 (3 patients), G542X/R553X (6 patients), F508del/CFTRdele2,3 (1 patient).

In conclusion, the spectrum of CFTR gene mutations was similar to that reported for European population.

E-P03.15

Rare mutations in CFTR gene. The difficulty of genotype-phenotype association in a Spanish family

J. Porta¹, J. M. Porta¹, S. Franco², E. Perez-Ruiz², V. Perez-Valero², C. Benito²;
¹Genologica, Malaga, Spain, ²Regional Hospital Laboratory of Malaga, Malaga, Spain,
³Section on Pediatric Pulmonology, Regional Hospital Laboratory of Malaga, Malaga, Spain.

Introduction: Cystic fibrosis (CF) is a genetic disorder characterized by the production of sweat with a high salt content and mucus secretions with an abnormal viscosity. Cystic fibrosis is an autosomal recessive disease, most common among Caucasian children. It is caused by mutations in CFTR gene which plays a role in the regulation of transmembrane hydroelectrolytic flux. The most common form of cystic fibrosis is associated with respiratory symptoms, pancreatic insufficiency, etc. There is considerable genotype-phenotype association but the rare mutations in CFTR gene hampers this objective.

Case: A 9-month-old girl with positive neonatal screening for cystic fibrosis (on the basis of sweat test results chloride concentration of 79 mmol/L) must be confirmed by identification of CFTR gene mutations.

Recurrent mutation CFTR panel was firstly analyzed. Traditional but precise Sanger DNA sequencing were used to search for specific mutations in the CFTR gene followed by MLPA CFTR gene deletion insertions variants.

Early detection of pancreatic insufficiency is essential to optimize health and outcomes in cystic fibrosis patients. Faecal elastase and other test were employed to measure pancreatic insufficiency. The results were associated with pancreatic insufficiency.

The research participants were the mother, the father and the paternal uncle and paternal aunt besides two brothers of the affected girl.

Results and Discussion: The genetic test detected two described probably pathogenic variants c.2988+1Kbdel8,6Kb and c.711+5G>A in heterozygosity and several polymorphism in the patient sample. This discussion describes the possible genotype-phenotype association between of these mutations, variants, polymorphisms, population and clinical data.

E-P03.16

The challenge of diagnosis of cystinuria

S. Vorskova, Z. Krumina, Z. Daneberga, I. Nartisa, P. Vevere;
Children Clinical University Hospital, Riga, Latvia.

Cystinuria is an autosomal recessive disease that can be classified into three subtypes: Type A involves the mutation of both alleles of SLC3A1 (2p21); heterozygotes exhibit a normal amino acid urinary pattern, Type B involves

the mutations of both alleles of SLC7A9 (19q13.11); heterozygotes typically exhibit increased cystine and dibasic amino acid urinary excretion, and Type AB is caused by one mutation in SLC3A1 and one mutation in SLC7A9; this mixed-type may be caused by the interaction of two distinct mutant genes. The prevalence is 1 in 7,000.

We report data of two brothers with similar clinical and laboratory findings born in a non-consanguineous family. The eldest brother was two years old at the time of genetic consultation, and the youngest brother was four months old. The brothers presented severe sharp spasmodic pain in the backs, sides, and abdominal areas. We measured markedly increased concentrations of protein and red blood cells in the brothers' urine. Amino acid analysis revealed an elevated concentration of urinary cystine and dibasic amino acid. An ultrasonographic investigation revealed the formation of kidneys stones in the eldest brother.

Mutation analysis of the SLC3A1 and SLC7A9 genes revealed that the eldest brother was a heterozygous carrier for mutation c.241C>T, exon 1 of the SLC3A1 gene; no mutations were found in the youngest brother. The genetic cause of the clinical findings in both patients remains unexplained. The differences in the genotypes of the brothers may suggest the presence of unknown genetic variations responsible for the siblings' clinical symptoms.

E-P03.18

Case report: 46,XX testicular disorders of sex development

Y. Shcherbak;
Center of medical genetics, National specialized children hospital, Kyiv, Ukraine.

Introduction: The XX-testicular disorders of sex development are characterized by disparity between female chromosomes and male phenotype. At first XX-form disorder has been described as a XX-male syndrome (syndrome de la Chappelle). In 85% of cases disorder due to the presence in the genome gene SRY (hidden translocation fragment Yp11 on chromosome X or on autosomes, or hidden chromosomal mosaicism). Was described SRY-positive and SRY-negative (mutations in the genes SOX3, SOX9 and other) forms.

Materials and methods: The retrospective analysis of 150 genetic cards of children with disorders of sex development was carried out. During the period 1999-2015 y. the 10 cases of XX- sex inversion was diagnosed. Patients were examined using molecular cytogenetic analysis with locus-specific probes CEP X and SRY.

Results: The patient's age at the time of the first consultation ranged from 6 months to 18 years. Statements were associated with abnormal external genitalia and the necessity to confirm the appropriateness of the chosen civil gender, or presence of cryptorchidism, hypogonadism and gynecomastia. Were described clinical cases with SRY-positive and SRY-negative 46,XX testicular disorder.

Conclusions: Only cooperation experts and using genetic analysis allow verifying the diagnosis and making gender selection optimally correct for patient. In the case of abnormal external genitalia newborn when deciding his gender should focus not only on karyotype because it does not always coincide with gonadal, hormonal and phenotypic sex.

Gene polymorphisms of eNOS 4a/4b and eNOS G894T in young nephrotic syndrome patients

F. Tripoi¹, A. G. Crauciuc¹, A. Boglis¹, C. Duicu^{1,2}, C. Banescu^{1,2};
¹University of Medicine and Pharmacy Tirgu Mures, Tirgu Mures, Romania, ²Clinical and Emergency Hospital, Tirgu Mures, Romania.

Introduction: Due to the fact that nitric oxide plays a role in regulation of renal sodium handling, vascular resistance and sympathetic activity we designed this study to investigate if there is any correlation between eNOS 4a/4b and eNOS G894T genes polymorphisms and nephrotic syndrome (NS) in young patients from Transylvania, Romania.

Material and methods: We performed a case-control study, approved by the ethic committee of the University of Medicine and Pharmacy Tirgu Mures (no.113/14.12.2015). Control group comprised of 100 children while patients group consisted of 68 NS cases. Genomic DNA was amplified using specific primers and technique.

Results: The mean age for both groups was 6.2 years ±3.1 standard deviation. According to the sex ratio 55% were boys and 45% girls with an approximated equally distribution between the groups. The genotype frequencies for eNOS 4a/4b in control group were 2% 4a/4a, 37% 4a/4b, 61% 4b/4b while in patients group were 13.23% 4a/4a, 47.05% 4a/4b and 39.72% 4b/4b. The frequencies of eNOS G894T genotypes in the control group were 56% GG, 18% GT, 24% TT while in patients group were 46.4% GG, 44.7% GT and 8.9% TT. From the patients with 4a/4a genotype 66.66% of them

were homozygotes variant TT for eNOS G894T while the remaining were heterozygotes.

Conclusion: The presence of eNOS 4a allele represent a risk factor for developing NS ($p=0.007$). The eNOS 894T allele is not associated with NS but in the case of combined variant genotype it is possible to play a role in predisposition to NS.

E-P03.20

An ARHGAP24 homozygous missense variant in a child with focal segmental glomerulosclerosis and end stage renal disease

A. Mory¹, D. Magen^{2,3}, T. Paperna¹, A. Kurolop¹, H. N. Baris^{1,2,3};

Introduction: Focal segmental glomerulosclerosis (FSGS) is a clinicopathologic syndrome, associated with proteinuria and progressive renal failure. In the pediatric age group, primary FSGS usually underlies steroid resistant nephrotic syndrome, and is caused by both idiopathic and genetic causes. We present a 10 year-old boy, born to healthy Muslim Arab first-degree cousins, who was referred to the Pediatric Nephrology Institute with end stage renal disease secondary to FSGS. Nephrotic syndrome was suspected and genetic testing was pursued.

Methods: The TruSight™ One panel, was employed on Illumina's Next-Seq500. Analysis focused on variation in candidate genes, followed by filtering rare variants ($<0.05\%$). We prioritized the variants using the VarElect tool with relevant clinical search terms.

Results: No pathogenic variants were detected in candidate genes, mainly NPHS1, NPHS2, and WT1. Further analysis revealed a homozygous variant in the ARHGAP24 gene, NM_001025616.2:c.1442C>T; p.T481M. This variant was previously implicated in association with FSGS.

Discussion: The ARHGAP24 gene encodes a RhoA-activated Rac1 GTPase-activating protein, which plays a role in differentiating podocytes and cell adhesion. A mutation in ARHGAP24 has been reported in association with autosomal dominantly inherited familial FSGS, while here we report for the first time a homozygous variant in a child with renal failure. In-silico pathogenicity prediction tools were contradicting; 122 heterozygote alleles, but no homozygotes, were observed in the Exom Aggregation Consortium (ExAC) database. Further studies are needed in order to establish the role of a biallelic mutation, in general, and the homozygous p.T481M mutation, in particular, in the pathogenesis of hereditary FSGS.

Results from GWAS studies regarding insulin resistance - usefulness in the clinical setting

A. Chirita-Emandi¹, N. Andreescu¹, S. Farcas¹, I. Velea², M. Puiu²;

¹University of Medicine & Pharmacy Victor Babes, Genetics Department, Center of Genomic Medicine, Timisoara, Romania, ²University of Medicine & Pharmacy Victor Babes, Paediatrics Department, Timisoara, Romania, ³University of Medicine & Pharmacy Victor Babes, Genetics Department, Center of Genomic Medicine, Regional Centre of Medical Genetics Timis, Emergency Hospital for Children "Louis Turcanu", Timisoara, Romania.

Background: Obesity is at epidemic levels worldwide. Insulin resistance, one of its complications, could be prevented/addressed through diet and medication. Therefore determining, at young age, which obese patients are predisposed to develop insulin resistance is important for clinical practice.

Aim: To provide a study design that would translate the findings from GWAS studies regarding insulin resistance into a model with high predictive value for use in the clinical setting.

Method: We reviewed the literature for GWAS studies regarding insulin resistance, and evaluated the potential cost and benefit for a genetic model involved in insulin resistance.

Results: Over 250 loci are significantly and robustly associated with type 2 diabetes (T2D) and/or obesity-related traits. However, less than 20 loci are directly associated with HOMA-IR in adults. For a robust predictive model, sample size needs to be larger than 2500. With a cross-sectional design, the price for clinical/metabolic assessment and genotyping is significant. Importantly, some studies replicating GWAS results on insulin resistance, have found only a slight increase in predictive ability of a model (using regression/neuronal networks) after adding the genetic signature specific for insulin resistance, while the BMI provided the highest predictive value.

Conclusion: Presently, clinical utility for prognosis of common variants whose allele frequencies are statistically correlated with insulin resistance is not established. Although, replication studies are costly, we plan to develop such a study to assess the improvement in significance of risk stratification, in

our Genomic Centre.

Clinical outcomes of gastroduodenal diseases in Yakut patients from Eastern Siberia: iceA1 strains of Helicobacter pylori associated with early onset of chronic gastritis

N. N. Gotovtsev¹, N. A. Barashkov^{1,2}, K. E. Savvinova², M. V. Pak³, M. P. Alexeeva², V. G.

Pshennikova², A. M. Rafailov², S. N. Lekhanova², S. A. Fedorova^{1,2};

Clinical outcome of Helicobacter pylori (Hp) infection is associated with virulence genotypes. The iceA gene of Hp have been reported to be associated with peptic ulcer, the importance of iceA on clinical outcomes is controversial [Shiota et al., 2010]. The iceA gene has two alleles iceA1 and iceA2 [Peek et al., 1998]. Until now, allele frequency of iceA Hp circulating in Eastern Siberia (Sakha Republic) is unexplored. We studied Hp DNA samples extracted from biopsies of 92 Yakut patients with gastroduodenal diseases, 43 of them were adolescents (mean age 15.05 ± 1.41 years) and 49 were adults (mean age 43.45 ± 12.42 years). The iceA1 was identified in 65.2% and iceA2 in 34.7% of cases (60 and 32 patients, respectively). We did not found associations of iceA1/iceA2 with erosions and ulcers ($p>0.05$), sex of patients ($p>0.05$), and place of birth or residence (urban and rural) ($p>0.05$). We found association between iceA1 and age of patients. The iceA1 allele was found among adolescent patients more frequently (79%) than among adult patients (53%) ($p<0.01$). Similar association was found in Tunisian patients with gastroduodenal diseases [Mansour et al., 2010]. In other reports of such kind associations with age was not performed. Thus, we suggest that iceA1 may be associated with early onset of chronic gastritis. This work was supported by the #6.656.2014/K project and Grant the head of the Sakha Republic (Yakutia) for young scientists, specialists and students in 2016 (February 8, 2016, #105-RG).

GWAS and HLA genotyping-based association analysis for hepatitis B virus-related chronic hepatitis and hepatocellular carcinoma

K. Tokunaga¹, H. Sawai¹, N. Nishida^{1,2}, H. Miyadera^{1,2}, M. Mizokami²;

¹Dept Human Genetics, Grad Sch Medicine, Univ Tokyo, Tokyo, Japan, ²Res Cent Hepatitis Immunol, Natl Cent Global Health Med, Ichikawa, Japan.

SNP-based genome-wide association studies (GWAS) performed in different ethnic groups, including our GWAS in the Japanese population, have consistently indicated that HLA-DPA1/DPB1 is the strongest susceptibility region to hepatitis B virus (HBV)-related chronic hepatitis (CHB). Follow-up studies based on genotyping of HLA-DPA1 and HLA-DPB1 showed multiple susceptible and protective alleles/haplotypes to CHB in Japanese, Chinese, Korean, and Thai populations. Moreover, additive effects of these susceptible or protective alleles on odds ratios were observed. Interestingly, heterozygotes of DPB1 protective and susceptible alleles were significantly associated with protection, indicating that one protective HLA-DPB1 molecule can provide dominant protection. Binding assays between susceptible or protective HLA-DP proteins and Hepatitis B virus-derived peptides detected specific peptides. Next, we expanded HLA genotyping-based association analyses to the other HLA class II genes, HLA-DQA1, DQB1 and DRB1. Unexpectedly, some DRB1-DQA1-DQB1 haplotypes clearly showed stronger associations than DPA1-DPB1 haplotypes. Furthermore, GWAS and HLA genotyping-based association analysis on HBV-related hepatocellular carcinoma (HCC) identified new protective alleles in HLA class I genes in addition to previously identified HLA-DPB1 protective allele. Since many diseases have been reported to be strongly associated with the HLA region by means of SNP-based GWAS, careful association studies based on HLA genotyping are essential to identify the primary susceptibility variants in this particular genome region.

²Univ. of Debrecen, Faculty of Medicine, Department of Biochemistry and Molecular Biology, Debrecen, Hungary, ³Univ. of Debrecen, Faculty of Medicine, Department of Biochemistry and Molecular Biology, Debrecen, Hungary.

Introduction: Inflammatory bowel diseases (IBD) show increasing incidence in the last few years in Hungary. Since genetic susceptibility of patients plays an important role in the pathogenesis of the disease, it is important to identify new susceptibility genes. Peroxisome proliferator-activated receptor gamma (PPARG) is expressed in the colon and has protective effects against inflammatory processes. Our aim was to examine the association of four polymorphisms of PPARG in a well-characterized Hungarian IBD cohort.

Material and Methods: 575 Crohn's disease (CD), 103 ulcerative colitis (UC) patients and 486 sex and age matched controls were examined in our study. Four polymorphisms of PPARG [rs10865710 (C-681G), rs2067819, rs3892175 and rs1801282 (Pro12Ala)] were genotyped by TaqMan genotyping assays.

Results: The Pro12Ala polymorphism showed significant association with CD when the frequencies of the homozygous variants (Pro/Pro vs. Ala/Ala) were compared. The minor Ala/Ala genotype was significantly less frequent in CD patients compared to the controls (OR= 0.33; 95%CI= 0.12-0.94; P= 0.03), suggesting a potential protective effect of the Ala allele. GAGG haplotype of PPARG also confers protective effect in CD (OR= 0.72, 95% CI: 0.53-0.97; P= 0.028) and in UC (OR= 0.14; 95% CI: 0.05-0.42; P= 3.78 × 10⁻⁵) too. While GAGC increases the risk of UC (OR= 6.70; 95% CI: 3.41-13.17; P= 3.85 × 10⁻¹⁰).

Conclusions: In the present study we demonstrated a significant association between PPARG polymorphisms and the development of CD and UC at single loci level and also in haplotype combinations.

Gross deletion of GHR in a patient with Laron Syndrome

A. Arman¹, H. Simsek², G. Y. Mutlu², H. K. Bekmez², S. Cici³, S. Hatun⁴;

¹The Department of Medical Genetics, Marmara University Medical School, İstanbul, Turkey, ²The Department of Pediatric Endocrinology, Zeynep Kamil Education and Research Hospital, İstanbul, Turkey, ³The Clinics of Children Disease, Zeynep Kamil Education and Research Hospital, İstanbul, Turkey, ⁴The Department of Pediatric Endocrinology and Diabetes, Kocaeli University Medical School, İstanbul, Turkey.

Introduction: Laron syndrome (LS) is an autosomal recessive disorder characterized by severe postnatal growth failure, short stature, normal or increased plasma growth hormone (GH), and low levels of insulin like growth factor-1 (IGF-1) and IGF binding protein 3 (IGFBP-3). These characteristics result from defective GH receptor (GHR) function and, thus, a GH insensitive state. We analyzed the GHR gene for mutations and polymorphisms in a patients with Laron-type dwarfism.

Materials and Methods: Patients were selected in this study based on their clinical and laboratory characteristics. Genomic DNA was isolated from bloods of LS children according to salting out method. Exon 2-10 specific PCRs and their flanking splice sites were amplified by polymerase chain reaction (PCR) using the primers. PCR products were visualized on 2% agarose gels.

Results: PCR results showed that GHR from patient was deleted from exon 4-10 and this deletion causes defective GHR missing intracellular domain, transmembrane domain and large part of extracellular domain (exon 4-7).

Conclusions: We identified gross deletion (exon 4-10) from GHR gene in patient with Laron and this is second report for deletion of exon 4-10 of GHR in patient with laron syndrome.

A novel single variant in MEFV gene causing Mediterranean Fever and Behçet disease: case report of Moroccan girl

M. Zerkaoui¹, F. Z. Laarabi², Y. Ahjoun³, B. Chkirate³, A. Sejjani^{1,2};

¹Centre de Génomique Humaine, Faculté de Médecine et Pharmacie de Rabat.

Mohammed V University in Rabat, Rabat, Morocco, ²Département de Génétique

Médicale, Institut National d'Hygiène, Rabat, Morocco, ³Service de Pédiatrie IV, Hôpital d'Enfant, Mohammed V University in Rabat, Rabat, Morocco.

Familial Mediterranean Fever (FMF) is an autoinflammatory disease of

unknown etiology, characterized clinically by recurrent attacks of sudden-onset fever with arthralgia and/or thoracoabdominal pain, and pathogenetically by autosomal recessive inheritance due to a mutation in the MEFV gene. Behçet's disease (BD) is an inflammatory disease characterized with recurrent oral and genital aphthous ulcerations, uveitis, and skin lesions. It has been reported that the MEFV gene mutation responsible for FMF is probably a susceptibility factor for BD, particularly for cases with vascular involvement, and both disorders can occur concurrently in a subject, as in this case. Herein, we present a case of Moroccan girl with FMF and BD coexistence. We analyzed the entire MEFV gene after exclusion of recurrent mutations in exons 2 and 10. Molecular testing revealed a novel single variant c.2078T>A (p.Met693Lys) that could be responsible of the association of FMF and BD.

Application of Urinary C-peptide to Creatinine Ratio (UCPCR) for Discrimination of Maturity Onset Diabetes of the Young (MODY) in the Emirati Population

H. Daggag¹, A. Buckley¹, N. Lessan¹, A. Al-Tikriti¹, K. Colclough², S. Ellard², M. Taysir Barakat¹;

¹Imperial College London Diabetes Centre, Abu Dhabi, United Arab Emirates, ²Royal Devon and Exeter NHS Foundation Trust, Exeter, United Kingdom.

It has become more challenging to distinguish between type 1, type 2 and monogenic diabetes using the standard parameters such as age, BMI and absence of islet cell or GAD antibodies. Besser et al. (2011) and Besser et al. (2013) have shown distinction is possible by utilising UCPCR.
