PL1 Opening Plenary Session

PL1.1

RAS genes and Human Disease: From Rasopathies to Cancer

M. Barbacid;

Molecular Oncology Programme, Centro Nacional de Investigaciones Oncológicas (CNIO), Madrid, Spain.

RAS genes have attracted a significant deal of attention in biomedical research due to central their role in mediating mitogenic signaling and to their oncogenic activation in at least one third of all human cancers including some of the most frequent and malignant tumor types such as colorectal carcinoma, lung adenocarcinoma and pancreatic ductal adenocarcinoma. More recently, Ras genes have also been implicated in developmental disorders including Costello and Noonan syndromes. In spite of the wealth of information accumulated over the last 30+ years on these genes we still have rather scant information regarding how their misregulation affects human health. More importantly, as of today, there are no efficacious inhibitors to treat those diseases caused by mutations or alterations in RAS genes. Our laboratory has been interested in the development of genetically modified (GEM) animal models that faithfully reproduce the natural history of these diseases and in the identification and subsequent validation of targets with potential therapeutic value. I will describe our GEM models for Costello (H-Ras^{G12V}) and Noonan (K-Ras^{G14V}) syndromes along with our efforts to validate potential therapeutic strategies to correct their developmental defects. I will also describe our new generation of GEM models for K-Ras mutant lung and pancreatic tumors and review the genetic approaches that we are utilizing to validate the therapeutic value of each of the kinases involved in the MAPK signaling cascade, the key pathway involved in K-Ras oncogenic signaling. We hope that these studies will serve to guide the design of future clinical trails to treat people suffering from Rasopathy syndromes as well as cancer patients carrying K-RAS mutant tumors.

PL1.2

The Spanish Experience of Retinal Dystrophies

C. Ayuso^{1,2};

¹Madrid, Spain, ²Fundacion Jimenez Diaz Univeristy Hospital (IIS-FJD, UAM), Madrid, Spain.

The retinal dystrophies (RDs) are degenerative diseases involving RPE and/or photoreceptors of the retina and currently without treatment options for the patients. RD may be syndromic or non-syndromic and can affect peripheral, central retina or both. They affect about 1:4,000 individuals and there are more than 270 known causative genes-loci. Mendelian (autosomal recessive, autosomal dominant or X-linked inheritance) and non-mendelian inheritance have been described.

This great clinical and genetic heterogeneity and the need for a genetic diagnosis to help and refine clinical management and guide genetic counseling are a real challenge.

Two decades ago, we started the study of RD in Spain (EsRetNet: Antiñolo, Baiget, Carballo, Millan, Valverde & Ayuso). The modes of inheritance frequency were established (15% Syndromic; and 12% dominant, 39% recessive, 4% Xlinked and 41% sporadic cases and 4% unclassified *Clin Genet.* 1995) and the first mutated genes (*RHO*, *CRB1*, *USH2A*, etc) affecting Spanish population were identified, using gene mutation screening approaches (SSCP, dHPLC) or Sanger sequencing.

From 2007, we used array-based primer extension (APEX) technology, with a diagnostic yield from 14% (for autosomal dominant RD; *Blanco-Kelly et al; Mol Vis* 2012) to 54% (for Stargardt cases; *Riveiro et al IOVS* 2012) in RD patients.

In 2011 new genomic analysis technologies, including next generation sequencing (NGS) and chromosome microarrays were implemented. In total 36% of the ≈3000 RD families were characterized and we identified new mutations and genes, and clinical associations.

Molecular characterization allowed us to refine clinical diagnosis, to confirm or change the pattern of inheritance, improving clinical management of RD cases and families. Moreover, we have established very well characterized cohorts of *USH2A*, *NR2E3*, *RHO*, *XLRS*, *CHM* or *ABCA4* patients, useful for natural history of disease studies. Additionally, mutated cases for *RPE65*, *PDEA*, among others can be offered to be included in current clinical trials. At present, a more accurate and efficient algorithms for molecular diagnosis are available for RD patients to improve their clinical care, however we need still to improve the diagnosis rate and fill the gap to obtain effective therapies.

International collaborative efforts for research on molecular, epidemiological and therapeutic aspects are needed to achieve these goals

Balanced chromosomal abnormalities (BCAs) represent a unique class of genomic variation that involves large rearrangement of the chromosomes. To date their detection has been limited to cytogenetic resolution as most first-tier genetic screening methods are blind to their presence. We defined the genomic landscape of de novo BCAs associated with human congenital anomalies in 235 subjects using whole-genome sequencing. We observed that 22% of all BCAs harbored additional cryptic complexity, ranging from three breakpoints to chromothripsis events involving up to 57 breakpoints. Compared to random expectations, BCAs were more likely to occur between loci in close physical proximity in the nucleus, and their breakpoints were significantly enriched for evolutionarily constrained and embryonically expressed genes. From our convergent genomic interpretation using orthogonal datasets, we predict that the congenital anomaly phenotype was likely attributable to the BCA in at least 30% of subjects. An additional 4% of BCAs disrupted long-range regulatory regions such as topologically associating domains (TADs) resulting in position effects on genes associated with specific clinical manifestations that were compatible with the proband sequenced here. Remarkably, we observed a cluster of six independent translocations that disrupted a TAD and consequently altered MEF2C expression, mimicking the 5q14.3 microdeletion syndrome. These results suggest that de novo BCAs represent a highly penetrant class of genomic variation associated with congenital anomalies, and that nucleotide resolution offers insights into phenotypic prediction from direct gene disruption and alteration of long-range regulatory domains that are likely to be a significant source of causal variation in human disease.

PL2.2

Formation and content of novel chromatin domains (neo-TADs) determine pathogenesis of genomic duplications

M. Franke¹, D. M. Ibrahim¹, G. Andrey¹, W. Schwarzer², V. Heinrich¹, R. Schöpflin¹, R. Kempfer³, I. Jerković⁴, W. Chan⁴, M. Spielmann⁵, B. Timmermann¹, L. Wittler¹, I. Kurth⁵, P. Cambiaso⁶, O. Zuffardi⁷, G. Houge⁸, L. Lambie⁹, F. Brancati¹⁰, A. Pombo³, M. Vingron¹, F. Spitz¹, S. Mundlos^{1,4};

Mammalian genomes are organized in distinctly folded chromatin modules, called topologically associated domains (TADs) that are separated from each other by boundary regions. TADs subdivide the genome into discrete chromatin domains that direct the contacts enhancers can establish with their target genes. How copy number variations interfere with TAD structure and how this might contribute to human disease, is not well understood.

Here, we analyze partially overlapping duplications at the *SOX9* locus, which are associated with a limb malformation (Cooks syndrome), sex reversal or no abnormality in humans. By analyzing patient cells and corresponding mouse models with chromosome conformation capture assays, we show that large duplications spanning a TAD boundary result in the formation of a novel chromatin domain, or neo-TAD. The formation of this neo-TAD explains the divergent phenotypes of the overlapping duplications at the *SOX9* locus. Furthermore, we demonstrate that the duplicated *cis*-regulatory information is functionally isolated and does not influence genes outside the neo-TAD. Instead, the pathogenicity of duplications depends on the combination of genes and *cis*-regulatory information that are contained within the neo-TAD. Taken together, our results show that duplications including TAD boundary regions can result in the formation of novel chromatin domains that are functionally and spatially separated from their genomic neighbors. Moreover, our findings provide a framework for interpreting the pathogenic effect of genomic duplications, frequently detected in patients with congenital malformations, intellectual disability or cancer.

PL2.3 Mutations in ACTRT1 and its transcribed non-coding elements lead to aberrant activation of the Hedgehog signaling pathway in inherited and sporadic basal cell carcinomas

E. Bal^{1,2}, Z. Belaid-Choucair^{1,2}, H. Kayserili³, M. Naville⁴, M. Madrange^{1,2}, C. Gordon^{1,2}, clinical investigators, G. Gyapay⁵, S. Fraitag⁶, H. Roest Crolius⁴, A. Munnich^{1,2}, P. Vabres⁷, A. Smahi^{1,2};

¹INSERM U1163, Institut Imagine, Hôpital Necker Enfants Malades, Paris, France, ²Université Sorbonne Paris Cité, Paris, France, ³Medical Genetics Department, Istanbul Medical Faculty, Istanbul University, Istanbul, Turkey, ⁴Institut de Biologie de l'ENS, UMR8197, INSERM U1024, Paris, France, ⁵Genoscope (CEA), CNRS UMR 8030, Université d'Evry, Evry, France, ⁶Service d'anatomie pathologique, Hôpital Necker Enfants Malades, Paris, France, ⁷Service de dermatologie, Centre Hospitalier Universitaire, Hôpital du Bocage, Dijon, France.

Basal cell carcinoma (BCCs) is the most common human cancer, resulting from aberrant activation of Hedgehog signaling pathway. While most cases are sporadic, some forms are inherited, as in Bazex-Dupré-Christol syndrome (BDCS), an X-linked dominant cancer-prone genodermatosis. Studying a series of 6 BDCS families, we found mutations in the *ACTRT1* gene, encoding the Arp-T1 protein, in 2/6 BDCS families, and absent expression of Arp-T1 in BDCS tumors and most of sporadic BCCs. High-throughput sequencing revealed germline mutations in non-coding sequences, belong to a new class of enhancers (eRNA), surrounding *ACTRT1* in the remaining families. Mutations reduced expression of the specific eRNAs and their enhancer capacity. Using Crisp-Cas9 technology, we demonstrated that induced mutations in these enhancers significantly decreased the expression of Arp-T1 protein. When stably expressed in MDA-MB231 breast cancer and U2OS osteosarcoma cell lines, wild type *ACTRT1* reduced cell proliferation and migration. Consistently, xenografts of *ACTRT1*-MDA-MB231 and *ACTRT1*-U2OS cells in nude mice demonstrated that *ACTRT1* normally inhibits tumor growth. Indeed, transcriptomic analyses revealed that *ACTRT1* could modulate the expression of genes involved in regulation of cell cycle progression, cell death and survival or cell migration. Finally, Arp-T1 acts as a tumor suppressor via its direct binding to Hedgehog signaling target genes, thus inhibiting their expression.

Our study identifies a novel mechanism accounting for hereditary and sporadic BCCs, and suggests that *ACTRT1* may be potential therapeutic targets in oncology.

This work was supported by the Association pour la Recherche contre le Cancer and Société Française de Dermatologie.

PL2.4 De novo mutations MSL3 gene cause a new recognizable syndrome

¹Équipe EA42271 GAD, Université de Bourgogne, Dijon, France, ²FHU-TRANSLAD, Université de Bourgogne/CHU Dijon, Dijon, France, ³Max Planck Institute of Immunobiology and Epigenetics, Freiburg, Germany, ⁴Clinical Genetics Unit, Birmingham Women's Hospital, Birmingham, United Kingdom, ⁵Centre de génétique, CHRU de Strasbourg, Strasbourg, France, ⁶Radboud University Medical Center, Department of Human Genetics, Nijmegen, Netherlands.

Whole-exome sequencing (WES) has proven to be useful for the identification of the molecular basis of heterogeneous conditions such as intellectual disability with congenital anomalies. A large number of results remain non-conclusive, especially when facing ultra-rare conditions that limit genotype-phenotype correlations. International data-sharing catalyzes the identification of additional cases and allows the delineation of new syndromes.

We report on a female patient with developmental delay, moderate intellectual disability, facial dysmorphism and severe constipation. Af-

ter a negative diagnostic work-up, a proband clinical WES was performed and pinpointed a de novo acceptor-splice variant of *MSL3* was (NM_001193270.1:c.1345+1G>T). To assess the relevance of this finding we asked international collaborators for patients with truncating variants of *MSL3*. Seven unrelated individuals from France, UK, the Netherlands, Germany, USA were identified with de novo single-nucleotide variants (4/7), whole-gene de novo deletions (2/7) or chromosomal inversion causing a fusion transcript of *MSL3* and *GAB3* genes (1/7). Clinical findings of patients with point mutation are very similar but less recognizable in patients with chromosomal anomalies. This include speech and walk delay, intellectual disability, neonatal hypotonia, facial dysmorphism, abnormal limbs, abdominal symptoms and cutaneous anomalies. The *MSL3* gene, located on the X chromosome, encodes a subunit of a transcriptional regulator complex responsible of lysine 16 of histone H4 acetylation (H4K16ac). Functional studies revealed a decreasing of H4K16ac mark and complex assembly defects. In conclusion, we delineate a new syndrome of the epigenetic machinery characterized by neurodevelopmental delay and multiple congenital anomalies.

PL2.5 Haplotype-assisted noninvasive prenatal diagnosis of common monogenic diseases using massively parallel sequencing of plasma cell-free DNA

Y. Gao¹, F. Chen^{1,2}, Y. Yuan³, Y. Wang³, S. Lu¹, H. Jiang¹, X. Xu¹;

¹BGI, Shenzhen, China, ²Section of Molecular Disease Biology, Department of Veterinary Disease Biology, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark, ³BGI Clinical Laboratories -Tianjin, Tianjin, China.

Introduction

Since 2012, haplotype-assisted noninvasive prenatal diagnosis (NIPD) has been developed in our laboratory, and validated in a number of monogenic diseases using clinical samples from trio families. The purpose of this study was to summarize the performance of this method in different monogenic diseases.

Method and Material

Customized panels were designed to capture the coding region and flanking area of disease-associated genes. Genomic DNA from each trio family (father, pregnant mother, and proband child) and plasma cell-free DNA from each pregnant mother was targeted-sequenced using the customized panels. Fetal fraction was calculated with the differently homozygous SNPs in both parents. Parental and fetal haplotype were deduced based on genetic information from the trio family and Hidden Markov Model. Amniocentesis was performed to confirm NIPD results.

Result

97 trio families covering 12 monogenic diseases have been tested before receiving prenatal diagnosis (Table). The mutations consisted of point mutations and copy number variants. Mean gestational age of pregnant women while receiving NIPD was 18 weeks. Fetal fraction was between 2.8% to 22.6%, with the mean of 9.1%. 60 pregnancies were identified as disease-affected. So far amniotic fluid was tested for prenatal diagnosis in 70 pregnancies, all consistent to NIPD results.

Conclusion

Haplotype-assisted NIPD showed high accuracy in predicting the existence of fetal monogenic disease, and can be used in different diseases and mutation types.

Haplotype-assisted NIPD of monogenic diseases			
Disease	Gene	Trio families	Amniotic fluid available for confirmation
Phenylketonuria (PKU)	PAH	13	12

PL2.6

Parent-of-origin specific signatures of de novo mutations

J. M. Goldmann¹, W. S. W. Wong², M. Pinelli³, T. Farrah⁴, D. Bodian², A. B. Stittrich⁴, G. Glusman⁴, L. E. L. M. Vissers⁵, A. Hoischen⁵, J. C. Roach⁴, J. G. Vockley^{2,6}, J. A. Veltman^{1,7}, B. D. Solomon^{2,6,8}, C. Gilissen⁵, J. E. Niederhuber^{2,9};

¹Department of Human Genetics, Radboud Institute for Molecular Life Sciences, Radboud University Medical Center, Nijmegen, Netherlands, ²Inova Translational Medicine Institute, Inova Health Systems, Falls Church, VA, United States, ³Telethon Institute of Genetics and Medicine, Naples, Italy, ⁴Institute for Systems Biology, Seattle, WA, United States, ⁵Department of Human Genetics, Donders Centre for Neuroscience, Radboud University Medical Center, Nijmegen, Netherlands, ⁶Department of Pediatrics, Virginia Commonwealth University School of Medicine, Richmond, VA, United States, ⁷Department of Clinical Genetics, Maastricht University Medical Centre, Maastricht, Netherlands, ⁸Department of Pediatrics, Inova Children's Hospital, Inova Health System, Falls Church, VA, United States, ⁹Johns Hopkins University School of Medicine, Baltimore, MD, United States.

Introduction: De novo mutations (DNMs) originating in gametogenesis are an important source of genetic variation and can cause human disease. Here, we investigate the properties of DNM on paternal and maternal alleles in order to understand the underlying mechanisms.

Methods: We applied whole-genome sequencing to a cohort of 816 parent-offspring trios, yielding in 35,793 autosomal single-nucleotide DNMs. Haplotype assembly could resolve the parental origin of 7,216 DNMs. We compare parental age effects, genomic regions and spectra of paternal versus maternal DNMs.

Results: Our results show that the number of DNMs in offspring increases not only with paternal age (0.9 DNMs/year), but also with maternal age (0.24 DNMs/year). The genome regions with highest enrichment for maternally derived DNMs are the known fragile sites FRA8B and FRA16D. We identify parent-of-origin-specific mutation signatures that become more pronounced with increased parental age, with transitions in A.G context being the most biased mutations. Moreover, we find DNMs that are spatially clustered to have a unique mutational signature with no significant differences between parental alleles, suggesting a different mutational mechanism.

Conclusions: We find that the different biology of male and female gametogenesis gives rise to distinct mutational patterns. These patterns are valuable to understand physiology and pathology of the human germ line.

PL3 My vision on genomic medicine

PL3.1

Our visions of genomic medicine: a dialog

J. L. Mandel^{1,2,3}, M. C. King⁴;

¹Strasbourg University, IGBMC, Department of Translational Medicine & Neurogenetics, Illkirch, France, ²CHU Strasbourg, Strasbourg, France, ³IGMA Genet Diagnostic Lab; Collège de France, Paris, France, ⁴University of Washington, Department of Medicine & Genome Science, Seattle, WA, United States.

The invitation from ESHG to both of us to present our thoughts on the current state and the future of genomic medicine bore the risk of having two monologues with undue overlaps or contradictions and too little time for open discussion. We have chosen instead an alternate form of dual presentation of some issues in the development of genomic medicine. We will each speak brief on these questions, in turn, and intermingle our comments with questions and comments from session chairs and from the audience. The topics we propose to address (not necessarily in the final order) are:

- 1) The application of genomics to prediction of risk, to non-invasive diagnosis, and to individualized treatment; given our experience, we think of these issues in the context of cancer;
- 2) Whole genome sequencing for everyone? why? when? For adults, newborns, fetuses, preconception?
- 3) Application of genomic medicine to rare diseases; in particular how to determine pathogenicity and causality given whole genome sequence (e.g. problems of missense variants, non-coding variants, hypomorphic variants). How best to obtain precise and useful natural history for more than 5000 different monogenic diseases? For how many families may specific treatments rather than symptomatic medical care be offered? Meanwhile, what is the place of prevention through prenatal diagnosis? How can one address the risk of uncontrolled eugenism, which already occurs in the context of sex selection in some countries?
- 4) Development of precision medicine for common diseases (beyond cancer, above). What is the current medical value of genotyping and sequencing? How will the value be increased? What is the role of various omics? Of knowledge of gene-environment interactions? How much can we expect new medications based on knowledge of causal genes?
- 5) How can services be made available to everyone? How may direct to con-

sumer testing evolve?

- 6) How can huge databases be made useful for interpretation of genomic sequence and relationships between health and genotype?

PL3.2

Our visions of genomic medicine: a dialog

- 4) Development of precision medicine for common diseases (beyond cancer, above). What is the current medical value of genotyping and sequencing? How will the value be increased? What is the role of various omics? Of knowledge of gene-environment interactions? How much can we expect new medications based on knowledge of causal genes?
- 5) How can services be made available to everyone? How may direct to consumer testing evolve?
- 6) How can huge databases be made useful for interpretation of genomic sequence and relationships between health and genotype?

PL4 Mendel Lecture

PL4.1

Mendel Lecture: Epigenetics and Rett syndrome

A. Bird;

Wellcome Trust Centre for Cell Biology, University of Edinburgh, Edinburgh, United Kingdom.

The word epigenetics excites great interest within biology and beyond, despite uncertainty about its definition. At one level it concerns the significance of the plethora of chemical marks on chromosomes that modulate gene activity (collectively known as the "epigenome"). Prominent among these marks is DNA methylation - a modification that is directly applied to DNA and affects its interaction with proteins. Several clinical disorders involve genes that interpret or lay down the epigenome. For example, the autism spectrum disorders Rett syndrome and MECP2-duplication syndrome are caused by mutations in the gene for the protein MeCP2. The MeCP2 protein binds to sites on DNA that are chemically altered by DNA methylation and appears to interpret this "epigenetic" mark to affect gene expression. Clues to the function of MeCP2 are provided by the spectrum of mutations causing Rett syndrome and the biochemical and genetic analyses. Recent evidence derived from animal and cellular models suggests that the primary function of this protein is to restrain transcription in a DNA methylation-dependent manner. Interestingly, the resulting defects are reversible in model systems suggesting that the disorder may be curable. Current research addressing these aspects of MeCP2 biology will be presented.

CONCURRENT SYMPOSIA

S01 ESHG/EMPAG SYMPOSIUM: The future lies in uncertainty

S01.1

Tolerating uncertainty in the clinic - the impact of new genetic technologies

A. Lucassen;

University of Southampton, Faculty of Medicine, Southampton, United Kingdom.

Despite the rhetoric of precision medicine afforded through advances in genetic technologies, and a common perception that genetic tests offer clear cut predictions, the reality in 2016 remains far from this in all but a few distinct areas. Whole genome approaches do provide novel diagnoses or predictions in some families where all previous targeted genetic investigations drew a blank, but for many others the clinical significance of findings from new genetic technologies is unknown until much more evidence -be that bioinformatic or clinical follow up- can be gathered. One of the problems for practice is that the inversion of the phenotype to genotype approach previously used in genetic clinics, to predicting phenotypes from geno[me]types is a quantitative qualitative as well as quantitative leap. This has important implications for how we seek consent for, for example, whole genome sequencing. We can no longer expect patients to be able to have considered all the possible outcomes from such testing in any detail as part of a consent process. Indeed as genomic medicine becomes a mainstream activity, discovery of genomic predispositions to disease that lies outside the clinical experience of the consentor will become more common place. Is 'fully informed' consent a desirable goal in genomic testing? Or should we instead begin to focus on mechanisms that engender greater trust in the venture in question? Using the example of 'incidental' findings from genomic testing, I will explore whether we are placing too much emphasis on consent as a gateway to testing and whether this, perhaps paradoxically, carries the risk of accusations of paternalism. Consent to genomic testing with a full understanding of all the possible outcomes and consequences will not be possible so we will need to consider how best to obtain broad or generic consent to testing that is realistic about the uncertainties and builds in mechanisms for revised interpretation in the wake of new knowledge.

S01.2

Personal genomic testing: How individuals understand and respond to genetic risk information

S. Roberts;

University of Michigan School of Public Health, Ann Arbor, MI, United States.

This presentation will discuss how individuals appraise and respond to genetic susceptibility testing for a range of medical conditions. Topics to be addressed include public understanding and attitudes regarding testing options, challenges in communicating test results, psychological effects of genetic risk information, and health behavior changes following testing. The author will draw upon his research program that includes the following projects: 1) the REVEAL (Risk Evaluation and Education for Alzheimer's Disease) Study, a series of randomized clinical trials examining the impact of different methods of disclosing APOE genotype status to individuals at risk for Alzheimer's disease, and 2) the Impact of Personal Genomics (PGen) Study, a longitudinal survey of over 1800 consumers of direct-to-consumer genetic testing services. Implications of research findings for practice and policy will be discussed.

S02 Understanding functional effects of genomic variants

S02.1

Using single-cell RNA-seq to understand effects of rare variants

A. Sekar^{1,2}, A. R. Bialas^{3,4}, H. de Rivera^{1,5}, A. Davis^{1,5}, T. R. Hammond³, N. Kamitaki^{1,5}, K. Tooley^{1,5}, J. Presumey⁶, M. Baum^{1,2}, V. Van Doren¹, G. Genovese^{1,5}, S. A. Rose², R. E. Handsaker^{1,5}, Schizophrenia Working Group of the Psychiatric Genomics Consortium, M. J. Daly^{5,6}, M. C. Carroll⁶, B. Stevens^{5,3}, S. A. McCarroll^{7,5};

¹Department of Genetics, Harvard Medical School, Boston, MA, United States, ²MD-PhD Program, Harvard Medical School, Boston, MA, United States, ³Department of Neurology, F.M. Kirby Neurobiology Center, Boston Children's Hospital, Harvard Medical

School, Boston, MA, United States, ⁴Program in Cellular and Molecular Medicine, Boston Children's Hospital, Boston, MA, United States, ⁵Stanley Center for Psychiatric Research, Broad Institute of MIT and Harvard, Cambridge, MA, United States, ⁶Analytical and Translational Genetics Unit, Massachusetts General Hospital, Boston, MA, United States, ⁷Harvard Medical School, Boston, MA, United States.

Schizophrenia is a heritable brain illness with unknown pathogenic mechanisms. Schizophrenia's strongest genetic association at a population level involves variation in the major histocompatibility complex (MHC) locus, but the genes and molecular mechanisms accounting for this have been challenging to identify. Here we show that this association arises in part from many structurally diverse alleles of the complement component 4 (C4) genes. We found that these alleles generated widely varying levels of C4A and C4B expression in the brain, with each common C4 allele associating with schizophrenia in proportion to its tendency to generate greater expression of C4A. Human C4 protein localized to neuronal synapses, dendrites, axons, and cell bodies. In mice, C4 mediated synapse elimination during postnatal development. These results implicate excessive complement activity in the development of schizophrenia and may help explain the reduced numbers of synapses in the brains of individuals with schizophrenia.

S02.2

RNA splicing is a primary link between genetic variation and disease

Y. Gilad;

Chicago, IL, United States.

Noncoding variants play a central role in the genetics of complex traits, but we still lack a full understanding of the molecular pathways through which they act. We quantified the contribution of cis-acting genetic effects at all major stages of gene regulation from chromatin to proteins, in Yoruba lymphoblastoid cell lines (LCLs). About ~65% of eQTLs (expression Quantitative Trait Loci) have primary effects on chromatin, while the remaining eQTLs are enriched in transcribed regions. Using a novel method, we also detected 2,893 splicing QTLs, most of which have little or no effect on gene-level expression. These splicing QTLs are major contributors to complex traits, roughly on a par with variants that affect gene expression levels. Our study provides a comprehensive view of the mechanisms linking genetic variation to variation in human gene regulation.

S02.3

Modeling genetic and non-genetic sources of variation in single cells

O. Stegle;

Cambridge, United Kingdom.

Recent technological advances have enabled assaying single-cell transcriptomes and DNA methylation on a genome-wide scale. In this talk, I will discuss some of the computational challenges when analyzing these data from genetics perspective. I will revisit statistical approaches for decomposing the sources of variation between cells using on linear mixed models, which is similar to approaches used for estimating heritability in genetics. These methods enable decomposing single-cell heterogeneity into biological divers, confounding factors and genetic effects. One of the main challenges when linking genetic variation with single-cell states is that most studies profiles cells from very few distinct genetic backgrounds. We show that recent advances in learning and inference can help to overcome these limitations, such that genetic effects on single-cell variability can be elucidated using cells from a single genome.

S03 Hereditary cancer

S03.1

Hereditary colorectal cancer: Recent advances and future perspectives

L. Valle;

Catalan Institute of Oncology, IDIBELL, Barcelona, Spain.

Family history of cancer is one of the strongest predictors of colorectal cancer (CRC) risk, being this risk higher with increasing number of affected relatives and when CRC occurs at young age. Crude estimates indicate that 20-25% of all CRC patients have at least one relative affected with the disease, which may be explained by shared genetic and/or environmental factors. Approximately 3-6% of all CRC patients carry germline mutations associated with syndromic hereditary colorectal cancer. This genetic predisposition to CRC has been classically associated with germline mutations (and epimutations) in the mismatch repair genes *MLH1*, *MSH2*, *MSH6* and

PMS2 for non-polyposis cases, and in *MUTYH* and *APC* for adenomatous colonic polyposis. Other CRC predisposing syndromes, characterized by the presence of hamartomatous polyps, are caused by mutations in *SMAD4*, *BM-PR1A*, *STK11* and *PTEN*. Despite this knowledge, much of the genetic predisposition to CRC remains unexplained.

The identification of a germline mutation that causes the increased risk and aggregation of CRC in a family has clear consequences in the clinical management of its members. Therefore, important efforts are being invested to identify novel genes that explain this predisposition, in particular in families with clear dominant inheritance of the disease. In the last decade, the rapid development and decrease in the economic cost of massively parallel sequencing-based approaches and genome-wide copy number techniques has allowed the identification of novel genes responsible of hereditary CRC cases, in some instances also associated with polyposis. For some of the identified genes, the evidence gathered to date is robust and their testing has been included in routine genetic diagnostics, while for others, the identification of additional pathogenic mutations in high risk families is mandatory to provide the required evidence to consider the study of the gene in the clinical setting. I will review the latest advances in this field and discuss current challenges and future perspectives.

S03.3

The genetics of skin and uveal melanoma

N. K. Hayward;

QIMR Berghofer Medical Research Institute, Brisbane, Australia.

Family and twin studies indicate that cutaneous melanoma (CM) susceptibility has a strong genetic component. CM sometimes runs in families in which there is an inherited mutation in a single 'high penetrance' gene, but in the general population CM predisposition is likely governed by variation in a combination of 'low penetrance' genes. To date, genome-wide association studies (GWAS) have identified 20 low penetrance loci associated with CM susceptibility in populations of European descent. The majority of these loci are related to well characterised CM risk phenotypes of light pigmentation and high numbers of melanocytic naevi. They include variants in or near pigmentation genes: *MC1R*, *ASIP*, *TYR*, *SLC45A2*, *OCA2*, *IRF4* and *TYRP1*; and genes associated with naevus count: *MTAP/CDKN2A*, *PLA2G6*, *IRF4* and *TERT/CLPTM1L*. Ten additional melanoma susceptibility loci not associated with either of these risk phenotypes have been identified. These lie in or near *ATM*, *CASP8*, *CCND1*, *MX2*, *FTO*, *PARP1*, *AGR3*, *CDKAL1*, *RAD23B* and *SETDB1*, suggesting a number of other pathways are involved in melanoma susceptibility. The *ATM* and *PARP1* loci allude to involvement of DNA repair, while *CCND1* and *CASP1* point to regulation of cell proliferation or death respectively. High penetrance germline mutations in the *CDKN2A* and *CDK4* genes account for susceptibility in ~40% of case-dense CM families. Recently, exome sequencing has identified several new familial CM genes. Initial success was the finding of a variant (p.E318K) in *MITF*, the lineage specific transcription factor and oncogene for melanoma, which was 2.33 times more prevalent in melanoma cases than population controls, indicating it is a medium-penetrance melanoma susceptibility variant. Subsequently, the identification of rare germline gain-of-function mutations in the promoter of *TERT*, as well as inactivating mutations in genes encoding the shelterin components *POT1*, *ACD* and *TERF2IP*, implicate telomere dysregulation as a novel risk pathway in familial melanoma. Additionally, mutations in *BAP1* have been associated both with CM and uveal melanoma (UM) predisposition, as well as susceptibility to mesothelioma and a range of other cancers. *BAP1* is currently the only documented high penetrance UM gene, however it is responsible for susceptibility in only ~5% of UM families, therefore other as yet unidentified familial UM genes are likely to exist. In contrast to CM, there have been no GWAS for UM to date. A worldwide collaborative effort is needed to establish such an endeavour to increase our understanding of UM genetics.

S04 From families to populations and back

S04.2

Population biobanks: a crucial hub in clinical research

C. Wijmenga;

University Medical Center Groningen, Department of Genetics, Groningen, Netherlands.

Next generation genetics builds bridges between clinical research and population biobanks. Many diseases are multifactorial in origin, implying that they are caused by a combination of genetic and environmental components. To date, common genetic variants have been identified associated

with almost every multifactorial disease or trait. Nevertheless the relation between carrying genetic risk factors and disease outcome is not clear-cut as some people develop disease while others are resilient despite carrying many genetic risk alleles. Population-based prospective cohort studies follow individuals before the onset of disease, allowing for studies that can identify biomarkers and disease-modifying effects (including protective factors). The LifeLines Cohort Study is a large population-based cohort study and biobank that was established as a resource for research on complex interactions between environmental, phenotypic and genomic factors in the development of multifactorial diseases. Baseline phenotypes, biochemistry and dietary data have been collected for 167,729 participants, aged 6 months to 93 years. Genetic information by GWAS is available for about 10% of the cohort. From a subset of approx. 1500 individuals (LifeLinesDEEP) more detailed genomic data was collected including genome-wide RNAseq, methylation, metabolomics and gut metagenomics, allowing us to investigate the intricate relationship between host genetics, diet and gut microbiome on the susceptibility to multifactorial diseases. Based on RNAseq data we are able to assess which common genetic risk variants impact the expression of nearby (cis-eQTL) or distant (trans-eQTLs) genes, even in a context-dependent manner by deconvolution of the data into different blood cell types. Allele specific expression (ASE) even allows investigation of single patients from clinical families. A comprehensive analysis of the gut microbiome revealed strong associations with dietary habits, life-style, medication use and health parameters. We showed for example that the use of proton pump inhibitors - one of the most widely used drugs in Western populations - lead to a less healthy gut microbiome. We also showed that the gut microbiome plays a larger role in the variation in body mass index and blood lipid levels than host genetics. Our study supports the potential of microbiota-modifying intervention by diet, prebiotics or probiotics to prevent or treat multifactorial diseases. The comprehensive analysis as we have performed in LifeLinesDEEP exemplifies a systems approach to understand health and disease and is expected to pave the way towards personalized health care.

S04.3

Cost effective designs with population specific imputation panels in the Sardinian isolate

S. Sanna;

IRGB-CNR, Monserrato, Italy.

Identification of rare and low frequency variants is possible by whole-genome sequencing, but to assure enough statistical power for analyses several thousands of individuals have to be sequenced, at a cost that is still not negligible. An alternative cost-effective approach is to integrate genotyping arrays data for a large number of individuals with a reference set of sequenced genomes, either using public resources or by direct sequencing a subset of the study samples. The benefits of the latter strategy are expected to be higher for homogenous populations, especially in isolates, as there are fewer haplotypes to be tracked down, and also because rare and less frequent alleles may have raised in frequency due to genetic drift or selection. We have generated a Sardinian-specific reference panel for imputation by low-pass whole-genome sequencing of to up to 3514 Sardinians, and used this panel to impute a cohort of 6,602 Sardinian individuals genotyped at ~900K SNPs. We observed that efficiency of imputation was remarkably higher when compared to inferences made with existing public resources, and that low frequency and rare variants could be predicted with proper precision. Inferred genotypes were subsequently tested for association with several quantitative traits, revealing that this genotyping-combined with population-specific sequencing approach provides not only an average benefit in accuracy, but also leads to the discovery of novel associations that would have been missed otherwise. Novel associated loci showing strong differences in frequency and linkage disequilibrium patterns compared to populations in 1000 Genomes or at which the causative variant was absent from the publicly available reference panels were indeed misplaced or completely missed when a non-Sardinian source of haplotypes was used for imputation. Overall, these results demonstrate the benefits of a population-specific panel in Sardinians for complex traits genetics.

S05 Circulating Cell-Free Nucleic Acids

S05.3

Genomewide plasma DNA sequencing for cancer detection and noninvasive prenatal testing

Y. Lo;

Li Ka Shing Institute of Health Sciences, The Chinese University of Hong Kong, Hong Kong, China.

Recently, there is a lot of interest on the use of circulating cell-free DNA in plasma for molecular diagnostics. In particular, the success in noninvasive prenatal testing using cell-free fetal DNA in maternal plasma has demonstrated the power of this approach. We have ongoing efforts to explore the applicability of a similar approach for the noninvasive detection of cancer, using genomewide plasma DNA sequencing. Using this approach, we have found that cancer-associated copy number aberrations and methylation aberrations can be detected in a genomewide manner in the plasma of cancer patients. We have also demonstrated that circulating tumor-derived DNA is shorter than that from non-tumor tissue in plasma. Very recently, we have shown that by using over 5800 methylation markers showing tissue-specific methylation changes, one can profile the origin of DNA in plasma. Using this approach, one can pinpoint the tissue of origin of an observed plasma DNA aberration, thus helping one to localize the site of a putative cancer. This technology, called plasma DNA tissue mapping, has also shed light on the origin of circulating DNA in healthy subjects. In this regard, we have shown that most of the circulating DNA in healthy subjects is derived from myeloid and lymphoid cells. We believe that plasma tissue mapping has diagnostic applications in many other clinical scenarios associated with cell death phenomena.

S06 Behavioural disorders

S06.1

Using next-generation sequencing to understand the genetics of autism

E. Eichler^{1,2};

¹Seattle, WA, United States, ²University of Washington & HHMI, Seattle, WA, United States.

Autism is a devastating neurodevelopmental disorder that afflicts approximately 1% of live births. It is characterized by deficits in language, social interaction and repetitive behaviors. I will summarize our findings regarding the discovery of genetic mutations and their contribution to autism spectrum disorder (ASD) and developmental delay (DD). I will present evidence from exome and molecular inversion probe sequencing of more than 10,000 children with simplex autism and show how these data may be used to pinpoint specific genes. The emerging data strongly argue that the development of the human brain is particularly sensitive to the timing and expression of many different genes; multiple genetic perturbations within specific neurodevelopmental pathways related to long-term potentiation, chromatin remodeling, synaptic function and Wnt signaling appear particularly important; and that the maternal and paternal contributions differ significantly. I will present data on how grouping patients based on a specific gene can be used to predict clinical subtypes of autism. Next-generation exome and genome sequencing data provide a powerful path forward for understanding the genetic architecture of these diseases but the heterogeneity demands an unprecedented level of global cooperation and networking.

S06.2

A highly conserved program of neuronal microexons is misregulated in autistic brains

M. Irimia¹, M. Quesnel-Vallieres², N. Parikshak³, D. H. Geschwind³, S. P. Cordes⁴, B. J. Blencowe²;

¹Centre for Genomic Regulation (CRG), Barcelona, Spain, ²University of Toronto, Toronto, ON, Canada, ³University of California Los Angeles, Los Angeles, CA, United States, ⁴Lunenfeld-Tanenbaum Research Institute, Toronto, ON, Canada.

A key challenge in understanding autism is to establish whether this genetically heterogeneous disorder is caused by common mechanisms. Transcriptomic profiling has revealed consistently altered signatures in autistic brains. These include a program of 3-27 nucleotide 'microexons', which is misregulated in the brains of individuals with autism spectrum disorder. Relative to all other types of alternative splicing, microexons display the most striking evolutionary conservation and switch-like regulation during

neuronal differentiation. These microexons modulate the function of interaction domains of proteins involved in neurogenesis and are modulated by neuronal activity. Most neural microexons are regulated by the neuronal-specific splicing factor nSR100/SRRM4 through its binding to adjacent intronic enhancer motifs, and reduced levels of this protein are also observed in autistic brains. Collectively, these results provide evidence that misregulation of a splicing network affected by neuronal activity is associated with associated with autism spectrum disorder.

S06.3

Genetics of schizophrenia

M. O'Donovan;

MRC Centre for Neuropsychiatric Genetics and Genomics, Cardiff University, Cardiff, United Kingdom.

Risk alleles for schizophrenia span the full spectrum of population frequencies and include common alleles of small effect sizes and rare alleles with large effect sizes. The past few years has seen a rapid expansion in the number of robustly implicated genetic risk factors associated with schizophrenia, increasingly facilitating analyses seeking to link genetic findings to biological processes that underlie some aspects of pathophysiology. In this presentation, I will summarize the progress in identifying schizophrenia associated variants from a diverse set of study designs based on published and unpublished data, show that they appear to converge on proteins involved in various facets of synaptic biology, and highlight work showing that some of the risk alleles have manifestations that are apparent in early childhood.

S07 Long distance regulation of transcription and translation

S07.1

Gene regulation dynamics and chromatin architecture during development and evolution

J. L. Gómez-Skarmeta;

Centro Andaluz de Biología del Desarrollo (CABD), Consejo Superior de Investigaciones Científicas/Universidad Pablo de Olavide, Sevilla, Spain.

Temporal and evolutionary dynamic of gene expression is critical for tissue formation during animal development and has been essential for morphological diversification along evolution. This depends on *cis*-regulatory information located at the non-coding DNA. What is the dynamic of this regulatory information along development and evolution and how this information is organized in the genome? Here I will present a comparative study of the vertebrate epigenome during development that reveals an evolutionary conserved process at *cis*-regulatory regions essential for vertebrate body plan formation. In addition, I will show the evolutionary history of the 3D chromatin architecture of critical genomic loci.

S07.2

Dissecting mammalian transcriptional organization by analyzing the content of transcription factories

A. Papantonis;

Cologne, Germany.

Mammalian cell nuclei contain three RNA polymerases (I, II, and III), each transcribing a different gene subset. The active forms of these polymerases are contained in supra-molecular complexes known as 'transcription factories'. These complexes harbor >95% of nuclear transcriptional activity, and are embedded in the 3D structure of the nucleus. We recently described a novel method by which the protein and RNA contents of transcription factories can be isolated and analyzed in a high throughput fashion. Using these approaches we may now directly interrogate aspects of mammalian transcriptional organization that remain elusive. For example, using nascent RNA isolated from factories, we were able to show for the first time that many human introns are spliced in a recursive manner. This molecular mechanism utilizes cryptic, non-canonical, sites embedded in introns. The tight association of these sites with intragenic *cis*-regulatory elements, and potentially with underlying genetic variants, suggest a whole new way by which results from both genetic and functional studies should now be approached.

S08 Sensory disorders

S08.1

Functional studies reveal how mutations of MYO15A cause human deafness DFNB3

T. B. Friedman, A. U. Rehman, J. E. Bird;

National Institute on Deafness and Other Communication Disorders, NIH, Bethesda, MD, United States.

Autosomal recessive mutations in any one of almost a hundred genes account for nearly half of the irreversible non-syndromic deafness found in newborn humans. Additionally, there are at least 400 clinically distinct syndromes described in the Online Mendelian Inheritance in Man that involve hearing loss. Twenty years ago, deafness segregating in a Balinese village was mapped to chromosome 17p11.2 and designated the DFNB3 locus. Subsequently, missense mutations of myosin 15 were found to cause DFNB3 and the shaker 2 deaf mouse phenotype. Across diverse ethnic groups, recessive mutations of MYO15A encoding myosin 15 are now recognized as a common cause of congenital, profound deafness. Myosins are molecular motors that generate tension and produce force to power motility along cytoskeletal actin filaments. Three distinct alternative splice isoform classes of myosin 15 have been discovered, of which the 395 kDa (3,530 residues) isoform 1 is the largest member of the myosin superfamily. Presently, 192 different recessive mutations of MYO15A associated with DFNB3 are distributed across 49 of its 67 exons (43% missense, 23% frameshift, 16% nonsense, 16% splice site and 2% indels). Several of the truncating mutations of MYO15A are located in giant exon 2 which alone encodes 1,233 amino acid residues, and yet it is surprising that there isn't a single convincing pathogenic missense mutation reported in this exon. The pathogenicity of MYO15A mutations and the wild-type functions of myosin 15 have been gleaned from biochemical studies and animal models of DFNB3. Isoform 2 of myosin 15 transports whirlin and EPS8 to the tips of stereocilia. This complex is essential for the metamorphosis of microvilli into mechanosensitive stereocilia bundles on the apical surface of hair cells. Shortly after birth, hair cells then switch expression to myosin 15 isoform 1 that maintains adult actin-cytoskeleton of stereocilia and is necessary for life-long hearing. Supported by NIDCD/NIH Intramural funds DC000048-19 to TBF

S08.2

Genetics of visual impairment

D. Schorderet;

Institut de Recherche en Ophtalmologie, Sion, Switzerland.

Inherited diseases of the eye encompass a large number of entities including recessive and dominant diseases, autosomal, X-linked and mitochondrial. As the eye is a complex structure, diseases affecting each of its structures may induce loss of vision. Developmental anomalies, corneal dystrophies, glaucoma, rod-cone or cone-rod dystrophies, vitreoretinopathies and even cancer may all lead to visual impairment. During this presentation I will focus on diseases of the cornea and retina, describing some of the most prevalent disorders. I will also show how current genetic research has accelerated the pace of discovery of new genes and discuss why geneticists should interplay much more with ophthalmologists for a better management of patients.

S09 ASHG/ESHG/EMPAG SYMPOSIUM: Debating germline genome editing

S09.3

Ethical aspect of germline gene editing

A. Bredenoord;

Utrecht, Netherlands.

Since the advent of recombinant DNA technology in the 1970s, genetic testing, selection and screening have been considered to be ethically justifiable and allowed under most jurisdictions, but genetic modification of the human germline has for many been an ethical line that should not be crossed. Germline modification encompasses any biomedical intervention that modifies the genome that a person can transmit to his or her child and the child's entire lineage. Until recently, the technological tools that enable a viable path to realizing human germline modification were not available. However, two recent scientific developments have revived the international discussion on the ethics of germline modification and underscore the need to address the ethics and governance of human germline modification now.

First, UK parliament recently legalized a novel reproductive genetic technology to prevent mitochondrial DNA disorders: mitochondrial replacement techniques. Now both the technological barriers as well as the policy barriers for MRT are considerably lowered, at least in the UK, the first clinical use is expected shortly. This would encompass a modification of the mitochondrial genome. Second, recent advances in genome editing techniques such as CRISPR/Cas9 make it possible to edit DNA sequences in virtually any organism of choice. In April 2015, Chinese scientists published the first report of the use of gene editing techniques for basic research in human embryos. Gene editing experiments in human embryos have now been approved in China, the UK and Sweden. These developments have sparked an international ethical debate. Leading scientific journals Nature and Science rejected the first Chinese publication for ethical reasons and published commentaries that called for an international moratorium. Others view the continuation of basic gene editing research on human embryos as a 'moral imperative' for its offers the future potential of correcting genetic disease, many of which are currently untreatable. Many, among which myself as a member of the Hinxton Group, emphasized the need for ethical and public deliberation about emerging genome editing techniques and (international) oversight. In this presentation I will review the key ethical arguments in favor and against germline modification and identify some of the ethical and governance questions that need to be examined in the coming period.

S09.4

ASHG statement on germline genome editing

K. Ormond;

Stanford, CA, United States.

The American Society of Human Genetics (ASHG) developed a workgroup to create a policy statement on human germline genome editing. This workgroup consists of a combination of clinician scientists and biomedical ethicists from the United States, Canada, and the UK. Somatic gene editing applications fall under already established guidelines in most countries, and are therefore not included in this statement. The presentation will discuss the current status of the policy draft and our key positions, as well as the ethical justifications.

S10 Brain genetics

S10.1

The genetics of brain calcification

C. Klein^{1,2};

¹Lübeck, Germany, ²Institute of Neurogenetics, Luebeck, Germany.

Linkage analyses of large families affected by autosomal dominant primary familial brain calcification (PFBC; formerly known as idiopathic basal ganglia calcification (IBGC)) identified three candidate loci (named IBGC1-3). In 2012, mutations in SLC20A2 were found within the IBGC3 locus. In the following years, using next-generation sequencing, three further PFBC genes (PDGFRB, PDGFB, XPR1) were discovered and the respective disease forms were subsequently designated as IBGC4-6. A systematic search of the MEDLINE database for articles published until 2014 for the three genes with more than one report in the literature (SLC20A2, PDGFRB, and PDGFB) and a search of individual reference lists of all identified articles left 15 reports of genetically confirmed cases with individual clinical information. A total of 179 cases were reported, including 162 individuals who belonged to 25 families. Availability of information ranged from 96.6% for ethnicity to 24.4% for age at onset. All cases, regardless of which of the three genes was mutated, had calcifications on comprehensive cranial computed tomography, most frequently located in the basal ganglia (70.6%), subcortical white matter (40.8%), cerebellum (34.1%), or thalamus (28.5%). Mean (SD) AAO was 27.9 (22.3) years, and the AAO was likewise comparable across genes ($P = .77$). The most frequently described clinical signs were movement disorders, such as parkinsonism (12%) and dystonia (19%). Penetrance of the imaging phenotype was 100% compared with only 61% of the clinical phenotype. Pathophysiological pathways of all four genes involved in PFBC converge on impaired phosphorus homeostasis and integrity of the blood-brain barrier.

S11 Human genomics: transcriptome, proteome and interactome

S11.1

The human transcriptome across tissues and individuals

R. Guigó;

Center for Genomic Regulation (CRG) and Universitat Pompeu Fabra (UPF), Barcelona, Spain.

The pilot phase of the Genotype-Tissue Expression (GTEx) project has produced RNASeq from 1,641 samples originated from up to 43 tissues from 175 post-mortem donors, and constitutes a unique resource to investigate the human transcriptome across tissues and individuals. Clustering of samples based on gene expression recapitulates tissue types, separating solid from not solid tissues, while clustering based on splicing separates neural from non-neural tissues, suggesting that post-transcriptional regulation plays a comparatively important role in the definition of neural tissues. About 47 % of the variation in gene expression can be explained by variation across tissues, while only 4% by variation across individuals. We find that the relative contribution of individual variation is similar for lncRNAs and for protein coding genes. However, we find that genes that vary with ethnicity are enriched in lncRNAs, whereas genes that vary with age are mostly protein coding. Among genes that vary with gender, we find novel candidates both to participate and to escape X-inactivation. In addition, by merging information on GWAS we are able to identify specific candidate genes that may explain differences in susceptibility to cardiovascular diseases between males and females and different ethnic groups. We find that genes that decrease with age are involved in neurodegenerative diseases such as Parkinson and Alzheimer and identify novel candidates that could be involved in these diseases. In contrast to gene expression, splicing varies similarly among tissues and individuals, and exhibits a larger proportion of residual unexplained variance. This may reflect that that stochastic, non-functional fluctuations of the relative abundances of splice isoforms may be more common than random fluctuations of gene expression. By comparing the variation of the abundance of individual isoforms across all GTEx samples, we find that a large fraction of this variation between tissues (84%) can be simply explained by variation in bulk gene expression, with splicing variation contributing comparatively little. This strongly suggests that regulation at the primary transcription level is the main driver of tissue specificity. Although blood is the most transcriptionally distinct of the surveyed tissues, RNA levels monitored in blood may retain clinically relevant information that can be used to help assess medical or biological conditions.

S11.3

Mapping Human Long Noncoding RNAs

R. Johnson;

Barcelona, Spain.

The Gencode manually-curated gene annotation is a fundamental resource for long noncoding RNA (lncRNA) research. Despite rapid growth it remains incomplete, both in terms of missing gene structure elements (splice sites, exons, transcription start and termination sites) in annotated genes, as well as unknown numbers of unannotated genes.

To address both issues, we are applying RNA Capture methodology coupled to Third Generation long-read sequencing ("Capture Long-Seq", CLS) in both Human and Mouse. We have designed capture libraries that target (a) the entire set of known intergenic lncRNA genes, and (b) thousands of regions suspected to harbour unannotated lncRNA based on small RNA, enhancer, conservation or orthology evidence.

Analysis of > 2 million complete long reads of captured RNA from 6 tissues deepens known lncRNA annotations several times over: using conservative filters, the set of canonical lncRNA splice junctions increases by 250%. Around 80% of lncRNAs are detected, at a mean depth of 70 reads. We observe numerous cases of new exons, unified gene models underlying multiple annotations, and mono-exonic genes. Taking advantage of long read information, we also map 132,305 polyadenylation sites genome-wide.

Combining this data with CAGE transcription start site maps, we create the first annotation of confident, complete lncRNA transcript models. We use this to define the fundamental properties of lncRNA gene structure.

S12 SeX and the citY

S12.1

Sex determination: why so many ways of doing it?

D. Bachtrog;

Tree of Sex Consortium, Berkeley, CA, United States.

Sexual reproduction is an ancient feature of life on earth, and the familiar X and Y chromosomes in humans and other model species have led to the impression that sex determination mechanisms are old and conserved. In fact, males and females are determined by diverse mechanisms that evolve rapidly in many taxa. Yet this diversity in primary sex-determining signals is coupled with conserved molecular pathways that trigger male or female development. Conflicting selection on different parts of the genome and on the two sexes may drive many of these transitions, but few systems with rapid turnover of sex determination mechanisms have been rigorously studied. I will discuss our current understanding of how and why sex determination evolves in animals and plants and identify important gaps in our knowledge that present exciting research opportunities to characterize the evolutionary forces and molecular pathways underlying the evolution of sex determination.

S12.2

Origins and functional evolution of Y chromosomes across mammals

H. Kaessmann;

Heidelberg University, Heidelberg, Germany.

Y chromosomes underlie sex determination in mammals, but their repeat-rich nature has hampered sequencing and associated evolutionary studies. In an ongoing project, we are tracing Y functional evolution across representative mammals based on various types of high-throughput sequencing data. We previously uncovered three independent sex chromosome originations in mammals and birds (the outgroup). The original placental and marsupial (therian) Y, containing the sex-determining gene SRY, emerged in the therian ancestor approximately 180 million years ago, in parallel with the first of five monotreme Y chromosomes, carrying the probable sex-determining gene AMH. The avian W chromosome arose approximately 140 million years ago in the bird ancestor. The small Y/W gene repertoires, enriched in regulatory functions, were rapidly defined following stratification (recombination arrest) and erosion events and have remained considerably stable. Despite expression decreases in therians, Y/W genes show notable conservation of proto-sex chromosome expression patterns, although various Y genes evolved testis-specificities through differential regulatory decay. Thus, although some genes evolved novel functions through spatial/temporal expression shifts, most Y genes probably endured, at least initially, because of dosage constraints. In my talk, I will describe these findings as well as other interesting aspects of Y chromosome evolution that we recently uncovered.

S12.3

A Y-like social chromosome causes alternative colony organization in fire ants.

L. Keller;

Department of Ecology and Evolution, Biophore, University of Lausanne, Lausanne, Switzerland.

Intraspecific variability in social organization is common, yet the underlying causes are rarely known. In this talk I will show that the existence of two divergent forms of social organization is under the control of a pair of heteromorphic chromosomes that have many of the key properties of sex chromosomes. The two variants, hereafter referred to as the social B and social b (SB and Sb) chromosomes, are characterized by a large region of approximately 13 megabases (55% of the chromosome) in which recombination is completely suppressed between SB and Sb. The lack of recombination can be explained by at least one large inversion, and this absence of recombination has led to the accumulation of deleterious mutations, including repetitive elements in the non-recombining region of Sb compared with the homologous region of SB. Importantly, most of the genes with demonstrated expression differences between individuals of the two social forms reside in the non-recombining region. These findings highlight how genomic rearrangements can maintain divergent adaptive social phenotypes involving many genes acting together by locally limiting recombination. <!--EndFragment-->

S13 Epigenetic reprogramming in disease

S13.1

Epigenetics in health and disease

M. Esteller;

IDIBELL, Cancer Epigenetics and Biology Program (PEBC), Hospital Duran i Reynals, Barcelona, Spain.

For the last twenty-five years an increasing amount of evidence has shown the relevance of epigenetics in cell biology and tissue physiology, being DNA methylation aberrations in cancer the flag-ship for the recognition of its disturbance in human diseases. From the candidate gene approaches, new powerful technologies such as comprehensive DNA methylation microarrays and whole genome bisulfite sequencing has recently emerged that have reinforced the notion of epigenetic disruption in the crossroad of many sickness. From the poster-boy cases of MGMT and GSTP1 hypermethylation in the prediction of alkylating drug response and prostate cancer detection, respectively, to the personalized treatment of leukemia with small molecules targeted to fusion proteins involving histone modifiers such as DOT1L and MLL, the field has walked a long path. The current talk will focus in the epigenetic profiling, basically at the level of DNA methylation and histone modifications, that is starting to provide clinical value in the diagnosis, prognosis and prediction of response to drug therapies, with an emphasis in neoplasia, but without forgetting the novel advances in other human disorders such as neurodegenerative or cardiovascular diseases. For cancer, we have already a wide view of the undergoing DNA methylation events that expand beyond classical promoter CpG islands of tumor suppressor genes and we have a growing list of mutated chromatin remodeler genes that contributes to the tumorigenesis process. It is time to apply this knowledge in practical clinical situations like the diagnosis of cancers of unknown primary, the screening of malignancies in high-risk populations or a biomarker selection of the patients that should receive treatment with epigenetic drugs. Beyond that, epigenetics is involved in the aging process and many others aspects of human biology.

S13.2

Intergenerational and Stochastic Epigenetic Control of Metabolic Disease: Evidence for polyphenism in mouse and man?

J. A. Pospisilik;

Max Planck Institute of Immunobiology and Epigenetics, Freiburg, Germany.

More than one half billion people are obese. Though substantial progress is being made in understanding genetic predisposition for obesity, much of the high heritability for the disease remains enigmatic. Our lab focuses on understanding how chromatin state biases can be established to generate or modify disease susceptibility. We have begun to dissect how core chromatin regulatory systems can impact metabolic phenotypes, their variability and their distribution. In a first study, we have identified a paradigm of paternal-diet-induced intergenerational metabolic reprogramming (IGMR). We find that diet can act as a physiological suppressor of variegation, capable of selectively modifying genomic output for the lifetime of the offspring individuals. This occurs in a chromatin-state-specified manner and controls transcriptome signatures in mature sperm of the father and in offspring embryos. This model has allowed us to identify Polycomb and core-hererochromatin machinery as required for the manifestation of intergenerational metabolic reprogramming (Ost, Cell 2014). In a second study, we identify a Trim28-sensitive epigenetic switch that triggers obesity stochastically and in an apparently 'On/Off' manner. Using genetic dissection and transcriptome analyses, we map this phenotype to control of a series of metabolically potent imprinted genes. We find that human children present in similarly distinct sub-populations stratifying by *Trim28* expression, imprinted gene dysregulation, and profoundly distinct transcriptome organization (Dalggaard Cell 2016). To the best of our knowledge, the latter data provide the first evidence of *polyphenism* in mouse and humans and break major assumptions made in our understanding of complex trait genetics, evolution and medicine. In the presentation, I will provide our latest updates on these ideas as well as their extensions towards tissue specificity of function.

S13.3

Epigenetic reprogramming in the germline and early embryo

G. Kelsey, K. Stewart, L. Veselovska, S. Smallwood, C. Hanna, J. Huang, H. Saadeh;
The Babraham Institute, Cambridge, United Kingdom.

Epigenetic mechanisms are fundamental for the orderly regulation of gene expression throughout the life-course, providing a critical memory of ear-

lier decisions. They can ensure resilience against environmental change, but also allow adaptation. Nowhere is this more important than in the gamete and the early embryo. We are seeking to understand what governs how DNA methylation and other epigenetic marks are patterned during gametogenesis and embryogenesis. Using mouse as a model, we have shown that transcription is the major determinant of the DNA methylation landscape in the oocyte. To understand the mechanistic connection between transcription and de novo methylation, we have profiled histone modifications in growing oocytes and identify chromatin states permissive for and resistant to DNA methylation characterised by reciprocal enrichment of H3K4me2/me3 and H3K36me3. This finding is reinforced by the consequences on the DNA methylation landscape of genetically ablating specific H3K4 demethylases and methyltransferases. Key to such studies is the development of methods for genome-wide profiling of epigenetic marks in low numbers of cells, including at the single-cell level, which could have application widely in epigenetic studies, particularly for rare cell types and for investigating cell-to-cell heterogeneity in epigenetic marks at critical developmental transitions.

S14 Reproductive genetics and genomics

S14.1

Cell fate decisions during early development

M. Zernicka-Goetz;

University of Cambridge, Dept. of Physiology, Development & Neuroscience, Cambridge, United Kingdom.

Embryonic development progresses through successive cell fate decisions and intricate three-dimensional morphogenetic transformations. Implantation is the defining event in mammalian pregnancy during which a fundamental morphogenetic transformation is initiated: the body axes are established and the embryonic germ layers created. Despite its importance, a comprehensive understanding of the molecular mechanisms, transcriptional pathways, cellular interactions, as well as the spatio-temporal development of the embryo at implantation stages is at present lacking, due to the embryo's inaccessibility. To overcome these limitations, we have generated a culture system that allows the development of implanting embryos outside of the mother. This system provides the opportunity to address how architectural features and signaling events integrate to induce the emergence of the body plan. I will describe our progress in using this system to analyse the pathways underlying the very first morphogenetic changes that occur in the embryo following implantation and how we can mimic these events using ESCs both for the mouse and for human embryos. Our next challenge is to establish how the pluripotent epiblast cells interact with flanking extra-embryonic tissues during this developmental stage to generate AP axis within the embryo and progress to gastrulation.

S14.2

Human Embryo Genome Activation

J. Kere, V. Töhönen;

Karolinska Institutet, Stockholm, Sweden.

After fertilization, massive oocyte RNA degradation takes place, followed by a cascade-like activation of transcription from the embryo genome (Embryo Genome Activation, EGA). We have characterized human EGA by single-cell RNA sequencing of over 340 oocytes, zygotes and isolated blastomeres from 4-cell and 8-cell stage embryos, focusing on the transcription start sites (TSS) using the STRT method (Töhönen, Katayama & al. Nat Comm 6:8207, 2015). Our results revealed that 32 transcripts, including seven previously incompletely annotated PRD-like homeodomain transcription factor genes, were the first to be transcribed at 4-cell stage (day 2 after fertilization), followed by 129 transcripts at 8-cell stage (day 3). The total content of mRNA remained essentially unchanged in oocytes and zygotes, but was reduced 16-fold in 4-cell blastomeres, consistent with the cell division effect and oocyte transcript degradation. Supporting degradation, at 4-cell stage the majority of transcript reads mapped elsewhere than the 5' promoter and upstream regions of genes. For the first activated genes, our TSS targeted data allowed the identification of critical regulators of EGA as 36 bp and 35 bp conserved promoter elements at the two stages of EGA, respectively. We cloned and verified the genomic structures of seven homeobox genes not present in the rodent genomes: ARGFX, CPHX1, CPHX2, DPRX, DUXA, DUXB, and LEUTX. Exploration of FANTOM5 data and other databases showed exclusive expression of these genes during the EGA and absent expression already in human embryonic stem cells (hESCs). Our functional analyses confirm their activity as transcription factors with a spectrum of activity

from strong activators to strong suppressors of transcription in hESC models (Jouhilahti, Madisson & al. unpublished work). Our data constitute a resource for understanding the earliest steps of human embryonal development and provide new genes of interest for the study of pluripotency and stem cell technologies.

S14.3

Mechanisms of lineage specification in human embryos and stem cells

K. Niakan;

The Francis Crick Institute, London, United Kingdom.

During early human development totipotent zygotes diverge into pluripotent embryonic cells, which form the fetus, and extra-embryonic cells, which contribute to the placenta and yolk sac. Understanding the molecular mechanisms that regulate pluripotency in human embryos and how it is disengaged during cellular differentiation is of fundamental biological importance. Using single-cell RNA-sequencing of human and mouse embryos we have elucidated conserved transcriptional programs along with those that are human-specific. By modulating signaling pathways we discovered a requirement for TGF- β signaling in the maintenance pluripotency in human embryos. By uncovering the molecular basis of these early cell lineage decisions we underscore their significant clinical implications for infertility, miscarriages, developmental disorders and therapeutic applications of stem cells.

S15 Therapy in rare diseases

S15.1

Gene therapy in Fanconi anemia

J. A. Bueren;

Division of Hematopoietic Innovative Therapies. CIEMAT, CIBER of Rare Diseases and IIS-Fundación Jiménez Díaz, Madrid, Spain.

Fanconi anemia (FA) is an inherited disease mainly characterized by congenital abnormalities, progressive bone marrow failure, and cancer predisposition. Gene therapy may constitute a good alternative for the treatment of Fanconi anemia (FA) patients lacking a HLA matched donor. However, in contrast to other disorders already treated by gene therapy, marked proliferation and differentiation defects have been observed in FA hematopoietic stem cells (HSC), complicating the harvesting of a high number of CD34+ cells to be used in gene therapy protocols. On the other hand, the proliferation advantage of gene-corrected FA HSCs may facilitate the hematopoietic reconstitution of the patient by a low number of transduced HSCs. For the collection of HSCs from FA patients, filgrastim and plerixafor have been used as mobilizing agents. The short transduction of small aliquots of mPB CD34+ samples from these patients with a GMP-produced lentiviral vector that harbors the *FANCA* therapeutic gene corrected the phenotype of 20-40% of these progenitor cells. To assess the repopulating ability of transduced FA-A CD34+ cells, samples were transplanted into immunodeficient NSG mice. Remarkably, most of the transplanted samples engrafted the NSG mice, and an *in vivo* proliferation advantage of gene-corrected CD34+ FA-A cells was observed in recipients' BM. Based on these preclinical studies, a gene therapy trial of FA-A patients is currently open in Spain. In addition to conventional gene therapy, we have also investigated the possibility of generating gene-corrected FA HSCs by conducting untargeted and also targeted gene addition approaches on FA fibroblasts that were subsequently reprogrammed to generate induced pluripotent stem cells. An update of our preclinical and clinical studies will be presented.

S15.2

Antisense therapy in Spinal Muscular Atrophy

R. Finkel;

Orlando, FL, United States.

Classic spinal muscular atrophy (SMA), a progressive motor neuron disorder, is the most common fatal autosomal recessive disease of infancy, with an incidence of approximately 1:10,000 and carrier frequency of 1:40 to 1:60. SMA is a monogenic disorder due to homozygous deletion or mutation in the survival of motor neuron 1 (*SMN1*) gene at 5q13. An inverted duplication of a nearly homologous "backup" gene, *SMN2*, is present only in humans. *SMN2* differs functionally from *SMN1* due to a c.840C>T substitution which creates an exon splice inhibitor and results in alternative splicing that largely excludes exon 7 and generates a non-functional SMN protein. Approximately 10% of transcripts, however, are full-length and translate a

normal protein. In effect, *SMN2* incompletely rescues an otherwise lethal condition. The number of copies of *SMN2* is inversely related to the severity of the phenotype. There is a broad range in phenotype. Over half of affected patients have the most severe form, type I, which presents in early infancy. These infants fail to sit or gain motor skills and generally die by 2 years of age, due to related respiratory muscle weakness and pulmonary infection. The less severe forms present as: type II, in later infancy with sitting achieved, and type III, in childhood with walking achieved.

Multiple treatment strategies for spinal muscular atrophy have entered clinical trials in recent years. Pre-clinical cell-based and animal model studies have identified several approaches to rescue the phenotype and possibly intervene pre-symptomatically. Initial drug trials in SMA examined repurposed use of existing drugs: HDAC inhibitors to increase gene transcription (valproic acid, phenylbutyrate), modulators of exon 7 inclusion in the *SMN2* gene (valproic acid, hydroxyurea, quinazolones), and inhibitors of excitotoxicity (glutaminergic: riluzole; GABAergic: gabapentin) or muscle mitochondrial enhancement (l-carnitine). None of these demonstrated meaningful clinical benefit.

Current drug development for SMA focuses on three strategies: (1) splice site modulation to promote inclusion of exon 7 in the *SMN2* transcript via: (a) intrathecal delivery of anti-sense oligonucleotides (ASO), "nusinersen" (Ionis/Biogen) or (b) small-molecule oral drugs, "LMI070" (Novartis) and "RG7916" (Roche); (2) intravenous gene transfer therapy using scAAV9-SMN1 (AveXis/Nationwide Children's Hospital) and; (3) down-stream modification via: (a) neuroprotective/mitochondrial enhancement, "olesoxime" (Trophos/Roche), or (b) troponin activation in muscle, "CK-2127107" (Cytokinetics).

This talk will focus mainly upon the ASO approach to generate full-length transcript in target motor neurons, and will summarize the clinical trials that have demonstrated promising improvement in survival and motor function. A pre-symptomatic study is also underway.

Summary: Both targeted *SMN2* gene editing drugs and AAV vector mediated *SMN1* gene replacement studies are advancing through clinical trials and show promising early safety and efficacy results. Downstream disease modifying drugs, by targeting motor neurons or muscle, may provide additional supplemental benefit. Combined treatment may eventually offer a rational multidimensional approach to optimizing therapeutic benefit. How early to treat and how much of the phenotype can be rescued remain critical questions.

S15.3

Novel Approaches to the Treatment of Cystic Fibrosis

M. D. Amaral;

University of Lisboa, Faculty of Sciences, BioISI – Biosystems & Integrative Sciences Institute, Lisboa, Portugal.

Cystic fibrosis (CF) is a major life-shortening genetic disease leading to severe respiratory symptoms caused by mutations in CF transmembrane conductance regulator (CFTR), a chloride/bicarbonate channel expressed at the apical membrane of epithelial cells. Absence of functional CFTR from the surface of respiratory cells reduces mucociliary clearance, promoting airways obstruction, chronic infections and ultimately lung failure [1]. To date ~2,000 CFTR mutations were reported [2] but one single mutation - F508del - occurring in ~85% of CF patients worldwide, is associated with intracellular CFTR protein retention and a severe clinical phenotype.

Major clinical advances in treating CF symptoms (with mucolytics, antibiotics, etc) have significantly increased survival beyond the second decade (~25 years in Europe). However, to further increase CF patients life expectancy, CF needs to be treated beyond its symptoms i.e., through treatments addressing the basic defect associated with each CFTR gene mutation [3,4]. One new drug, potentiator VX-770 (ivacaftor/Kalydeco) has hit the clinical setting but only for ~5% of all CF patients, i.e., those bearing G551D and 8 other mutations causing a similar defect in the channel [5]. More recently, a new drug (Orkambi), which combines corrector VX-809 (lumacaftor) rescuing F508del-CFTR to the cell surface with potentiator ivacaftor, went into the clinic, following proven efficacy, albeit modest, in a phase III clinical trial for F508del/ F508del patients [6].

As these therapies correcting defective CFTR become available, we should quickly pre-assess how other CFTR mutations respond to such new drugs. This is the way forward to extend them more CF patients, namely to those with ultra-rare („orphan“) mutations in an effective and expedite way. Indeed, for such mutations, „classical“ clinical trials are not possible due to low numbers of patients and their geographic dispersion. It is thus crucial to use the above novel methods to pre-assess directly on patient's cells/tissues how each individual responds to these novel drugs. These can include a swelling assay in intestinal organoids [7] or measurement of CFTR Cl- cur-

rents in polarized primary cultures of nasal cells [8]. Such pre-assessment may become a standard basis for a drug clinical use in a precision medicine approach.

Work in the author's lab is supported by strategic grant PEst-OE/BIA/UI4046/2011 centre grant (to BioISI) from FCT/MCTES, Portugal; and by research grants (to MDA): „INOVCF“ from CF Trust, UK (SRC Award No. 003), Gilead GENESE (Ref PGG/008/2015) and AMARAL15XX0, AMARAL15XX1, AMARAL1610 from CFF-Cystic Fibrosis Foundation, USA.

S16 Cardiovascular genetics (joint with ESC)

S16.1

Update on the genetics of thoracic aortic aneurysms

B. Loeyts;

University of Antwerp/Antwerp University Hospital, Antwerp, Belgium.

Thoracic aortic aneurysms (TAA) are often asymptomatic but predispose to aortic dissections, which are associated with high mortality rates. Thoracic aortic aneurysms and dissections (TAAD) can be subdivided into syndromic (associated with systemic manifestations) and non-syndromic forms, although recent clinical observations are blurring this distinction. A positive family history occurs in circa 20% of all TAA individuals. Most commonly, familial TAADs segregate in an autosomal dominant manner, but rare autosomal recessive and X-linked families have been described. Non-syndromic forms of TAA are strongly associated with mutations in genes encoding for proteins of the vascular smooth muscle contractile apparatus (ACTA2, MYH11) or its modifiers (PRKG1, MYLK, FOXE3). Syndromic presentations can be linked to alterations in the extracellular matrix (FBN1, FBLN4, MFAP5, LOX) and the transforming growth factor beta signalling pathway (TGFB1/2, SMAD2/3, TGFB2/3). Marfan syndrome (MFS) is an autosomal dominant connective tissue disorder in which affected individuals present with ocular, skeletal and cutaneous signs besides aneurysm and dissection. Loeyts-Dietz syndrome (LDS) is an aneurysmal connective tissue disorder that can be distinguished from MFS by the unique presence of craniofacial, skeletal, cutaneous, and/or vascular manifestations, prominently including hypertelorism, cleft palate or bifid uvula and arterial tortuosity with aneurysms distant from the aortic root. In addition, aneurysms in individuals with LDS tend to dissect at an earlier age and smaller diameter compared to individuals with MFS. Whereas MFS is caused by mutations in FBN1, coding for an extracellular matrix protein, LDS is caused by loss-of-function mutations in genes coding for components of the transforming growth factor beta signalling pathway. Significant clinical overlap exists between the phenotypes caused by mutations in the currently known LDS genes (TGFB1/2, SMAD2/3, TGFB2/3). Recent work has demonstrated that both MFS and LDS lead to dysregulation of the TGFbeta signalling pathway. The latter has opened interesting avenues for the application of new therapeutic strategies. Current next generation sequencing based gene panel testing for TAAD individuals yields a molecular diagnosis in up to one third of the patients, suggesting that several genes remain to be discovered.

S16.3

Molecular mechanisms responsible for inherited hypertension with brachydactyly

S. Bähring¹, P. G. Maass^{2,3}, A. Aydin², C. Schächerle², O. Toka⁴, E. Klusmann², F. C. Luft^{1,2};
¹Experimental and Clinical Research Center (ECRC), a joint cooperation between the Charité Medical Faculty and the Max Delbrück Center for Molecular Medicine in the Helmholtz Association (MDC), Berlin, Germany, ²Max Delbrück Center for Molecular Medicine in the Helmholtz Association (MDC), Berlin, Germany, ³Harvard University, Cambridge, MA, United States, ⁴Department of Pediatric Cardiology, Children's Hospital, Friedrich Alexander University Erlangen, Erlangen, Germany.

Autosomal-dominant hypertension with brachydactyly (HTNB) is a salt-independent Mendelian syndrome caused by activating mutations in the gene encoding phosphodiesterase 3A (PDE3A). These mutations increase the protein kinase A (PKA)-mediated phosphorylation of PDE3A resulting in enhanced cAMP-hydrolytic affinity and accelerated cell proliferation. The phosphorylated vasodilator-stimulated phosphoprotein (VASP) is dimi-

nished, and parathyroid hormone-related peptide (PTHrP) is dysregulated, potentially accounting for all phenotypic features. Untreated patients die prematurely of stroke; however, hypertension-induced target-organ damage is otherwise hardly apparent. Large-vessel and cardiac function is preserved in HTNB. The patients have normal platelet function. Cell-based studies demonstrated that available PDE3A inhibitors inhibit the mutant isoforms. However, increasing cGMP to indirectly inhibit the enzyme appears to have particular utility. Since our report we have been referred additional families with suspected HTNB. We identified a novel aspartic acid substitution at the same site featured by one of our earlier families (p.G449D). We verified increased PDE3A phosphorylation at Ser438 with a peptide SPOT assay. Our results shed light on PDE3A activation and could be relevant to the treatment of hypertension in the general population.

EDUCATIONAL SESSIONS

E1 Novel genome sequencing technologies

E1.1

Long-read sequencing of complex genomes

E. Eichler;

Department of Genome Sciences and Howard Hughes Medical Institute, University of Washington, Seattle, WA, United States.

The human genome is arguably the most-well assembled reference assembly yet many gaps remain and aspects of its structural variation remain poorly understood ten years after its finishing. The discovery and resolution of this variation is critical to understanding disease. I will present our most recent work sequencing human and non-human primate genomes using single molecule sequencing (SMS) technology. We have developed methods to detect indel and structural variants from several bases up to 50 kbp. We have closed or extended ~50% of the remaining interstitial gaps in the human genome and find that 80% of these carry long polypyrimidine/purine tracts multiple kilobases in length. Comparing the single haplotype to the human reference we resolve >35,000 structural variants and >500,000 indels at the basepair level with 99.9% sequence accuracy. 92% of insertions and 60% of deletions between 50-5000 bp in length are novel representing large swaths > 15 Mbp of undiscovered genetic variation within human genomes. We find that such sequences vary extensively in copy number and affect functional elements in the genome. In addition, the analysis uncovers other categories of complex variation that have been difficult to assess including mobile element insertions (eg SVA) as well as inversions mapping within more complex and GC-rich regions of the genome. Our results suggest a systematic bias against longer and more complex repetitive DNA that can now be partially resolved. I will discuss the potential of this technology to create accurate de novo assemblies of additional human genomes and non-human that more comprehensively capture the full spectrum of human genetic diversity and its importance to our understanding of genetic variation and disease.

E2 Genetic Privacy and Data Sharing joint with EMPAG

E2.1

The hitchhiker's guide to genome hacking

Y. Erlich;

Columbia University, New York, NY, United States.

We have entered to the era of ubiquitous genetic information for research, clinical care, and personal curiosity. Sharing these datasets is vital to realize the promise of the genetic revolution. However, one growing concern is the ability to protect the genetic privacy of the data originators. Here, I will technically map threats to genetic privacy and emphasize the limitation of mitigation strategies for privacy-preserving dissemination of genetic data. As an alternative to the zero-sum game of privacy versus utility, I will propose to focus on trust-enabling techniques to create partnerships between researchers and participants.

E2.2

The role of policy in navigating the privacy landscape and promoting responsible genomic data sharing

E. S. Dove;

University of Edinburgh, Edinburgh, United Kingdom.

The world is more connected than ever as we craft far-reaching networks of communication. A tangible effect of our networked world in the genomic and personalized medicine context is the increased sharing of genomic and clinical data between professionals, laboratories, hospitals, organizations, patients, participants, and—increasingly—across national borders. Sharing data facilitates both translational and precision medicine, not to mention research discovery. As various stakeholders in biomedical research and clinical practice laudably move towards a data sharing culture, challenges arise. In particular, privacy and data privacy regulation play a large role in defining the proper contours of global data sharing. Data sharing is a social activity, and privacy is fundamentally a social consideration. Like any partnership, there are responsibilities on both sides. A central concern is that genomic (and clinical) data must be collected, used, and shared in ways that respect the fundamental rights and interests of individuals and society, as reflected in national and international laws, and most notably, privacy. Data sharing carries a spectrum of risks, particularly re-identification of individuals and related others, and thereby represents a prima facie threat to their privacy. In this presentation, I outline the practices and benefits of genomic data sharing; the dimensions of privacy and data privacy regulation that challenge data sharing; and the ways in which one organization that I am familiar with, the Global Alliance for Genomics and Health, is addressing these challenges.

E4 Peroxisomal disorders -still a need for metabolic assays?

E4.1

Overview of peroxisomal disorders - diagnosis and management

N. Braverman;

McGill, Montreal, QC, Canada.

The peroxisome biogenesis disorders (PBD) include the Zellweger spectrum disorders (ZSD) and Rhizomelic chondrodysplasia punctata type 1 (RCDP1). These disorders are due to defects in anyone of 14 PEX genes, whose protein products, or peroxins, are required for the assembly of functional peroxisomes, which includes the process of matrix enzyme import, new peroxisome membrane formation and division of existing peroxisomes. Defects in 13 genes result in a ZSD phenotype due to the common end-effect of reduced peroxisome enzyme functions and correlates best to the B-oxidation defects and accumulation of toxic products. In contrast, the distinct RCDP phenotype is due to a single pathway deficit in the synthesis of specialized membrane lipids, plasmalogens. In this lecture we will review peroxisome clinical, biochemical and molecular pathways, their relation to ZSD and RCDP phenotypes, new information on these disorders, single enzyme defects of peroxisome function that relate to PBD and rational management approaches. We will emphasize how scientists, physicians and families have worked together in a rare disease, to push the field forward.

E4.2

The value of functional assays in peroxisomal disorders

H. R. Waterham;

Academic Medical Center at the University of Amsterdam, Amsterdam, Netherlands.

Peroxisomes are dynamic organelles, which, in humans, play an essential role in a variety of cellular catabolic and anabolic metabolic pathways, including fatty acid alpha- and beta-oxidation, and plasmalogen and bile acid synthesis. Defects in genes encoding peroxisomal proteins can result in a large variety of peroxisomal disorders affecting either specific metabolic pathways, i.e. the single peroxisomal enzyme deficiencies, or causing a generalized defect in function, assembly and maintenance of peroxisomes, i.e. peroxisome biogenesis disorders. Clinically, patients with peroxisomal disorders may present with variable severity ranging from early lethality to subtle neurosensory aberrations.

Up till recently, laboratory diagnosis of peroxisomal disorders primarily relied on metabolite analysis followed by biochemical testing and establishment of the underlying gene defect. The increasing implementation of Next Generation Sequencing (NGS) technology as first choice of diagnostic evaluation is changing the diagnostic landscape. While this approach should readily identify genetic defects in classical peroxisomal disorders, it may result in the identification of genetic variants with unknown consequences for peroxisomal functioning and short- or long-term pathogenicity in variant

disorders or in patients with mild disease. Insight into the possible of such DNA variants on metabolism and, as an extension thereof, on the individual requires a multidisciplinary approach combining genetic, biochemical and molecular biological studies. I will briefly review clinical, biochemical and genetic aspects of the different human peroxisomal disorders known to date, with emphasis on some recently discovered defects and including examples of cases where functional assays have been imparitive in the final diagnosis.

E5 Ciliopathies

E5.1

Cilia in human developmental anomalies

E. Valente;

University of Salerno, Salerno, Italy.

The primary cilium is a solitary organelle protruding from the surface of almost all vertebrate cell types. Long considered a vestigial remnant, this organelle has recently become the focus of intensive research, that demonstrated its many roles in sensing the extracellular environment, and in coordinating key signaling pathways. In particular, during the embryonic development, the primary cilium is known to critically regulate main pathways such as Sonic Hedgehog, Wnt and planar cell polarity, that are implicated in left-right axis formation, limb development and neurogenesis. Thus, it is not surprising that mutations in genes encoding ciliary proteins underlie a wide spectrum of "ciliopathies", that are characterized by substantial overlap among distinct conditions. Indeed, ciliopathies such as Joubert syndrome (JS), Meckel syndrome (MKS), Bardet-Biedl syndrome (BBS), Senior-Loken syndrome (SLS), some oral-facial-digital syndromes (OFD), Jeune asphyxiating thoracic dystrophy (JATD) and other short rib polydactylies, may variably share features such as retinal dystrophy, nephronophthisis or cystic dysplastic kidneys, congenital liver fibrosis, polydactyly and other skeletal abnormalities, situs inversus, occipital encephalocele and midline oral and facial defects. Clinical heterogeneity is mirrored by genetic heterogeneity, with each ciliopathy being caused by mutations in several genes and, on the other hand, mutations in one gene causing a wide phenotypic spectrum, often encompassing different syndromes of variable severity. For instance, JS and the lethal MKS ciliopathy are allelic at 9 loci. Similarly, mutations in three genes (CSPP1, KIAA0586 and CEP120) cause a spectrum of phenotypes with overlapping features of JS, MKS, JATD and OFD. The mechanism through which mutations in the same gene may cause such wide phenotypic variability remains unexplained, with genotype-phenotype correlates only partly explaining this variability. The identification of genetic modifiers and other factors able to influence the penetrance and expression of ciliary mutations, represents one of the biggest challenges of current research on ciliopathies.

E6 Cost-effectiveness in genetic testing

E6.1

Cost-effectiveness of diagnostics in rare diseases

K. Payne;

Manchester Centre for Health Economics, The University of Manchester, Manchester, United Kingdom.

The existence of finite healthcare budgets and the scarcity of healthcare resources mean that there is an opportunity cost for every decision made to introduce a new healthcare package, medicine, surgical procedure or diagnostic test into clinical practice. The decision to allocate resources to a particular healthcare intervention excludes those resources from alternative possible uses within a healthcare system. Therefore, ideally, robust evidence is required to inform decision-makers allocating healthcare resources about the potential costs and benefits of incorporating a healthcare intervention within clinical practice. Cost-effectiveness analysis offers a potential framework to evaluate the relative costs and benefits of healthcare interventions compared with current practice. Performing cost-effectiveness analysis of diagnostics for rare diseases may be problematic for many reasons. The aim of this presentation is to describe the key challenges (methodological, practical, technical and organisational) when conducting robust cost effectiveness analysis of diagnostic tests for rare diseases. The presentation will begin by presenting an overview of methods of cost effectiveness analysis and explain how they are used by decision-making bodies such as the National Institute for Health and Care Excellence. Diagnostic tests for rare diseases will then be described using the framework of a complex intervention. The key challenges of performing a cost-effectiveness analysis of

example diagnostic tests will then be described, and illustrated with applied examples, under the following four headings: methodological; practical; technical and organisational. The presentation will conclude by describing the further work required to ensure the methods and practical approaches to perform cost effectiveness analyses of diagnostic tests for rare diseases are sufficiently robust to inform their introduction into clinical practice and maximise the potential benefits for patient populations.

E7 Cleaning the noise from Big Data

E7.1

Removing unwanted variation in RNA-seq data

T. Speed^{1,2};

¹Melbourne, Australia, ²Walter & Eliza Hall Institute of Medical Research, Parkville, Australia.

Like other kinds of 'omic data, RNA-seq data can be affected by unwanted variation. This is often called batch effects, and includes variation due to time, space, technology, reagents, operators, environmental conditions, and unwanted biological variation, such as between biological replicates. Standard normalization methods for such data may not deal adequately with all unwanted variation. In this talk I will explain and illustrate how methods developed for microarray data can be modified to be effective at removing unwanted variation from RNA-seq data. We make use of negative controls and, when available, replicates. The methods will be illustrated with RNA-seq libraries made from brain tissue. The results discussed are all from joint work with Davide Risso, Lucia Peixoto and others to be named.

E8 Clinical interpretation of genetic variants

E8.1

Methods for the assessment of variant pathogenicity in cardiac diseases

S. Cook;

Singapore, China.

The accurate interpretation of genetic variation in Mendelian disease genes has lagged behind data generation as sequencing has become increasingly accessible. Ongoing large sequencing efforts present huge interpretive challenges, but also provide an opportunity to characterize the range and importance of rare variation. In this presentation I will discuss the analysis of sequence data from 7,855 clinical cardiomyopathy cases and 60,706 ExAC reference samples that we used to better understand genetic variation in cardiomyopathy that causes heart failure and sudden death. The analyses show that in some genes previously reported as important causes of a given cardiomyopathy, rare variation is not clinically informative whereas, in other genes, diagnostic laboratories appear overly conservative when assessing variant pathogenicity. The impact of cardiomyopathy research studies in the era of comprehensive sequencing is also discussed. The data point to analytical approaches to evaluate which genes and variant classes are interpretable for cardiomyopathy and may be applied to other multi-allelic Mendelian diseases.

E8.2

Recommendations for the Interpretation of Genetic Variants from the American College of Medical Genetics and Genomics and the Association for Molecular Pathology

H. Rehm;

Laboratory for Molecular Medicine, Partners Personalized Medicine; The Broad Institute of Harvard and MIT; Brigham & Women's Hospital; Harvard Medical School, Boston, MA, United States.

With the plummeting cost of sequencing, genetic data is becoming increasingly available for use in the diagnosis, treatment and prediction of disease. However, robust and accurate use of genomics in the practice of medicine requires high quality knowledgebases and the accurate interpretation of DNA variation. To address these needs, several efforts have been launched. The American College of Medical Genetics and Genomics (ACMG), in collaboration with the Association for Molecular Pathology (AMP), has published a guideline to enable a more systematic assessment of evidence for and against pathogenicity of DNA variants for Mendelian, or monogenic, disease. This includes recommendation for the use of standard terms: 'pathogenic', 'likely pathogenic', 'uncertain significance', 'likely benign', and 'benign' to de-

scribe variants related to monogenic diseases. Variants are classified into these five categories based on combinations of criteria of varying strength (e.g. supporting, moderate, strong, very strong) and type (e.g. population data, computational data, functional data, segregation data, etc.) These guidelines have now been tested by the NIH Clinical Sequencing Exploratory Research Consortium and implemented by many clinical laboratories and commercial platforms. In addition, clinical laboratories and expert working groups operating within the NIH funded Clinical Genome Resource Program (ClinGen) are applying the ACMG/AMP guidelines to resolve differences in variant interpretation identified in the NCBI's ClinVar database and build more granularity into the criteria using gene and disease specific parameters to enable expert review of variants in ClinVar. As of Apr. 2016, over 500 laboratories had submitted over 125,000 unique interpreted variants to ClinVar. Prior analyses in May 2015 showed that ~11% of variants had interpretations submitted by more than one laboratory, and of those ~17% were interpreted differently. Through pilot efforts the majority of these differences in variant interpretation appear to be resolvable and efforts are underway to resolve these differences using the ACMG/AMP guidelines.

CONCURRENT SESSIONS

C01 Reproductive Genetics

C01.1

Genome-wide haplotyping of preimplantation embryos in the clinic: principles guiding embryo selection in Leuven

K. Van Den Bogaert¹, E. Dimitriadou¹, C. Melotte¹, S. Debrock², K. Devriendt¹, T. de Ravel¹, T. D'Hooghe², J. R. Vermeesch¹;

¹Centre for Human Genetics, UZLeuven, Leuven, Belgium, ²Leuven University Fertility Centre, UZLeuven, Leuven, Belgium.

Recently, we developed haplarithmisis, a method enabling accurate concurrent haplotyping and copy number profiling and we demonstrated its validity in preimplantation genetic diagnosis for embryo analysis. The introduction in a diagnostic setting raised novel ethical questions. Here we present the principles guiding embryo selection and prioritization that are applied at our center according to the chromosomal content and mutational load of the embryos. Our embryo selection principles are based not only on technical and biological, but also on ethical criteria and have a profound impact on the organization of PGD operations and on the information that is transferred amongst the genetic unit, the fertility clinic and the patients. Those principles are also important for the organization of pre- and post-counselling and influence the way of interpreting and reporting preimplantation genotyping results.

From June 2014 until November 2015, 314 embryos from 50 couples have been tested in 82 cycles, leading to 16 clinical pregnancies (36% clinical pregnancy rate per cycle for which embryo transfer has been finalized) and the birth of 5 healthy babies, so far. Thirty-one different indications, i.e. 27 for monogenic disorders, 3 chromosomal aberrations and 1 case of combined monogenic disorder with chromosomal aberration have been included. As novel genome-wide approaches for embryo selection are revolutionizing the field of reproductive genetics, national and international discussions to set general principles are warranted.

C01.2

Mosaic embryos can achieve good IVF success rates

R. Morales¹, B. Lledó¹, J. Ortiz¹, H. Blanca¹, J. Llúcer², R. Bernabeu²;

¹Instituto Bernabeu Biotech, Alicante, Spain, ²Instituto Bernabeu, Alicante, Spain.

Introduction: Classification of mosaic embryos as aneuploid embryos is a controversial topic, since the association between mosaicism in trophoctoderm cells and inner mass cells is unknown. Moreover, it seems that there is a mechanism by which mosaicism could be corrected. To clarify this issue the outcomes of transfer cycles with mosaic and euploid blastocysts were compared.

Material and Methods: We retrospectively reanalyzed array-CGH results from trophoctoderm biopsies of 816 blastocysts. We considered a mosaic embryo when the percentage of mosaicism, calculated by the log2 ratio, was higher than 25%. Array-CGH analysis was performed using Agilent SurePrint G3 8x60K CGH microarrays with previous whole genome amplification of genomic DNA. The main outcome measures were implantation rate, pregnancy rate and biochemical and clinical miscarriage rate.

Results: We detected chromosomal mosaicism in 107 blastocysts (13.1%). Moreover, 49.4% of the analysed embryos were euploid, 30.9% aneuploid

and the remaining 6.6% without diagnosis. In the mosaic group, 57.9% were euploid embryos with mosaicism and 42.1% were also aneuploidy. The outcomes of the cycles were compared between cycles where only mosaic embryos were transferred and cycles where euploid embryos were transferred. Significant differences were observed in the clinical pregnancy rate (20.6% in mosaic group vs 38.9% in euploid group; $p=0.042$).

Conclusions: Our data show that the transfer of mosaic embryos affects the outcomes of the IVF cycles. Even so, the mosaic embryos have a relatively good IVF success rate and therefore they should not be discarded in couples that don't have euploid embryos for transfer.

C01.3

Gonadic mosaicism and prenatal diagnosis options: insights from retinoblastoma

C. Houdayer¹, C. Dehainault², L. Golmard², A. Charpin², A. Laugé², I. Aerts³, N. Cassoux⁴, G. A. Millot⁵, D. Stoppa Lyonnet⁶, M. Gauthier Villars²;

¹Institut Curie, oncogenetics, INSERM U830 and Paris Descartes Sorbonne Paris Cité University, Paris, France, ²Institut Curie, oncogenetics, Paris, France, ³Département d'oncologie pédiatrique, adolescents jeunes adultes, Institut Curie, Paris, France, ⁴Département d'oncologie chirurgicale, service d'Ophthalmologie, Institut Curie and Université Paris Descartes, Sorbonne Paris Cité, Paris, France, ⁵Institut Curie, CNRS UMR 3244 and Sorbonne Universités, UPMC Univ Paris 06, Paris, France.

Mosaicism impacts on the recurrence risk. In sporadic cases, a post-zygotic event signifies a somatic mosaicism in the affected child and thus parents and siblings are freed from follow up. On the other hand, a pre-zygotic mutation transmitted by an unaffected mosaic parent implies recurrence risk in future offspring and thus prenatal diagnosis options might be discussed. To better estimate the contribution of pre- and post-zygotic events, we used sporadic retinoblastoma as a model because 80% of Rb cases are due to de novo mutations.

We analysed 124 consecutive bilateral retinoblastoma probands carrying a heterozygous RB1 mutation previously ascertained by Sanger sequencing and their unaffected, non-carrier parents. In order to evaluate somatic mosaicism in blood, the deleterious mutation identified in the proband was searched for in the trios using targeted deep sequencing. Observed recurrences, which should represent an estimate of germline and somatic mosaicism, were recorded for the 124 sibships.

Deep sequencing evidenced one mosaic unaffected parent out of 124 tested couples, i.e. a 0.8 % risk of mosaicism and thus a theoretical 0.4% risk of recurrence. Follow up in the sibships showed one recurrence out of 199 novel births, i.e. an observed 0.5 % recurrence risk. Similar estimates were obtained by two independent methods, which is convincing. Consequently a mean 0.5% risk could be used or, more cautiously, a maximum recurrence risk of 2 out of 124 i.e. 1.6%. We believe these results could be considered for genetic counseling in other diseases with a high de novo mutation rate.

C01.4

Zygotes segregate entire parental genomes in distinct blastomere lineages causing cleavage stage chimaerism and mixoploidy

A. Destouni^{1*}, M. Zamani Esteki^{2*}, M. Catteeuw³, O. Tsuiko^{1,4}, E. Dimitriadou¹, K. Smits⁵, A. Kurg⁴, A. Salumets^{5,6}, A. Van Soom³, T. Voet^{2,7}, J. R. Vermeesch^{**1}, *Joint first-authors, ** Co-senior authors;**

¹Laboratory of Cytogenetics and Genome Research, Center of Human Genetics, KU Leuven, Leuven, Belgium, ²Laboratory of Reproductive Genomics, Center of Human Genetics, KU Leuven, Leuven, Belgium, ³Department of Obstetrics, Reproduction and Herd Health, Ghent University, Ghent, Belgium, ⁴Institute of Molecular and Cell Biology, Tartu University, Tartu, Estonia, ⁵Competence Centre on Health Technologies, Tartu, Estonia, ⁶Department of Obstetrics and Gynecology, University of Tartu, Tartu, Estonia, ⁷Sanger-EBI Single Cell Genomics Centre, Wellcome Trust Sanger Institute, Hinxton, Cambridge, United Kingdom.

Introduction: Chimaerism and mixoploidy are defined by the presence of cell lineages with different parental genomes or different ploidy states in a single individual, respectively. However, our knowledge on their mechanistic origin is limited, as it results from indirect observations, often when the cell lineages have been subject to rigorous selective pressure during development.

Materials and Methods: We applied haplarithmisis on SNP genotype data to infer the haplotypes and the copy number of parental genomes in 116 single blastomeres comprising entire in vitro produced preimplantation bovine embryos (n=23). Haplarithmisis uncovers copy number aberrations and determines their mechanistic/segregational origin at the single-cell level in unprecedented detail, enabling reliable reconstruction of the each embryo's cleavage history back to the zygote stage.

Results: We demonstrate that chromosome instability is comparable between bovine and human cleavage embryos. We further uncover a novel form of genomic instability whereby zygotes spontaneously segregate entire pa-

rental genomes into different cell lineages during the first post-zygotic cleavage division. Importantly, we observed that parental genome segregation was not exclusively triggered by abnormal dispermic fertilization, but also normally fertilized zygotes can spontaneously segregate entire parental genomes into distinct cell lineages during cleavage of the zygote. Preliminary data show the mechanism to be conserved in humans as well.

Conclusions: We discover a novel mechanism of aberrant cell division in the zygote culminating with the segregation of the parental genomes into distinct cell lineages. We coin this "Heterogoneic" cell division. This mechanism is likely the main cause for chimaerism and mixoploidy in mammals.

C01.5

Differential expression of parental alleles of BRCA1 in human preimplantation embryos

P. Tulay, 99138^{1,2}, A. Doshi³, P. Serha³, S. B. SenGupta²;

¹Near East University, Nicosia, Cyprus, ²UCL, Institute for Women's Health, London, United Kingdom, ³The Centre for Reproductive and Genetic Health, London, United Kingdom.

Introduction: The expression of parental genomes is required for completion of embryogenesis. Differential methylation of each parental genome has been observed in mouse and human preimplantation embryos. It is possible that differences in methylation affect the level of gene transcripts from each parental genome in early developing embryos. The aim of this study was to investigate if there is a parent specific pattern of *BRCA1* expression in human embryos and to examine if this affects embryo development when the embryo carries a *BRCA* mutation.

Materials and Methods: Differential parental expression of *ACTB*, *SNRPN*, *H19* and *BRCA1* was semi-quantitatively analysed by mini-sequencing in 95 human preimplantation embryos obtained from couples undergoing preimplantation genetic diagnosis (PGD).

Results: *BRCA1* was shown to be differentially expressed favouring the paternal transcript in early developing embryos. Methylation specific PCR showed a variable methylation profile of *BRCA1* promoter region at different stages of embryonic development. Embryos carrying paternally inherited *BRCA* mutations were shown to develop more slowly compared to the embryos with maternally inherited *BRCA* mutations.

Conclusions: The results of this study suggest that differential gene expression can influence the early development of preimplantation embryos. When the paternal *BRCA1* transcript present in the embryo carries a mutation, the embryo may become more vulnerable to stress due to rapid demethylation of the paternal genome and the gradual demethylation of the maternal genome. Further extrapolation of this data suggests that the risk of transmitting a *BRCA* mutation may be modulated by the parental origin of the mutation.

C01.6

Novel autosomal genes linked with male infertility

D. V. S. Sudhakar¹, R. Phanindranath¹, R. Singh², N. J. Gupta³, M. Deenadayal⁴, Y. Sharma⁴, K. Thangaraj¹;

¹Centre for Cellular and Molecular Biology, Hyderabad, India, ²Central Drug Research Institute, Lucknow, India, ³Institute of Reproductive Medicine, Kolkata, India, ⁴Infertility institute and research center, Hyderabad, India.

Introduction: Approximately 15% of the couples are infertile worldwide. Impaired fertility of male partner is causative in approximately 50% of infertile couples. Earlier studies from our lab have shown that about 8.5% infertility among Indian men is due to the Y chromosome microdeletions. Further, autosomal and mitochondrial mutations accounted for 20.5% of the genetic factors responsible for infertility among Indian men. However, etiology of large proportion (71%) of infertile men still remained unknown. Therefore, we performed exome sequencing to identify novel genes responsible for male infertility.

Materials and methods: we sequenced exome of 44 idiopathic infertile men using Illumina HiSeq-2000 platform with 100X coverage. Using various bioinformatics tools, we have identified 32 novel and rare variants and they were further genotyped in 1000 cases and controls. Of the novel genes identified, *CETN1* was found to be a strong candidate; hence we have sequenced complete *CETN1* in 875 infertile and 552 ethnically matched fertile men. Identified variants were characterized using biophysical and cell biology approaches.

Results: We have identified a total of 32 novel, stop gain and missense variants from 30 genes. Sequencing of *CETN1* revealed that one 5'UTR (rs367716858) and a missense (rs61734344) variant are associated with male infertility. Functional studies have shown that rs61734344 (p. Met-72Thr) alters calcium binding affinity, thermodynamic properties and sur-

face hydrophobicity. Functional analysis of 5'UTR variant (rs367716858) revealed that mutation causes increased expression of Centrin-1 protein. Conclusion: Our study has identified novel autosomal genes linked with male infertility.

C02 Intellectual Disability

C02.1

FRRS1L Mutations link intellectual disability to altered priming of AMPA-receptor biogenesis

A. Brechet¹, R. Buchert², J. Schwenk^{3,4}, S. Boudkazi¹, G. Zolles¹, K. Siquier-Pernet⁵, D. Loreth¹, I. Schaber¹, A. Saadi⁶, C. Bole-Feysot⁵, P. Nitschke⁵, A. Reis⁷, H. Sticht⁸, N. Al-Sanna⁹, A. Rolfs¹⁰, A. Kulik³, U. Schulte^{1,4}, R. Abou-Jamra^{7,11}, L. Colleaux¹², B. Fakler^{1,4}; ¹Institute of Physiology, University of Freiburg, Freiburg, Germany, ²Institute of Human Genetics, University of Erlangen, Erlangen, Germany, ³Institute of Physiology, University of Freiburg, Freiburg, Germany, ⁴Center for Biological Signaling Studies (BLOSS), Freiburg, Germany, ⁵Institut IMAGINE INSERM U1163, PARIS, France, ⁶Department de Neurologie, Etablissement Hospitalier Spécialisé de Benaknoun, Algiers, Algeria, ⁷Institute of Human Genetics, University of Erlangen, Erlangen, Germany, ⁸Institute of Biochemistry, Emil-Fischer Center, Erlangen, Germany, ⁹Dharan Health Center, Saudi Aramco, Saudi Arabia, ¹⁰Albrecht-Kossel-Institute for Neuroregeneration, Medical University Rostock, Rostock, Germany, ¹¹Institute of Human Genetics, University of Leipzig Hospitals and Clinics, Leipzig, Germany, ¹²Institut IMAGINE INSERM U1163, Paris, France.

Identifying causes of intellectual disability remains a considerable medical challenge. Here, we report on six patients from three unrelated consanguineous Algerian, Syrian and Saudi Arabian families presenting with a core phenotype of moderate to severe intellectual disability, speech delay and seizures. High-throughput sequencing identified three distinct homozygous mutations in the FRRS1L gene: a missense variant (p.Lys155Glu), a one base-pair deletion (p.Val195Glu*35) and a nonsense mutation (p.Gln321*). FRRS1L encodes a previously uncharacterized peripheral constituent of the AMPA glutamate receptors (AMPA-Rs). AMPA-Rs are key elements of the mammalian brain responsible for a variety of processes including fast excitatory neurotransmission, postsynaptic plasticity, or synapse development. These macromolecular complexes assemble from more than 30 different constituents. The inner core determines the biophysical properties of the receptors while the periphery is involved in various aspects of synapse physiology.

To further characterize the physiological role of FRRS1L upon brain development and function, we used reverse proteomics, biochemical, morphological and functional analyses to identify and characterize FRRS1L-containing AMPA-R assemblies.

We demonstrated that AMPA-R complexes containing FRRS1L are restricted to the endoplasmic reticulum and lack the inner core constituents of AMPA-Rs at the plasma membrane. Virus-directed deletion and overexpression of FRRS1L in adult rats alters the number of AMPA-Rs in individual synapses resulting in markedly reduced or increased amplitudes of the EPSCs without effects on their time courses

Our data identify FRRS1L as a new neurodevelopmental-disease gene and highlight the key role of this gene in the priming step of AMPA-R biogenesis and fast excitatory synaptic transmission.

C02.2

PIGG: a novel gene causing intellectual disability, seizures and hypotonia

P. Makrythanasis^{1,2}, M. Kato³, M. Zaki⁴, H. Saitsu⁵, K. Nakamura⁶, F. A. Santoni^{1,2}, S. Miyatake⁵, M. Nakashima⁵, M. Y. Issa⁷, M. Guipponi², A. Letourneau¹, C. Logan⁷, N. Roberts⁷, D. A. Parry⁷, C. A. Johnson⁷, N. Matsumoto⁵, H. Hamamy¹, E. Sheridan⁸, T. Kinoshita³, S. E. Antonarakis^{1,2,9}, Y. Murakami¹⁰;

¹Department of Genetic Medicine and Development, University of Geneva, Geneva, Switzerland, ²Service of Genetic Medicine, University Hospitals of Geneva, Geneva, Switzerland, ³Department of Immunoregulation, Research Institute for Microbial Diseases, and World Premier International Immunology Frontier Research Center, Osaka University, Osaka, Japan, ⁴Department of Clinical Genetics, National Research Centre, Cairo, Egypt, ⁵Department of Human Genetics, Yokohama City University Graduate School of Medicine, Yokohama, Japan, ⁶Department of Pediatrics, Yamagata University Faculty of Medicine, Yamagata, Japan, ⁷School of Medicine, University of Leeds, Leeds, United Kingdom, ⁸School of Medicine, University of Leeds, L, United Kingdom, ⁹IGE3, Institute of Genetics and Genomics of Geneva, University of Geneva, Geneva, Switzerland.

Glycosylphosphatidylinositol (GPI) is a glycolipid that anchors >150 various proteins to the cell surface. At least 27 genes are involved in biosynthesis and transport of GPI anchored proteins (GPI-APs). To date mutations in 13 of these genes are known to cause inherited GPI deficiencies (IGDs); all inherited as recessive traits. IGDs mainly show intellectual disability, epilepsy, coarse facial features and multiple organ anomalies. Those sym-

ptoms are caused by the decreased surface expression of GPI-APs or by structural abnormalities of GPI. Here we present five affected individuals from three families, two consanguineous from Egypt and Pakistan and one from Japan showing intellectual disability, hypotonia and early onset seizures. We identified pathogenic variants in PIGG, a GPI pathway gene. In the consanguineous families, homozygous variants, c.928C>T:p.(Gln310*) and c.2261+1G>C were found, while the Japanese individual was compound heterozygous for c.2005C>T: p.(Arg669Cys) and a 2.4Mb deletion that involved PIGG. PIGG is the enzyme that modifies the second mannose with ethanolamine phosphate, which is removed soon after GPI is attached to the protein. Physiological significance of this transient modification has been unclear. Using B lymphoblasts from affected individuals of families from Egypt and Japan, we revealed that PIGG activity was almost completely abolished; however the GPI-APs were normally expressed on the surface with the normal structure, indicating that the pathogenesis of PIGG deficiency is not yet fully understood. The discovery of pathogenic variants in PIGG expands the spectrum of IGD, and further enhances our understanding of this etiopathogenic class of intellectual disability.

C02.3

De novo mutations in Histone 3 Family 3B are associated with a severe neurodegenerative disorder and brain atrophy

A. Telegraf¹, E. F. Joiner², M. T. Cho¹, K. Retterer¹, J. L. Schuette³, J. W. Innis⁴, B. Fregeau⁴, E. H. Sherr⁴, A. Pizzano⁵, A. Vanderver⁶, S. Lüttgen⁶, J. Denecke⁷, T. M. Strom^{8,9}, D. Lessel⁶, J. Jussola¹, K. G. Monaghan¹, W. K. Chung^{10,11};

¹GeneDx, Gaithersburg, MD, United States, ²Department of Pediatrics, Columbia University Medical Center, New York, NY, United States, ³Departments of Human Genetics and of Pediatrics and Communicable Diseases, University of Michigan, Ann Arbor, MI, United States, ⁴Department of Neurology, University of California, San Francisco, San Francisco, CA, United States, ⁵Children's National Health System, Washington, DC, United States, ⁶Institute of Human Genetics, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, ⁷Department of Pediatrics, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, ⁸Institute of Human Genetics, Helmholtz Zentrum München, Neuherberg, Germany, ⁹Institute of Human Genetics, Technische Universität München, Munich, Germany, ¹⁰Department of Pediatrics, Columbia University Medical Center/Dx, New York, NY, United States, ¹¹Department of Medicine, Columbia University Medical Center, New York, NY, United States.

We describe four patients with a severe and progressive neurological phenotype characterized by developmental delays, seizures, and brain atrophy due to de novo predicted pathogenic variants in the Histone 3 Family 3B (H3F3B) gene (MIM # 601058). H3F3B gene encodes histone variant H3.3, a displacement histone critical to neuronal and glial development and transcription as well as formation and maintenance of synaptic connectivity in the brain. Clinical whole exome sequencing (WES) was performed on 3,235 patients with developmental delay or intellectual disability. Four affected individuals from four unrelated proband-parent trios were heterozygous for a de novo missense H3F3B variant. All variants were absent from NHLBI Exome Sequencing Project, 1000 Genomes, Exome Aggregation Consortium public databases and our internal WES database of unaffected individuals. All variants occurred within highly conserved domains, and were predicted to be damaging or possibly damaging from multiple in silico models. The patients range in ages from 22 months to 13 years old. The clinical phenotype is dominated by developmental delay, intellectual disability, seizures, with microcephaly and brain atrophy present in the three oldest children. Brain abnormalities are characterized by cortical atrophy and white matter abnormalities in all three; whereas thin corpus callosum in one child. Additional features include tone abnormalities, aspiration, gastroesophageal reflux, vision or oculomotor disturbances. To our knowledge, the findings presented in this case series are the first germline variants in this gene associated with a neurological phenotype and may facilitate the identification of additional affected patients to further characterize this novel neurodegenerative disorder.

C02.4

Autosomal recessive mutations of the neuron specific β3B subunit of clathrin-associated adaptor protein complex 3 (AP3B2) cause an early onset epileptic encephalopathy with optic atrophy

Early-onset epileptic encephalopathies (EOEE) represent a heterogeneous group of severe disorders characterized by severe seizures, interictal epileptiform activity on a disorganized EEG background, developmental regression or retardation, and onset before one year of age. Among a cohort of 50 patients with EE, we ascertained two unrelated patients with EOEE associated with severe developmental impairment and autosomal recessive variants (namely missense changes and splice-site variants) of AP3B2 by means of whole-exome sequencing. The targeted sequencing of AP3B2 in 86 additional unrelated individuals with EOEE led to the identification of an additional family with two affected children carrying a homozygous 4-bp deletion leading to a frameshift and premature stop-codon. Two additional families with four affected individuals were gathered through the Matchmaker Exchange initiative by matching on autosomal recessive mutations of AP3B2. This report presents eight individuals from five unrelated families presenting with global hypotonia, an EOEE with stagnation or regression of psychomotor acquisitions with absent speech. Eye contact was poor and associated with an optic atrophy when assessed (5/5). Patients presented with a post-natal microcephaly (7/8) and brain MRI identified a superior cerebellar vermis atrophy. AP3B2 encodes for a neuron specific subunit of the AP-3B complex, which is involved in synaptic vesicles biogenesis and transport. Conversely, a natural ap3b2 knockout mouse strain was reported with neurodevelopmental disorders including tonic-clonic seizures. To conclude, these genetic evidences support the implication of autosomal recessive mutations of AP3B2 in EOEE with optic atrophy.

C02.5 **De novo germline mutations of mTOR pathway genes RHEB and RAC1 cause developmental phenotypes with alterations in brain size**

M. R. F. Reijnders¹, M. Kousi², G. M. van Woerden³, G. M. Mancini⁴, T. van Essen⁵, C. Marcellis¹, M. Proietti-Onori³, M. van Gastel⁶, E. Smeets⁷, S. J. C. Stevens⁸, C. Gillissen¹, R. Pfundt¹, P. L. Tan², T. Kleefstra¹, Y. Elgersma², N. Katsanis², H. G. Brunner¹;

One of the pathways known to regulate cell growth is the mTOR pathway through the MTORC1 and MTORC2 complex. Somatic mutations in genes within the mTOR pathway are a well-known cause of hemimegalencephaly in humans by upregulating mTOR activity. Subsequently, germline mutations in mTOR pathway genes might also affect brain size. Here, we report germline de novo missense mutations in the mTOR activators RHEB (2 families, 3 patients) and RAC1 (2 families, 2 patients). Mutations in both mTOR pathway genes cause an intellectual disability (ID) syndrome with aberrant head and brain size. Whereas patients with RHEB mutations show severe ID with hypotonia, epilepsy and macrocephaly, microcephaly was observed in patients with RAC1 mutations. Concordant with the human phenotype, we found that overexpression of mutant rheb in zebrafish embryos results in megalencephaly and increased neural proliferation, while overexpression of mutant rac1 causes microcephaly, decreased neuronal proliferation and cerebellar defects. Intrauterine transfer of mutant Rheb into the brain of embryonic mice disrupted neuronal migration and caused epilepsy. Neurocognitive phenotypes observed in zebrafish carrying mutant RHEB peptides could be ameliorated through pharmacological treatment with the mTOR pathway antagonist rapamycin, providing clues for potential future therapeutic targets in patients with activating de novo RHEB mutations. Based on our genetic and functional data de novo germline mutations of mTOR

pathway regulator genes RHEB and RAC1 cause ID with opposite alterations in head and brain size, which reflect the functional effect of these mutations during vertebrate development.

C02.6 **De novo germline mutations in exon 5 of PPM1D cause intellectual disability.**

S. Jansen¹, R. Pfundt¹, R. Brough², J. C. Herkert³, E. J. Marco⁴, M. H. Willemsen¹, T. Kleefstra¹, J. A. Veltman^{1,5}, C. J. Lord⁶, L. E. L. M. Vissers¹, B. B. A. De Vries¹;

PPM1D (Protein phosphatase, Mg2+/Mn2+ dependent 1D), or *Wip1*, is a type 2C phosphatase that regulates stress response pathways including the DNA Damage Response, through inhibiting p53 and other tumour suppressors.

Mosaic mutations in non-tumour cell lineages in the last exon (exon 6) of *PPM1D* have been found in patients with breast and ovarian cancer. These truncating mutations, which might have been chemotherapy-induced, retained the phosphatase catalytic domain, leading to a gain-of-function effect. We diagnosed 4 children (2-14 years) with mild-moderate intellectual disability (ID) who had *de novo* germline frameshift, nonsense or splice site mutations in exon 5 of *PPM1D*. Various behavioral and neurological problems were noted, such as ADHD, ODD, anxiety disorder, neonatal feeding problems, hypotonia, gait problems and a high pain threshold. Shared facial dysmorphisms show a broad forehead, lateral hypoplasia of eyebrows, long palpebral fissures, upturned nose, short philtrum and broad mouth.

In fibroblasts and lymphoblastoid cell lines derived from three patients, we tested p53 activation in response to ionizing radiation (IR) exposure. All three cell lines showed normal to increased p53 activation compared to controls, in contrast to the suppression of IR-induced p53 activation previously seen in HeLa cells and U2OS cells transfected with cancer associated truncated *PPM1D* cDNA alleles with exon 6 mutations.

In conclusion, we show that *de novo* germline mutations in exon 5 of *PPM1D* cause syndromic ID. Notably, these mutations do not appear to cause gain-of-function effects on p53 as has been shown for exon 6 mutations in breast and ovarian cancer patients.

C03 Mutational Mechanisms

C03.1 **Copy number variation morbidity map of congenital limb malformations reveals that the majority of pathogenic variants affect non-coding regulatory elements**

M. Spielmann^{1,2}, R. Flöttmann¹, B. Kragsteen², M. Socha³, S. Geuer⁴, L. Allou², A. Sowińska-Seidler⁵, J. Wagner⁶, A. Jansheer³, B. Oehl-Jaschkowitz⁷, D. de Silva⁸, I. Kurth⁶, I. Maya⁹, F. Santos⁸, W. Hülsemann², D. Horn¹, S. Mundlos^{1,2};

Congenital limb malformations can occur as part of a syndrome or as an isolated form. Microarray studies in single affected families have previously demonstrated the importance of copy number variations (CNVs) in limb malformations, but no large scale study has been performed so far and the majority of cases remain undiagnosed. Here we applied high resolution array CGH to 300 patients with congenital limb malformations. We found 31 pathogenic CNVs in known disease loci and identified 6 new loci previously not known to be associated with limb malformations. The pathogenic CNVs affected non-coding cis regulatory elements more frequently than expected (21 non-coding vs 16 coding). We performed functional studies in transgenic mice using the CRISPR/Cas9 system and/or segregation studies in these families to investigate the pathogenicity of 6 novel CNVs causing limb defects. Overall we reached a diagnostic yield of 12%, which is comparable to copy number studies in other cohorts such as intellectual disability. However, the majority of the pathogenic CNVs (57%) were likely to result from changes in the non-coding cis regulatory landscape, while only 43% were due to gene dosage effects or haploinsufficiency. Additionally, we identified 20 rare CNVs of unknown clinical significance (7%) that were inherited

from an unaffected parent. Due to reduced penetrance, a key feature of limb malformations, these rare CNVs might still have an important impact on the skeletal phenotypes of our patients. Our results suggest that CNVs affecting non-coding regulatory elements are a major cause of congenital limb malformations.

C03.2

Microhomology underlies the formation of balanced germline human translocations

D. Nilsson^{1,2,3}, M. Pettersson¹, P. Gustavsson^{1,2}, A. Förster⁴, W. Hofmeister¹, J. Wincent¹, V. Zachariadis¹, B. Anderlid^{1,2}, A. Nordgren^{1,2}, O. Mäkitie^{1,4,5}, V. Wirta^{6,3}, F. Vezzi^{7,3}, J. R. Lupski^{8,9}, M. Nordenskjöld^{1,2}, E. Syk Lundberg^{1,2}, C. M. B. Carvalho⁸, **A. Lindstrand**^{1,2}; ¹Karolinska Institutet, Stockholm, Sweden, ²Karolinska University Hospital, Stockholm, Sweden, ³SciLifeLab, Stockholm, Sweden, ⁴University of Helsinki, Helsinki, Finland, ⁵Folkhälsan Institute of Genetics, Helsinki, Finland, ⁶KTH Royal Institute of Technology, Stockholm, Sweden, ⁷Stockholm University, Stockholm, Sweden, ⁸Baylor College of Medicine, Houston, TX, United States, ⁹Texas Children's Hospital, Houston, TX, United States.

Introduction: Most apparently balanced translocations are thought to result mechanistically from non-homologous end-joining (NHEJ) or, in rare cases of recurrent events, by nonallelic homologous recombination (NAHR). However, few events have been studied with breakpoint resolution.

Materials and Methods: Here, we use low coverage mate pair whole genome sequencing to identify and fine map rearrangement breakpoint junctions in individuals with previously detected germ line translocations. In total, 46 junctions from 22 carriers of balanced translocations including both phenotypically normal individuals (n=8) and affected individuals (n=14) were characterized.

Results: Genes were disrupted in 48% of the breakpoints; recessive genes in 50% of the normal carriers (inferring a risk of mendelian disease in the offspring) and known dominant intellectual disability genes in 21% of the affected carriers. Finally, seven disrupted candidate disease genes involved in various cellular functions and pathways were identified. Microhomology (2 to 6 bp) was observed in 69% of translocation events. Surprisingly, small insertions (5 to 12 bp), originating from local genomic sequences, were observed in 23%.

Conclusions: Microhomology associated with templated-insertions is a characteristic of breakpoint junctions for rearrangements mediated by the error prone replication-based repair mechanisms (RBMs). Our data therefore indicate, that even though NHEJ likely underlie many of the balanced translocations reported here, RBMs contribute to the formation of at least 20% of the cases. The involvement of RBM in these rearrangements supports the contention that a significant portion of so-called germ line translocations may have a mitotic origin.

C03.3

A distinct class of chromoanagenesis events characterized by focal copy number gains

H. Maset¹, **M. S. Hestand**¹, H. Van Esch¹, P. Kleinfinger², J. Plaisancie³, A. Afenjar⁴, R. Molignier⁵, C. Schluth-Bolard⁶, D. Sanlaville⁶, J. R. Vermeesch¹; ¹KU Leuven, Leuven, Belgium, ²Laboratoire Cerba, Saint-Ouen l'Aumône, France, ³Hôpital Purpan, Toulouse, France, ⁴Hôpital Armand-Trousseau, Paris, France, ⁵Clinique Saint Jean Languedoc, Toulouse, France, ⁶Hospices Civils de Lyon, Lyon, France.

Introduction: Chromoanagenesis is the process by which a single catastrophic event creates complex rearrangements confined to a single or a few chromosomes. It is usually characterized by the presence of multiple deletions and/or duplications, as well as by copy neutral rearrangements. In contrast, an array CGH screen of patients with developmental anomalies revealed three patients in which a single chromosome carries from 8 to 11 large copy number gains confined to a single chromosome, but the absence of deletions. Surprised by this finding, we set out to further characterize these derivative chromosomes.

Materials and Methods: Chromosome structure was evaluated using fluorescence in situ hybridization (FISH), Illumina massive parallel sequencing, and PacBio single-molecule sequencing. Breakpoints were validated by PCR and Sanger sequencing.

Results: FISH and Illumina/PacBio sequencing revealed derivative chromosomes maintain their original order, with inserted duplicons clustered together in distinct locations. Breakpoint junction sequences showed both microhomology and non-templated insertions of up to 40 bp.

Conclusions: Here we present three patients with a single altered chromosome composed of clustered insertional duplications, no deletions, and breakpoint junction sequences showing microhomology and/or non-templated insertions. These observations are difficult to reconcile with current mechanistic descriptions of chromothripsis and chromoanagenesis. Therefore, we hypothesize those rearrangements to be of a mechanistically different origin. In addition, we suggest that large untemplated insertional sequences

observed at breakpoints are driven by a non-canonical non-homologous end joining mechanism.

Gradual accumulation of mutations in human adult stem cells during life is associated with various age-related diseases, including cancer. The number of stem cell divisions throughout life is believed to be a major determinant for mutation accumulation and could explain the extreme variation of cancer incidence across different organs. Yet, mutation patterns and rates of healthy adult stem cells remain unknown.

Here, we determined genome-wide mutation patterns in primary adult stem cells of the small intestine, colon and liver of human donors with ages ranging from 3 to 87 years.

We find that the number of mutations increases linearly with age up to several thousand mutations per cell at 87 years of age, while mutation spectra remain constant throughout life. Small intestine and colon stem cells have a 2-fold higher mutation rate per year compared with liver stem cells. These differences could be exclusively attributed to the mutagenic action of spontaneous deamination of cytosine residues and may reflect the high stem cell division rate in these tissues.

The genomic distribution of somatic mutations is non-random and predominantly associated with DNA replication dynamics in the small intestine and colon, and with transcription in the liver. These results indicate that a stable balance, between various mutagenic and DNA repair processes, is maintained throughout life and that the activity of these processes in adult stem cells varies between tissues.

C03.5

Exome-wide evaluation of splice-disrupting mutations in 4,294 families with severe developmental disorders

J. Lord, J. McRae, M. Hurler, on behalf of the Deciphering Developmental Disorders study; Wellcome Trust Sanger Institute, Hinxton, United Kingdom.

Mutations affecting splicing are a significant contributor to human disease. Classification of splicing variants is often binary, with only those that fall within the canonical splice site (CSS) assumed to affect splicing, and to be akin to other protein-truncating variants (PTVs). We performed both population genetic and disease-burden analyses to better understand the distribution of splice-disrupting variants in and around the CSS using 4,294 exome sequenced trios from the Deciphering Developmental Disorders (DDD) study. We also used these data to compare the performance of several splicing prediction tools.

We observed that a subset of positions outside the CSS (including the 5th base after the intron/exon boundary at the donor end, and the last base of the exon) exhibited evidence of both high levels of purifying selection, and excess de novo mutations in patients. Additionally, within the two bases of canonical donor sites we observed strong evidence of discordant impact on splicing, with the base proximal to the exon showing significantly higher de novo enrichment and singleton ratio. We observed high concordance of the splicing prediction tools with our observations, however they failed to capture completely the landscape of splice-disrupting variation.

Taken together, these data suggest binary classification of variants as "splicing" only if they are in the CSS is oversimplified, and that this has a substantial impact on both the sensitivity and specificity of identifying genuine PTVs.

C03.6

Proteome-wide expression and turnover analysis quantify genetic impact in Down Syndrome

Y. Liu¹, C. Borel², L. Li³, T. Mueller⁴, P. Boersema⁴, P. Germain⁵, G. Testa⁵, A. Beyer³, S. Antonarakis^{2,6}, R. Aebersold^{1,4};

¹Institute of Molecular Systems Biology, ETH Zurich, Zurich, Switzerland, ²Department of Genetic Medicine and Development, University of Geneva Medical School, and University Hospitals of Geneva, Geneva, Switzerland, ³University of Cologne, Cologne, Germany, ⁴Institute of Biochemistry, Department of Biology, ETH Zurich, Zurich, Switzerland, ⁵Department of Experimental Oncology, European Institute of Oncology, Milan, Italy, ⁶These labs contribute equally, Zurich and Geneva, Switzerland.

Introduction: Trisomy 21 (T21) is the cause of Down Syndrome. However, how T21 impact human functional proteome remains unclear. We hypothesize that the proteome-wide turnover analysis is crucial to understand the functional impact of T21.

Materials and Methods: We investigated the effect of the extra chr21 at the levels of transcript quantity, proteome quantity and protein turnover rate. We analyzed the primary fetal skin fibroblasts derived from a pair of monozygotic twins discordant for T21, which uniquely allowed us to characterize the proteome changes due to T21 without the noise of genomic variability. To validate, we also analyzed the fibroblasts from 11 unrelated T21 individuals and 11 controls. We applied the cutting-edge SWATH mass spectrometry to reproducibly measure the proteomes.

Results: We quantified 4056 unique proteins for expression and ~2200 proteins by pulsed SILAC experiment for turnover analysis in both normal and T21 fibroblasts from the twins. The proteome-wide T21/normal fold-change correlation was extremely low, indicating substantial post-transcriptional regulation and buffering effects in T21. Overall, the protein degradation was faster in trisomy cells than the controls. Remarkably, those Chr21 encoded proteins that are members of heteromeric protein complexes in particular seemed to be exempt from responding to copy number alternations, likely through accelerated protein degradation. Moreover, we found that both mitochondrial and cytosolic ribosomal proteomes were degraded heavily in T21, but different degree of translational regulation shaped their final, divergent expression levels.

Conclusion: Prevalent, organelle specific proteome remodeling was identified as the proteomic hallmark of T21 as compared to normal.

C04 Complex Traits

C04.1

More than 1500 genetic variants regulate haematopoiesis in humans revealing novel genes and pathways

Butterworth¹, N. Soranzo^{3,1};

¹Institute of Cambridge, Cambridge, United Kingdom, ²Cambridge Institute of Public Health, Cambridge, United Kingdom, ³The Wellcome Trust Sanger Institute, Cambridge, United Kingdom, ⁴NHS Blood and Transplant, Oxford, United Kingdom, ⁵National Health Service (NHS) Blood and Transplant, Cambridge, United Kingdom, ⁶Barts Health NHS Trust, London, United Kingdom, ⁷National Institute for Health Research Cambridge Biomedical Research Centre, Cambridge, United Kingdom, ⁸University of Geneva, Geneva, Switzerland, ⁹Radboud University, Nijmegen, Netherlands, ¹⁰University of Oxford, Oxford, United Kingdom, ¹¹UK Biobank Ltd, Stockport, United Kingdom, ¹²European Bioinformatics Institute, Cambridge, United Kingdom, ¹³University of Amsterdam, Amsterdam, Netherlands, ¹⁴Sanquin Research and Landsteiner Laboratory, Amsterdam, Netherlands, ¹⁵Churchill Hospital, Oxford, United Kingdom, ¹⁶Addenbrooke's Hospital, Cambridge, United Kingdom.

Mature blood cells are essential for oxygen transport, haemostasis and immune response. We studied 36 haematological traits (relating to mature and immature red cells, platelets and myeloid and lymphoid white cells) in individuals of European ancestry selected from the UK Biobank, UK BiLEVE and INTERVAL cohorts. For the genetic association study, we considered a total of 173,480 individuals with phenotype and genotype data passing stringent quality control filters at 29.5 million genetic variants (MAF > 0.01%). Effect size estimates and their standard errors were combined across the three studies using inverse-variance weighted meta-analyses.

Overall, 182,105 variants were declared to be associated with at least one blood cell trait, represented here by a set of 1,652 distinct sentinel variants. Of these 148 corresponded to previously reported GWAS hits thereby validating almost all the blood trait associations previously reported in European samples. Associations with the remaining 1,504 variants are novel, augmenting the number of known associations by over 10-fold. Remarkably,

these include 270 rare and 258 low-frequency variants (allele frequency <1% and 1-5% respectively), and 44 „high impact“ variants of large phenotypic effects. Significant enrichments of the corresponding gene sets within relevant biological pathways, rare haematological and immune disorders, mouse phenotypes, and human complex disease confirm their importance for understanding of haematopoietic processes and pathogenesis. This research was supported by MRC, BHF, NIHR, NHSBT and Cambridge-BRC.

C04.2

Genome-wide association study identifies 15 novel genetic variants contributing to variation in cytokine levels

V. Kumar¹, Y. Li¹, M. Oosting², I. Ricaño-Ponce¹, S. Smeekens², M. Jaeger², L. Joosten², C. Wijmenga¹, M. Netea²;

¹University Medical Center Groningen, Groningen, Netherlands, ²Radboud University Medical Center, Nijmegen, Nijmegen, Netherlands.

Introduction: The genetic basis of human immune responses to pathogens has a profound effect on susceptibility to human infectious and immune-mediated diseases. A highly diverse set of immune cells is involved in producing cytokines to regulate these immune responses. However, the impact of genetic variation on the production of these regulatory cytokines during the course of infection is unknown.

Materials and methods: In this study we profiled genome-wide SNP genotypes, FACS assessment of the cell-populations as well as cytokine responses to major human pathogens (bacteria, virus and fungus) in whole blood, PBMCs, macrophages and T-cells of 500 healthy individuals. We performed a systematic study to reveal organization of cytokine responses to different pathogens in different cell-types. We then correlated the cytokine levels to SNPs and performed integrative genomics analysis to identify genes that control cytokine production in different immune cells.

Results and conclusions: We have identified 15 novel loci significantly associated (P<5x10⁻⁸) with different cytokine levels in response to pathogens. We show that the cytokine-QTLs are under positive selection and are enriched to be associated with human diseases. Furthermore, SNPs affecting monocyte-derived cytokines are enriched to be associated with infectious diseases, whereas SNPs that affect T-cell derived cytokines are associated with autoimmune diseases. We show that the genetic variability in the immune pathways is organized around a physiological response to specific pathogens. In summary, we show that upon stimulation genetic variation plays a significant role in influencing human immune responses and diseases.

C04.3

Genetic variants regulate adaptive and innate immune cell levels in the healthy Dutch population

R. Aguirre-Gamboa¹, H. J. P. M. Koenen², I. Ricano-Ponce¹, R. G. van der Molen², E. van Rijssen³, B. van Cranenbroek³, V. Magadi Gopalaiiah¹, C. Wijmenga¹, M. Netea¹, I. Joosten², Y. Li¹;

¹University of Groningen, University Medical Center Groningen, Department of Genetics, Groningen, Netherlands, ²Radboud University Nijmegen Medical Center, Department of Internal Medicine, Nijmegen, Netherlands, ³Radboud University Nijmegen Medical Center, Laboratory Medicine, Nijmegen, Netherlands, ⁴Radboud University Nijmegen Medical Center, Department of Medicine and Nijmegen University Centre for Infectious Diseases, Nijmegen, Netherlands.

Levels of immune cell subpopulations vary greatly between healthy individuals, yet the origin of such variation is only partially known. In this study we explore the immune cell landscape for factors that influence cell abundance. We measured over 210 different absolute cell levels and cell percentages from B, NK and T cells subpopulations from fresh blood samples of 500 healthy Dutch individuals. We observed a consistent gender effect, where females have higher cell levels, an overall negative correlation with age and a considerable fluctuation with respect to season. In addition, we assessed the influence of hormones and circulating antibodies in the immune system and found no significant effect of these on cell variation. Next, we profiled the genotype of the 500 volunteers and searched for genetic associations to the absolute cell levels and proportions, these traits were controlled for gender, age effect and date of collection to evaluate for cell count QTLs (ccQTL) on ~7 million variants. We identified 11 independent loci associated with at least one cell type. Of these, 5 previously reported loci were replicated. Additionally, we performed an integrative genomics analysis to identify genes implicated to the variation of the cell levels, using RNA-seq data from blood of ~600 samples from an independent Dutch cohort, we performed cis-eQTL mapping and prioritized candidate genes for the novel loci. Furthermore, we detected that ccQTLs are enriched for SNPs associated with immune-related diseases. These results link genetic information with cellular and molecular phenotypes and explore its involvement in immune diseases.

C04.4 Capture Hi-C reveals a novel causal gene, *IL20RA*, in the pan-autoimmune genetic susceptibility region 6q23

A. J. McGovern¹, P. Martin¹, S. Schoenfelder², P. Fraser¹, S. Eyre¹, G. Orozco¹; ¹University of Manchester, Manchester, United Kingdom, ²The Babraham Institute, Cambridge, United Kingdom.

Introduction: The majority of complex disease associations are with single nucleotide polymorphisms (SNPs) located in non-coding enhancer regions, which may regulate transcription through long-range interactions with their target genes. The 6q23 locus, associated with several autoimmune diseases including RA, contains many intergenic SNPs situated a large distance from any gene. The aim of this work was to identify causal disease genes at the locus by studying long range chromatin interactions in human T and B cell lines.

Materials and Methods: Capture Hi-C (CHI-C) targeting both the disease intergenic region and all promoters within 500kb of associated SNPs was used to investigate potential interactions between RA associated variants and their functional targets. Targeted 3C-qPCR analysis in B-cell lines containing the appropriate SNP genotype was used to study genotype-specific interactions.

Results: CHI-C identified numerous looping interactions between restriction fragments containing intergenic SNPs and the *IL20RA* gene, upstream of *IFNGR1* and lncRNAs downstream of *TNFAIP3*. *IL20RA* and *TNFAIP3* interacted with the same lncRNAs, and with each other. 3C-qPCR showed that the risk allele of the most likely causal SNP, rs6927172, was correlated with a higher frequency of interactions with *IL20RA*. The risk allele was also associated with increased expression of *IL20RA* mRNA, and increased binding of enhancer histone marks and transcription factors in T-cells.

Conclusions: Complex looping interactions within the 6q23 region bring RA associated SNPs, genes and regulatory elements together. This work shows that GWAS associated SNPs cannot simply be assigned to the nearest gene, potentially identifying novel targets for new therapies.

Background: The unexplained heritability of type 2 diabetes is high, suggesting that low frequency or rare genetic variants might explain additional proportions. Diabetes-related metabolites may aid the identification of novel risk variants for type 2 diabetes.

Material and Methods: We used the Illumina HumanExome v1.1 Bead Array to genotype individuals from the German EPIC-Potsdam study. Within a representative subsample (n=2500) we explored the association between single genetic variants and diabetes-related metabolites measured by a targeted metabolomics platform (Biocrates). Findings (p<1.64×10⁻⁷) were replicated within the German KORA F4 study. For the replicated genetic variants associations with type 2 diabetes risk were investigated within the EPIC-Potsdam case-cohort (n=2891; n_{cases}=758) and by look-up in DIAGRAM and other consortia.

Results: We identified one new association between rs499974 (*MOGAT2*) and a diacyl-phosphatidylcholine ratio (PC aa C40:5/PC aa C38:5) and identified seven associations of loci which have been previously described with regard to metabolites, but found new ratios including sphingolipids: rs7412 (*APOE*) and SM (OH) C22:2/SM (OH) C22:1; rs7157785 (*SGPP1*) and SM C16:1/PC aa C28:1; SM (OH) C22:2/SM C24:0; SM (OH) C22:2/SM (OH) C14:1; SM (OH) C22:2/SM (OH) C22:1; rs364585 (*SPTLC3*) and SM C16:1/

SM C18:0; SM (OH) C22:2/SM C16:1. Previously known variants are located in *FADS1-2*, *CPS1*, *REV3L*, *NTAN1* and *PNLIPRP2*. Four replicated common variants (rs3204953, rs174550, rs499974, rs7157785) showed nominally significant associations with type 2 diabetes in DIAGRAM.

Conclusion: We identified eight new associations between genetic variants and diabetes-related metabolic traits providing insights into metabolic pathways underlying the development of type 2 diabetes.

C04.6 StatinGWAS: A genome-wide association study demonstrating the research potential of nationwide prescription drug registries

P. Helkkula^{1,2}, I. Surakka^{1,2}, P. Häppölä¹, V. Salomaa³, A. Palotie^{4,5}, M. J. Daly⁶, S. Ripatti^{1,2,7}; ¹Institute for Molecular Medicine Finland, FIMM, Helsinki, Finland, ²Unit of Public Health Genomics, National Institute for Health and Welfare, Helsinki, Finland, ³Department of Health, National Institute for Health and Welfare, Helsinki, Finland, ⁴Psychiatric and Neurodevelopmental Genetics Unit, Massachusetts General Hospital, Boston, MA, United States, ⁵The Broad Institute of MIT and Harvard, Cambridge, MA, United States, ⁶Analytic and Translational Genetics Unit, Massachusetts General Hospital, Boston, MA, United States, ⁷Wellcome Trust Sanger Institute, Hinxton, Cambridge, United Kingdom.

National prescription drug registries are a potential wealth of insight into the clinical status of large populations. While hospitalization records (e.g. ICD codes) may provide complete ascertainment of serious diseases, prescription registries may provide insights into the onset and severity of chronic disease not available solely through hospitalizations - particularly in populations with complete and relatively homogeneous access to medical care. We took this approach using the FINRISK cohort studies (N=19,678) with registry data from the Finnish social insurance prescription medicine purchase database by studying genetic associations to statin use, defined as more than two purchases of statins or ezetimibe during the follow-up period 1995-2011. Using logistic regression, we detected associations in five loci, including well-known LDL cholesterol (LDL-C) loci: LDLR (rs141787760, p=1.95e-14), PCSK9 (rs11591147, p=1.78e-14) and APOE (rs7412, p=6.13e-22). Additionally, we saw strong association to the statin target gene HMGCR (rs10045497, p=1.38e-9). Our results validate the statin use data and the drug registry for various genome-wide association study designs. Furthermore, we demonstrate that by combining a scan for LDL-C in the untreated population with the independent case-control analysis of statin use vs non-statin use, we obtain a more powerful statistical scan for LDL-C loci. Retrospective drug use data enables us to extend our study into other statin-related outcomes, such as switching medications and discontinuation for possible identification of genetic markers associated with side-effect sensitivity. We will also pursue this study approach into other drug categories, including antihypertensive drugs.

Introduction: Dysembryoplastic neuroepithelial tumors (DNETs) are benign brain tumors associated with intractable, drug-resistant epilepsy. Distinguishing DNETs from other low-grade glioneuronal tumors is challenging for neuro-pathologists. We set out to identify the genetic causes of DNETs and to clarify the molecular mechanisms underlying this condition.

Methods: We studied a family with multinodular DNETs together with 100 sporadic tumors referred to us as DNETs. Whole-exome sequencing was performed on 46 tumors and targeted sequencing for hotspot FGFR1 mutations and BRAFp.V600E was used on the remaining samples. Blind neuropathology review, FISH, copy number variation assays and Sanger sequencing were

used to validate the findings. Supporting evidence for functional defects was obtained by in silico modelling, Flow Cytometry and β -galactosidase staining.

Results: We identified a novel germline FGFR1 mutation (p.R661P) and somatic activating FGFR1 mutations (p.N546K or p.K656E) in a father and his two children with DNETs. Pathology review distinguished DNETs (WHO grade I) (45%) from non-DNETs (55%). FGFR1 alterations, mainly intragenic tyrosine kinase duplication and multiple mutants in cis, characterized DNETs (58.1%) whereas FGFR1 mutations (19%) ($p=3.698e-05$) and hotspot BRAFp.V600E (22.6%) ($p=0.00046$) were identified in non-DNETs. Phospho-ERK overexpression in FGFR1p.R661P and p.N546K cells support enhanced MAPK/ERK activation in this condition.

Conclusions: This study identifies constitutional and somatic FGFR1 alterations and hotspot BRAF-V600E as key events in DNETs and non-DNET tumors respectively. The integrated pathology and molecular characterization performed reveals the key role of the MAP-Kinase pathway in these seizure-prone tumours, pointing the way towards existing targeted therapies.

Introduction: Familial medullary thyroid cancer (MTC) and its precursor, C cell hyperplasia (CCH), is associated with germline RET mutations causing multiple endocrine neoplasia type 2. However, some rare families with apparent MTC/CCH predisposition do not have a detectable RET mutation.

Materials and Methods: To identify novel MTC/CCH predisposition genes we undertook exome resequencing studies in a family with apparent predisposition to MTC/CCH and no identifiable RET mutation.

Results: We identified a novel ESR2 frameshift mutation, c.948delT, which segregated with histological diagnosis following thyroid surgery in family members and demonstrated loss of ESR2 encoded ER β expression in the MTC tumour. ER α and ER β form heterodimers binding DNA at specific estrogen response elements (ERE) to regulate gene transcription. ER β represses ER α mediated activation of the ERE and the RET promoter contains three ERE. In vitro, we showed that ESR2 c.948delT results in unopposed ER α mediated increased cellular proliferation, activation of the ERE and increased RET expression. In vivo, immunostaining of CCH and MTC using an anti-RET antibody demonstrated increased RET expression.

Conclusions: Together these findings identify germline ESR2 mutation as a novel cause of familial MTC/CCH and provide important insights into a novel mechanism causing increased RET expression in tumorigenesis.

Classifying DNA sequence variants to explain their clinical consequences is an integral component of clinical molecular testing. The International Society for Gastrointestinal Hereditary Tumors (InSiGHT) has developed criteria for clinical interpretation of mismatch repair (MMR) gene variants and subsequently performed a comprehensive assessment of the variants present in their database. To assess the value of the components of the InSiGHT classification system, and of additional points of evidence not considered in their approach, we have performed a systematic investigation of 24 MSH2 and MLH1 variants identified in a single institution, six of which had not been previously classified. The data used for evaluation included: population frequency, co-segregation, tumor molecular characteristics (including loss of heterozygosity), RNA analyses, and in vitro functional assays. In addition, evaluation of the variants with multiple in silico programs was performed. Overall, previous classifications of 18 variants were confirmed based on novel lines of evidence, supporting the utility of the InSiGHT approach. Among the in silico programs, PON-MMR2 and MAPP-MMR had the best overall accuracy when assessed versus classifications according to InSiGHT criteria. Since one of the major problems associated with InSiGHT classification is the need of independent replication of functional results due to lack of clinically validated in vitro assays, we propose that concordance of the two programs in predicting deleterious effects might be used as a surrogate for the functional MMR test. In sum, we propose an improved strategy for MMR gene variant interpretation, which can serve as a model for other disease genes.

C05.4

Chromosomal mosaicism in peripheral blood and cancer risk in Fanconi Anemia

J. Reina^{1,2,3}, R. Pujo^{1,4}, M. López-Sánchez^{1,2,5}, B. Rodríguez-Santiago^{1,2,6}, M. Aza-Carmona^{3,4}, L. A. Pérez-Jurado^{1,2,3}, J. Surrallés^{3,4};

Introduction: Clonal mosaicism for chromosomal rearrangements, detectable by SNP array of DNA from any tissue, has been associated with aging and cancer risk. Fanconi anemia (FA) is a genetic disorder characterized by congenital defects, bone marrow (BM) failure and cancer susceptibility. FA patients require strict follow-up including periodic BM testing. We have studied the prevalence of clonal mosaicism in FA patients and whether it could be an early marker for cancer.

Methods: Retrospective blood DNA samples of 129 FA patients (0-50yo) were analyzed by SNP array. Mosaic events were detected with MAD software and experimentally validated by microsatellite and MLPA analyses.

Results: We detected and validated 45 mosaic events in 14/129 patients, including 7 uniparental disomies, 15 deletions, 13 duplications, 3 complex rearrangements, 2 monosomies and 5 tri/tetrasomies. We detected 6 gains in 3q in 5 patients where 4 of them developed hematologic cancer and 3 events whose interstitial BP was within HLA loci. Compared to age-matched population controls, FA individuals had a 110-250X rate of detectable mosaicism. Cancer was more frequently diagnosed (4X) in cases with detectable mosaicism during a 0-10 year follow-up.

Conclusions: In FA, clonal mosaicism prevalence is increased and related to higher cancer risk. 3q gain, typically related to leukemia, is the most common rearrangement found in mosaicism in our cohort and in those patients with leukemia. Therefore, mosaicism detection in blood by SNP array could be used as an early marker for cancer in FA.

C05.5

Parent inheritance of RB1 hypomorphic mutations and somatic mosaicism can explain low penetrance in retinoblastoma.

V. Imperatore¹, A. Pinto^{2,1}, S. Amtrano³, S. Somma^{1,2}, M. Bruttini^{1,2}, T. Hadjistilianou³, S. De Francesco³, P. Toti³, E. Gussone³, M. Mencarelli^{1,2}, F. Mari^{1,2}, A. Renieri^{1,2}, F. Ariani^{2,4}; ¹Medical Genetics, Department of Medical Biotechnology, University of Siena, Policlinico, Santa Maria alle Scotte, Siena, Italy, ²Medical Genetics, Azienda Ospedaliera Universitaria Senese, Siena, Italy, ³Unit of Ophthalmology, and Retinoblastoma Referral Center, Department of Surgery, University of Siena, Policlinico, Santa Maria alle Scotte, Siena, Italy, ⁴Department of Human Pathology and Oncology, Section of Pathology, University of Siena, Policlinico, Santa Maria alle Scotte, Siena, Italy, ⁵Unit of Ophthalmology, Azienda Ospedaliera Universitaria Integrata, Verona, Italy.

Retinoblastoma (RB) represents one of the most extensively studied pediatric cancers but many questions still remain unsolved, including incomplete penetrance. In 2009, it has been demonstrated a ~3 fold excess of the RB1 maternal canonical transcript due to an imprinting mechanism. As a consequence, maternally inherited hypomorphic mutations may retain sufficient suppressor activity to prevent tumor development. Here, we change the perspective of retinoblastoma field demonstrating a differential allelic expression of hypomorphic variants that significantly influence the phenotypic outcome in families at risk for RB onset. In one family, the father who presented with retinoma and the two children who developed retinoblastoma were all identified harboring a hypomorphic splicing variant (c.2663+2T>C). RT-PCR quantitative analysis showed a higher expression of the abnormally spliced product in the father along with an inversion of the ratio between the two differentially spliced isoforms. A parent-of-origin-effect was demonstrated for another hypomorphic mutation (p.Arg661Trp) able to induce RB in a child of a male carrier with an anamnestic history positive for osteosarcoma. For the first time, here we also identified somatic mosaicism as important factor that can impact the phenotypic expression. Indeed, segregation analysis performed by high-depth NGS assay in another family, showed a ~50% of mutated molecules in the proband with retinoblastoma in comparison with a ~30% in the father with retinoma, accordingly with a somatic mosaicism. These findings completely change the genetic and prenatal counselling and the clinical management of the families. They also underline the importance of performing high-sensitivity NGS for RB diagnosis.

C05.6

Low-level APC mutational mosaicism is the underlying cause in a substantial fraction of unexplained colorectal adenomatous polyposis cases

Background: In 30-50% of patients with colorectal adenomatous polyposis, no germline mutation in the known genes APC, causing familial adenomatous polyposis (FAP); MUTYH, causing MUTYH-associated polyposis (MAP); or POLE or POLD1, causing Polymerase-Proofreading-associated polyposis (PPAP) can be identified, although a hereditary etiology is likely. This study aimed to explore the impact of APC mutational mosaicism in unexplained polyposis. Methods: To comprehensively screen for somatic low-level APC mosaicism, high-coverage next-generation sequencing of the APC gene was performed using DNA from leukocytes and a total of 53 colorectal tumors from 20 unrelated patients with unexplained sporadic adenomatous polyposis. APC mosaicism was assumed if the same loss-of-function APC mutation was present in ≥ two anatomically separated colorectal adenomas/carcinomas per patient. All mutations were validated using diverse methods. Results: In 25% (5/20) of patients, somatic mosaicism of a pathoge-

nic APC mutation was identified as underlying cause of the disease. In 2/5 cases, the mosaic level in leukocyte DNA was slightly below the sensitivity threshold of Sanger sequencing; while in 3/5 cases, the allelic fraction was either very low (0.1-1%) or no mutations were detectable. The majority of mosaic mutations were located outside the somatic Mutation Cluster Region of the gene. Conclusions: The present data indicate a high prevalence of pathogenic mosaic APC mutations below the detection thresholds of routine diagnostics in adenomatous polyposis, even if high-coverage sequencing of leukocyte DNA alone is taken into account. This has important implications for both routine work-up and strategies to identify new causative genes in this patient group.

C06 Carrier and Newborn Screening (joint with EMPAG)

Carrier screening is the detection of carrier status of recessive diseases in persons who do not have an a priori increased risk of being a carrier based on his/her personal or family history. Carrier screening aims to identify couples who have an increased risk of having an affected child to facilitate informed reproductive decision-making. Expanded carrier screening offers screening for multiple recessive disorders, facilitated by new genetic testing technologies. Expanded carrier screening panels that have been introduced to date have been advertised and offered on a commercial basis. In 2014, recommendations regarding responsible implementation of expanded carrier screening were developed by the Public and Professional Policy Committee (PPPC) of the European Society of Human Genetics (ESHG) and posted on the ESHG website (Feb-March 2015), for membership consultation. The recommendations address the challenges that expanded carrier screening might pose in the context of the lessons learnt from decades of population-based carrier screening. The final recommendations include e.g. the following: priority should be given to carrier screening panels that include (a comprehensive set of) severe childhood-onset disorders; the main focus should be on reporting sequence variants that clearly affect function; evaluation of new models of consent (e.g. 'generic consent') in this context is required; and, governments and public health authorities should adopt an active role in discussing the responsible introduction of expanded carrier screening. With these recommendations we aim to contribute to the public and professional discussion and to arrive at better clinical and laboratory practice guidelines.

C06.2

Setting the scope of screening: ethical reflections on the offer of reproductive choice

G. Stapleton;

Maastricht University, Maastricht, Netherlands.

Introduction: International normative guidelines recommend that prenatal screening for the purpose of reproductive choice should only be offered for serious medical conditions that affect childhood. Whilst this position is widely endorsed, ethical concerns have been raised that such limitations to the scope of screening may challenge health services in maintaining a position of non-directivity with respect to couples' reproductive choices. In view of near future opportunities for whole genome sequencing with non-invasive prenatal testing this concern should be addressed. This paper examines whether the proposed limitations conflict with principles of non-directivity. Methods: A normative discourse analysis was performed in order to identify the aims of offering screening in line with proposed limitations. An integrated model for ethical reflection was then used to assess the consistency of each aim with respect to maintaining the non-directivity of

health services. Results: Three aims of the proposed scope were identified: to avoid suffering of the future child, to avoid suffering of the prospective parents, and to reduce the burden of care on society. All three aims conflict with the principle ethical requirement that health services should maintain a position of non-directivity with respect to couples' reproductive choices. Discussion: The aim of avoiding the suffering of prospective parents may be acceptable provided additional criteria are met relating to the wider social context of screening: i) is private access available for other screening options, ii) are services provided equitably following the outcomes of reproductive choice, and iii) is screening also offered prior to conception?

C06.3

Factors for successful implementation of population-based expanded carrier screening: what can we learn from existing initiatives?

K. C. A. Holtkamp¹, I. B. Mathijssen², P. Lakeman², M. C. Van Maarle², W. J. Dondorp³, L. Henneman¹, M. C. Cornel¹;
¹VU University Medical Center, Amsterdam, Netherlands, ²Academic Medical Center, Amsterdam, Netherlands, ³Maastricht University, Maastricht, Netherlands.

Background: Carrier screening for autosomal recessive disorders aims to enhance reproductive decision making by identifying couples at a 1-in-4 risk in every pregnancy of having an affected child. Except for few countries or regions, carrier screening is not widely offered, and is mostly ancestry-based. Technological advances enable carrier screening for multiple diseases simultaneously. This allows universal screening regardless of ancestry (population-based expanded carrier screening). It is important to study how this can be successfully implemented, and what can be learned from already existing initiatives.

Methods: Factors associated with successful implementation were identified by: 1) a literature review, and 2) two case studies; studying experiences with carrier screening in two high-risk communities (a Dutch founder population, and the Ashkenazi Jewish population), including a survey among community members.

Results: Factors identified were: familiarity with (specific) genetic diseases and (the availability of) testing, high perceived benefits of screening (e.g. screening avoids much suffering), acceptance of reproductive options, perceived risk of being a carrier, and low perceived social barriers (e.g. stigmatization). In contrast to the Jewish community, the initial demand for screening in the Dutch founder population did not entirely come from the community itself. However, the large social cohesion of the community facilitated the implementation process.

Conclusion: In order to ensure successful implementation of population-based expanded carrier screening, effort should be made to increase knowledge about genetic diseases, create awareness and address personal benefits of screening in a non-directive way.

Grant: The Netherlands Organisation for Health Research and Development

C06.4

Advantages of expanded universal carrier screening: What is at stake?

S. van der Hout¹, K. Holtkamp², L. Henneman², G. De Wert¹, W. Dondorp¹;
¹Department of Health, Ethics and Society, Faculty of Health, Medicine and Life Sciences, Maastricht University, Maastricht, Netherlands, ²Department of Clinical Genetics, Section of Community Genetics, EMGO Institute for Health and Care Research, VU University Medical Center, Amsterdam, Netherlands.

Background: Expanded universal carrier screening (EUCS) entails a twofold expansion of long-standing (preconception) screening protocols: it not only allows the simultaneous screening of a large list of diseases ('expanded'), but also refers to a pan-ethnic screening offer ('universal'). Advocates of EUCS mention three main moral advantages of this new proposition as compared with traditional (targeted and/or ancestry-based) forms of carrier screening: EUCS will (1) further enhance the autonomy of prospective parents by providing them with more information relevant for making reproductive choices; (2) provide equal access to carrier testing services; (3) reduce the risk of stigmatisation. Our empirical ethics study aims to widen this account and provide a balanced picture of the potential pros and cons of EUCS.

Methods: Semi-structured interviews with 17 health (policy) professionals and representatives of patient organisations about their views on carrier screening including a possible EUCS-scenario.

Results: Stakeholders acknowledged the potential benefits of EUCS, but also expressed five main moral concerns: (1) Does EUCS respond to an urgent problem or population need? (2) Is it possible to offer couples both understandable and sufficient information about EUCS? (3) How will societal views on 'reproductive responsibility' change as a result of EUCS? (4) Is EUCS the best way to reach high-risk populations? (5) Will EUCS reinforce disability-based stigmatisation?

Conclusions: While having the potential to overcome some moral limits inherent in traditional carrier screening, EUCS comes with moral challenges of its own. More research is needed to (further) anticipate the moral and practical implications of EUCS.

C06.5

Clinical utility of expanded carrier screening: reproductive behaviors of at-risk couples

C. Ghiozzi¹, K. Ready², C. Lieber², J. D. Goldberg², I. S. Haque², G. A. Lazarin², K. K. Wong²;
¹California State University Stanislaus, Turlock, CA, United States, ²Counsyl, South San Francisco, CA, United States.

Introduction: Expanded carrier screening panels analyze dozens or hundreds of recessive disease genes for couples planning to have children, but literature on the clinical utility of screening conditions beyond professional guidelines is scarce. We surveyed at-risk couples for this purpose.

Methods: Patients used an expanded carrier screen for up to 110 genes. At-risk couples were those whose partners were also carriers for the same autosomal recessive diseases. We invited 465 consecutive at-risk couples to participate in an IRB-approved survey.

Results: 70 completed the survey; 13 that reported a family history were excluded from analysis. 41 were not pregnant at time of screening. Of those that were not pregnant, 63% indicated that they would choose IVF with PGD, prenatal diagnosis, gamete donation, adoption, or no reproduction. 27% indicated that they were not planning to alter reproductive plans. The remainder did not indicate clear plans. Participants who do not plan to pursue alternative options indicated perceived severity as a major reason.

Of pregnant participants, 43% elected fetal diagnosis. Two reported interest in testing, but miscarried before the procedure could be done. Seven did not consider the condition sufficiently severe to consider pregnancy termination. Of 7 pregnancies that underwent prenatal diagnosis, 5 were unaffected and 2 were affected. One of the affected pregnancies was terminated and one was continued.

Conclusion: Most at-risk couples altered reproductive planning, demonstrating clinical utility of this information. Perceived severity of the condition factored into decision making with milder diseases less likely to change planning.

C06.6

Genetic counseling in an oocyte donation program: knowledge, satisfaction and psychological impact of the expanded carrier screening

J. Pla¹, E. Clua², M. Boada², B. Coroleu², P. N. Barr², A. Veiga², X. Estivil¹, G. Lasheras³, A. Abul¹;

¹Unit of Medical Genomics, Department of Obstetrics, Gynaecology and Reproduction, Dexeus Women's Health, Barcelona, Spain, ²Service of Reproduction Medicine, Department of Obstetrics, Gynaecology and Reproduction, Dexeus Women's Health, Barcelona, Spain, ³Department of Psychiatry, Psychology and Psychosomatics, Quirón-Dexeus University Hospital, Barcelona, Spain.

NGS technologies have allowed to test the carrier status of a large number of diseases in a cost-effective manner and some reproductive centres call for the implementation of an Expanded Carrier Screening (ECS) test in oocyte donation (OD) programs. One of the main arguments against ECS in reproductive medicine is that its results may turn out to be psychosocially harmful to the donors. Hence, this study aims to assess the emotional and psychological impact of ECS in an OD program.

Our studied population consisted of 100 oocyte donors assessed in the framework of an OD program at Dexeus Women's Health in Barcelona. We evaluated participant's acquired knowledge, satisfaction with genetic counselling, perceived usefulness of ECS, and emotional and psychological impact (anxiety and depression measured by STAI and HADS-D scales) at three different moments: before pre-test genetic counselling session, after post-test genetic counselling session and after post-donation follow-up appointment. Although carriers' donors scored higher in the emotional and psychological impact questionnaires than those who were not carriers, none of the subjects had HADS-D and STAI scores considered pathologic at baseline, immediate or follow-up surveys. No correlation was found between the remaining variables and the psychological impact.

Our findings suggest that ECS results in oocyte donors do not seem to have a meaningful emotional and psychological impact and seems to be well tolerated and accepted by our participants. Genetic counselling at different stages of the clinical process is essential in order to achieve the purposes of decreasing anxiety in the gamete donors.

C07 Genome Technology in the Clinic

C07.1

Rapid screening of severely ill newborns and infants using whole genome sequencing

B. Sikkema-Raddatz¹, C. van Diemen¹, W. Kerstjens-Frederikse¹, T. de Koning², R. Sinke¹, J. Jongbloed¹, K. Abbott¹, J. Herkert¹, P. Neerincx¹, G. de Vries¹, M. Meems-Veldhuis¹, M. Viel¹, A. Scheper¹, K. de Lange¹, J. Dijkhuis¹, J. van der Velde¹, M. de Haan¹, M. Swertz¹, K. Bergman², C. van Ravenswaaij-Arts¹, I. van Langen¹, R. Sijmons¹, C. Wijmenga¹;
¹University Medical Center Groningen, Department of Genetics, Groningen, Netherlands, ²University Medical Center Groningen, Beatrix Children's Hospital, Groningen, Netherlands.

For severely ill newborns quick molecular diagnoses are of utmost importance for clinical decision-making and can prevent unnecessary and sometimes invasive diagnostics. To date, immediate molecular testing is not a routine procedure for all patients since this is available only for few diseases. Here we present a procedure to analyze 2800 genetic disorders in severely ill newborns and infants by rapid whole-genome sequencing (WGS), and completed in approximately 2 weeks. WGS is carried out in parallel to standard diagnostic procedures. The final evaluation of the results is done by a multidisciplinary team. Thus far we have included 22 patients in the study and have provided a diagnosis of a monogenic disease for four patients. These patients presented with different clinical characteristics and that could be explained by mutations in the EIF2B5, EPG5, KLHL41 and RMND1 genes. One patient was diagnosed with a 1p36 microdeletion upon routine diagnostic testing.

In 12 patients without a diagnosis we got informed consent from the parents for further analysis in research setting. We prioritized genes using Network analysis based on gene co-expression and patient-specific Human Phenotype Ontology (HPO) terms. In addition RNA sequencing has been performed in a subset of child-parent trios to assess whether aberrant expression patterns can help interpreting possible pathogenic variants. This research follow up has led to three potential new diagnoses. Currently we are evaluating the procedure. We will emphasize on phenotype selection, technical aspects of coverage and filtering methods.

C07.2

Image analysis of patients with dysmorphic facial features boosts diagnostic yield in exome studies

M. A. Mensah¹, N. Hajjir¹, N. Ehmke¹, F. Alisch¹, C. Ott¹, R. Flöttmann¹, M. Spielmann¹, A. Thorwarth¹, D. Korinth¹, P. N. Robinson¹, S. Köhler¹, T. Zemojtel¹, P. Lorini², K. Dathe¹, S. Dölken³, M. Schülke-Gerstenfeld¹, S. Mundlos¹, L. Graul-Neumann¹, D. Horn¹, P. M. Krawitz¹;
¹Institut für Medizinische Genetik und Humangenetik, Charité - Universitätsmedizin - Berlin, Berlin, Germany, ²Institut für Genetik, Medizinische Fakultät - Martin-Luther-Universität - Halle, Halle, Germany, ³Medizinische Genetik Klein und Rost - München, München, Germany.

The combination of phenotype and genotype-based prioritization-strategies proved to be highly effective for detecting disease-causing mutations in high-throughput sequencing studies. However, the performance of these approaches also depends on the precision of the clinical description and requires some expert knowledge. Facial recognition technology, that detects dysmorphic features from two-dimensional photographs, holds the promise to assist in deep phenotyping of syndromic patients. Therefore, we evaluated the syndrome predictions of image analyses in a cohort of more than 100 patients with a diverse spectrum of confirmed molecular diagnoses of monogenic disorders with the Facial dysmorphology Novel Analysis (FDNA) technology. Automated facial recognition yields the correct diagnosis amongst the first ten suggested syndromes in more than two thirds of the cases and shows a high correlation with syndrome predictions that were based on expert annotated features. Hereby, we could confirm the diagnosis in cases with only subtle facial features amongst them patients with Rothmund-Thomson syndrome, Mowat-Wilson syndrome, Ectodermal Dysplasia, Fragile X syndrome, Rubinstein-Taybi syndrome and Mabry syndrome. When exome data of patients was filtered for rare sequence variants and intersected with genes that were associated with the likeliest syndromes according to image analysis, the pathogenic mutations could be identified in all cases with few false positives. Our results show that computer-assisted facial recognition is not only a promising technology that could be applied in the routine diagnostic workflow, but also a technology that allows diagnosis in cases with non-typical clinical presentation.

C07.3

Detection of clinically relevant copy number variants by exome sequencing in a large cohort of genetic disorders

J. Y. Hehir-Kwa¹, R. Pfundt¹, M. del Rosario¹, L. E. L. M. Vissers¹, M. P. Kwint¹, I. M. Janssen¹, N. de Leeuw¹, H. G. Yntema¹, M. R. Nelen¹, D. Lugtenberg¹, E. Kamsteeg¹, N. Wieskamp¹, A. P. A. Stegmann², S. J. C. Stevens², R. J. T. Rodenburg¹, A. Simons¹, A. R. Mensenkamp¹, T. Rinne¹, C. Gilissen¹, H. Scheffer^{1,2}, J. A. Veltman^{1,2};
¹Radboudumc, Nijmegen, Netherlands, ²Maastricht University Medical Centre, Maastricht, Netherlands.

Copy number variation (CNV) is a common source of genomic variation and an important genetic cause of disease. Microarray based CNV analysis has become a first tier diagnostic test for patients with intellectual disability, with a diagnostic yield of 10-20%. However, for most other genetic disorders the role of CNVs is less clear and genetic studies are generally limited to the study of single nucleotide variations (SNVs) and other small variants. With the introduction of exome and genome sequencing it is now possible to detect both SNVs and CNVs in a single test. Here, we have performed exome based CNV screening on data from 2,603 patients affected by a range of 14 different genetic disorders for which exome sequencing was performed in a diagnostic setting. Using read depth analysis we identified 131 clinically relevant CNVs ranging in size from 729bp - 8.4Mb. This results in 53 conclusive diagnoses, an overall diagnostic yield of 2%. CNVs were found exerting both dominant and recessive effects, as well as CNVs unmasking a recessive mutation that results in pathogenic compound heterozygous events. This study shows that CNVs play an important role in a broad range of genetic disorders and nicely illustrates how these CNVs can be readily detected from exome sequencing, without the need for additional genetic tests. This brings us closer to single test genomics.

C07.4

Ultra-sensitive mosaic mutation detection for clinical applications

A. Hoischen¹, M. Steehouwer¹, M. Kwint¹, R. Acuna Hidalgo¹, E. Mersy², C. Gilissen¹, J. A. Veltman^{1,2}, J. Shendure³, A. Goriely⁴;
¹Department of Human Genetics, Radboud university medical center, Nijmegen, Netherlands, ²Department of Clinical Genetics, Maastricht University Medical Centre, Maastricht, Netherlands, ³Department of Genome Sciences, University of Washington, Seattle, WA, United States, ⁴Weatherall Institute of Molecular Medicine, University of Oxford, Oxford, United Kingdom.

Despite the great advances in the next generation sequencing field there is still room for improved targeted re-sequencing assays that combine high throughput with ultra-high sensitivity. We have now further optimized a single-molecule molecular inversion probe (smMIP) based targeted re-sequencing approach¹. Single-molecule tracing is enabled using up to 4¹⁰ (1,048,576) molecular tags. Consensus calling of respective PCR-duplicates allows correction for PCR and sequencing errors. The improved assay allows low-frequency or sub-clonal variant detection with variant levels of <0.05%. This assay provides very robust genotyping accuracy, high throughput, fast turnaround and cost-effectiveness. We anticipate that this or similar assays allow novel applications in which mutations are present in very low relative abundance in any given DNA sample with important new applications beyond cancer genetics.

Here we present first successful applications that include: 1.) Accurate determination of the fraction of mutated alleles for post-zygotic *de novo* mutations². 2.) Detection of previously unrecognized mosaic disease causing mutations for rare clinical syndromes. 3.) Detection of known 'paternal age effect disorders' causing mutations as small clonal events in dissected testis material³. 4.) First evidence for presence or absence of parental alleles in cell free DNA from plasma of pregnant women.

C07.5

Enrichment of unamplified DNA and long-read SMRT Sequencing to unlock repeat expansion disorders

Y. Tsai, D. Greenberg, T. A. Clark;
 Pacific Biosciences, Menlo Park, CA, United States.

Nucleotide repeat expansions are a major cause of neurological and neuromuscular disease in humans, however, the nature of these genomic regions makes characterizing them extremely challenging. Accurate DNA sequencing of repeat expansions using short-read sequencing technologies is difficult, as short-read technologies often cannot read through regions of low

sequence complexity. Additionally, these short reads do not span the entire region of interest and therefore sequence assembly is required. Lastly, most target enrichment methods are reliant upon amplification which adds the additional caveat of PCR bias.

We have developed a novel, amplification-free enrichment technique that employs the CRISPR/Cas9 system for specific targeting of individual human genes. This method, in conjunction with PacBio's long reads and uniform coverage, enables sequencing of complex genomic regions that cannot be investigated with other technologies. Using human genomic DNA samples and this strategy, we have successfully targeted the loci of Huntington's Disease (HTT; CAG repeat), Fragile X (FMR1; CGG repeat), ALS (C9orf72; GGGGCC repeat), and Spinocerebellar ataxia type 10 (SCA10; variable AT-TCT repeat) for examination. With this data, we demonstrate the ability to isolate hundreds of individual on-target molecules in a single SMRT Cell and accurately sequence through long repeat stretches, regardless of the extreme GC-content. The method is compatible with multiplexing of multiple targets and multiple samples in a single reaction. This technique also captures native DNA molecules for sequencing, allowing for the possibility of direct detection and characterization of epigenetic signatures.

C07.6

Detection of AGG interruptions in FMR1 premutation females by single-molecule sequencing

S. Ardui¹, V. Race², G. Matthijs², J. R. Vermeesch¹;

¹Laboratory for Cytogenetics and Genome Research, Centre for Human Genetics, KU Leuven, Leuven, Belgium, ²Laboratory for Molecular Diagnosis, Centre for Human Genetics, KU Leuven, Leuven, Belgium.

The FMR1 contains an unstable CGG repeat in the 5' untranslated region. This repeat is expanded from around 30 (normal) to a range of 55-200 repeats in female premutation carriers. Premutations occur in the population with an estimated frequency of about 1 in 200 and are at risk for developing FXTAS and POF. Furthermore, the germline transmission of the repeat is highly unstable, and therefore premutation females will often transmit a full mutation to their offspring.

The risk that a premutation female will transmit a full mutation is variable. The larger CGG repeats expand faster to full mutations. In addition, AGG triplets interrupting the CGG repeat reduce the risk for expansions. Despite its importance, AGG measurement is not yet a standard feature of FMR1 diagnostic work-up. If determined, AGG interruptions are detected by a Triplet-Primed PCR. Unfortunately, those AGG interruptions can be obscured because the normal and premutated allele camouflage each other's interruptions. Here, we explore single-molecule sequencing (Pacific Biosciences) to determine the AGG interruptions in a cohort of premutation females. We demonstrate that single-molecule sequencing correctly determines the size of both the normal and premutated allele for each female of the cohort. More interestingly, the single-molecule sequencing also allows the unambiguous separation of the normal from the premutated allele which enables the detection of the location and number of AGG interruptions for each allele. We foresee that this technology will replace current tests and has the potential to improve risk estimates allowing for improved genetic counseling. IWT 131787

C08 Sharing and Mining Omics Data

C08.1

Multi-tissue transcriptome analysis reveals disease-relevant and causal links between obesity and gene expression

T. Tukiainen^{1,2}, T. H. Pers³, F. Aguec², A. Rissanen³, K. Ardlie², C. M. Lindgren⁴, K. Pietiläinen⁵, S. Ripatti^{1,6,7};

¹Institute for Molecular Medicine Finland (FIMM), Helsinki, Finland, ²Broad Institute of Harvard and MIT, Cambridge, MA, United States, ³Obesity Research Unit, Research Programs Unit, University of Helsinki, Helsinki, Finland, ⁴Wellcome Trust Centre for Human Genetics, Oxford, United Kingdom, ⁵Obesity Research Unit, Research Programs Unit, University of Helsinki, Helsinki, Finland, ⁶Public Health, Faculty of Medicine, University of Helsinki, Helsinki, Finland, ⁷Wellcome Trust Sanger Institute, Hinxton, Finland.

Obesity is a world-wide epidemic with severe health consequences. To elaborate the mechanisms linking obesity to its many sequelae, we investigated the association of body mass index (BMI), a common measure for adiposity, with gene expression (GE) assessed via RNA-sequencing in 44 tissue types, including the rarely accessible ones (e.g. brain and internal organs), in 450 genotyped donors from the GTEx project.

Significant (FDR<0.05) BMI-GE-associations are seen in several tissues, including expectedly adipose tissue and liver, but also skin and lung. These

obesity-associated genes are only partly shared between tissues indicating tissue-dependent pathophysiologies. Gene set enrichment analyses further reveal the plethora of BMI-related alterations and between-tissue interplay, including the previously documented downregulation of mitochondrial pathways in adipose tissue, which contrarily appear to be activated in adrenal gland. We also find a strong signature pointing to DNA damage in small intestine. Highlighting the disease-relevance of these BMI-associations, we observe an overlap between genes discovered in the BMI-GE analysis and genes implicated in genome-wide association studies (GWAS). E.g. GE-alterations in adipose tissue significantly overlap with immune-GWAS loci, underlining the role of inflammation in obesity and supporting epidemiological observations of potential link between obesity and immune system function. Further, we provide evidence, utilizing a Mendelian randomization framework, for BMI causally driving several of these associations.

Comparison of BMI-associated expression changes of dozens of human tissues simultaneously provides an unprecedentedly extensive view into the pathophysiology of obesity. The pathways and causal links identified provide potential avenues for the treatment of the complications of obesity.

C08.2

Identification of novel low frequency variants associated with susceptibility with a variety of cancers through the re-analysis of publicly available genome-wide association studies

M. Guindo-Martínez¹, F. Sánchez¹, S. Bonàs-Guarch¹, P. Cortés-Sánchez¹, S. González¹, C. Díaz¹, R. M. Badia^{1,2}, J. M. Mercader¹, D. Torrents^{1,3};

¹Barcelona Supercomputing Center, Barcelona, Spain, ²Artificial Intelligence Research Institute, Bellaterra, Spain, ³Institució Catalana de Recerca i Estudis Avançats, Barcelona, Spain.

Introduction: The overall contribution of shared and specific genetic factors involved in cancer is still poorly understood. The reanalysis of available Genome-Wide Association Studies (GWAS) data with novel sequencing-based reference panels is a promising and cost-effective approach to unravel and to better characterize the genetic factors that give susceptibility to tumor related processes.

Materials and Methods: We developed GWImp-COMPSs, an integrated framework that performs imputation and association testing, to re-analyze 9 different cancer data, comprising around 80,000 subjects, through imputation with UK10K, 1000 Genomes phase 3 and Go-NL. To date, we have analyzed 9,124 samples for bladder cancer and 11,209 samples for lung cancer. Results: Beyond confirming and fine-mapping known loci for these cancers, we identified two novel loci associated with bladder cancer in the *ZCCHC7* gene (MAF= 0.01, OR=0.28, p=5.7e-11, regulatory region variant) and in the *GRIN2B* gene (MAF= 0.01, OR=4.77, p=9.1e-11, intron variant). For lung cancer, a novel associated locus was found near the *TECRL* gene (MAF=0.01, OR=3.16, p=2.4e-8).

Importantly, the *ZCCHC7* intragenic variant is highly conserved and, according to ENCODE and TRANSFAC, is a DNase I hypersensitive site with open chromatin histone marks (H3K4Me1, H3K4Me3 and H3K27Ac), and it is predicted to disrupt the transcription factor binding site for several transcription factors, including the binding of the tumor suppressor gene *BRCA1*. Conclusions: By reanalyzing existing GWAS data with newer sequencing-based reference panels, we identified novel low-frequency variants associated with cancer risk. These findings, will ultimately allow the development of prognosis, diagnosis and therapeutic protocols.

C08.3

Summary statistic imputation method enables conditional analysis across meta-analysis studies: Application to GIANT height associations from exome-chip & HapMap

S. Rieger^{1,2}, A. R. Wood³, E. Marouli⁴, M. Graff⁵, C. Medina-Gomez^{6,7}, K. Sin Lo⁸, GIANT consortium, Z. Kutalik^{1,2};

¹Institute of Social and Preventive Medicine, University Hospital (CHUV), Lausanne, Switzerland, Lausanne, Switzerland, ²Swiss Institute of Bioinformatics, Lausanne, Switzerland, ³Genetics of Complex Traits, University of Exeter Medical School, University of Exeter, Exeter, United Kingdom, ⁴William Harvey Research Institute, Queen Mary University of London, London, United Kingdom, ⁵Department of Epidemiology, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, ⁶Department of Internal Medicine, Erasmus Medical Center, Rotterdam, Netherlands, ⁷Department of Epidemiology, Erasmus Medical Center, Rotterdam, Netherlands, ⁸Montreal Heart Institute, Montréal, QC, Canada.

Last year the GIANT consortium established 697 height-associated HapMap SNPs through a meta-analysis of ~250,000 individuals. Recently, the consortium combined exome-chip association results from 381'600 individuals to provide more insight into the role of coding regions in human stature regulation. While this new (unpublished) study revealed 99 height-asso-

ciated exome-chip variants (mapping to 74 loci) that are not present in the HapMap panel it remained unclear which variants represent truly novel association signals.

To ensure that the newly discovered height-associated exome-chip variants are independent of the 697 known height SNPs the conditional effect sizes derived from the same sample have to be calculated. To this end, the association summary statistics for exome-chip variants ought to be imputed using published HapMap association results.

We improved on existing methods for summary statistics imputation by more accurate calculation of the imputation quality, accounting for variations in available sample size, and using UK10K sequencing data for LD estimation with optimized shrinking. Our approach yielded a 10% reduction in root mean square error compared to standard methods. Variants with poor imputation quality (r^2 0.8) markers, we additionally performed conditional summary statistic analysis to derive the effect of each (imputed) top exome variant conditional on all previously reported HapMap SNPs.

Three of those 45 variants were found to be independent of HapMap SNPs (SERPINA1, SNRPC, TSGA10IP).

Financial support: Swiss National Science Foundation (31003A-143914).

RD-Connect (rd-connect.eu) is an EU FP7 funded project building an integrated platform to narrow the gaps in rare disease research, where patient populations, clinical expertise and research communities are small in number and highly fragmented. The RD-Connect platform securely integrates -omics data with biosample and clinical information, providing not only a centralised data repository but also a sophisticated and user-friendly online analysis system. Raw Whole Genome, Exome or gene panel NGS data are deposited at the European Genome-phenome archive and processed by RD-Connect's standardised analysis and annotation pipeline. The corresponding clinical information is recorded in a connected PhenoTips instance using the Human Phenotype Ontology, OMIM and Orpha codes. The results are made available to authorised users through the highly configurable and efficient platform, which runs on a Hadoop cluster and uses ElasticSearch (platform.rd-connect.eu). The user-friendly interface enables filtering and prioritization of variants using the most common quality, genomic location, effect, pathogenicity and population frequency annotations. Additional tools, such as Exomiser, DiseaseCard, Alamut Functional Annotation (ALFA) and UMD Predictor (umd-predictor.eu) are integrated at several levels. RD-Connect has lit a GA4GH Beacon within the Beacon Network (www.beacon-network.org) and is actively involved in the development of the Matchmaker Exchange (www.matchmakerexchange.org) 1-sided match prototype. The latter will be useful to locate, without disclosing personal information, similar patients (by phenotype and genotype) in other databases which store unfiltered genomic data.

Many families with a child having a developmental disorder are facing major delays in reaching a diagnosis. Families often have to cope with the difficulties of having a disease without a name, lacking a precise genetic counselling hampering parenthood projects and inappropriate clinical management. Whole exome sequencing (WES) offers an unprecedented tool for genetic testing without a priori hypotheses, specifically appropriated for undiagnosed patients with a developmental disorder. For patients with negative results of a diagnostic interpretation, a genotype-first approach may be fruitful in assessing whether a genotype, or variants in a candidate gene, can recurrently be responsible for clinically recognizable phenotypes. International data sharing allows the identification of similar patients with ultra-rare disorders. Here we present the results of a data sharing of candidate variants affecting putative disease-causing genes. This was proposed to families after a clinical WES performed in a regional centre in a diagnostic setting. By combining several methods for data sharing, and participating to the 'Matchmaker Exchange' initiative, new disease-causing genes were identified and could ultimately lead to a diagnosis for the families. From approximately 400 negative clinical WES, we have participated to the description of 20 new disease-causing genes for developmental disorders. Some examples will be given including: 1) candidate genes in a recognized ultra-rare disease, with no national clinical replication; 2) previously unrecognized syndromes arising as homogeneous disorders; 3) identification of recurrently mutated genes in clinically heterogeneous conditions that could be demonstrated by a sum of genetic results and clinical reports.

C08.6

DNA.Land: A community-wide platform to study millions of genomes-phenomes

Y. Erlich;

New York Genome Center/Columbia University, New York, NY, United States.

Understanding the genetic architecture of complex traits is a key challenge for personalized medicine. But obtaining the genomes and phenomes of large cohorts using traditional ascertainment methods are logistically challenging and cost-prohibitive. As of today, two million individuals have already obtained genome-wide information on their DNA using Direct to Consumer (DTC) genomics companies. These individuals are usually driven by self-interest in genealogy and ancestry research. In our previous studies, we built a 13-million member family tree by crowdsourcing information from the same vibrant citizen genealogy community.

We developed a web-platform called DNA.Land (<https://DNA.Land>) where anyone can securely contribute her or his own DTC-generated genome data for research and connect phenotypes using questionnaires and his/her streams of social media information.

A critical concept of DNA.Land is reciprocation. To serve participants' curiosity in their genomes and family histories, our platform is built to efficiently offer analyses unavailable through DTC companies, including whole-genome imputation, refined ancestry inference, and kin-matching across company cohorts. We hope to work closely, trustworthily, and fruitfully with participants, to apply the platform for scientific benefit. We will discuss our efforts to collect family trees and phenotype streams using social media, while respecting individuals' preferences according to our data sharing guidelines. Our vision is that this platform will serve the human genetics-wide community to reach the massive scale of data needed to understand complex traits.

C09 Prenatal Decision Making (joint with EMPAG)

Introduction of non-invasive prenatal testing as a first-tier screening test: A survey among Dutch midwives about their role as counselors

L. Martin^{1,2,3}, J. Gitsels-van der Wal^{1,2,3}, L. Henneman^{3,2};

¹Midwifery Science, AVAG, Amsterdam, Netherlands, ²EMGO Institute for Health and Care Research, Amsterdam, Netherlands, ³VU University Medical Center, Amsterdam, Netherlands.

Background: In the Netherlands, non-invasive prenatal testing (NIPT) is currently only available for women at high-risk for fetal aneuploidy based on the first-trimester combined test (FCT, >1:200) or medical history. Should NIPT become available as a first-tier screening test, the role of midwives will become even more important as 80% of pregnant women are counseled in primary care. We assessed midwives' attitudes, knowledge and educational needs regarding NIPT.

Methods: Online survey completed by 436 (of the 2106) Dutch midwives, April-June 2015.

Results: The majority (68%) of midwives were in favour of replacing FCT by NIPT, although 40% preferred to maintain nuchal translucency measurement. Only 2% preferred to implement NIPT after FCT with a lower risk cut-off (>1:1000). Midwives were worried that women would not want to (74%) and/or cannot (65%) pay the estimated costs of NIPT (~530 euros). In total, 63% had followed training on NIPT. Overall knowledge was good, although 52% did not know fetal DNA originates from the placenta, and 35% did not know an increased (NT) is no indication for NIPT. Most midwives (87%) felt confident about counseling for NIPT; 60% believed counseling will become easier.

Conclusions: Midwives' attitudes towards NIPT as first-tier screening test are positive, but many prefer to maintain NT measurement. Midwives worry that many women will not or cannot pay for NIPT which may lead to inequality. Knowledge seems good but can be improved in some aspects. Education should continue to focus on counseling competences in order to facilitate women's informed reproductive decision-making.

C09.2

Should we be worried about children born after PGD for Huntington's Disease?

M. den Heijer¹, A. Tibben², G. de Wert³, W. Dondorp³, M. van der Sangen³, C. de Die³;
¹Erasmus MC, Rotterdam, Netherlands, ²Leiden University Medical Center, Leiden, Netherlands, ³Maastricht University Medical Centre, Maastricht, Netherlands.

Introduction: In the Netherlands, there is broad societal and political support for preimplantation genetic diagnosis (PGD) if one of the parents is a carrier of HD. However, policymakers and funders expressed concerns about facilitating reproductive options that lead to children who will inevitably be confronted with a parent with HD, and grow up in potential distressing circumstances with consequently impairment of the quality of their life. To meet those concerns, we examined psychological functioning, coping and dynamics in these families.

Methods: We conducted 10 semi-structured interviews with 7 couples and 3 single parents who gave birth to at least one child after PGD. None of the carriers were symptomatic at the time of testing (1994 - 2011). At the time of the interview, 2 parents were symptomatic, one was deceased. Interviews were audio-taped, transcribed verbatim and analyzed thematically.

Results: PGD met parents' expectations regarding relief from guilt feelings towards their child(ren). Those who had previous prenatal diagnosis reported that termination of pregnancy was extremely psychological burdening, whereas for PGD the procedure was more physically distressing. As long as the carrier-parent was asymptomatic, the couple's focus was mainly on the individual future disease process. When the carrier-parent becomes symptomatic, the family becomes insidiously aware of the far-reaching impact on all involved, which may initially have been underestimated.

Conclusions: We did not observe specific issues related to PGD. However, it is of uttermost importance that parents have access to specific health care supporting the family system in issues related to (future) HD.

C09.3

Informed choice in prenatal genetic testing: the choice between non-invasive and invasive prenatal testing

S. L. van der Steen¹, K. E. M. Diderich¹, I. M. Bakkeren¹, M. M. F. C. Knapen¹, A. T. J. I. Go¹, A. Tibben², M. I. Srebniak³, D. Van Opstal¹, M. G. Polak³, R. J. H. Galjaard¹, S. R. Riedijk¹;
¹Erasmus University Medical Center, Rotterdam, Netherlands, ²Leiden University Medical Center, Leiden, Netherlands, ³Erasmus University, Rotterdam, Netherlands.

Background and aims: In case of an increased risk at first trimester screening, most centers offer further testing by non-invasive prenatal testing (NIPT), or invasive prenatal diagnosis (PND) with rapid aneuploidy detection. In contrast, we offer whole genome SNP array analysis at 0.5 Mb resolution, which has a broader scope. We aimed to investigate whether pregnant women and their partners made informed choices between NIPT and array testing after routine pre-test counselling.

Methods: 330 women and 103 partners participated. Informed choice was defined as a behaviorally implemented choice that is attitude-consistent and based on sufficient knowledge, measured with the Measure of Informed

Choice. Three categories of informed decision-making were formed, 1) completely informed, 2) partly informed and 3) completely uninformed.

Results: 87% chose NIPT, 12% chose invasive PND. Twenty-six percent of the NIPT group made completely informed choices, versus 85% of the participants who opted for PND. In the NIPT group, 60% of choices were based on sufficient knowledge, but were inconsistent with attitude, versus 32% in the PND group. Scrutinizing the attitudes, we found that 25% of participants choosing NIPT did prefer broader testing, but were held back by risks of an invasive procedure.

Conclusions: Most women and their partners highly valued the avoidance of a miscarriage risk over invasive PND. Their attitudes indicate they would prefer results comparable to whole genome testing, but safely, i.e. performed by NIPT. For informed decision-making during counselling, we advocate more focus on attitude-consistency as compared to only a strong focus on knowledge.

C09.4

Attitudes, decision-making and experiences of preimplantation genetic diagnosis (PGD) users

S. Zuckerman¹, S. Gooldin², G. Altarescu¹;

¹Hebrew University; Shaare Zedek Medical Center, Jerusalem, Israel, ²Hebrew University, Jerusalem, Israel.

PGD is an accepted procedure for prenatal diagnosis (PND), worldwide. The psychosocial aspects of the technology has been discussed among experts and were evaluated among various population groups but only paucity of empirical data focused on PGD users' expectations, concerns, decision-making and experiences, involved in the process.

In order to evaluate Israeli PGD users' attitudes we used mixed methods: Semi-structured in-depth interviews of 37 users (carriers of various genetic disorders) were performed. Fifty seven questionnaires, based on themes emerged in the interviews, were filled by people in various stages of PGD procedure.

Seventy nine subjects (84%) consider performing PND for a transmissible genetic disorder, yet 43 (46%) were not sure PGD should be the first choice. Once being involved in the procedure, 71 people (76%) thought PGD is the best option comparing to CVS and amniocentesis, and 54 (57%) view PGD as the preferred option for future pregnancies. Interestingly, all others adopted to avoid PND or would perform CVS, but not amniocentesis.

PGD users viewed as advantages: the reassurance of the unaffected embryo status from the beginning of pregnancy (65%), avoiding pregnancy termination (65%) and invasive prenatal tests (29%). The disadvantages included the medical actions involved (57%), the need for hormonal treatment (56%) and long waiting lists for the procedure (42%).

Understanding attitudes and experiences of couples who already performed PGD will deepen the insights of the special needs of this particular group, and should play a crucial role in developing programs for counseling, directing and accompanying future PGD users.

C09.5

What do pregnant women think of prenatal whole-exome sequencing? A cross-cultural comparison

C. Richards¹, S. Dheensa¹, A. Newson², Z. Deans³, S. Shkedi-Rafid⁴, J. Hyett², Z. Richmond², A. Fenwick¹;

¹University of Southampton, Southampton, United Kingdom, ²The University of Sydney, Sydney, Australia, ³University of Bristol, Bristol, United Kingdom, ⁴Hebrew University of Jerusalem, Jerusalem, Israel.

Introduction: Prenatal whole-exome sequencing (PWES) is suggested to have a greater diagnostic yield than chromosomal-microarray analysis for diagnosing fetal anomalies. Despite falling costs and increasing speeds, clinical practice has not incorporated PWES because its clinical validity is disputed and it produces a huge range of results, some of which could influence decisions to terminate (potentially healthy) pregnancies. As almost no research explores what pregnant women think about PWES, we are comparing opinions between the UK, Australia, and Israel.

Methods: We created a questionnaire by first developing a pool of questions from the literature about genome tests; refined questions and thus content validity through discussion with experts; and conducted cognitive interviewing with pregnant women to increase the questionnaire's sensitivity, reliability, and validity. Piloting (n≈150) and administration of the final questionnaire (n≈600) will soon be underway across the three countries.

Results: We are illuminating views about what 'incidental findings' should be reported, when, and why; the meaning of variants of uncertain significance and whether they are grounds to terminate pregnancies; the accep-

tability and feasibility of trio or family-sequencing during pregnancy to clarify uncertain results; and acceptable turnaround times for results and who should communicate them.

Conclusions: We will contribute to international debates about whether clinical care should integrate PWES and highlight what women need from genetic counselling to make informed decisions. Results will also provide the first step in identifying cultural norms, ethical frameworks, and political landscapes that could affect whether and how different countries translate this technology into clinical care.

C09.6

Why do pregnant women accept or decline prenatal diagnosis for Down syndrome?

C. Ingvaldstad¹, E. Ternby², O. Axelsson^{2,3}, G. Annerén⁴, P. Lindgren¹;

¹Dept of Clinical Science, Intervention and Technology, Division of Obstetrics and Gynaecology, Stockholm, Sweden, ²Department of Women's and Children's Health, Uppsala University, Uppsala, Sweden, ³Centre for Clinical Research Sörmland, Uppsala University, Eskilstuna, Sweden, ⁴Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, Sweden, Uppsala, Sweden.

Objective: To investigate if knowledge of Down syndrome (DS), influences the decision to accept or decline prenatal diagnosis (PND). Secondary aims were to elucidate reasons for accepting or declining PND and investigate differences between the accepting and declining group in perceived information, knowing someone with DS and thoughts about decision-making.

Method: A questionnaire was completed by 76 pregnant women who underwent invasive testing and 65 women who declined tests for chromosomal aberrations.

Results: Apart from one question no significant differences were found in knowledge of DS between women declining or accepting PND for DS. Both groups had varying and in several aspects low levels of knowledge about DS and its consequences. Most common reasons to accept PND were 'to ease my worries' and 'to do all possible tests to make sure the baby is healthy'. Corresponding statements declining PND were 'termination of pregnancy is not an option' and 'because invasive tests increase the risk of miscarriage'. More women declining PND knew someone with DS.

Conclusion: Knowledge of DS at these levels is not a major factor when women decide to accept or decline PND for DS. Their choice is mostly based on opinions and moral values.

C10 Epigenetic mechanisms in development and disease

C10.1

Evolving skeletal traits by cis-regulatory changes in bone morphogenetic proteins

V. Indjeian;

MRC Clinical Sciences Centre, London, United Kingdom.

Changes in bone size and shape are defining features of many vertebrates, and underlie many of the traits that make us uniquely human. To uncover the genomic changes that control species-specific skeletal alterations, we did high-resolution mapping of dermal bone traits in sticklebacks. We identified the gene for a secreted bone morphogenetic protein, *Growth/Differentiation Factor 6 (GDF6)*, as a major locus controlling flat bone size in natural populations. Freshwater fish have a *cis*-acting regulatory change that increases *GDF6* expression, and transgenic overexpression phenocopies evolutionary changes in dermal bone size. Comparative genomics revealed that the human *GDF6* locus also has undergone distinctive regulatory evolution, including complete loss of an enhancer that is highly conserved in other mammals. Functional tests show that the ancestral enhancer drives expression in hindlimbs but not forelimbs, in locations that have been specifically modified during the human transition to bipedalism. These results add to growing evidence that *cis*-regulatory modifications of BMP genes represent a common mechanism for evolving specific skeletal changes in humans and other vertebrates.

C10.2

Genetic and functional interactions between SOX10, ZEB2 and EDN3/EDNRB during mouse enteric nervous system development

Y. Watanabe^{1,2}, L. Stanchina^{1,3}, L. Lecker^{1,2}, V. Baral^{1,2}, V. Pingault^{1,4}, D. Huylebroeck⁵, N. Bondurand^{1,2};

¹INSERM U955 IMRB Team 6, Créteil, France, ²Université Paris Est, Faculté de Médecine,

Créteil, France, ³current address: Centre d'Etude des Cellules Souches (CECS), I-Stem, AFM, Evry, France, ⁴current address: Institut Imagine, INSERM UMR 1163 Embryologie et génétique des malformations, Paris, France, ⁵Department of Cell Biology, Erasmus MC, Rotterdam, Netherlands.

Hirschsprung disease (HSCR) is characterized by the absence of enteric ganglia along a variable portion of the distal gastrointestinal tract, which results in functional intestinal obstruction. This rare developmental disorder (1/5,000 live births) is attributed to a failure of the neural crest cells (NCC) to migrate, proliferate, differentiate or survive and to form the enteric nervous system (ENS). Isolated or syndromic forms of HSCR have a complex genetic etiology with a dozen factors involved, including EDN3, its receptor EDNRB and the transcription factors SOX10 and ZEB2.

Over the last ten years, we have studied the role of these factors during ENS development and characterized the genetic and functional interactions among them. We showed that genetic interactions between Sox10 and Zeb2 or Edn3/EdnrB are essential for enteric NCC survival and differentiation. However, the cellular and molecular contribution of Zeb2 remains unclear. Here, the generation and characterization of the double-mutant mice Zeb2-Edn3 and Zeb2-EdnrB revealed a genetic interaction between these three genes in ENS development. Indeed, double-mutants present with increased distal aganglionosis as compared to single mutants. In parallel, gene regulation studies combined with enteric progenitor culture and rescue experiments allowed us to demonstrate the transcriptional regulation of EDNRB by SOX10 and ZEB2 and the essential role of the SOX10/ZEB2/EDN3 "triade" in controlling the differentiation status of enteric NCC.

With these results, we can now integrate ZEB2 in the genetic interaction network known to be involved in ENS development, leading to a better understanding of the cellular bases of HSCR.

C10.3

Knockout of the zinc finger protein ZNF274 in PWS-specific stem cell neurons activates expression of repressed maternal 15q11.2-q13 transcripts

M. Langouet;

Uconn Health, Farmington, CT, United States.

Prader-Willi syndrome (PWS) is characterized by neonatal hypotonia and failure to thrive during infancy, and, subsequently, by obesity, hyperphagia, cognitive disability and behavioral abnormalities. This neurobehavioral disorder of genomic imprinting is caused by the lack of expression of genes on the paternally inherited chromosome 15q11.2-q13 region. The detailed genetic basis of PWS is complex involving the loss of active copies of a cluster of non-coding box C/D class small nucleolar RNAs, the SNORD116 snoRNAs. In stem cell models of PWS, we previously identified a new epigenetic complex, composed of the zinc-finger protein ZNF274 and the SET domain, bifurcated 1 (SETDB1) histone H3 lysine 9 (H3K9) methyltransferase, that is involved in silencing the maternal copy of the PWS critical region (PWS-CR) encompassing the SNORD116 cluster.

Here, using genome editing approaches, we have knocked out ZNF274 expression in PWS-specific iPSC lines from multiple PWS patients with diverse genetic abnormalities and showed that the extent of transcriptional re-activation of PWS-CR genes varies during *in vitro* neurogenesis. While PWS-CR gene expression in ZNF274 knockout (KO) iPSCs is ~5 % of normal levels, wild-type mRNA levels are completely restored in neurons derived from PWS ZNF274 KO iPSCs. Surprisingly, the DNA methylation at the PWS-IC remains unchanged upon ZNF274 KO, suggesting that the ZNF274 complex acts as a second imprinting mechanism regulating the PWS-CR gene expression during the course of neurogenesis. Our data further support the finding that ZNF274 may represent a potential target for future therapeutic applications to rescue the PWS phenotype.

C10.4

Features of FMR1 hypermethylation and CGG instability in FXS pluripotent stem cells

H. Mor-Shaked¹, M. Avitzour¹, G. Altarescu², T. Geva-eldar², S. Epsztejn-Litman¹, R. Eiges¹;

¹Shaare Zedek Medical Center affiliated with the Hebrew University School of Medicine, Jerusalem, Israel, ²Shaare Zedek Medical Center, Jerusalem, Israel.

Our research focuses on when and how FMR1 gains aberrant methylation, and whether hypermethylation is mechanistically associated with CGG somatic instability. Taking advantage of a large set of FXS HESC lines (9 in total), we show that *FMR1* epigenetic gene silencing commonly occurs in the undifferentiated cells and that FXS HESC lines are heterogeneous for repeat size and methylation levels. By monitoring single cell lineages of FXS HESCs and patient-derived iPSC cells over time in culture, we demonstrate that CGG instability in fact exists in these cells, and is largely correlated with

transcriptional activity of FMR1. Furthermore, we provide evidence for the existence of R-Loops near the CGG repeats in FXS HESCs/iPS with an active FMR1, and demonstrate their co-existence with single strand DNA slip-outs from the G-rich non-template DNA. Taken together, we propose that the variability in methylation levels within undifferentiated FXS HESC lines reflects a widespread event within mutant FMR1 embryos, where methylation state is initially set. In accordance with our findings, we put forward a model that relies on R-loop formation to explain how epigenetics and gene transcription are mechanistically associated with CGG somatic instability in FXS.

C10.5

Fractal nature of chromatin modules of the human genome

K. Popadin¹, O. Delaneau², M. Zazhytska¹, S. Kumar^{3,4}, A. Giovanna^{3,4}, A. R. Gschwind¹, C. Borel⁵, D. Marbach⁵, D. Lamparter⁵, P. Bucher^{3,4}, S. E. Antonarakis⁵, E. T. Dermitzakis⁵, A. Reymond¹;

¹University of Lausanne, Center for Integrative Genomics, Lausanne, Switzerland, ²University of Geneva, Department of Genetic Medicine and Development, Geneva, Switzerland, ³Swiss Institute for Experimental Cancer Research (ISREC), School of Life Sciences, EPFL, Lausanne, Switzerland, ⁴Swiss Institute of Bioinformatics (SIB), EPFL, Lausanne, Switzerland, ⁵University of Lausanne, Faculty of Biology and Medicine, Department of Computational Biology, Lausanne, Switzerland.

It has been recently shown that the chromatin landscape of the human genome is organized into non-uniformly distributed chromatin modules - regions of coordinated behavior of multiple chromatin marks. These modules may represent either active elements of regulatory transcription units or their passive chromatin footprints. To describe the structures of these units, find the patterns of their location, decipher the main factors driving these coordinated behaviors and ultimately reveal their functions, we need to be able to define and reconstruct these modules with high precision. Towards this we have annotated genome-wide inter-individual variation in several chromatin modifications representing active marks (i.e. enrichment of H3K27ac histone modifications), promoter marks (H3K4me3), enhancer marks (H3K4me1), genetic polymorphisms (>7.5M SNPs) and expression level (RNA-seq) in lymphoblastoid cell lines of 200 individuals. Using this high resolution data-set we discovered a fractal structure of the chromatin interactions. To uncover main factors and mechanisms maintaining these chromatin interactions along the human genome we analyzed their distribution upon stratification for evolutionary (i.e. density and properties of genes involved in the interactions), topological (i.e. variation in DNA topology between different cell lines and species) and replication (i.e. variation in replication timing) constraints. We consider the fractal network of the chromatin interactions as a meta-phenotype which can explain better the links between genotype and higher level phenotypes such as transcriptome variation.

C10.6

Hotspots of aberrant enhancer activity punctuate the colorectal cancer epigenome

P. Scacheri^{1,2}, A. Cohen¹, O. Corradin¹, J. Luppino¹, C. Bartels¹, J. Morrow¹, S. Mack², G. Dhillon¹, M. Kalady², J. Willis¹, R. Kerl¹, N. Berger¹, S. Markowitz¹;

¹Case Western Reserve University, Cleveland, OH, United States, ²Cleveland Clinic, Cleveland, OH, United States.

In addition to somatic mutations in genes, aberrant enhancer activity at non-coding regions of the genome is a key driver of tumor formation across cancer types. Through ChIP-seq of the characteristic enhancer histone marks, H3K4me1 and H3K27ac, we mapped putative gene enhancer elements across the epigenomes of a cohort of more than forty colorectal cancer (CRC) cell lines, primary CRC tumors, and normal colon epithelium samples, representing the most comprehensive characterization of enhancer elements in a single type of cancer to date. We identified sets of enhancers that are recurrently commissioned and decommissioned in CRC, including 75 and 67, respectively, present in every CRC sample analyzed, regardless of clinical stage. Multiple lines of evidence support the pathological relevance of the recurrently altered enhancers, particularly those that acquired enhancer activity. Many activate known and novel oncogenes and most are constituents of super enhancers. Nearly half of all GWAS CRC risk loci identified to date map to the recurrently acquired enhancers. CRC growth can be mitigated through pharmacologic inhibition or targeted knockout of genes activated by the recurrent enhancers. The majority of the recurrently acquired enhancers originate from primed chromatin, suggesting that activation of primed chromatin is the mechanism for their formation. Overall, these findings indicate that the CRC epigenome is defined by highly recurrent epigenetic alterations at enhancer elements, or "hotspots". These hotspots activate a common aberrant transcriptional program necessary for CRC tumor growth and survival, and therefore represent promising targets for anti-cancer therapies.

Reciprocal 16p11.2 CNVs are characterized by considerable variance in their impact on cognition, behavior, head size and BMI suggesting that yet unidentified modifying factors may contribute to the patients' phenotypic outcome. Our recent findings indicated a possible contribution of ciliary dysfunction to the phenotypes of the 16p11.2 CNVs. To potentially identify driver and modifier genes of the 16p11.2 endophenotypes we have sequenced the exomes and the transcriptomes of 250 deeply phenotyped individuals from 16p11.2 families. To avoid ascertainment bias and better represent the phenotypic spectrum, we recruited carriers among unselected population cohorts, as well as in clinical settings. We are cataloging potentially deleterious variants in the 16p11.2-altered pathways, and performing correlative analyses between quantitative traits (e.g. BMI, IQ) and transcript levels. Our results will be replicated with 306 exomes of 16p11.2 trios from the Simons VIP Consortium.

The pilot phase of data analysis identified slightly deleterious variants in 16p11.2-interacting genes that potentially contribute to vertebral and Müllerian duct defects recurrently seen in a subset of 16p11.2 patients. We have also identified, for example, an individual carrying a 16p11.2 deletion and a heterozygous loss-of-function variant in the pan-ciliopathy gene CEP290, and an individual with a 16p11.2 duplication and a non-synonymous mutation in the rasopathy gene PTPN11. Compatible with our "two-hit" hypothesis these patients present alleviated and aggravated phenotype spectra, respectively. Our study will have potential implications for precise clinical management of 16p11.2 CNV carriers, and will shed light to the mechanisms contributing to the complex etiologies of genomic disorders.

C11.2

The power of protective modifiers in human genetics: Plastin3 and Coronin1C unravel endocytosis as an essential cellular mechanism disturbed in spinal muscular atrophy

L. Torres Benito^{1,2,3}, S. M. Hosseinibarkoobe^{1,2,3}, M. Peters^{1,2,3}, R. Rastetter⁴, K. Hupperich^{1,2,3}, A. Hoffmann^{1,2,3}, N. Mendoza Ferreira^{1,2,3}, A. Kaczmarek^{1,2,3}, E. Janzen^{1,2,3}, T. Lamkaemeyer⁵, C. Guschlbauer⁶, A. Büschges⁷, M. Hammerschmidt^{2,5,8}, M. Riessland^{1,2,3}, M. J. Kye^{1,2,3}, C. Clemen⁹, B. Wirth^{1,2,3};

¹Institute of Human Genetics, Cologne, Germany, ²Center for Molecular Medicine Cologne, University of Cologne, Cologne, Germany, ³Institute for Genetics, University of Cologne, Cologne, Germany, ⁴Center for Biochemistry, Institute of Biochemistry, Cologne, Germany, ⁵Excellence Cluster on Cellular Stress Responses in Aging Associated Diseases (CECAD), Cologne, Germany, ⁶Biocenter, Institute for Zoology University of Cologne, Cologne, Germany, ⁷Biocenter Cologne, Institute for Zoology, University of Cologne, Cologne, Germany, ⁸Institute for Developmental Biology, University of Cologne, Cologne, Germany, ⁹Center for Biochemistry, Institute of Biochemistry, Medical Faculty, University of Cologne, Cologne, Germany.

Paradoxically, mutations in some ubiquitously expressed housekeeping genes impair only a specific cell type. A particularly remarkable example is spinal muscular atrophy (SMA), one of the most common autosomal recessive disorders in humans. Twenty years after SMN1 has been discovered as the SMA determining gene, a major unsolved question is still which cellular mechanism leads to motoneuron dysfunction and ultimately to SMA.

Here we demonstrate the power of the protective genetic modifier, plastin 3 (PLS3) to answer this question. Homozygous loss of SMN1 causes SMA. SMN2 produces ~10% functional SMN protein, insufficient to counteract

SMA. In contrast, elevated PLS3, an F-actin -bundling protein fully protects against SMA in SMN1-deleted individuals, carrying 3-4 SMN2 copies. We prove here that PLS3 rescued survival (>250 days) and motoric abilities in an intermediate SMA mouse model. Since PLS3 knock-out in yeast impairs endocytosis, we hypothesized that disturbed endocytosis might be a key cellular mechanism underlying impaired neurotransmission and NMJ maintenance in SMA. Indeed, SMN deficit dramatically reduced endocytosis, which was restored to normal levels by PLS3 overexpression. Under low frequency electro-stimulation, endocytic FM-143 uptake at NMJ level was restored to control levels in SMA-PLS3 as compared to SMA mice. Moreover, proteomics and biochemical analysis unraveled CORO1C, another F-actin binding protein, to directly bind to PLS3 in a calcium-dependent manner. As PLS3, CORO1C overexpression restored fluid-phase endocytosis in SMN knockdown cells by elevating F-actin levels and rescued the axonal truncation and branching phenotype in Smn-depleted fish.

M. van Engelen², S. M. van der Maarel¹;

¹Leiden University Medical Center, Leiden, Netherlands, ²Radboud University Medical Centre, Nijmegen, Netherlands, ³University of Helsinki and Helsinki University Hospital, Helsinki, Finland, ⁴National Institute of Neuroscience, National Center of Neurology and Psychiatry, Tokyo, Japan, ⁵Medisch Centrum Leeuwarden, Leeuwarden, Netherlands, ⁶Tampere University Hospital and University of Tampere, Tampere, Finland, ⁷University of Rochester Medical Center, Rochester, NY, United States, ⁸Fred Hutchinson Cancer Research Center, Seattle, WA, United States.

Facioscapulohumeral muscular dystrophy (FSHD) is associated with the partial chromatin relaxation of the *DUX4* encoding D4Z4 macrosatellite repeat located on chromosome 4, and transcriptional derepression of *DUX4* in skeletal muscle. D4Z4 chromatin relaxation is consistently marked by CpG hypomethylation at the *DUX4* promoter.

In the most common form, FSHD1, D4Z4 chromatin relaxation is caused by a D4Z4 repeat array contraction to 1-10 units (normal range 8-100 units). In the rare form of FSHD, FSHD2, D4Z4 chromatin relaxation occurs on all D4Z4 arrays and is most often caused by mutations in the D4Z4 chromatin repressor *SMCHD1*.

Not all FSHD2 cases can be explained by *SMCHD1* mutations, thus we performed whole exome sequencing in FSHD families with D4Z4 hypomethylation lacking *SMCHD1* mutations. In two families we identified heterozygous mutations in *DNMT3B*, which segregated with D4Z4 hypomethylation and increased FSHD penetrance. Recessive *DNMT3B* mutations were previously shown to cause Immunodeficiency, Centromeric instability and Facial anomalies syndrome type 1 (ICF1). These FSHD patients don't have immunodeficiency, but ICF1 patients might be at risk of expressing *DUX4* and developing FSHD. We propose that the effect of *DNMT3B* mutations on *DUX4* expression and disease presentation, like for *SMCHD1*, depends on several aspects associated with the FSHD locus including D4Z4 repeat size, and the presence of a polymorphic *DUX4* polyadenylation signal. This study suggests that multiple factors are involved in the epigenetic state at D4Z4 and the regulation of *DUX4*.

INSERM UMRS974, CNRS FRE3617, Center for Research in Myology, GH Pitié-Salpêtrière, Paris, France, ⁷Centre de référence de Pathologie Neuromusculaire Paris-Est, Institut de Myologie, GHU Pitié-Salpêtrière, Assistance Publique-Hôpitaux de Paris, Paris, France, ⁸Rare Neurological Diseases Group, Department of Neurology and Neurosurgery, Montreal Neurological Institute, McGill University, Montreal, QC, Canada.

Background: Congenital myopathies are a heterogeneous group of diseases characterized by early childhood hypotonia and muscle weakness. They are sub-classified in seven distinct types based on clinical presentation and characteristic features on biopsy. To date, more than 30 genes have been associated with congenital myopathies and a large number of patients are still without a diagnostic.

Methods: In order to identify the causative gene, three consanguineous families, from different ethnic backgrounds, were exome sequenced independently. RNA-sequencing was also performed on muscle biopsy from one affected.

Results: Whole-exome sequencing identified homozygous truncating mutations in ZAK, encoding for the sterile alpha motif and leucine zipper containing kinase. RNA-sequencing confirmed a decreased expression of ZAK in muscle, suggesting mRNA decay. Transcriptome analysis showed similarities of affected pathways with other muscle diseases including the up-regulation of extracellular matrix components as well as a down-regulation of sarcomeric genes.

Conclusion: In this study, we linked a loss-of-function mutation in ZAK with congenital myopathy. Although transcriptome analysis was performed on only one patient, we obtained results suggesting affected pathways common to other myopathies. The identification of mutations in ZAK will allow accurate genetic counseling and potentially lead to the identification of novel therapeutic targets.

MT received a post-doctoral fellowship from the CIHR.

C11.5

Expanding the allelic and locus heterogeneity of tRNA synthetase-related neuromuscular disease

A. Antonellis¹, L. Griffin¹, S. Opreacu¹, M. Shy², M. Meisler¹, J. Kitzman¹, A. Beg¹;

¹University of Michigan, Ann Arbor, MI, United States, ²University of Iowa, Iowa City, IA, United States.

Four genes encoding aminoacyl-tRNA synthetases (ARSs) cause dominant, axonal Charcot-Marie-Tooth (CMT) disease, which is characterized by impaired motor and sensory function in the distal extremities. ARS genes implicated in dominant CMT disease thus far are glycyl-(GARS), tyrosyl-(YARS), alanyl-(AARS), and histidyl-tRNA synthetase (HARS). Functional analyses revealed that CMT-associated ARS mutations reduce enzymatic activity, suggesting that impaired tRNA charging is a component of disease pathogenesis. Currently, ARS variants of unknown pathogenicity are being discovered rapidly, making it important to proactively determine the subset of variants relevant to CMT disease. We performed a forward mutation screen in yeast that revealed 17 novel loss-of-function GARS and AARS mutations, one of which was subsequently found in a patient with CMT disease. These functional data contributed to a rapid patient diagnosis. We are expanding these efforts via programmed allelic series (PALS) in allelically heterogeneous yeast growth assays. If impaired tRNA charging causes CMT disease, then mutations in other ARS genes may cause this phenotype. To test this, we identified loss-of-function missense mutations in an ARS not yet associated with disease [threonyl-(TARS)] and evaluated them for dominant toxicity in *C. elegans*. This revealed two classes of mutations: those toxic to neurons and those not toxic to neurons. These "separation of function" mutations will be essential for determining the molecular pathology of ARS-associated CMT disease, which we are pursuing in mouse. Combined, our data suggest that mutations in a broader panel of ARS genes cause dominant CMT disease and that improving ARS function is a relevant therapeutic strategy.

Chorea is a hyperkinetic movement disorder resulting from dysfunction of striatal medium spiny neurons (MSNs), which form the main basal ganglia output projections. Here we used whole exome sequencing to unravel the underlying genetic cause in three unrelated individuals with a very similar and unique clinical presentation of childhood-onset chorea and characteristic brain MRI showing symmetrical bilateral striatal lesions. All cases were identified to carry a *de novo* heterozygous mutation in *PDE10A* (c.898T>C; p.Phe300Leu in two cases and c.1000T>C; p.Phe334Leu in one case), encoding a phosphodiesterase highly and selectively expressed in MSNs. *PDE10A* contributes to the regulation of the intracellular levels of cyclic adenosine monophosphate (cAMP) and cyclic guanosine monophosphate (cGMP). Both substitutions affect highly conserved amino acids located in the regulatory GAF-B domain, which, by binding to cAMP, stimulates the activity of the *PDE10A* catalytic domain. *In silico* modeling shows that the mutated residues are located deep into the binding pocket, where they are likely to alter cAMP binding properties. *In vitro* functional studies showed that both substitutions do not affect the basal *PDE10A* activity, but severely disrupt the stimulatory effect mediated by cAMP binding to the GAF-B domain. The identification of *PDE10A* mutations as a cause of chorea further motivates the study of cAMP signaling in MSNs, and highlights the crucial role of striatal cAMP signaling in the regulation of basal ganglia circuitry. Pharmacological modulation of this pathway may offer promising aetiologically-targeted treatments for chorea and other hyperkinetic movement disorders.

C12 Molecular Dysmorphology

C12.1 Mutations in MAP3K7 and TAB2 that alter the activity of the TAK1 signalling complex cause frontometaphyseal dysplasia

Frontometaphyseal dysplasia (FMD) is a sclerosing skeletal dysplasia affecting the long bones and the skull, however individuals present with a range of developmental abnormalities. Approximately 50% of instances of FMD are allelic to the otopalatodigital spectrum disorders caused by gain-of-function mutations in *FLNA*, the mechanism by which these mutations result in hyperostosis is unknown. Using whole-exome and targeted Sanger sequencing in 20 cases of *FLNA*-negative FMD, we found three mutations in genes encoding two components of the TGFβ-activated-kinase (TAK1) complex. Fifteen individuals had the same mutation, c.1454C>T, in *MAP3K7* which encodes TAK1 kinase. A second *de novo* mutation in *MAP3K7*, c.502G>C was discovered in a single individual. A second gene, *TAB2* which encodes TAK1-binding-protein-2, was shown to have the *de novo* mutation, c.1705G>A in a single instance. TAK1, a MAP-3-kinase, is activated via autophosphorylation within its kinase domain. We show the TAK1 mutations are gain-of-function, resulting in a hyper-phosphorylated protein when expressed with TAB2. All three mutations variably alter the activity of more than one signalling pathway regulated by this kinase complex. This includes increased p38 MAPK activation, a key pathway which regulates osteoblastogenesis. These find-

ings show dysregulation of the TAK1 signalling complex produces a close phenocopy of FMD caused by mutations in *FLNA*. Furthermore they suggest that the pathogenesis of some of the filaminopathies caused by *FLNA* mutations may be mediated by misregulation of signalling co-ordinated through the TAK1 signalling complex.

Supported by the Marsden Fund (Royal Society of NZ), Cure Kids NZ and a University of Otago Scholarship.

C12.2 Mutations in MYT1, encoding the myelin transcription factor 1, are a rare cause of Goldenhar syndrome within the RA signaling pathway

M. Berenguer¹, E. Lopez¹, A. Tingaud-Sequeira¹, S. Marlin², A. Toutain³, F. Denoyelle⁴, A. Picard⁵, S. Charron¹, G. Mathieu¹, H. de Belvalet¹, B. Arveiler^{1,6}, P. J. Babin¹, D. Lacombe^{1,6}, C. Rooryck^{1,6};

¹Univ. Bordeaux, Maladies Rares: Génétique et Métabolisme (MRGM), U 1211 INSERM, Bordeaux, France, ²Hôpital Universitaire Necker-Enfants-Malades, Département de Génétique, Centre de Référence des Surdités Génétiques, Paris, France, ³Hôpital Bretonneau, Service de Génétique, Centre Hospitalier Universitaire, Tours, France, ⁴Hôpital Universitaire Necker-Enfants-Malades, Service d'ORL pédiatrique et de chirurgie cervicofaciale, Centre de Référence des malformations ORL rares, Paris, France, ⁵Hôpital Universitaire Necker-Enfants Malades, Service de chirurgie maxillo-faciale, Paris, France, ⁶CHU de Bordeaux, Service de Génétique Médicale, Centre de Référence Anomalies du Développement et Syndromes Malformatifs, Bordeaux, France.

Goldenhar syndrome (GS) or Oculo-Auriculo-Vertebral Spectrum (OAVS) is a developmental disorder involving first and second branchial arches, characterized by asymmetric ear anomalies, hemifacial microsomia, ocular defects, and vertebral malformations. Although numerous chromosomal abnormalities have been associated with OAVS, no causative gene has been identified so far. Among other environmental factors, Retinoic Acid (RA) has already been described as a teratogenic agent leading to OAVS features in humans.

As sporadic cases are mostly described in GS, we have performed whole exome sequencing on selected affected individuals and their unaffected parents, looking for *de novo* mutations. Consequently, we identified a heterozygous nonsense mutation in one patient in the *MYT1* gene. Further, we detected one heterozygous missense mutation in another patient from a cohort of 169 OAVS patients. This gene encodes the Myelin Transcription factor 1 which is highly expressed in the developing central nervous system. Functional studies by transient knockdown of *myt1a*, homolog of *MYT1* in zebrafish, led to specific craniofacial cartilages alterations and to the up-regulation of Neural Crest Cells marker *sox10*. Moreover, cells studies confirmed close links between *MYT1*, RA and the RA receptor beta (*RARB*). Indeed, All-trans RA (ATRA) treatment led to an upregulation of cellular endogenous *MYT1* expression. Additionally, cellular wild-type *MYT1* overexpression induced a down-regulation of *RARB* leading to a negative feedback of the RA signaling pathway, whereas mutated *MYT1* did not, confirming the pathogenic effect of the mutations.

Overall, we report *MYT1* as a candidate gene implicated in Goldenhar syndrome, within the RA signaling pathway.

C12.3 A novel gene responsible for Treacher Collins-Franceschetti syndrome.

Treacher Collins/Franceschetti syndrome (TCFS; MIM 154500) is a rare genetic disorder. The TCFS is the most common cause of mandibulo-facial dysostosis in human with an estimated prevalence of 1 in 10,000 to 50,000 births. The TCFS is characterized by craniofacial features with bilateral involvement of the first arc brachial responsible for microtia associated with hearing loss, malar and mandibular hypoplasia, cleft palate and other facial abnormalities. To date three genes have been identified as responsible for TCFS, namely *TCOF1*, *POLR1C* and *POLR1D*. These genes are involved in the synthesis of ribosomal RNA and are also important for the differentiation and migration of neural crest cells which lead to the formation of the craniofacial massif. After working for genotyping a large French cohort of TCFS

patients, we realized trio exome in four patients suffering from TCFS and negatives for the three known genes. We identified two different *de novo* non-sense mutations in the same gene. We achieved a morpholino against the RNA of this gene in zebrafish models with a reporter of derived neural crest cells (FOXD3) and cartilage structures (COL2A1). We observed cranio-facial malformations mimicking the human phenotype namely a significant decrease of the mandible and gills and the impression of a decrease in the migration of cells from the neural crest. In conclusion we have identified a 4th gene in STCF inherited in an autosomal dominant manner. This discovery extends the number of ribosomopathies.

C12.4 Loss of a non-coding regulatory element on chromosome 9 in a family with a Cornelia de Lange syndrome (CdLS)-like phenotype

J. Požojec¹, E. Watrin^{2,3}, B. Geidner¹, I. Parenti¹, K. S. Wendt⁴, R. Siebert⁵, A. Rakovic⁶, G. Gillissen-Kaesbach⁷, F. J. Kaiser¹;

CdLS is a dominantly inherited malformation syndrome caused by mutations in genes encoding subunits (SMC1A, SMC3, RAD21) or regulators (NIPBL, HDAC8) of the cohesin complex. This DNA-bound complex regulates chromatin-related processes like chromosome segregation, DNA-damage repair, transcription and chromatin structure. Here we report on a family with two children and a mother with clinical features reminiscent of CdLS. While gene panel sequencing approaches failed to identify the disease-causing mutation, an 87 kb spanning deletion co-segregating with the phenotype was identified by array-CGH. Besides the coding region of CYLC2, encoding a sperm head protein, no other genes were affected. Subsequent in-silico analyses predicted the existence of a ~3 kb tissue-specific regulatory element within this region, approximately 1 Mb distant from the next protein-coding gene SMC2, which encodes a subunit of the cohesin-related condensin complex.

Significant reduction of SMC2 expression was verified in patient's fibroblasts by qPCR analysis. Accordingly, a strong dysregulation of SMC2 was observed in SH-SY5Y cells deficient for the putative 3 kb regulatory element, that was deleted by CRISPR/Cas9 genome editing. Reporter gene assays further highlighted the functional relevance of the identified regulatory element in regulating the SMC2 gene promoter. Interestingly, dysregulation of SMC2 correlated with the dysregulation of another condensin subunit SMC4 in patient's samples as well as CRISPR/Cas9-generated cells. Furthermore, siRNA-mediated reduction of SMC2 in different cell types also resulted in a decreased SMC4 expression.

Our data indicate for the first time a putative relevance of condensin for human disease, which might be dosage-sensitive and/or tissue specific.

C12.5 PCGF2 syndrome—distinctive facies, hypotonia, poor feeding, constipation, thin hair, and global developmental delay with deep cerebral white matter changes—due to *de novo* missense mutations affecting the same conserved proline residue in PCGF2

P. D. Turnpenny¹, M. Wright², C. Tysoe¹, T. van Essen³, R. Pfundt⁴, S. White⁵, N. Lotan⁶, L. Carpenter⁷, B. Schaefer⁸, W. K. Chung⁹, H. McLaughlin¹⁰, L. B. Henderson¹⁰, A. Roberts¹¹, R. Gjergja-Juraški¹², K. Forbes¹³, A. E. Fry¹⁴, D. T. Pilz¹²;

¹Royal Devon & Exeter Hospital, Exeter, United Kingdom, ²Norther Regional Clinical Genetics, Newcastle, United Kingdom, ³University of Groningen, Groningen, Netherlands, ⁴Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, ⁵Victorian Clinical Genetics Services, Melbourne, Australia, ⁶Hadassah-Hebrew University Medical Center, Jerusalem, Israel, ⁷St Francis Genetics, Tulsa, OK, United States, ⁸Arkansas Children's Hospital, Little Rock, AR, United States, ⁹Columbia University, New York, NY, United States, ¹⁰GeneDX, Gaithersburg, MD, United States, ¹¹Boston Children's Hospital, Boston, MA, United States, ¹²Children's Hospital Srebrnjak, Zagreb, Croatia, ¹³Queen Elizabeth University Hospital, Glasgow, United Kingdom, ¹⁴University Hospital of Wales, Cardiff, United Kingdom.

We report 10 subjects, 4 males and 6 females aged 3-18 years with 'PCGF2 syndrome', ascertained worldwide following the identification of 2 cases through the DDD Study by whole exome sequencing of family trios. All individuals have a *de novo* missense mutation in a novel gene, *PCGF2*, affecting the same highly conserved proline residue; eight with p.P65L and MZ twins with p.P65S. The range of features and intellectual disability, including MRI brain imaging, is now evident. Most have a highly distinctive flat and myo-

pathic facial profile with malar hypoplasia, short palpebral fissures, unusual ear helices, and small oral stoma. Birth weight was <10th centile in 8/10; height <10th in 4/10; and weight <10th in 8/10. Head circumference varied widely: <10th centile in 4/10 and ≥90th in 3/10. Some had minor skeletal anomalies, including three with kyphosis/scoliosis and/or formation anomalies of the spine. All have global developmental delay, speech delay (two non-verbal), hypotonia, poor feeding, constipation, and thin hair to a variable degree. Neuroimaging, available in 7/10 patients, showed extensive areas of abnormal white matter; in the MZ twins and 1 other patient this was associated with polymicrogyria.

PCGF2 encodes a polycomb group ring finger protein. Polycomb group proteins form multimeric complexes and repress target gene expression. *PCGF2* has a known role as a tumour suppressor; however, this is the first report of a consistent, syndromic neurodevelopmental phenotype in humans with neuroimaging anomalies caused by germline mutations in the gene.

C12.6 Genetic and functional comparison of identical germline and somatic SETBP1 mutations

R. Acuna-Hidalgo¹, P. Deriziotis², G. M. Findlay³, C. Gillissen¹, International Schinzel-Giedion syndrome collaboration, J. A. Veltman^{1,4}, S. E. Fisher², J. Shendure³, A. Hoischen¹, B. W. van Bon¹;

¹Department of Human Genetics, Radboud UMC, Nijmegen, Netherlands, ²Department of Language and Genetics, Max Planck Institute for Psycholinguistics, Nijmegen, Netherlands, ³Department of Genome Sciences, University of Washington, Seattle, WA, United States, ⁴Department of Clinical Genetics, University of Maastricht, Maastricht, Netherlands.

Schinzel-Giedion syndrome (SGS) is a rare severe developmental disorder characterized by malformations in multiple organ systems. SGS is caused by *de novo* germline mutations clustering within a 12-bp exonic region in SETBP1. Interestingly, identical mutations in SETBP1 occur somatically in myeloid leukemia, leading to increased cell proliferation. The aim of our study is to analyze comparatively germline and somatic SETBP1 mutations to gain insight into genotype-phenotype correlations for SGS and into the molecular basis of SGS.

We have gathered clinical information from over 45 SGS patients, constituting the largest SGS cohort yet. Comparing SETBP1 mutations in SGS and in leukemia shows that, despite sharing an overlap, the distribution of mutations within the hotspot differs between both conditions. Overexpression experiments confirm that mutations in the SETBP1 hotspot destroy a de-gon and lead to increased SETBP1 protein, with different mutations having varying effects on SETBP1 stability and protein levels. Furthermore, we perform saturation genome editing (Findlay et al. Nature 2014) to analyze the effect of all theoretically possible mutations in the SETBP1 hotspot and surrounding region. In silico modeling and functional studies substantiate that mutations seen more frequently in SGS are functionally weaker than those more prevalent in leukemia. Clinical data supports this finding; SGS patients with germline SETBP1 mutations shown to be functionally stronger and more prevalent in leukemia show increased cell proliferation in vitro, increased incidence of malignancy and decreased survival.

Our results support a correlation between the genotype, molecular and cellular consequences and the phenotype in germline SETBP1 mutations.

C13 Prenatal Genetics and carrier screening

C13.1 Validation of non-invasive prenatal diagnosis (NIPD) of multiple single gene disorders for clinical implementation

M. Parks, S. Court, S. Cleary, S. Clokie, J. Hewitt, D. Williams, T. Cole, F. MacDonald, M. Griffiths, S. Allen; Birmingham Women's NHS Foundation Trust, Birmingham, United Kingdom.

In an effort to implement NIPD for single gene disorders (SGDs) into clinical practice (NIPSIGEN project), we have recently developed and validated an NIPD test for Duchenne and Becker muscular dystrophies (DMD/BMD). Building on this experience, we have now designed an improved method for the NIPD of multiple SGDs, namely DMD/BMD, spinal muscular atrophy (SMA) and congenital adrenal hyperplasia (CAH). This was achieved through targeted enrichment of 9054 highly heterozygous SNPs in total (800 Kb of captured genomic region across 6 Mb windows on ChrX, Chr5, and Chr6) and massively parallel sequencing of cfDNA followed by relative haplotype dosage (RHDO) analysis. Maternal, paternal and proband genomic DNA samples were also tested alongside cfDNA for haplotype phasing and to measure the fetal fraction. The test achieved 100% sensitivity and speci-

ficity on patients tested so far, which included four pregnancies at risk of DMD/BMD, five at risk of SMA, and nine healthy control pregnancies (where the fetal DNA obtained from the CVS was used to simulate the proband DNA in seven cases for DMD/BMD testing, and in two cases for SMA and CAH testing). Our improved method is capable of testing 2-3 patients on a single MiSeq run for any of these three SGDs, thus increasing the multiplexing capacity and decreasing testing costs for clinical laboratories. This leads us to believe that NIPD for the most common SGDs might soon become available as a clinical service to patients in the UK and elsewhere.

Funded by: Health Innovation Challenge Fund (DoH, Wellcome Trust).

C13.2

Non-invasive prenatal testing of single-gene disorders: fact or fiction?

Y. Rozenholc¹, L. Orhant², F. Leturcq^{2,3}, E. Girodon², C. Costa², D. Vidaud^{2,4}, M. Vidaud^{2,4}, D. Desauille¹, T. Bienvenu^{2,5}, J. Nectoux^{2,5};

¹MERIT - UMR IRD 216, Sorbonne Paris Cité, Université Paris Descartes, Faculté de Pharmacie de Paris, Paris, France, ²Biochimie et Génétique Moléculaire, HUPC Hôpital Cochin, Paris, France, ³Sorbonne Universités, UPMC Université Paris 06, INSERM UMRS974, CNRS FRE3617, Centre de recherche en Myologie, Paris, France, ⁴EA7331, Faculté de Pharmacie Paris, Université Paris Descartes Sorbonne Paris Cité, Paris, France, ⁵INSERM, U1016, Institut Cochin, CNRS UMR8104, Université Paris Descartes, Paris, France.

Background. In recent years, the deployment of technologies for the analysis of cell-free fetal DNA, such as digital-PCR and NGS, allowed for the implementation of various non-invasive prenatal tests in clinical practice and opened the way to the diagnosis of single-gene disorders. However, to date, it has only been offered for paternal and *de novo* mutation exclusion, the study of the maternal inheritance remaining challenging because of the high levels of maternal background.

Methods. We collected 190 plasma samples from women that underwent a classic invasive prenatal diagnosis for Achondroplasia, Cystic-Fibrosis, Duchenne Myopathy, Hemophilia or Neurofibromatosis Type 1. Digital-droplet PCR assays specifically designed for wild-type and mutant alleles were used to evaluate the observed allelic balance in maternal plasma. A precisely derived Likelihood Ratio Test, taking account of the inheritance pattern, the nature of the mutation and the observed fetal fraction, was used to infer the fetal genotype.

Results. Concerning *de novo* and paternally-inherited mutations, fetal genotype was determined correctly in 100% of the tested cases (49 samples) with fetal fraction >1%. About maternally-inherited mutations, we showed that the percentage of conclusive results highly depends both on the available amount of cell-free DNA and the fetal fraction, thus leading us to propose recommendations in terms of blood volume to collect, for each type of single-gene disorder.

Conclusion. This proof-of-concept study of non-invasive droplet-digital PCR technology for the analysis of both paternally and maternally inherited fetal alleles demonstrates that NIPT for single-gene disorders is now becoming achievable.

C13.3

Maternal incidental findings during non-invasive prenatal testing for fetal aneuploidies

N. Brison¹, K. Van Den Bogaert¹, J. M. E. Van den Oever², L. Dehaspe¹, K. Janssens³, B. Blaumeiser³, H. Peeters¹, H. Van Esch¹, G. Van Buggenhout¹, A. Vogels¹, T. de Ravel¹, E. Legius¹, K. Devriendt¹, J. R. Vermeesch¹;

¹Centre for Human Genetics, UZ Leuven, Leuven, Belgium, ²Leiden University Medical Center, dept. of Clinical Genetics, Leiden, Netherlands, ³Centre for Medical Genetics, University and University Hospital Antwerp, Antwerp, Belgium.

Non-invasive prenatal testing (NIPT) for common fetal aneuploidies by either targeted or whole genome sequencing of circulating free DNA (cfDNA) has become standard prenatal care. Random genome-wide cfDNA sequencing enables not only the detection of fetal chromosomal imbalances but also of maternally derived copy number variants (CNVs). Following routine clinical analysis of over 10,000 prospective pregnancies using an accredited in-house developed analysis pipeline we identified five different clinically relevant constitutional CNVs and imbalanced translocations of maternal origin which were reported back to the mother because they (i) were either relevant for the pregnancy management, (ii) had potential consequences for the fetus or (iii) could have consequences for future reproductive choice. Hence, genome wide cfDNA profiling of maternal plasma improves not only fetal but also more general pregnancy management.

C13.4

A prenatal targeted exome sequencing approach - Fetalis - designed specifically for fetuses with ultrasound abnormalities reveals an important fraction of cases with associated gene defects

C. Pangalos¹, B. Haghefelt¹, K. Lilakos², C. Konialis¹;

¹InterGenetics-Diagnostic Genetics Center, Athens, Greece, ²Department of Haematology, University of Athens Medical School, Athens, Greece.

Introduction: The underlying genetic cause of fetal malformations and other fetal structural abnormalities is often elusive, leading to an inability to provide a precise diagnosis and accurate reproductive and fetal risk assessment. We report the development and first clinical applications of an expanded exome sequencing-based test, coupled to a bioinformatics-driven prioritization algorithm, targeting gene disorders presenting with abnormal prenatal ultrasound findings.

Materials and Methods: We applied the testing strategy to 14 euploid fetuses, from 11 on-going pregnancies and 3 products of abortion, all with various ultrasound abnormalities. Whole exome sequencing (WES) was followed by variant prioritization, utilizing a custom analysis pipeline (Fetalis algorithm), targeting 758 genes associated with genetic disorders which may present with abnormal fetal ultrasound findings.

Results: A definitive or highly-likely diagnosis was made in 6 of 14 cases (43%), involving 3 abortuses and 3 on-going pregnancies. In the remaining 8 on-going pregnancy cases (57%), a ZIC1 variant of unknown clinical significance was detected in one case, while 7 cases did not harbor pathogenic variant(s). Pregnancies were followed-up to birth, resulting in one neonate harboring the PROKR2 mutation and presenting with isolated minor structural cardiac abnormalities, and in 7 apparently healthy neonates.

Conclusions: The expanded targeted exome sequencing-based approach described herein (Fetalis), provides strong evidence suggesting a definite and beneficial increase in our diagnostic capabilities in prenatal diagnosis of chromosomally balanced fetuses with troubling ultrasound abnormalities. Furthermore, the proposed strategy, overcomes many of the problems and limitations associated with clinical wide-scale WES testing in a prenatal setting.

C13.5

Exome sequencing of parental samples is a powerful strategy for the diagnosis of lethal recessive disorders

K. L. Stals¹, J. Baptista¹, A. Bussell¹, R. Caswell², M. Johnson², G. Jones¹, H. Lango Allen², A. Parrish¹, C. Tysoe¹, M. Wakeling², S. Ellard^{1,2};

¹Royal Devon and Exeter NHS Foundation Trust, Exeter, United Kingdom, ²Institute of Biomedical and Clinical Science, University of Exeter, Exeter, United Kingdom.

Rare disorders resulting in prenatal or neonatal death are both phenotypically and genetically heterogeneous, making these disorders difficult to diagnose. Some affected fetuses can be diagnosed by ultrasound scan but often not until mid-gestation of a pregnancy and there is generally only a limited quality and quantity of fetal DNA available for genetic testing. We previously reported a novel strategy of sequencing parental DNA samples to identify potential causative heterozygous mutations that were confirmed as biallelic in the affected fetuses of two couples. We now report exome analysis in a further 19 couples (total cohort 21 couples) who had previous pregnancies affected with a lethal disorder. Likely or definitely causative mutations were identified in 14/21 couples (67%) and where two or more fetuses were affected a genetic diagnosis was obtained in 11/14 (78%) cases. Mutations were identified in 12 different genes (*RYR1* n=2, *GLE1* n=2, *MRPS22*, *CENPJ*, *LRP4*, *BBS9*, *BBS10*, *SASS6*, *DYNC2H1*, *B3GALTL*, *FRAS1* and *ITGA8*). In most cases the reported phenotypes associated with these genes are consistently lethal, but the mutations identified in the *RYR1* and *LRP4* genes represent the most severe form of a variable phenotypic spectrum. Eight referrals involved an ongoing pregnancy, with five diagnoses reported in time to inform management. At least one couple has had prenatal testing in a subsequent pregnancy. Exome sequencing of parental samples is a highly effective strategy for the diagnosis of lethal recessive disorders in outbred couples where there is limited fetal DNA available for testing.

C13.6

Application of a NGS assay for the identification of individuals carrying recessive genetic mutations in reproductive medicine

B. Rodríguez-Santiago¹, A. AbulF², M. Boada³, M. García⁴, S. Carbonell¹, B. Coroleu², A. Veiga³, P. N. Barri³, X. Estivill^{2,4,5}, L. A. Pérez-Jurado^{6,7}, L. Armengol¹;

¹qGenomics, Esplugues del Llobregat, Spain, ²Unit of Medical Genomics, Department of Obstetrics, Gynaecology and Reproduction, Dexeus Women's Health, Barcelona, Spain, ³Service of Reproduction Medicine, Obstetrics, Department of Obstetrics, Gynaecology and Reproduction, Dexeus Women's Health, Barcelona, Spain, ⁴Genetics Unit, Department of Experimental and Health Sciences, Pompeu Fabra University (UPF), Barcelona, Spain, ⁵Centre for Genomic Regulation (CRG), The Barcelona Institute of Science and Technology, Barcelona, Spain, ⁶Hospital del Mar Research Institute (IMIM), Barcelona, Spain, ⁷CIBER in Rare Disorders (CIBERER), Barcelona, Spain.

Introduction: One of the main challenges of current genetic medicine is to provide preventive actions. Utilisation of next-generation sequencing technologies (NGS) for screening carriers of recessive mutations has the capacity of providing information to make medical interventions in gamete donation programs.

Methods: We have developed and validated a NGS carrier-screening test (qCarrier test) that includes 200 genes associated with 218 autosomal recessive and 22 X-linked diseases. Carrier screening is performed to oocyte donation candidates and the male partner of oocyte recipient. Carriers of X-linked conditions are discarded from the program, while donors are chosen not carrying mutations for the same gene/disease as the recipients.

Results: The validation phase showed a high sensitivity (>99%) detecting all single nucleotide variants, 13 indels and 25 copy number variants included in the validation set. A total of 1,301 individuals were analysed with the qCarrier test, including 483 candidate oocyte donors and 635 receptor couples, 105 females receiving sperm donation and 39 couples seeking pregnancy. We identified 56% of individuals who are carriers for at least one genetic condition and 1,7% of female donors who were discarded from the program due to a carrier state of X-linked conditions. Globally, 3% of a priori assigned donations had a high reproductive risk that could be minimized after testing. Genetic counselling at different stages is essential in helping to a successful and healthy pregnancy.

C14 Cancer Genetics: From modeling to profiling

C14.1

LYNCH SYNDROME MOUSE: A MODEL FOR COLON CARCINOGENESIS

M. Pussila¹, P. Törönen¹, E. Einarsson^{2,3}, S. Katayama², J. Linden⁴, J. Kere^{2,3}, M. Nyström¹;

¹Department of Biosciences, University of Helsinki, Helsinki, Finland, ²Department of Biosciences and Nutrition, Karolinska Institutet, Huddinge, Sweden, ³Folkhälsan Institute of Genetics, University of Helsinki, Helsinki, Finland, ⁴Department of Basic Veterinary Sciences, University of Helsinki, Helsinki, Finland.

Western-style diet (WD), which is rich in fat and scarce of fiber and vitamin D, predispose to colorectal cancer (CRC). We performed a long-term diet experiment with WD in the mouse to address putative cancer-predisposing events in colonic mucosa. Transcriptome-wide gene expression profiles were studied for 12 and 18 month old mice analogous to human Lynch syndrome (LS) (Mlh1^{-/-}), and their wild type littermates (Mlh1^{+/+}). Furthermore, tumor phenotypes, microsatellite instability (MSI) and mismatch repair protein (MMR) loss, linked to LS were characterized. Altogether 6 CRCs were detected and 5 of them in WD fed mice. Interestingly, our results show that expression profiles of histologically normal mucosa from mice which developed CRC form a distinct cluster compared to healthy controls in MDS plot created with 100 most regulated genes in the CRC developing samples. The genes were selected with shrinkage-T test. This kind of clustering clearly indicates a colon-wide field effect of CRC-predisposing events in the normal colon mucosa. It is assumed that MMR gene inactivation and consequent tumor initiation follows the classical two-hit model. Our results, however, suggest that already decreased amount of Mlh1, when MMR is still intact, may be sufficient to initiate tumorigenesis. Lynch syndrome mice did not lack Mlh1 or show MSI in their tumors, although Mlh1 RNA expression was already significantly decreased in their mucosa.

The study was supported by grants from European Research Council (2008-AdG-232635), Jenny and Antti Wihuri foundation.

C14.2

Frameshift mutations in microsatellite unstable colorectal cancers: from immune signature to personalized immunotherapy

P. Maby^{1,2}, H. Kora¹, M. Hamieh^{1,3}, D. Tougeron^{1,4}, G. Bindea², B. Mlecnik^{1,3}, H. Angell^{2,5}, T. Fredriksen², N. Elie⁶, J. Leprince⁷, J. Mauillon^{8,9}, F. Le Pessot¹⁰, R. Sesboué¹, T. Frebourg^{1,8}, J. Galon², **J. Latouche^{1,8}**;

¹Inserm U1079-IRIB, Normandy Centre for Medical Genomics and Personalized Medicine, Rouen University, Rouen, France, ²Inserm U1138, Paris Descartes University, Pierre et Marie Curie University, Paris, France, ³The Center for Cell Engineering, Memorial Sloan Kettering Cancer Center, New York, NY, United States, ⁴Department of Gastroenterology, Poitiers University Hospital and EA 4331, Poitiers University, Poitiers, France, ⁵AstraZeneca Pharmaceuticals, Cambridge, United Kingdom, ⁶Imaging Core Facility, Caen University Hospital, Caen, France, ⁷Inserm U982-IRIB, Cell Imaging Platform of Normandy PRIMACEN, Rouen University, Mont-Saint-Aignan, France, ⁸Department of Genetics, Rouen University Hospital, Rouen, France, ⁹Department of Gastroenterology, Le Havre Hospital, Le Havre, France, ¹⁰Department of Pathology, Rouen University Hospital, Rouen, France.

Microsatellite instability (MSI), due to DNA mismatch repair (MMR) machinery deficiency, is found in 15% of all colorectal cancers (CRCs), including Lynch syndrome, the most frequent hereditary form of CRC. In MSI-CRCs, overall tumor-infiltrating lymphocyte (TIL) density and survival rate are known to be higher than in microsatellite stable CRCs (MSS-CRCs). Indeed, frameshift mutations within coding repeat sequences could lead to the synthesis of immunogenic neo-antigens recognized by anti-tumor CD8⁺ T lymphocytes. However, the clear links between MMR machinery deficiency, TIL density and prognosis remain to be established.

Starting from 141 MSI-CRCs, we showed by gene expression profiling and immunohistochemistry, that these cancers, compared to MSS-CRCs, expressed more immune-related genes and were infiltrated with more *in situ* proliferative T cells, functional CD8⁺ T cells, B cells and macrophages, which correlated with prolonged survival. Moreover, we found that CD8⁺ TIL density was associated with the total number of tumor frameshift mutations (FSMs), characterized by multiplex PCRs, and was especially higher when a FSM was present in *ASTE1*, *HNF1A* or *TCF7L2* gene. Finally, using artificial antigen presenting cells developed in the laboratory, starting from peripheral blood of HLA-A2⁺ MSI-CRC Lynch patients, we could mount *in vitro* efficient CD8⁺ T cell responses against neo-antigens derived from FSMs present in their tumor.

Altogether, we describe, for the first time to our knowledge, the precise immune signature of MSI-CRCs, and our results pave the way for developing personalized immunotherapy strategies in these cancers, especially for young Lynch patients.

C14.3

Studying the functionality of the homologous repair pathway in zebrafish embryos: heading for an *in vivo* functional test to evaluate the pathogenicity of BRCA2 variants identified in breast/ovarian cancer patients

K. B. M. Claes¹, J. Vierstraete¹, A. Willaert¹, K. Vleminckx¹, P. Vermassen¹, P. Coucke¹, A. Vraf²;

¹Center for Medical Genetics, Ghent University Hospital, Ghent, Belgium, ²Dept Basic Medical Sciences, Ghent University, Ghent, Belgium.

Aims: Currently, one of the major challenges in genetic testing is determining the functional effect of (rare) variants. Here, we propose a novel *in vivo* approach to study the functionality of BRCA2 missense variants in zebrafish. We propose an *in vivo* functional assay to measure in embryos the capacity of homologous recombination for human BRCA2 mRNA containing variants of unknown clinical significance (VUS).

Methods: We create DNA double strand breaks (DSB) in zebrafish embryos by irradiation. We use *yH2AX* and *RAD51* foci assays as markers for DSB and HR repair respectively. We generated zebrafish *brca2* knockdown models by morpholino injection and Crispr-Cas9. After synthesis of human BRCA2 mRNA, rescue experiments will be performed with wild type mRNA and mRNA containing the VUS of interest.

Results: We developed a protocol for visualising and quantifying *RAD51* foci in tissues of wild type zebrafish embryos. Knockdown of *brca2* by a morpholino results in almost complete absence of *RAD51* foci in irradiated embryos. Similar results are currently being generated in the Crispr-Cas9 *brca2* knockout model. In a next step we will rescue the phenotype by microinjection of wild type human BRCA2 mRNA and mRNA containing VUS to study the effect of these VUS on the HR capacity.

Conclusions: The zebrafish genome contains nearly all the genes involved in different DNA repair pathways in eukaryotes, including, homologous recombination (HR), in which BRCA2 plays a major role. Therefore, zebrafish provide an ideal *in vivo* model for studying variants in genes involved in DNA damage and repair.

C14.4

Cancer treatments contribute to the development of multiple primary tumours in Li-Fraumeni syndrome

E. Kasper¹, Y. Zerdoumi¹, E. Colasse², E. Angot², L. Nico¹, S. Adriouch⁴, Y. Lacoume⁵, J. Sabourin², T. Frebourg¹, G. Bougeard¹, J. Flaman¹;

¹Inserm U1079, Rouen University and Department of Genetics, Rouen University Hospital, Normandy Centre for Genomics and Personalized Medicine, Rouen, France, ²Inserm U1079, Rouen University and Department of Pathology, Rouen University Hospital, Normandy Centre for Genomics and Personalized Medicine, Rouen, France, ³Small Animal Magnetic Resonance Imaging Facility, Rouen University, Rouen, France, ⁴Inserm U905, Rouen University, Rouen, France, ⁵Animal Facility, Rouen University, Rouen, France.

Li-Fraumeni syndrome, due to TP53 germline mutations, is characterized by an exceptional high risk of multiple primary tumours. Considering that p53 pathway is activated in response to DNA damage, we recently developed an universal genotoxicity assay based on the transcriptional induction of TP53 target genes in human lymphocytes exposed to DNA damaging agents (Zerdoumi et al., *Mutat Res* 2015). To evaluate the impact of genotoxic agents in vivo, we first characterized the mouse transcriptome in response to DNA damage, selected Trp53 target genes, developed a similar genotoxic assay in mice based on the ex vivo exposure of mouse splenocytes and then directly performed the assay after intraperitoneal (IP) injection of chemotherapies. The mouse ex vivo and in vivo genotoxic assays showed, like the assay performed in human lymphocytes, that all classical chemotherapies, except microtubule poisons, are strongly genotoxic. We then submitted 6 weeks old Trp53 -/- LFS mice and Trp53 wt/wt control mice to IP injection of chemotherapies or radiotherapy and performed monthly total body MRI. We found that genotoxic chemotherapies and radiotherapy accelerate the development of malignant solid tumours and hemopathies in Trp53 -/- mice. All these results strongly support that cancer treatments contribute to the development of secondary tumours in LFS and explain the sequential occurrence of tumours observed in LFS patients. This indicates that, in LFS patients, radiotherapy should be avoided, whenever possible, and that non genotoxic chemotherapies should be evaluated in order to reduce the risk of multiple primary cancers.

C14.5

Single-cell transcriptional profiling identifies rare cell types with gene markers for classification and prognosis in Acute Myeloid Leukemia

A. Sartori¹, E. Falconnet¹, P. Ribaux¹, S. E. Antonarakis^{1,2,3}, T. Matthes², C. Borel¹;

¹University of Geneva Medical School, Geneva, Switzerland, ²University Hospitals of Geneva, Geneva, Switzerland, ³IGE3 Institute of Genetics and Genomics of Geneva, Geneva, Switzerland.

Acute myeloid leukemia (AML) is a particularly aggressive blood cancer difficult to treat because of its recurrence affecting differentiation of hematopoietic progenitors. It is hypothesized that relapse of AML is due to incomplete eradication of leukemic stem cells (LSC) with self-renewal and leukemia-initiating properties. Our ultimate goal is to characterize LSC based on their transcriptional profiling.

Evidence suggests that CD34+CD38- cell population is enriched for LSCs but they remain rare and difficult to identify. Thus, we present a single-cell RNA-seq approach to characterize CD34+CD38- sorted cells in 2 AML individuals (AML1(M0), AML2(M5)) at the time of diagnosis and in 4 unaffected individuals (N). For 311 single-cells, 1764 genes were detected on average (RPKM>10). We identified 763 and 858 significantly differentially expressed genes in AML2 and AML1, respectively using D3E. We demonstrate that the captured AML cells possess the hallmarks of LSC. The top highly expressed genes are stem markers including SOX4, CD74, CD69 and CXCL8. In particular, HOXA-B cluster genes appeared markedly dysregulated demonstrating their leukemia-initiating capability. Gene ontology revealed enrichment for annotation of apoptotic resistance and self-renewal capacity as well. Furthermore, 3 distinct clusters of co-expressed genes were identified that distinguished between N cells and AML cells with M0 and M5 (SEURAT-tool). Finally, we hypothesized that prognostic gene-expression signature is present at diagnosis. Using TCGA RNA-seq and clinical datasets, we identified genes whose expression correlated with AML patient survival. We confirmed their differential expression in AML single-cells and thus, their contribution in leukemogenesis and potential relevance for clinical-outcome prediction.

C14.6

Tracing the origin of disseminated tumor cells in breast cancer using single-cell sequencing

P. Kumar^{1,2}, E. Moller^{3,4}, J. Demeulemeester^{1,5}, S. Nord^{3,4}, D. Wedge², M. Zamani Esteki¹, A. Børresen-Dale³, K. White⁶, B. Naume³, V. Kristensen³, P. Van Loo^{5,2}, T. Voet^{1,2};

¹University of Leuven, Leuven, Belgium, ²Wellcome Trust Sanger Institute, Hinxton, United Kingdom, ³University of Oslo, Oslo, Norway, ⁴Institute for Cancer Research, Oslo, Norway, ⁵The Francis Crick Institute, London, United Kingdom, ⁶University of Chicago, Chicago, IL, United States.

Single-cell micro-metastases of solid tumors often occur in bone marrow. These disseminated tumor cells (DTCs) may lay dormant, resist therapy and may cause overt bone and visceral metastases. Unfortunately, the molecular nature of DTCs remains elusive, as well as when and where they spring from the tumor. Here, we apply single-cell sequencing to identify and trace the origin of DTCs in breast cancer.

Results: We sequenced 40 single cells isolated by micromanipulation from the bone marrow of six patients using established immunocytochemical markers and morphologic characteristics for epithelial tumor cells. Comparison of the cells' DNA copy number (CN) profiles with those of the primary tumors and lymph node metastasis established that a quarter of the cells disseminated from a tumor clone. The remaining cells represented non-aberrant 'normal' cells and 'aberrant cells of unknown origin' that have CN landscapes discordant from the tumor. Genotyping somatic mutations called on bulk tumor exomes in the SC sequences confirmed that these latter cells did not derive from the same lineage as the breast cancers. Evolutionary reconstruction analysis of bulk tumor and DTC genomes enabled ordering of CNA events in molecular pseudo-time and tracing the origin of the DTCs to either the main tumor clone, primary tumor subclones, or subclones in lymph node metastases.

Conclusions: SC sequencing, in parallel with intra-tumor genetic heterogeneity profiling from bulk DNA, is a powerful approach to identify and study DTCs, yielding insight into metastatic processes. A heterogeneous population of CNA-positive cells of unknown origin is prominent in bone marrow.

C15 Neurogenetic disorders

C15.1

A Complex Mutational Spectrum of Structural Variation Contributing to Autism

M. E. Talkowski^{1,2,3}, R. Collins¹, C. Redin¹, M. Stone¹, J. Glessner¹, S. Sanders⁴, H. Brand^{1,2};

¹Massachusetts General Hospital, Boston, MA, United States, ²Harvard Medical School, Boston, MA, United States, ³Broad Institute, Cambridge, MA, United States, ⁴University of California San Francisco, San Francisco, CA, United States.

Recent genomic studies of autism spectrum disorder (ASD) have relied upon genome-wide characterization of coding mutations using whole-exome sequencing (WES) and copy number variants (CNV) using chromosomal microarray (CMA). In ASD, these efforts have revealed a strong association with de novo loss-of-function (LoF) mutations and CNVs segments that alter the dosage of genes under evolutionary constraint. Unfortunately, the impact of balanced and complex structural variation (SV), which also represent LoF variation, remains uncharacterized in ASD and other human disease studies. Here, we explored the full mutational spectrum of SV contributing to ASD by integrating large-insert, short-insert and synthetic long-read whole-genome sequencing (WGS) technologies with CMA in 307 idiopathic ASD probands and 120 family members from the Simons Simplex Collection. Analyses revealed a diverse landscape of SVs beyond canonical CNVs, including inversions, insertions, and translocations. We also categorized 13 distinct subclasses of recurrent complex SVs and demonstrate that each genome sequenced harbored at least one such large complex rearrangement (~5 kb resolution). We identified 26 de novo SVs likely contributing to ASD, 50% of which were cryptic to detection by previous technologies on these same samples. These data confirmed 13 previously proposed ASD risk factors and discovered 12 novel candidates. We estimate that the overall contribution of de novo SVs in ASD at this resolution to be at least 8.2%, or a two-fold increase over previous analyses restricted to CNVs. These data suggest that cryptic and complex SV represent an important and presently underappreciated component of ASD etiology.

C15.2

A potential role for the linker for activation of T-cells (LAT) in the neuroanatomical phenotype of the 220kb 16p11.2 BP2-BP3 CNVs

M. Loviglio¹, T. Arbogast², M. Leleu³, G. Giannuzzi⁴, K. Männik⁵, 16p11.2 Consortium, J. S. Beckmann⁶, S. Jacquemont⁷, N. Katsanis⁸, C. Golzio⁹, A. Raymond¹⁰;

¹Center for Integrative Genomics, Lausanne, Switzerland, ²Center for Human Disease Modeling - Duke University, Durham, NC, United States, ³EPFL, Lausanne, Switzerland, ⁴Swiss Institute of Bioinformatics (SIB), Lausanne, Switzerland, ⁵CHUSJ - Université de Montréal, Montréal, QC, Canada.

Copy number variants (CNVs) of the distal 16p11.2 220kb BP2-BP3 region show mirror effect on BMI and head size, and association with autism spectrum disorders (ASD) and schizophrenia, as previously reported for the proximal 16p11.2 600kb BP4-BP5 deletion and duplication. These two CNVs-prone regions at 16p11.2 are also reciprocally engaged in complex chromatin looping, successfully confirmed by 4C, FISH, Hi-C and concomitant expression changes. We assessed the 220kb BP2-BP3 duplication by overexpressing each of the 9 encompassed human transcripts, CD19, NFAT-C2IP, ATXN2L, TUFM, ATP2A1, RABEP2, SPNS1, LAT and SH2B1, in zebrafish embryos. Overexpression of the linker for activation of T cells (LAT) induced a reduction in dividing cells in the brain and number of post-mitotic neurons in the anterior forebrain at 2dpf, and of intertectal axonal tracts at 3dpf, resulting in microcephaly at later stages. We showed similar results upon overexpression of CD247 and ZAP70, two genes belonging to the LAT's immune system signaling pathway. Co-injections experiments showed that KCTD13, MVP, and MAPK3, three genes mapping within the 600kb BP4-BP5 locus and major driver and modifiers, respectively, of the head circumference phenotype linked to that region, and LAT acted in an additive manner to increase the severity of the microcephaly phenotype, suggesting the presence of genetic interaction. Chromatin conformation capture further showed that LAT cis- and trans-interacting chromatin partners were enriched for ASD genes ($p=5.6E-03$, $OR=1.9$). Our results suggest that LAT, besides its well-recognized function in T-cells development, is a major contributor in the 16p11.2 (BP2-BP3) 220kb CNVs neurodevelopmental phenotypes.

Introduction: Intellectual disability (ID) and autism spectrum disorders (ASD) are genetically heterogeneous, and associated genes for both conditions overlap substantially. Few mutations in POGZ were reported in recent exome studies. However, these studies did not provide detailed clinical information, leaving the pathogenicity and a clear phenotypic definition of the POGZ patient unknown.

Patients and Methods: We collected the clinical and molecular data of 25 individuals with disruptive mutations in POGZ identified by diagnostic whole-exome, whole-genome, or targeted sequencing of 5,223 individuals with neurodevelopmental disorders (ID primarily) or by targeted resequencing of this locus in 12,041 individuals with ASD and/or ID. In parallel, we utilized a Drosophila knockdown model of the POGZ orthologue row to provide further support for the importance of POGZ in cognitive function.

Results: We defined common phenotypic features of POGZ patients, including variable levels of developmental delay and more severe speech and language delay compared to motor delay and coordination issues. We also identified significant associations with vision problems, microcephaly, hyperactivity, a tendency to obesity and feeding difficulties. In addition, we

found that downregulation of row expression, specifically in neurons, leads to deficits in habituation, a form of non-associative learning that is highly relevant for both ID and ASD.

Conclusion: Combined, these data underscore the pathogenicity of loss-of-function mutations in POGZ and define a novel POGZ-related syndrome. Some features may be explained by the high expression of POGZ early in fetal brain development, particularly in the cerebellum and pituitary.

C15.4

CLOZUK2: A population-based approach to the genomics of treatment-resistant schizophrenia

A. F. Pardiñas¹, S. Legge¹, S. Ripke², the CRESTAR Consortium, K. D. Chambert³, J. L. Moran³, S. A. McCarroll⁴, M. J. Owen¹, M. C. O'Donovan¹, J. T. R. Walters¹;

¹MRC Centre for Neuropsychiatric Genetics and Genomics, Cardiff University, Cardiff, United Kingdom, ²Universitätsmedizin Berlin: Charité, Berlin, Germany, ³Stanley Center for Psychiatric Research, The Broad Institute of MIT and Harvard, Cambridge, MA, United States.

About one third of patients with schizophrenia do not respond adequately to antipsychotic medication, and are thus considered to have treatment-resistant schizophrenia (TRS). This is one of the most disabling forms of mental illness and constitutes a major challenge and cost to public health, affecting at least 1 million people solely in Europe. The only drug backed by evidence-based studies as a prescription for TRS is the atypical antipsychotic clozapine, which requires frequent blood monitoring due to rare but potentially lethal adverse effects.

Through an agreement with the major pharmaceutical companies that market clozapine in the UK (Novartis and Leyden Delta) we collected blood samples of 15,210 anonymous clozapine takers, which were genotyped on the Illumina OmniExpress beadchip by the Broad Institute of MIT and Harvard (Cambridge, USA) and deCODE genetics (Reykjavík, Iceland). We obtained genotype data from 25,811 unscreened control individuals through public sources and collaboration with large-scale genotyping projects. Analysis of this dataset showed significant associations in known schizophrenia loci (TSNARE1, CACNA1C, DRD2) and novel signals (RAPGEF4, ZNF664) which have been previously linked to brain development. In order to clarify the relationship between broad-sense schizophrenia and TRS, we generated polygenic risk prediction scores from the largest available schizophrenia GWAS (Ripke et al. 2015), which were used to calculate risk profiles in TRS individuals. There was no compelling evidence of a stronger polygenic signal in this analysis, disputing the view that TRS represents simply a severe form of schizophrenia.

Funding source: European Community's FP7/2007-2013, grant n° 279227.

Introduction: Microtubules are crucial cytoplasmic structures regulating neuronal cells migration and polarity which are key processes in brain morphogenesis. Their important role in human brain development is highlighted by the neurological disorders arising from mutations in genes encoding tubulins or their cellular interacting partners.

Materials and methods: Using genome wide SNP genotyping paralleled with whole exome sequencing, we investigated a large multigenerational Omani pedigree and a single nuclear family from India to identify the genetic basis of a severe autosomal recessive neurodevelopmental condition with cardinal features of microcephaly and global developmental delay. We performed in vitro cell assays to examine the functional consequences of the identified mutations in key cellular processes.

Results: We identified two novel mutations in the PRUNE gene affecting key functional motifs of the encoded protein: (c.88G>A/ p.Asp30Asn) in the

extended Omani family, and (c.889C>T/ p.Arg297Trp) in the Indian family. Our studies identified PRUNE as a binding partner of β -tubulin crucial for tubulin polymerization. This interaction is impaired by both mutations as shown by disrupted subcellular co-localizations and undermined in vitro microtubules assembly. We also show that both mutations impair in vitro cell migration, proliferation and differentiation which are processes normally enhanced by wild type PRUNE.

Conclusions: Our data confirm the essential role of tubulin-related proteins in cortical development and define PRUNE as a pivotal interacting molecule important for normal microtubule assembly which may be mutated to result in human microcephaly and a global neurodevelopmental delay phenotype. Supported by MRC grant: G1002279

C15.6 Primary microcephaly: ALFY-controlled DVL3 autophagy regulates Wnt signaling, determining human brain size

R. Kadir¹, T. Harel¹, B. Markus¹, Y. Perez¹, A. Bakhrat², E. Chervinski³, J. Zlotogora⁴, S. Sivan⁵, R. Y. Birnbaum², U. Abdu², S. Shalev³, O. S. Birk^{6,7};
¹Human Genetics and the Genetics Institute, Soroka Medical Center, Ben-Gurion University, Beer Sheva, Israel, ²Department of Life Sciences, Ben Gurion University, Beer Sheva, Israel, ³Genetics Institute, HaEmek Medical Center, Afula, Israel, ⁴Department of Community Genetics, Public Health Services, Ministry of Health, Jerusalem, Israel, ⁵The Morris Kahn Laboratory of Human Genetics, National Institute for Biotechnology in the Negev and Faculty of Health Sciences, Ben Gurion University, Beer Sheva, Israel, ⁶Genetics Institute, Soroka University Medical Center, Ben Gurion University, Beer Sheva, Israel.

Primary microcephaly is a congenital neurodevelopmental disorder of reduced head circumference and brain volume, with fewer neurons in the cortex of the developing brain due to premature transition between symmetrical and asymmetrical cellular division of the neuronal stem cell layer during neurogenesis. We now show through linkage analysis and whole exome sequencing, that a dominant mutation in ALFY, encoding an autophagy scaffold protein, causes human primary microcephaly. We demonstrate the dominant effect of the mutation in drosophila: transgenic flies harboring the human mutant allele display small brain volume, recapitulating the disease phenotype. Moreover, eye-specific expression of human mutant ALFY causes rough eye phenotype. In molecular terms, we demonstrate that normally ALFY attenuates the canonical Wnt signaling pathway via autophagy-dependent removal specifically of aggregates of DVL3 and not of Dvl1 or Dvl2. Thus, autophagic attenuation of Wnt signaling through removal of Dvl3 aggregates by ALFY acts in determining human brain size.

C16.1 FINEMAP: Ultrafast high-resolution fine-mapping using summary data from genome-wide association studies

C. Benner^{1,2}, C. Spencer³, A. S. Havulinna⁴, V. Salomaa⁴, S. Ripatti^{1,2,5}, M. Pirinen¹;
¹Institute for Molecular Medicine Finland (FIMM), Helsinki, Finland, ²Department of Public Health, University of Helsinki, Helsinki, Finland, ³Wellcome Trust Centre for Human Genetics, University of Oxford, Oxford, United Kingdom, ⁴National Institute for Health and Welfare (THL), Helsinki, Finland, ⁵Wellcome Trust Sanger Institute, Wellcome Genome Campus, Hinxton, United Kingdom.

Genome-Wide Association Studies (GWAS) have identified thousands of loci associated with complex diseases. A next crucial step is fine-mapping: identifying causal variants that point to molecular mechanisms behind the associations and, eventually, suggest therapeutic targets. Recently, fine-mapping methods have been extended to use only GWAS summary data together with pairwise correlations of the variants. Common to these approaches is that they rely on computationally expensive exhaustive search restricting their use to a few hundred variants. We introduce a software package FINEMAP that replaces the exhaustive search by an ultrafast stochastic search and thereby allows fine-mapping analyses to scale up to whole chromosomes.

We show that FINEMAP (1) opens up completely new opportunities by, e.g., exploring 15q21/LIPC locus for HDL-cholesterol with 20,000 variants in less than 90 seconds while exhaustive search would require more than 9,000 years, (2) provides similar accuracy to exhaustive search when the latter can be completed, (3) achieves even higher accuracy when the latter must be restricted due to computational reasons, and (4) identifies more plausible variant combinations than conditional analysis. At 15q21/LIPC locus with at least a 3-SNP association pattern with HDL, a missense variant and a promoter polymorphism are likely to be causal whereas the lead

variant in single-SNP testing has less evidence than a regulatory variant correlated with it.

We believe that FINEMAP's approach of jointly modeling the whole locus together with its unprecedented computational efficiency will help reveal valuable knowledge that could otherwise remain hidden due to limitations of existing fine-mapping methods.

C16.2 Phenotype similarity regression for identifying the genetic determinants of rare diseases

E. Turro¹, D. Greene¹, S. Richardson², NIHR BioResource;
¹University of Cambridge, Cambridge, United Kingdom, ²MRC Biostatistics Unit, Cambridge, United Kingdom.

Rare genetic disorders, which can now be studied systematically with affordable genome sequencing, are often caused by high-penetrance rare variants. Such disorders are often heterogeneous and characterised by abnormalities spanning multiple organ systems ascertained with variable clinical precision. Existing methods for identifying genes with variants responsible for rare diseases summarise phenotypes with unstructured binary or quantitative variables. The Human Phenotype Ontology (HPO) allows composite phenotypes to be represented systematically but association methods accounting for the ontological relationship between HPO terms do not exist. We present a Bayesian method to model the association between an HPO-coded patient phenotype and genotype. Our method estimates the probability of an association together with an HPO-coded phenotype characteristic of the disease. We thus formalise a clinical approach to phenotyping that is lacking in standard regression techniques for rare disease research. We demonstrate the power of our method by uncovering a number of true associations in a large collection of genome-sequenced and HPO-coded cases with rare diseases.

C16.3 PRSLice: A new polygenic risk score approach that leverages pleiotropy to improve prediction of complex traits

J. Euesden, Y. Ruan, A. Socrates, J. R. I. Coleman, C. M. Lewis, P. F. O'Reilly;
 King's College London, London, United Kingdom.

Polygenic Risk Scores (PRS) are widely applied in human disease genetics. We have developed the first dedicated software for calculating, testing and plotting the results of polygenic risk scores - PRSLice ('precise'). To improve PRS predictive power further, we investigate an alternative approach to the selection of SNPs to calculate genetic risk, in particular in the context of applying PRS to assess shared genetic aetiology between different traits. By splitting the genome into chunks (eg. 5Mb regions) and selecting an optimum threshold for each chunk, we are able to select SNPs with large effects on the target phenotype but more modest effects on the discovery phenotype, which would have been omitted based on discovery P-value alone. We demonstrate, via application to real and simulated data, that this novel method - PRSLice - can improve phenotype prediction across a number of common contingencies. We firstly focus on using summary data for one disease to predict risk of another comorbid phenotype - this not only improves disease prediction in scenarios where the highest powered GWAS available is in a different but related trait, such as using BMI genetic risk to predict hypertension - but also provides insight into the shared genetic architecture between complex traits. Secondly, we demonstrate the value of this approach for predicting genetic risk across different worldwide populations, an increasingly common analysis strategy, demonstrating that the effects of allelic heterogeneity can be accounted for.

C16.4 Emergence of a Homo sapiens-specific gene family and the evolution of disease risk at chromosome 16p11.2

Recurrent pathogenic deletions and duplications at chromosome 16p11.2 are mediated by a complex set of highly identical and directly oriented segmental duplications. This disease-predisposing architecture results from recent, *Homo sapiens*-specific duplications (i.e. absent in Neanderthal and Denisovan) of a segment including the *BOLA2* gene, the latest among a series of genomic changes that dramatically restructured the region during hominid evolution. All humans examined (n = 2,359) carry one or more copies of the duplication, which nearly fixed early in the human lineage—a pattern unlikely to have arisen so rapidly in the absence of selection (p < 0.009). We show that *BOLA2* duplications affect its expression levels among individuals and between humans and other primates. Its copy number correlates with both RNA expression (r = 0.36) and protein level (r = 0.65) in human lymphoblastoid cell lines. *BOLA2* is highly expressed in embryonic stem cells, where it shows the greatest expression difference between human and chimpanzee. *BOLA2* localizes to the cell cortex and forms a [2Fe-2S]-bridged heterotrimeric complex with GLRX3 (glutaredoxin 3). We show that *in vitro* increasing *BOLA2* results in a shift from dimeric GLRX3 to heterotrimeric *BOLA2*/GLRX3 complex and the latter is 3-fold more stable upon air exposure. We are currently investigating the cellular phenotypes associated with *BOLA2* differential expression and oxidative stress conditions to gain insights into the possible advantage linked to the emergence of the *BOLA2* gene family at the root of the *Homo sapiens* lineage.

C16.5

Using whole exome sequence based imputation panel to boost considerably the number of successfully imputed low-frequency and rare coding variants in the Finnish founder population

I. Surakka^{1,2}, A. Sarin^{1,2}, K. Karczewski^{3,4}, R. Durbin⁵, D. MacArthur^{3,4}, V. Salomaa², A. Palotie^{1,4,6}, S. Ripatti^{1,5,7}, SISu project group;

¹Institute for Molecular Medicine Finland (FIMM), Helsinki, Finland, ²National Institute for Health and Welfare, Helsinki, Finland, ³Analytical and Translational Genetics Unit, Massachusetts General Hospital, Boston, MA, United States, ⁴Program in Medical and Population Genetics, Broad Institute of Massachusetts Institute of Technology (MIT) and Harvard, Cambridge, MA, United States, ⁵Wellcome Trust Sanger Institute, Hinxton, United Kingdom, ⁶Psychiatric & Neurodevelopmental Genetics Unit, Department of Psychiatry, Massachusetts General Hospital, Boston, MA, United States, ⁷Department of Public Health, University of Helsinki, Helsinki, Finland.

It has been shown that population specific reference panel improves imputation accuracy especially in the case of rare and low-frequency variants. We studied how much better we can impute variants using a population based sequence reference panel instead of commonly used global 1000 Genomes or the Haplotype Reference Consortium (HRC) reference panels. Specifically, we evaluated the utility of extending the Finnish low-coverage whole genome sequencing (WGS) panel (N = 1,941) with a jointly called whole exome sequencing (WES) based reference panel (N = 4,932) to successfully impute coding variation into our test dataset of 10,489 Finns. Using the Finnish WGS reference panel we saw a ~100% increase in the number of well-imputed exonic variants in 0.1-0.5% allele frequency range compared to the 1000G panel. The HRC reference panel gave us 7% more variants compared to the Finnish WGS panel but also introduced 0.8% false positive variant calls compared to 0.1% with the Finnish WGS reference panel mostly driven by rare variants with allele frequency <0.1%. By combining the WES panel with the population specific WGS reference panel, we observed over 20% more well-imputed variants in the 0.1-0.5% allele frequency range compared to the Finnish WGS only panel. As an example, we successfully imputed 422 loss-of-function (LoF) variants enriched in the Finnish population into the test dataset. These variants are now the basis of an intense phenome-wide association (PheWAS) testing. Our results show that population specific WES based reference panel boost considerably the imputation of rare and low-frequency coding variants.

C16.6

Genetic history of Latin America: Fine-scale population structure and phenotypic diversity

J. Chacón-Duque¹, K. Adhikari¹, V. Acuña-Alonzo^{2,1}, S. Canizales-Quintero³, C. Gallo⁴, G. Poletti⁴, F. Rothhammer⁵, M. Bortolini⁶, G. Bedoya⁷, R. Gonzalez-José⁸, D. Balding¹, CANDELA Consortium, G. Hellenthal¹, A. Ruiz-Linares¹;

Latin America has a complex history of extensive admixture between Native Americans, Europeans and Africans. Thus far, this process has been explored with genetic data to examine patterns of continental ancestry. Here we explore sub-continental ancestry using ~700,000 autosomal SNPs in a sample of ~7,000 Latin Americans from Brazil, Chile, Colombia, Mexico and Peru (DOI: 10.1371/journal.pgen.1004572).

We describe a novel statistical approach exploiting patterns of haplotype similarity with increased precision over a related approach that was applied successfully to study the fine scale patterns of worldwide populations (DOI:10.1126/science.1243518) and Great Britain (DOI:10.1038/nature14230). We identify the contributions of geographically precise ancestral components, including those from Africa and Europe, to both regions and individuals. For Brazil, we highlight how the sources of European ancestry vary considerably, reflecting influx at different times from the Iberian Peninsula, Italy and Northern Europe. In the former Spanish colonies, we identify ancestry from specific regions in Spain at the individual level. Strikingly, Native American ancestry within Latin Americans shows a strong correlation with DNA patterns of specific local Native groups. We demonstrate that genetic patterns among these Native groups, as well as among different migrant groups, are clearly differentiated, which has important implications in understanding how genetic associations to phenotypes vary across Latin Americans with widely heterogeneous ancestral backgrounds. Overall, we are able to identify ancestry patterns at higher resolution than has been previously achieved, allowing us a fine grained analysis of how history shaped the genetic makeup of Latin America and how this affects association studies.

C17 Metabolic and mitochondrial disorders

C17.1

Comprehensive genomic analyses of Japanese cases with mitochondrial respiratory chain complex deficiencies

M. Kohda¹, Y. Tokuzawa¹, Y. Kishita¹, Y. Moriyama¹, Y. Mizuno¹, T. Hirata¹, Y. Yatsuka¹, Y. Yamashita-Sugahara¹, Y. Nakachi¹, H. Kato¹, S. Tamaru¹, H. Nyuzuki¹, N. N. Borna¹, H. Harashima¹, T. Yamazaki¹, M. Mori², K. Murayama³, A. Ohtake¹, Y. Okazaki¹;
¹Saitama Medical University, Hidaka, Japan, ²Matsudo City Hospital, Matsudo, Japan, ³Chiba Children's Hospital, Chiba, Japan.

Mitochondrial disorders have the highest incidence among inborn errors of metabolism and are characterized by biochemical respiratory chain complex deficiencies. It occurs at a rate of 1 in 5,000 births, and has phenotypic and genetic heterogeneity. Mutations in about 1,500 nuclear encoded mitochondrial proteins may cause mitochondrial dysfunction of energy production and mitochondrial disorder. More than 250 genes that cause mitochondrial disorder have been reported to date. However exact genetic diagnosis for patients still remained largely unknown. To reveal this heterogeneity, we performed comprehensive genomic analyses for 142 patients with childhood-onset mitochondrial respiratory chain complex deficiencies. The approach includes whole mtDNA and exome analyses using high-throughput sequencing, and chromosomal aberration analyses using high-density oligonucleotide arrays. We identified 41 mutation in known mitochondrial disease genes, of which 37 were novel. We also identified and 4 mitochondria-related genes (*MRPS23*, *QRS1*, *SLC25A26* and *PNPLA4*) as novel causative genes. We further identified 2 genes known to cause monogenic diseases (*MECP2* and *TNNI3*) and 3 chromosomal aberrations (6q24.3-q25.1, 17p12, and 22q11.21) as causes in this cohort. Our approaches enhance the ability to identify pathogenic gene mutations in patients with biochemically defined mitochondrial respiratory chain complex deficiencies in clinical settings. They also underscore clinical and genetic heterogeneity of mitochondrial respiratory chain complex deficiencies and will improve patient care of this complex disorder.

C17.2

Recessive mutations in TRMT10C cause defects in mitochondrial RNA processing and multiple respiratory chain deficiencies

Mitochondrial disorders are both clinically and genetically diverse since defective expression of mitochondrial (mt)DNA can be caused by mitochondrial or nuclear gene mutations. Recently, several novel genes encoding factors involved in mt-tRNA processing have been identified as important causes of mitochondrial disease. Using whole exome sequencing, we identified mutations in the *TRMT10C* gene (encoding the mitochondrial protein MRPP1), in two unrelated individuals who presented at birth with elevated CSF and serum lactate levels, hypotonia and deafness. Together, MRPP1, MRPP2 and MRPP3 form the mitochondrial ribonuclease P (mt-RNase P) protein that is responsible for cleaving the 5' end of mt-tRNAs from polycistronic precursor RNA molecules. Additionally, a stable complex of MRPP1 and MRPP2 has m¹R9 methyltransferase activity which methylates mt-tRNAs at position 9, a vital modification required for folding mt-tRNAs into their correct tertiary structures. Analysis of subject fibroblasts harboring *TRMT10C* missense variants revealed decreased protein levels of MRPP1 and defective mitochondrial protein synthesis. Cell lines from affected individuals showed an increase in mt-RNA precursors indicative of defective mt-RNA processing. The pathogenicity of the detected variants - compound heterozygous p.(Arg181Leu) and p.(Thr272Ala) changes in subject 1, a homozygous p.(Arg181Leu) variant in subject 2 - was confirmed by the functional rescue of associated OXPHOS and mt-RNA processing defects following lentiviral transduction of wild type *TRMT10C*. Our study suggests that these variants affect MRPP1 stability and mt-tRNA processing without effects on m¹R9 methyltransferase activity, identifying *TRMT10C* as a novel mitochondrial disease gene and highlighting the importance of post-transcriptional RNA processing for mitochondrial function.

C17.3

Mitochondrial inorganic pyrophosphatase (PPA2) mutations underlie a spectrum of cardiomyopathy disorders

We have identified biallelic missense mutations in the nuclear-encoded mitochondrial inorganic pyrophosphatase (PPA2) in a family with four affected individuals, two of whom died separately in their second decade following the intake of small amounts of alcohol. Post-mortem results identified mid-myocardial fibrosis, however years of biochemical and genetic investigation failed to elucidate possible causes and any links to their highly sensitive alcohol response. Whole exome sequencing of the family revealed

compounding mutations in PPA2, a nuclear encoded mitochondrial protein most commonly associated with complex V in the oxidative phosphorylation respiratory chain. A further three unrelated pedigrees with six acutely affected neonatal individuals were recently identified with homozygous and compound heterozygous PPA2 mutations, resulting in much more severe symptoms including seizures, lactic acidosis and cardiac arrhythmia leading to death within days or months of birth. Comparison of fibroblast mitochondria from normal and mutated PPA2 individuals showed the activity of inorganic pyrophosphatase was significantly reduced in affected individuals. Recombinant PPA2 enzymes modelling hypomorphic missense mutations exhibit decreased activity that correlated with disease severity. These findings confirm the pathogenicity of PPA2 mutations, and suggest that PPA2 is a new cardiomyopathy-associated protein, which has a greater physiological importance in mitochondrial function than previously recognised.

C17.4

Biallelic mutations of PPA2 (pyrophosphatase inorganic 2) in 2 families with recurrence of sudden unexpected infant death

Sudden unexpected death in infancy (SUDI) occurs in apparently healthy infants and remains unexplained despite thorough investigation including complete autopsy. The vast majority of cases are sporadic. We investigated two families with recurrence of SUDI in 4/5 and 2/2 siblings between 4 and 20 months of age. Whole exome sequencing of two affected cases in family 1 and one in family 2 revealed compound heterozygous missense variations in the *PPA2* gene, encoding mitochondrial pyrophosphatase inorganic 2. This protein is thought to catalyze hydrolysis of inorganic pyrophosphate, the homeostasis of which is exceedingly important for the cell. The four missense variations were confirmed by Sanger sequencing and segregated according to autosomal recessive inheritance in both families. PPA2 protein levels were decreased in the patients' fibroblasts compared to controls. We show that yeast cells lacking the orthologous gene (*ppa2Δ*) are not viable due to the loss of mitochondria and are rescued by the human *PPA2* gene but not when it carries the mutations found in patients. Using a regulatable (doxycycline-repressible) gene expression system we show that the primary consequences of the pathogenic *ppa2* mutations are a decreased rate of oxygen consumption and ATP synthesis and a drop in the electrical mitochondrial membrane potential. Altogether these data demonstrate that *PPA2* is an essential gene in yeast and that biallelic mutations in *PPA2* cause a novel mitochondrial disease associated with sudden death in infants.

Isolated complex I deficiency is the most common biochemical phenotype observed in patients with mitochondrial disease, and with an estimated 1300 proteins in the mitoproteome it is often associated with clinical and genetic heterogeneity. Massively parallel sequencing (MPS) technologies including custom, targeted gene panels or unbiased whole exome sequencing (WES) are hugely powerful in identifying the underlying genetic defect in a clinical diagnostic setting, yet a significant proportion of patients still lack a genetic diagnosis. These patients may harbour mutations in poorly understood or uncharacterised genes, and their diagnosis relies upon characterisation of these orphan genes. Complexome profiling has recently identified TMEM126B as a component of the mitochondrial complex I assembly (MCIA) complex alongside the ACAD9, ECSIT, NDUFAF1 and TIMMDC1 proteins. We describe the clinical, biochemical and molecular findings in six cases of TMEM126B-related mitochondrial disease from four unrelated families. We provide functional evidence to support the pathogenicity of these TMEM126B variants and unequivocally establish this gene as a cause of complex I deficiency in association with either a severe multisystem presentation in infancy or pure myopathy in later adulthood. Functional experimentation including lentiviral rescue and complexome profiling of subject cell lines establishes TMEM126B as the tenth complex I assembly factor associated with human disease and validates the importance of proteomic approaches in characterising novel disease genes whose physiological roles were previously undetermined.

C17.6

A syndrome characterized by recurrent episodes of acute liver failure, peripheral neuropathy, cerebellar vermis atrophy, and ataxia is caused by disruptive mutations in SCYL1

R. E. Bittner¹, W. M. Schmidt¹, B. Mayerhofer¹, S. Rutledge², R. Schüle^{3,4,5}, S. Züchner⁵, E. Boltshauser⁶;

¹Medical University of Vienna, Vienna, Austria, ²Department of Genetics, University of Alabama at Birmingham, Birmingham, AL, United States, ³Hertie-Institute for Clinical Brain Research, University of Tübingen, Tübingen, Germany, ⁴German Research Center for Neurodegenerative Diseases, University of Tübingen, Tübingen, Germany, ⁵Dr John T Macdonald Department of Human Genetics and John P. Hussman Institute for Human Genomics, University of Miami, Miami, FL, United States, ⁶Division of Pediatric Neurology, University Children's Hospital, Zurich, Zurich, Switzerland.

Hereditary cerebellar ataxias are heterogeneous disorders characterized by gait disturbances, often accompanied by additional neurological symptoms and involvement of other organs. Here, we report on three human individuals from two unrelated families, who presented with recurrent episodes of acute liver failure in early infancy, peripheral neuropathy, cerebellar vermis atrophy, and ataxia. By whole exome-sequencing, we identified compound heterozygous mutations within the SCYL1 gene in all affected individuals. All mutations identified were predictably disruptive, causing loss of SCYL1 at the protein level. Despite clear parallels in clinical phenotypes between a Scyl1 deficient mouse model and human patients, recurrent hepatic failure represents a non-neurological clinical manifestation that has not been anticipated from the mouse study. SCYL1 belongs to the evolutionarily highly conserved SCY1-like family of catalytically inactive protein kinases and plays an important constituent of the coatomer (COPI)-coated vesicles mediated membrane trafficking machinery. We showed that in SCYL1-deficient human fibroblasts the Golgi apparatus is massively enlarged, substantiating the notion that SCYL1 maintains Golgi morphology by interacting with several key components of COPI coats. Intriguingly, SCYL1 shares a functional role in retrograde Golgi transport with the NBAS gene, which was recently implicated in a syndromic as well as a non-syndromic form of recurrent episodes of infantile liver failure, which suggests a common pathogenetic underpinning.

Our study demonstrates that the discovery of human disease related genes can be accelerated by studying naturally occurring mouse mutants and further argues for an unbiased genome-wide strategy in the molecular diagnosis of patients with rare inherited disorders.

Ocular developmental anomalies (ODA) including Anophthalmia/Microphthalmia (AM) have an estimated combined prevalence of 3.7 in 10,000 births.

Mutations in SOX2 are the most frequent contributors to severe ODA, yet account for a minority of the genetic drivers. To identify novel ODA loci, we conducted targeted high-throughput sequencing of 407 candidate genes in an initial cohort of 22 sporadic ODA patients. Patched 1 (PTCH1), an inhibitor of sonic hedgehog (SHH) signaling, harbored an enrichment of rare heterozygous variants in comparison to either controls, or to the other candidate genes; targeted resequencing of PTCH1 in a second cohort of 48 ODA patients identified two additional rare nonsynonymous changes. Using multiple transient models and a CRISPR/Cas9 mutant, we show physiologically relevant phenotypes altering SHH signaling and eye development upon abrogation of ptch1 in zebrafish for which in vivo complementation assays using these models showed that all six patient missense mutations affect SHH signaling. Finally, through transcriptomic and ChIP analyses, we show that SOX2 binds to an intronic domain of the PTCH1 locus to regulate PTCH1 expression, findings that were validated both in vitro and in vivo.

These results demonstrate that PTCH1 mutations contribute to as much as 10% of ODA, identify the SHH signaling pathway as a novel effector of SOX2 activity during human ocular development, and indicate that ODA is likely the result of overactive SHH signaling in humans harboring mutations in either PTCH1 or SOX2.

C18.2

Non-coding mutations in the promoter of OVOL2 cause autosomal dominant corneal endothelial dystrophies congenital hereditary endothelial dystrophy 1 (CHED1) and posterior polymorphous corneal dystrophy 1 (PPCD1)

A. E. Davidson¹, P. Liskova², C. J. Evans¹, L. Dudakova², L. Noskova², N. Pontikos³, C. Zarouchlioti¹, V. Plagno⁴, M. Filipce⁴, S. Kmoch², S. J. Tuft^{5,1}, A. J. Hardcastle¹;

Congenital hereditary endothelial dystrophy 1 (CHED1) and posterior polymorphous corneal dystrophy 1 (PPCD1) are autosomal dominant corneal endothelial dystrophies which map to overlapping loci on chromosome 20. To identify the genetic cause(s) of disease we recruited extensive pedigrees comprising over 100 affected individuals. Whole-genome sequencing and targeted re-sequencing experiments resulted in identification of unique heterozygous mutations within a conserved region of the OVOL2 proximal promoter sequence; c.-339_361dup in a large British CHED1 pedigree and c.-370T>C in a Czech PPCD1 cohort. In additional families, we identified two other mutations within the highly conserved proximal promoter sequence (c.-274T>G and c.-307T>C) by direct sequencing of the OVOL2 promoter. OVOL2 is a transcription factor and a direct transcriptional repressor of the established PPCD-associated gene ZEB1. Both transcription factors regulate mesenchymal-to-epithelial transition. Using a dual luciferase reporter assay we demonstrated that all four OVOL2 promoter mutations display significantly (P<0.001) increased transcriptional activity compared to the

corresponding wild-type promoter sequence. Furthermore we demonstrate that OVOL2 is not normally expressed in healthy adult corneal endothelium and in vitro culture of patient derived primary corneal endothelial cells (CECs) harbouring an OVOL2 promoter mutation reveals aberrant OVOL2 expression. Our data establish CHED1 and PPCD1 as allelic conditions and implicates transcriptional dysregulation of OVOL2 as a common cause of dominantly inherited corneal endothelial dystrophies. We hypothesise that the non-coding mutations identified create cryptic cis-acting regulatory sequence binding sites that drive the aberrant OVOL2 expression detected in patient derived CECs.

Introduction. Gillespie syndrome (GS) is a rare variant form of aniridia characterized by nonprogressive cerebellar ataxia, intellectual disability, and iris hypoplasia. Unlike the more common dominant and sporadic forms of aniridia, there has been no significant association with PAX6 mutations in individuals with GS and the mode of inheritance of the disease had long been regarded as uncertain. The aim of the present study was to characterize the molecular bases of GS.

Material and Methods. We used a combination of trio-based whole exome sequencing and Sanger sequencing in five simplex GS families. Functional analysis of the identified mutations was assessed in cell models.

Results and conclusions. We found homozygous or compound heterozygous truncating mutations and de novo heterozygous mutations in a unique gene supporting the genetic homogeneity of this rare disease. The gene encodes a protein involved in calcium homeostasis. Expression in a heterologous cell system of the truncation mutants and of the missense mutants -alone or in combination with the wildtype counterpart- supported that both loss-of-function and dominant negative mutations cause Gillespie syndrome ending the long debate regarding the transmission of this rare syndrome.

C18.4

Hypomorphic mutations in RCBTB1 cause autosomal recessive isolated and syndromic inherited retinal dystrophy

F. Coppiepers¹, G. Ascari¹, K. Nikopoulos², M. Xu³, K. Dannhausen⁴, M. K. Tsimbaris⁵, T. Chrysanthi⁶, B. Stylian⁶, M. Karlstetter⁴, M. Bauwens¹, M. De Bruyne¹, F. Meire⁶, T. Langmann⁴, R. Chen³, C. Rivolta², C. P. Hamel⁷, B. P. Leroy^{1,8,9}, E. De Baere¹;
¹Center for Medical Genetics, Ghent University Hospital, Ghent, Ghent, Belgium, ²Department of Medical Genetics, University of Lausanne, Lausanne, Switzerland, ³Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX, United States, ⁴Department of Ophthalmology, University of Cologne, Cologne, Germany, ⁵Department of Ophthalmology, Medical School, University of Crete, Heraklion, Greece, ⁶Department of Ophthalmology, Hôpital des Enfants Reine Fabiola, Brussels, Belgium, ⁷INSERM U 1051, Institut des Neurosciences de Montpellier, Montpellier, France, ⁸Department of Ophthalmology, Ghent University Hospital and Ghent University, Ghent, Belgium, ⁹Division of Ophthalmology, The Children's Hospital of Philadelphia, Philadelphia, PA, United States.

We identified a homozygous missense variant in RCBTB1 c.973C>T p.(His325Tyr) in individuals with a syndromic inherited retinal dystrophy (IRD), consisting of retinitis pigmentosa (RP), hypothyroidism, primary ovarian insufficiency, and mild intellectual disability. Here, we aimed to investigate the contribution of RCBTB1 in IRD and to assess the underlying pathogenetic mechanism.

Whole exome sequencing data of over 1000 IRD patients were inspected for RCBTB1 mutations, and targeted next-generation sequencing of the coding region of RCBTB1 was performed in 280 IRD patients. In six families with isolated and syndromic IRD five distinct homozygous missense variants were found. All changes segregate with disease, affect highly conserved amino acids and are predicted to be deleterious. A Mediterranean founder haplotype was identified for mutation c.919G>A, p.(Val307Met), occurring in two families of Italian and Greek origin, respectively. Ocular phenotypes range from typical RP starting in the second decade to chorioretinal dystrophy with a later age of onset. RCBTB1 mRNA expression was demonstrated in human retina and RPE, and protein immunostaining was observed mainly in the inner retina. As RCBTB1 has previously been identified as a Cullin3 substrate adaptor, different components of the Cullin3 and Nrf2 pathway were quantified. This revealed a decreased mRNA expression of Nrf2 and five Nrf2 target genes.

In conclusion, hypomorphic RCBTB1 missense mutations were identified in families with non-syndromic and syndromic IRD respectively, putting forward RCBTB1 as a new IRD disease gene. Finally, our data suggest a potential role of the ubiquitination pathway in the pathogenetic mechanism underlying RCBTB1-associated IRD.

C18.5

Novel genes and phenotypic correlations in inherited retinal disease

G. Arno^{1,2}, A. Fiorentino^{1,2}, N. Pontikos^{1,3}, C. Chakarova¹, A. G. Robson^{1,2}, UKIRG, G. E. Holder^{1,2}, M. E. Cheetham¹, V. Plagno⁴, M. Michaelides^{1,2}, A. J. Hardcastle¹, A. R. Webster^{1,2};
¹UCL Institute of Ophthalmology, London, United Kingdom, ²Moorfields Eye Hospital, London, United Kingdom, ³UCL Genetics Institute, London, United Kingdom.

Introduction: Inherited retinal disease displays vast genetic and allelic heterogeneity. On cohorts from a UK-wide consortium we used an integrated genomic and phenotypic approach to i) accelerate novel gene discovery ii) determine the phenotypic and severity spectrum for specific molecular subtypes and iii) accumulate whole exome and genome data to identify alleles modifying the action of known genes.

Methods: Extensive pre-screening using next-generation sequencing of known genes on over 1000 inherited retinal disease families led to a cohort likely enriched for novel genes for further whole exome/genome sequencing. An integrated database-server was developed based on the ExAC and Phenotips software to query genes and phenotypes (using human phenotype ontology (HPO)) in the pool of families.

Results: To date, 84 families have undergone analysis (76 exome, 8 genome). In 13 probands, likely disease causing mutations in known genes were revealed. Amongst these, specific alleles of ceroid lipofuscinosis 7 (*CLN7/MFSD8*) were consistently associated with a non-syndromic retinal degeneration. Three genes, previously unreported in human retinal disease, have been discovered. These include *GNB3* mutated homozygously (c.124C>T; p.Arg42Ter) in a patient with a distinct stationary retinal dysfunction. 102 exomes of probands with inherited retinal dystrophy (from UCLEx) with detailed phenotypic data have been integrated into a computer searchable framework.

Discussion: Pooling, sharing and integration of genomic and phenotypic data increases the power of gene discovery. An extensible, programmatic infrastructure which includes both genomic and phenotypic data has been developed to efficiently determine genotype-phenotype correlations and modifier alleles.

Support: RPF, NIHR-BRC, Fight For Sight.

C18.6

Molecular inversion probe based sequence analysis of 108 genes associated with non-syndromic inherited retinal disease in 4,000 probands

M. Imran Khan¹, C. Gilissen¹, C. Ayuso², D. Sharon³, R. K. Koenekoop⁴, C. Rivolta⁵, E. deBaere⁶, C. F. Inglehearn⁷, M. van de Vorst¹, S. Kohl⁸, C. P. Hamel⁹, A. Hoischen^{1,10}, F. P. M. Cremers^{1,10};

¹Department of Human Genetics, Radboud university medical centre, Nijmegen, Netherlands, ²Department of Genetics, University Hospital Fundación Jiménez Díaz, Madrid, Spain, ³Departments of Ophthalmology, Hadassah-Hebrew University Medical Center, Jerusalem, Israel, ⁴Departments of Paediatric Surgery, Human Genetics and Ophthalmology, McGill University Health Center, Montreal, QC, Canada, ⁵Department of Medical Genetics, University of Lausanne, Lausanne, Switzerland, ⁶Center for Medical Genetics, Ghent University Hospital, Ghent, Belgium, ⁷Department of Ophthalmology and Neuroscience, University of Leeds, Leeds, United Kingdom, ⁸Molecular Genetics Laboratory, Institute for Ophthalmic Research, Centre for Ophthalmology, University of Tuebingen, Tuebingen, Germany, ⁹National Center in Genetic of Sensory Diseases, Institute for Neurosciences of Montpellier, University of Montpellier, Montpellier, France, ¹⁰Radboud Institute for Molecular Life Sciences, Radboud University Medical Center, Nijmegen, Netherlands.

Purpose: Inherited retinal diseases (IRDs) are clinically and genetically very heterogeneous, as ~125 genes have been associated with non-syndromic IRDs. The purpose of this study was to develop a flexible, comprehensive and cost-effective sequencing procedure for IRDs.

Methods: About 4,000 probands with non-syndromic IRDs were ascertained by partners of the European Retinal Disease Consortium (ERDC). In total, 6,200 molecular inversion probes (MIPs) were designed to capture ~1,600 protein-coding exons and flanking intronic sequences of 108 IRD-associated genes. The captured targets were sequenced on a NextSeq500 Illumina sequencer and the data were analyzed using an in-house pipeline to find the causal genetic variants.

Results: In pools of 120 samples the average coverage per probe was ~500X, where 95% of the probes were covered >10X. Analysis was completed for 2,500/4,000 samples. Sanger validation was performed for a representative set of variants identified in 290 probands from Nijmegen. We have identified the causal variants in 59% (172/290) of the cases, which included a number of plausible de novo variants and several novel genotype-phenotype correlations. Material costs for sequencing 108 IRD genes was €65 per sample, rendering it very cost-effective.

Conclusions: Taken into consideration that the Nijmegen cohort was previously prescreened using various genotyping methods, the corrected yield would be ~71%. At 1/10th of WES cost, this efficiency is equal or superior to other published gene-panel (36 - 62%) or WES-based (49 - 66%) sequence analysis. Based on preliminary results, we estimate to identify causal variants in at least 2,000 IRD probands.

C19 Big data Analyses of Intellectual Disability

C19.1

The prevalence and architecture of dominant developmental disorders

M. E. Hurles, *Deciphering Developmental Disorders Study; Wellcome Trust Sanger Institute, Cambridge, United Kingdom.*

Children with severe, undiagnosed developmental disorders (DDs) are enriched for damaging de novo mutations in developmentally important genes. We exome sequenced 4,295 families with children with DDs, and meta-analysed these data with published data on children with similar disorders. We identified over 90 genes in which damaging de novo mutations show genome-wide significant ($p < 1e-6$) evidence for causing developmental disorders, including 15 novel genes reaching this level for the first time. We also identified a novel seizure disorder associated with truncating mutations in *SMC1A*, a gene in which missense mutations are known to cause a different disorder. We estimated that we have statistical power to detect ~50% of all haploinsufficient genes, and that most haploinsufficient genes causing DDs have already been discovered. Our large number of genome-wide significant findings allow us to compare empirically the power to detect novel DD-associated genes using exome or genome sequencing. We find that, at current cost differentials, exome sequencing has much greater power for novel gene discovery for genetically heterogeneous disorders. Finally, we estimate that ~45% of our cohort likely carry pathogenic de novo mutations in coding sequences, with approximately half operating by a loss-of-function mechanism, and the remainder being gain-of-function or dominant negative in action. By extrapolating from the DDD cohort to the general population, we estimate that de novo dominant developmental disorders have an average birth prevalence of 1 in ~400.

C19.2

Meta-analysis of 2,104 trios provides support for 10 novel candidate genes for intellectual disability

S. H. Lelieveld¹, M. R. F. Reijnders², R. Pfundt², H. G. Yntema², E. Kamsteeg², P. de Vries², B. A. de Vries², M. H. Willemsen², T. Kleefstra², K. Löhner³, M. Vreeburg⁴, S. ¹Department of Human Genetics, Radboud Institute for Molecular Life Sciences, Radboud University Medical Center, Nijmegen, Netherlands, ²Department of Human Genetics, Donders Centre for Neuroscience, Radboud University Medical Center, Nijmegen, Netherlands, ³Department of Genetics, University Medical Center Groningen, Groningen, Netherlands, ⁴Department of Clinical Genetics, Maastricht University Medical Centre, Maastricht, Netherlands.

Introduction: Intellectual disability (ID) and other neurodevelopmental disorders are in part due to de novo mutations. Large-scale whole-exome sequencing (WES) studies of patient-parent trios have efficiently identified genes enriched for de novo mutations in ID patient cohorts. As part of routine

genetic diagnostics at the Radboud University Medical Center, we sequenced the exome of 820 ID-patients and their parents. Here we utilize this dataset to identify novel genetic causes of ID.

Methods: Based on gene specific mutation rates we performed a statistical analysis to detect genes that are significantly enriched for loss-of-function or functional de novo mutations. To achieve the best possible power to identify novel candidate ID genes, we added data from previously published exome-sequencing trio studies giving rise to a combined cohort of 2,104 trios.

Results: In our cohort of 820 ID patients we identified 4 novel genes significantly enriched for functional or loss-of-function de novo mutations. We reproduce these results in the combined ID-set of 2,104 trios and identify 6 further novel genes enriched for de novo mutations. In addition, we show that similar to known ID genes, these 10 candidate genes are highly intolerant to normal variation. A phenotype comparison of patients with de novo mutations in the same gene provides further support for a shared genetic cause.

Conclusions: In summary, we identified 10 novel candidate ID genes by performing a meta-analysis on WES data of 2,104 ID trios, highlighting the potential of unbiased statistical analyses of large trio-based sequencing studies to identify novel candidate genes.

C19.3

Whole exome sequencing in 150 consanguineous families with intellectual disability: high diagnostic yield and identification of novel candidate genes

M. Reuter¹, H. Tawamie¹, R. Buchert¹, T. Froukh², O. Hosny Gebri³, T. Strom⁴, S. Hoffman⁵, D. Wieczorek⁶, H. Sticht¹, **A. Reis¹**, R. Abou Jamra^{1,7};

¹Friedrich-Alexander Universität Erlangen-Nürnberg, Erlangen, Germany, ²Philadelphia University, Amman, Jordan, ³National Research Center, Dokki, Cairo, Egypt, ⁴Helmholtz Zentrum München, Neuherberg, Germany, ⁵University of Bochum, Bochum, Germany, ⁶Heinrich-Heine-Universität, Düsseldorf, Germany, ⁷University Medical Center Leipzig, Leipzig, Germany.

Autosomal recessive intellectual disability (ARID) represent a significant fraction of ID, especially in consanguineous families. Several hundred ARID genes were identified to date, and many more are presumed. We performed genetic mapping and whole exome sequencing (WES) in 150 consanguineous families with one (29%) or multiple (71%) affected children with ID. Most affected persons showed additional symptoms including muscular hypotonia, epilepsy, and microcephaly. We identified relevant variants in 114 (76%) of families. Among these, 53 are meanwhile confirmed genes and likely clarify the cause of ARID in the corresponding families while in 60 the homozygous variant is located in a candidate gene. Despite the high heterogeneity we found variants in two unrelated families for four already described genes, *AHI1*, *GPR56*, *PRRT2*, and *PLA2G6*. At least one patient has two distinct phenotypes because of two homozygous variants in different genes. In order to prove the pathogenicity of non-truncating variants, we applied a wide spectrum of functional experiments. Until now, we have shown a deleterious effect for 12 variants in 10 genes (*FARI*, *PGAP1*, *PGAP2*, *EZR*, *EDC3*, *PTEN*, *TAF13*, *FRRS1L*, *ZIP8*, *KIAA0586*). In order to prove the causality of the candidate variants, identifying further likely pathogenic variants in similarly affected individuals is necessary. Therefore we initiated a Consortium of Autosomal Recessive Intellectual Disability (CARID) to share data which allowed identification of additional independent cases for 12 candidate genes, so far. WES in consanguineous families with ID has the highest diagnostic yield and should therefore become part of a first line diagnostic approach.

C19.4

Common morphological and transcriptome changes in Rett spectrum disorders justify a shared therapeutic approach

A. Pinto^{1,2}, E. Landucci¹, L. Bianciardi¹, S. Daga¹, E. Frullanti¹, M. Brindisi³, S. Butini³, V. Imperatore¹, F. Ariani^{1,2}, S. Brogi¹, G. Campiani¹, A. Renieri^{1,2}, I. Meloni¹;

¹Medical Genetics, University of Siena, Siena, Italy, ²Genetica Medica, Azienda Ospedaliera Universitaria Senese, Siena, Italy, ³European Research Centre for Drug Discovery & Development Dept. Biotechnology, Chemistry and Pharmacy University of Siena, Siena, Italy.

Rett syndrome is a neurodevelopmental disorder ranging from the classic MECP2-related form to a FOXP1-related congenital variant. The FOXP1-related variant shows a shorter perinatal normal period and more severe microcephaly. Given the presence of shared signs/symptoms and the overlapping function of the involved genes, we hypothesized a common molecular mechanism behind RTT phenotypic spectrum. Therefore, to better investigate this hypothesis, taking advantage of the breakthrough genetic reprogramming technology, we investigated morphological and RNA-seq transcriptome changes on iPSC-derived neurons from several patients for each disease-related gene. Such analysis led to the identification of a unique neuronal

morphological phenotype probably related to axon guidance signal disruption. RNA-seq analysis showed changes in the expression level of genes related to cell migration, adhesion and to the proper establishment of the GABAergic circuit. The transcriptome analysis also revealed an upregulation of enzymes that regulate the acetylation of tubulin and microtubules-related genes MAP2 and MAPT in the iPSC-derived neurons for each disease-related gene and a reduction in acetylated α -tubulin was demonstrated by Western blot. These findings strongly support the involvement of common pathways in the pathomechanism of the whole Rett phenotypic spectrum. Notably, in line with the molecular findings, *in vitro* experiments with drugs selective for the tubulin acetylation pathway (a newly developed HDAC6 inhibitor) and the GABAergic circuits (repurposed drug) showed a significant reversal of the unique discovered morphological phenotype, providing a real possibility of an efficacious common treatment for Rett disorders.

C19.5 Haploinsufficiency of MECP2-interacting transcriptional co-repressor SIN3A causes mild intellectual disability by affecting the development of cortical integrity

J. Witteveen^{1,2}, M. H. Willemsen³, T. C. D. Dombroski^{1,2}, N. H. van Bakel^{1,2}, W. M. Nillessen³, J. A. van Hulst^{1,2}, E. J. R. Jansen^{1,2}, I. E. Veenstra-Kno^{1,4}, C. M. Next-generation sequencing has revealed numerous genes that are associated with a broad range of neurodevelopmental disorders including intellectual disability (ID) and autism spectrum disorders (ASD), but detailed knowledge of their associated protein dysfunction is mostly lacking. Here, we identified dominant mutations in the gene encoding the transcriptional repressor and MeCP2-interactor switch-insensitive 3 family member A (SIN3A) in individuals with predominantly mild ID who display a strikingly similar facial gestalt and various additional features as ASD, microcephaly, short stature, epilepsy, hypermobile joints and hearing loss. Brain MRIs revealed subtle abnormalities, such as corpus callosum hypoplasia and ventriculomegaly. Intriguingly, *in vivo* functional knockdown of SIN3A using *in utero* electroporation led to changes in the developing mouse brain such as reduced cortical neurogenesis, altered neuronal identity and aberrant cortico-cortical projections, observations that have a high translational value with the clinical features of our individuals. Together, our data establish that haploinsufficiency of SIN3A is associated with mild ID and associated characteristics as observed in the atypical 15q24 microdeletion syndrome, and that Sin3A is a key transcriptional regulator crucial for proper developmental expansion and connectivity of cortical brain areas.

C19.6 Genes controlling cell movement and migration are deregulated in ARID1B-associated ID

G. Vasileiou, M. V. Hadjihannas, A. Reis;
Institute of Human Genetics, Friedrich-Alexander Universität Erlangen-Nürnberg, Erlangen, Germany.

The human BRG1-associated factors (BAF) chromatin remodeling complex (also known as SWI/SNF-A complex) regulates the structure and position of nucleosomes and can facilitate both activation as well as repression of gene transcription. Non-syndromic Intellectual disability (ID) and Coffin-Siris syndrome (CSS) are associated with loss-of-function mutations in various components of the BAF complex, such as ARID1B, which is expressed in the human brain and in mammalian embryonic stem cells. To understand how mutated *ARID1B* affects human brain development and leads to develop-

mental delay phenotypes, we performed whole transcriptome sequencing (RNA-seq) analysis in fresh peripheral blood lymphocytes from ID individuals harboring *ARID1B* mutations and control subjects. Pathway analysis of 452 genes showing prominent transcriptional changes between affected and control subjects indicated deregulation in cell movement related processes, especially of embryonic stem cells. In ID individuals, qRT-PCR expression analysis confirmed downregulation of two key regulators of actin organization and inducers of cell migration, Rho-associated protein kinases ROCK1 and ROCK2. Using models for cell migration we found that siRNA-mediated knockdown of ARID1B strongly reduced cell migration and led to downregulation of both ROCK1 and ROCK2. In addition to ROCK1/ROCK2, in both neuroblastoma and osteosarcoma cells, ARID1B knockdown led to downregulation of NCK1, an important mediator of activated receptor tyrosine kinase signaling that reorganizes the actin cytoskeleton and promotes cell polarization and directional migration via pseudopodia formation. Our results indicate that ARID1B can regulate cell migration and raise the possibility that compromised cell migration due to ARID1B mutations could be implicated in *ARID1B*-associated ID syndromes.

C20 Gene Editing: To Fear or to Cheer? (joint with EMPAG)

C20.3 Are biomedical research fundamental principles appropriate for using genome editing in humans?

E. Rial-Sebbag, A. Cambon-Thomsen;
INSERM UMR 1027, Toulouse, France.

Genome editing with CRISPR-Cas 9 is considered as a revolution in life sciences since 2013. Thanks to this technology a sequence implicated in a disease could be modified in the DNA of various cell types: somatic, germinal or in embryo. This technology is still under scientific evaluation which poses the question of its validation in embryos and humans and its future applications in therapy. However, the fundamental principles and bioethics basis for conducting research in these three areas can vary according different legal regimes and are implemented into national regulations in a heterogeneous manner.

Beyond these legal regimes Scientific Academies, research institutes and ethics committees have provided materials (reports, opinions) based on core ethical principles coming from the biomedical field for using Genome editing for medical applications. In this paper we analyse the different positions adopted by those bodies and we compare their points of convergence and divergence as well as the ethical and legal principles underlying their conclusions. We then compare the results with the only binding instrument in Europe for Bioethics: the Oviedo Convention (articles 13 and 18). Finally, we survey the fundamental rights principles expected to be relevant for Genome editing: How could they conflict with the research supported by several institutions in Europe? Can an inheritable modification of the genome, illegal according to the Convention, still can be envisaged? EUcelLex project (FP7 grant 601806)

C20.4 One small edit for man, one large edit for mankind? Points to consider for a responsible way forward with gene editing

H. C. Howard¹, G. de Wert², C. G. van EF³, F. Forzano⁴, D. Radojkovic⁵, E. Rial-Sebbag⁶, M. C. Cornel⁷, on behalf of the Public and Professional Policy Committee of the European Society of Human Genetics;

¹Centre for Research Ethics and Bioethics, Uppsala University, Uppsala, Sweden, ²Department of Health, Ethics & Society, Research Schools CAPHRI and GROW, Maastricht University, Maastricht, Netherlands, ³Department of Clinical Genetics, Section Community Genetics and EMGO Institute for Health and Care Research, VU University Medical Center, Amsterdam, Netherlands, ⁴Medical Genetics Unit, Ospedale Galliera, Genova, Italy, ⁵Laboratory for Molecular Genetics, Institute of Molecular Genetics and Genetic Engineering, University of Belgrade, Belgrade, Serbia, ⁶INSERM, Faculté de médecine Université Toulouse 3, Paul Sabatier, Toulouse, France, ⁷Department of Clinical Genetics, Section Community Genetics and EMGO Institute for Health and Care Research, VU University Medical Center, Amsterdam, Netherlands.

A recent resurgence of debate over genetic modification has been ignited, due to the recent advent of a novel tool for site-specific gene editing, CRISPR-Cas9, and the publication in April 2015 that human embryos had been edited in research. CRISPR-Cas9 allows for increased efficiency, specificity, relative ease and speed of use, and accessibility to researchers. Increased access to, and novel uses of, new technologies leads to the need for further reflection on the potential scientific, and medical impacts as well as ethical,

legal and social issues (ELSI). While some of the risks and ELSI of somatic and heritable gene editing in humans have been discussed previously (e.g. re: IVF, PGD, cloning) what is particular to the current discussion is that we have, technically, never been so close to having the technology to conduct gene editing in humans in a potentially safe and effective manner. Contributing to a constructive discussion within the ESHG, the Public and Professional Policy Committee has outlined different areas that require attention in order to move forward and ensure a responsible use and application of gene editing. These include: education and engagement of different stakeholders, including lay stakeholders to support meaningful discussions; identification and monitoring of risks; ethical reflection identifying generic risks and issues as well as those specific to gene editing; attention to governance and legal issues; addressing the potential roles and impacts of commercial actors in the development of gene editing; and the consideration of alternative methods that could be used instead of gene editing.

C20.5 Ethical issues of gene editing: what does popular media report?

E. Niemiec^{1,2,3}, B. M. Zimmermann^{4,5}, H. C. Howard⁶;
¹Joint International PhD Program in Law, Science and Technology, University of Bologna, Bologna, Italy, ²Department of Law, University of Turin, Turin, Italy, ³Centre for Ethics and Law in the Life Sciences, Leibniz University Hannover, Hannover, Germany, ⁴Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, Sweden, ⁵Department for Biomedicine, University of Basel, Basel, Switzerland, ⁶Centre for Research Ethics and Bioethics, Uppsala University, Uppsala, Sweden.

CRISPR Cas9 gene editing technology was reported to have been used in human embryos for the first time in April 2015. This research led by Junjiu Huang has sparked controversy, prompted debate and extensive media coverage on this issue. Since then, a number of meetings have been held to discuss this issue, and reports, statements, and recommendations have been issued by groups, including the Washington Summit organizers, the Hinxtion Group, and The European Group on Ethics in Science and New Technologies. These highlight the need to have an ongoing discussion with a multitude of stakeholders including experts and lay public. Discussing a novel technology with different stakeholders can be difficult if stakeholders are not aware of, or do not have much information about said technology. One of the widely accessible educational as well as opinion-forming resources for lay public about new scientific advancements may be media coverage. To study the information disseminated through the media on gene editing, a content analysis of a subset of English newspaper articles was performed. Articles were identified from five of the most popular online newspaper websites: USAToday.com, NYTimes.com, DailyMail.co.uk, WashingtonPost.com, TheGuardian.com. A preliminary study of a subset of articles shows that articles regularly present a basic explanation of the science as well as some ethical concerns regarding (germ line) gene editing, including the potential benefits and harms. Studying media messages is important as they may influence public attitudes and debate and ultimately influence the acceptability (or lack thereof) for gene editing.

C20.6 Optimising CRISPR genome editing using machine learning

R. Doyle, E1 2ST;
 Desktop Genetics, London, United Kingdom.

Decision rules are commonly used to select guide RNA sequences for a particular CRISPR genome editing application. Such rules use sequence-level and contextual features of the predicted cut site locations to predict the activity, specificity, and outcome of using CRISPR.

We designed a library of guides to test common rules for indel-mediated gene disruption. Our library maximized the orthogonality of the guide population, internally and with respect to previously published guides (rather than maximize guide performance), to create a better training data set for machine learning. We compared our machine-selected guides to a set of manually-selected guides, and tested different types of negative control guides. Our rules enriched for performant guides at a population level but could not select or eliminate individual guides with certainty. We find that combining decision rules has a cumulative effect; machine selection may be superior to manual; and using prior performance data and co-located genome features are critical.

We demonstrated significant sources of variance which impact guide activity and may confound statistical learning algorithms. We recommend: filtering guides using several rules, incorporation of genomic context, maximizing library orthogonality, inclusion of randomly chosen control guides, explicit incorporation of prior guide performance, and machine selection of guides.

C21 Disorders with skin abnormalities

C21.1 Antisense oligonucleotide-mediated exon skipping as a potential systemic treatment for recessive dystrophic epidermolysis bullosa

Introduction: Patients with the devastating skin disorder ‘generalized severe’ recessive dystrophic epidermolysis bullosa (RDEB) suffer lifelong blistering upon the slightest trauma and die of skin cancer before the age of 40. RDEB is caused by biallelic null-mutations in *COL7A1*, resulting in a complete absence of type VII collagen (ColVII). There is no cure for RDEB. Since 91% of *COL7A1* exons are in-frame and encode repetitive amino acid stretches, and low levels of ColVII already drastically improve the phenotype, *COL7A1* seems a perfect candidate for antisense oligonucleotide (AON)-mediated exon skipping therapy.

Materials and Methods: We examined the feasibility of AON-mediated exon skipping *in vitro* in primary cultured keratinocytes and fibroblasts, and *in vivo* in a human skin-graft mouse model after systemic delivery. The functionality of the resulting protein was assessed in diverse *in vitro* and *in vivo* functional assays.

Results: Treatment with AONs designed against a mutant exon 105 led to in-frame exon 105 skipping at the RNA level and restored ColVII expression *in vitro*. Moreover, systemic administration of these AONs to nude mice induced *in vivo* re-expression of ColVII in skin grafts, generated from mutant patient cells, engrafted on the mice’s back. Additionally, the resulting ColVII proved functional *in vitro* in trypsin digestion, type IV collagen binding and fibroblast migration assays, and *in vivo* in a ColVII-deficient mouse model.

Conclusions: This study provides strong proof-of-concept for AON-mediated exon skipping as a systemic therapeutic strategy for RDEB.

C21.2 Osteoporosis in the segmental progeroid disorder geroderma osteodysplastica is caused by defective decorin glycanation and TGF-β induced oxidative stress.

U. Kornak¹, W. Chan¹, M. Steiner¹, J. Egerer¹, A. C. Ma², B. Busse³, S. Mizumoto⁴, J. Pestka³, H. Zhang¹, I. Hausser⁵, K. Sugahara⁶, M. Amling⁷, D. Chan⁶, S. Mundlos¹;

Age-related tissue deterioration is a multifactorial process that can be exemplarily studied in segmental progeroid disorders like geroderma osteodysplastica (GO), a recessive condition characterized by skin laxity and early-onset osteoporosis. The GO disease gene *GORAB*, which encodes a small Golgi protein, was conditionally inactivated in mesenchymal progenitor cells of the limb skeleton. These *Gorab*Prx1 mice showed hallmarks of age related bone changes including a disorganization of collagen fibrils and thinned, porous cortical bone culminating in spontaneous fractures of long bones. Reduced dermatan sulfate levels and impaired glycanation of decorin, indicating abnormal modification of extracellular matrix proteins, were associated with an increase of activated TGF-β in tissues. Elevation of TGF-β downstream signalling components included the reactive oxygen species (ROS) producing enzyme Nox4. The subsequent oxidative stress entailed an accumulation of DNA damage and cellular senescence in *Gorab*Prx1 bone and in cultured human GO fibroblasts. Elevated ROS levels were also found after inactivation of *gorab* in a zebrafish model. Antioxidant treatment of *Gorab*Prx1 mice ameliorated the osteoporosis phenotype underlining the importance of oxidative stress for the GO pathogenesis. Our data unravel a pathway involving Golgi function, matrix composition, TGF-β signalling and oxidative stress in the pathogenesis of osteoporosis.

C21.3

Mutations in either TUBB or MAPRE2 cause circumferential skin creases Kunze type

M. Isrie¹, M. Breuss², G. Tian³, A. H. Hansen², F. Cristofoli¹, J. Morandell¹, E. Porta Dapena⁴, K. Leonard⁵, F. Tinsa⁶, S. Moortgat⁷, H. Ulucan⁸, E. Kopari⁹, E. Karaca⁹, N. Katsanis¹⁰, V. Marton¹¹, J. R. Vermeesch¹, E. Davis¹⁰, N. Cowan¹², D. A. Keys², H. Van Esch¹;

Circumferential skin creases Kunze type (CSC-KT) is a specific congenital entity with an unknown genetic cause. The disease phenotype comprises characteristic circumferential skin creases accompanied by intellectual disability, cleft palate, a short stature and dysmorphic features. Here we report that mutations in either MAPRE2 or TUBB underlie the genetic origin of this syndrome. MAPRE2 encodes a member of the microtubule end-binding family of proteins that bind to the GTP cap at growing microtubule plus ends, while TUBB encodes a beta-tubulin isotype that is expressed abundantly in the developing brain. Functional analyses of the TUBB mutants show multiple defects in the chaperone-dependent tubulin heterodimer folding and assembly pathway that leads to a compromised yield of native heterodimers. The TUBB mutations also have an impact on microtubule dynamics in vivo. For MAPRE2, we show that the mutations result in enhanced MAPRE2 binding to microtubules, implying an increased dwell time at microtubule plus ends. Further, in vivo analysis of MAPRE2 mutations in a zebrafish model of craniofacial development show that the variants likely perturb the patterning of branchial arches, either through excessive activity (under a recessive paradigm) or through haploinsufficiency (dominant de novo paradigm). Taken together, our data add CSC-KT to the growing list of tubulinopathies, and highlight how multiple inheritance paradigms can affect dosage-sensitive biological systems so as to result in the same clinical defect.

C21.4

Two new genetic disorders presenting with lymphatic-related hydrops fetalis

E. Fotiou¹, S. Martin-Almedina¹, I. Martinez-Corra², R. Holdhus³, A. Vicente⁴, M. A. Simpson⁵, S. Lin⁶, K. Petersen⁷, C. Gilissen⁷, H. Jeffery¹, G. Atton¹, J. W. Wiseman⁸, M. Wedin⁹, K. Gordon¹, G. ¹St George's University of London, London, United Kingdom, ²Uppsala University, Uppsala, Sweden, ³University of Bergen, Bergen, Norway, ⁴University College London, London, United Kingdom, ⁵King's College London School of Medicine, London, United Kingdom, ⁶Stanford University, Stanford, CA, United States, ⁷Radboud University Medical Center, Nijmegen, Netherlands, ⁸AstraZeneca R&D, Molndal, Sweden, ⁹King's College Hospital, London, United Kingdom, ¹⁰St George's University of London Centre de Référence des Déficiences Intellectuelles de Causes Rares, Paris, France, ¹¹Birmingham Women's Hospital, Birmingham, United Kingdom, ¹²Haukeland University Hospital, Bergen, Norway.

Hydrops fetalis describes fetal fluid accumulation in at least two of the following: the serous cavities or in body tissue. Previous studies have shown that non-immune hydrops fetalis is a heterogeneous condition and accounts for 85% of all cases of hydrops fetalis. A lymphatic abnormality is known to be the cause in approximately 15% of those, however, not much is known about the cause. The aim of this study was therefore to describe two inherited forms of lymphatic-related hydrops fetalis (LRHF); one autosomal dominant, the other autosomal recessive.

Exome sequencing on families, with a large number of *in utero* and neonatal deaths associated with non-immune hydrops fetalis, identified novel variants in the genes encoding Ephrin-receptor-B4 (EPHB4) (dominant form) and Piezo-type mechanosensitive ion channel component 1 (PIEZO1) (recessive form). Biochemical analysis of the mutant EPHB4 proteins demonstrate that they are devoid of tyrosine kinase activity. We further show that lymphatic endothelial specific inactivation of *Ephb4* in mouse embryos lead to subcutaneous edema due to defective lymphatic vessel formation. Mutations in *PIEZO1* were also shown to affect expression of *PIEZO1*.

Together, these findings identify EPHB4 and PIEZO1 as critical regulators of early lymphatic vascular development and that mutations in these genes can cause two new forms of lymphatic-related non-immune hydrops fetalis with a high mortality. This also suggests not only is LRHF genetically heterogeneous, but it should also be considered in both dominant and recessive forms. This work was funded by British Heart Foundation (SP/13/5/30288) and Newlife Foundation for Disabled Children (12-13/01).

C21.5

Natural history of Ehlers-Danlos Syndrome (EDS) caused by CHST14/D4S11 deficiency: from an international collaborative clinical study by the International Consortium for EDS

Ehlers-Danlos syndrome (EDS) caused by CHST14/D4S11 deficiency, also named as EDS musculocontractural type 1, is a recently-identified disorder with 38 published patients (25 families). We, on behalf of the International Consortium for EDS, have conducted an international collaborative study to establish the natural history. Comprehensive clinical information has been obtained from 20 published patients (17 families) and 15 additional patients (14 families). Patients had craniofacial characteristics in infancy (large fontanelle, hypertelorism, short/downslanting palpebral fissures, blue sclera, low-set and rotated ears, high arched palate, long philtrum, small mouth, micro-retrognathia) and from adolescence (slender, asymmetrical shape with protruding jaw), congenital multiple contractures (adducted thumbs, clubfoot), characteristic finger shapes (tapering, slender, cylindrical), progressive deformities of feet (pes planus with valgus) and spine (kypho/scoliosis), skin hyperextensibility, fragility, and bruisability, wrinkling palmar creases, large subcutaneous hematomas (the most serious problem, occurring after minor traumas, spreading with severe pain, and sometimes accompanying hemorrhagic shock), ocular complications (retinal detachment), cryptorchidism in males, and other malformations (atrial septal defects). Two fatal events were described: a massive skin necrosis resulting from a large subcutaneous hematoma all around the leg; perforation of descending colon diverticula followed by skin rupture, with deterioration of general conditions to death. The disorder presents with an arthrogyposis-like appearance at birth and later fit the hallmark of EDS with a decrease of ADL/QOL and potential lethality due to progressive skeletal deformities, large subcutaneous hematomas, and visceral/ophthalmological complications. Grants: Practical Research Project for Rare/Intractable Diseases, Japan Agency for Medical Research and Development; Japan Foundation for Pediatric Research.

C21.6

Duplicated enhancer region upstream of the CTSB gene segregates with keratolytic winter erythema in South African and Norwegian families

T. Ngcungcu¹, M. Oti², B. I. Haukanes³, J. C. Sitek⁴, F. Yang⁵, R. Brucoleri^{6,5}, T. Stokowy⁷, E. J. Oakeley⁸, B. Linghu⁵, J. Zhu⁵, M. Sultan⁹, J. Schalkwijk⁹, C. von der Lippe¹, H. G. Ramsay¹; ¹University of the Witwatersrand, Johannesburg, South Africa, ²Radboud University, Nijmegen, Netherlands, ³Haukeland University Hospital, Bergen, Norway, ⁴Oslo University Hospital, Oslo, Norway, ⁵Novartis Institutes for BioMedical Research, Cambridge, MA, United States, ⁶Congenomics, Glastonbury, CT, United States, ⁷University of Bergen, Bergen, Norway, ⁸Novartis Institutes for BioMedical Research, Basel, Switzerland, ⁹Radboud University Medical Center, Nijmegen, Netherlands, ¹⁰Maastricht University Medical Center+, Maastricht, Netherlands, ¹¹Dalhousie University, Halifax, NS, Canada, ¹²Bristol-Myers Squibb, Princeton, NJ, United States.

Keratolytic winter erythema (KWE) is a rare autosomal dominant skin disorder characterized by recurrent episodes of palmo-plantar centrifugal erythema and epidermal peeling. KWE was previously mapped to 8p23-p22 (KWE critical region) in South African families, who are expected to share the same mutation due to a founder effect. Using targeted resequencing of the KWE critical region in three South African families and SNP array/whole genome sequencing in two Norwegian families, we identified two overlap-

ping tandem duplications of 7.67 kb and a 15.93 kb respectively. The duplications are located upstream of the *CTSB* gene, and the 2.63 kb overlapping region includes an enhancer element that is active in keratinocytes. Based on NHEK cell line Hi-C data and MCF-7 cell line CTCF ChIA-PET data, three potential topological domains were revealed, all containing the enhancer and *CTSB*, plus either *FDFT1* and even *NEIL2*. However, the activity of the enhancer correlated with *CTSB* but not with *FDFT1* and *NEIL2* gene expression in differentiating keratinocytes and other cell lines, and MCF-7 RNAII ChIA-PET data showed that the enhancer interacts with the *CTSB* promoter but not with the *FDFT1* or *NEIL2* promoters, suggesting that the enhancer normally regulates *CTSB* expression. In conclusion, we show that KWE in South African and Norwegian families is caused by tandem duplications in non-coding DNA containing an active enhancer element for *CTSB*. Duplication of this region may cause aberrant expression of nearby genes due to changes in the topological domain structure, in response to environmental triggers.

Background: Genetic determinants of stroke, the leading neurological cause of death and disability, are poorly understood and have seldom been explored in the general population.

Methods: We performed a genome-wide screen for common genetic variants associated with incident stroke risk in 18 prospective population-based cohorts comprising 84,961 participants, of whom 4,348 experienced stroke. We followed-up variants with $p < 5 \times 10^{-6}$ in the largest available cross-sectional studies (70,804 participants of whom 19,816 experienced stroke). For genome-wide significant findings ($p < 5 \times 10^{-8}$), we explored associations with additional cerebrovascular phenotypes and undertook functional analyses in mouse and zebrafish mutants.

Results: We replicated seven of eight known loci for ischemic stroke and identified a novel locus at chr6p25 (rs12204590, near *FOXF2*) associated with risk of all stroke: odds ratio (OR) = 1.08 (95%CI: 1.05-1.12), $p = 1.48 \times 10^{-8}$ (minor allele frequency 21%). The rs12204590 stroke risk allele also increased MRI-defined white matter hyperintensity (WMH) burden, a marker of cerebral small artery disease, in stroke-free adults (N=21,079; $p = 0.0025$). Consistently, young patients with segmental deletions of *FOXF2* exhibited extensive WMH burden. Conditional (inducible) deletion of *Foxf2* in adult mice resulted in cerebral infarction, reactive gliosis, and microhemorrhage. The zebrafish equivalents of *FOXF2* (orthologs) *foxf2b/foxf2a* were expressed in brain pericytes and mutant *foxf2b*^{-/-} cerebral vessels showed decreased smooth muscle cell and pericyte coverage.

Conclusion: In our study of 155,765 persons in total (24,164 with stroke), we identified common variants near *FOXF2* associated with increased stroke susceptibility. Extensive epidemiological and experimental data suggest that *FOXF2* mediates this association, potentially via differentiation defects of cerebral vascular mural cells.

C22.2

Whole exome sequencing identifies ALPK3 as a new disease gene causing both severe paediatric and 'milder' adult-onset cardiomyopathies.

Paediatric cardiomyopathies are a heterogeneous group of disorders characterized by structural and functional cardiac abnormalities. Up to 40% of affected children die or undergo cardiac transplantation within five years of diagnosis. While understanding the molecular basis of paediatric cardiomyopathy has greatly improved over the last decades, in many cases the underlying cause remains unknown. Currently available (targeted/custom based) diagnostic tests do not represent the whole spectrum of genetic etiologies and lead to a genetic diagnosis in a subset of paediatric patients only. Using homozygosity mapping and exome sequencing in two consanguineous families with idiopathic paediatric cardiomyopathy, we identified homozygous truncating mutations in a new disease gene: alpha-kinase 3 (ALPK3). This gene encodes a nuclear kinase essential for early differentiation of cardiomyocytes, being involved in important transcription factor pathways. A third family carrying mutated ALPK3 was identified upon cohort screening. Patients with biallelic mutations presented with severe cardiomyopathy leading to early lethality or biventricular dysfunction in childhood. Some heterozygous family members showed adult-onset cardiomyopathy with atypically distributed hypertrophy, indicating that this gene may also play a role in dominantly inherited cardiomyopathies. We provide microscopic evidence of intercalated disc remodelling, as previously observed in *Alpk3* knockout mice. Further functional experiments and studies on the role of the gene in adult-onset cardiomyopathies and cardiac hypertrophy are ongoing.

In conclusion, biallelic truncating mutations in ALPK3 cause severe paediatric cardiomyopathy. Our findings highlight the importance of transcription factor pathways in the molecular mechanisms underlying human cardiomyopathies and underscore the high genetic heterogeneity of paediatric cardiomyopathies.

C22.3

Exome sequencing reveals distinct genetic architectures for syndromic and nonsyndromic congenital heart defects

Congenital Heart Defects (CHD) have a neonatal incidence of 0.8-1%. Despite abundant examples of monogenic CHD in humans and mice, CHD has

a low absolute sibling recurrence risk (~2.7%), suggesting a considerable role for de novo mutations, and/or incomplete penetrance. De novo protein-truncating variants have been shown to be enriched among the 10% of 'syndromic' patients with extra-cardiac manifestations (Homsy et al., 2015). However, these findings do not explain the recurrence risk in the majority (~90%) of CHD cases which present themselves clinically as isolated cardiac defects. We exome sequenced 4,593 individuals from 1,823 CHD families (1,365 trios, 32 multi-sibling families and 458 singletons), including both syndromic (n=610) and non-syndromic cases (n=1,281). In the syndromic CHD cohort, we confirmed a significant enrichment of de novo, but not inherited, protein-truncating variants, in known CHD-associated genes, consistent with recent findings. Conversely, in non-syndromic CHD we observed significant enrichment of protein-truncating variants inherited from unaffected parents in known CHD genes. These findings point towards a role for variants with reduced penetrance in these non-syndromic cases. Additionally, we identified three novel genome-wide significant syndromic CHD disorders caused by de novo mutations in CHD4, CDK13 and PRKD1. To summarise, our study reveals distinct genetic architectures underlying the low sibling recurrence risk in syndromic and non-syndromic CHD.

C22.4

Defective connective tissue remodeling in Smad3 mice leads to accelerated aneurysmal growth through disturbed downstream TGF-β signaling

I. van der Pluijm, N. van Vliet, J. von der Thusen, J. Robertus, Y. Ridwan, P. van Heijningen, B. van Thiel, M. Vermeij, R. Buijs-Offerman, R. Kanaar, A. Bertoli-Avella, J. Essers;
Erasmus Medical Center, Rotterdam, Netherlands.

Aneurysm-osteoarthritis syndrome (AOS, or Loeys-Dietz syndrome type3, LDS3) is characterized by aortic aneurysms and early-onset osteoarthritis, caused by SMAD3 mutations. Smad3 is part of the Smad2/3/4 transcription factor, essential for TGF-β-activated transcription. Although mutations in TGF-β-related genes result in aneurysm formation, the underlying mechanism is unknown. Here, we examined aneurysm formation and progression in Smad3^{-/-} animals.

Smad3^{-/-} animals developed aortic aneurysms rapidly, resulting in premature death, earlier in males than females. Aortic wall immunohistochemistry showed no increase in extracellular matrix and collagen, nor loss of vascular smooth muscle cells (VSMCs) but instead revealed medial elastin disruption and adventitial inflammation. Remarkably, matrix metalloproteases (MMPs) were not activated in VSMCs, but were specifically activated in inflammatory areas. Although Smad3^{-/-} aortas showed increased nuclear pSmad2 and pErk, indicative of TGF-β receptor activation, downstream TGF-β-activated genes were not upregulated. Increased pSmad2 and pErk staining in pre-aneurysmal Smad3^{-/-} aortas without immune infiltrates implied that the aortic damage and subsequent TGF-β receptor-activated signaling precede aortic inflammation. Finally, increased pErk together with impaired downstream TGF-β-activated transcription resulted in increased Smad3^{-/-} VSMC proliferation.

Smad3^{-/-} animals recapitulate the aortic phenotype observed in patients with SMAD3 mutations. Smad3 deficiency leads to imbalanced activation of downstream genes and no activation of MMPs in VSMCs, causing an immune response resulting in rapid dilatation and rupture of the aortic wall. Our findings uncover new possibilities for treatment of patients carrying SMAD3 mutations; instead of treating with drugs targeting the TGF-β pathway, they may benefit more from immune suppression.

Loss-of-function mutations in the X-linked gene BGN cause a severe syndromic form of thoracic aortic aneurysms and dissections

J. A. N. Meester¹, G. Vandeweyer¹, I. Pintelon², K. Waitzman³, L. Young³, L. W. Markham⁴, J. Vogt⁵, J. Richer⁶, L. M. Beauchesne⁷, S. Unger⁸, A. Superti-Furga⁹, E. Reyniers¹, A. Verstraeten¹, L. Van Laer¹, B. L. Loeys¹;

¹Center of Medical Genetics, University of Antwerp and Antwerp University Hospital, Antwerp, Belgium, ²Department of Cell Biology and Histology, University of Antwerp, Antwerp, Belgium, ³Department of Pediatric Cardiology, Lurie Children's Hospital of Chicago, Chicago, IL, United States, ⁴Divisions of Pediatric and Adult Cardiology, Vanderbilt University, Nashville, TN, United States, ⁵Birmingham Women's NHS Foundation Trust, Birmingham, United Kingdom, ⁶Department of Medical Genetics, University of Ottawa Heart Institute, Ottawa, ON, United States, ⁷Division of Cardiology, University of Ottawa Heart Institute, Ottawa, ON, United States, ⁸Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland, ⁹Service of Medical Genetics, Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland.

Thoracic aortic aneurysm and dissection (TAAD) is typically inherited in an

autosomal dominant manner but rare X-linked families have been described. So far, FLNA is the only X-linked gene associated with a syndromic form of TAAD, namely the periventricular nodular heterotopia type of Ehlers-Danlos syndrome. However, FLNA only explains a small number of the X-linked TAAD families.

We performed targeted resequencing of nearly 500 extracellular matrix and TGFβ related genes in a cohort of 11 Marfan-like probands without known causal mutation. We identified two patients with loss-of-function mutations in BGN, encoding the extracellular matrix small leucine-rich proteoglycan biglycan. Subsequent Sanger sequencing of BGN in 400 male and 200 female TAAD-patients, negative for known TAAD genes, identified a splice site mutation in a male proband and suggested a deletion in two other male probands. The latter were confirmed by micro-array analysis. The clinical phenotype is characterized by early onset aortic aneurysm (age 1 year) and dissection (age 15 years). Other recurrent findings include hypertelorism, pectus deformity, joint hypermobility, contractures and mild skeletal dysplasia. Histological stainings of the patients' aortic wall revealed a substantial reduction in collagen content, while elastin fibers appeared normal. Biglycan deficiency in male BALB/cA mice leads to sudden death from aortic rupture, indicating that biglycan is both structurally and functionally essential for the integrity of the aortic wall.

These results confirm that BGN gene defects in human cause an X-linked syndromic form of severe TAAD.

Introduction: Life expectancy of men is about 5 years shorter compared with women but the underlying factor(s) have been elusive. Our previous results show that mosaic loss of chromosome Y in blood cells (LOY) is associated with age, smoking, all-cause mortality and non-hematological tumors (Nat. Genet. 2014 PMID:24777449, Science 2015 PMID:25477213). The aim of the present study was to test if men with LOY are more susceptible to Alzheimer's disease (AD).

Materials and Methods: LOY in blood cells was estimated using SNP-array data from >3200 men from one AD case-control study and two prospective cohorts. Whole genome sequencing was used for validations. A set of statistical techniques were used to evaluate association between LOY in blood and AD diagnosis.

Results: LOY was detected in ~17% of participants (median age=73, range=37-96). We found that men with AD diagnosis had a higher degree of LOY mosaicism in the case-control study (adjusted odds ratio=2.80, AD events=606, p=0.0184). Furthermore, analysis of the two prospective cohorts showed that men with LOY in blood at sampling had an increased risk for incident AD during follow-up time (HR=6.80, 95% CI=2.16-21.43, AD events=140, p=0.0011).

Conclusions: Our results suggest that LOY in blood cells is associated with increased risk for both AD and cancer, suggesting a role of LOY in blood cells on disease processes in other tissues, possibly via defective immunosurveillance functions of immune cells without the Y chromosome. Hence, as a male-specific genetic risk factor, LOY might help explain why males on average live shorter than females.

C23.2

Single cell allele specific expression (ASE) in T21 and common trisomies: Novel approach to understand gene dosage effects in Down syndrome and common aneuploidies

G. Stamoulis¹, F. Santoní², P. Makrythanasis², A. Letourneau¹, M. Guipponi², M. Garieri¹, N. Panousis¹, E. Falconnet¹, P. Ribaux¹, C. Borel¹, S. E. Antonarakis^{1,2,3};
¹Department of Genetic Medicine and Development, University of Geneva Medical School, Geneva, Switzerland, ²Geneva University Hospitals-HUG, Service of Genetic Medicine, 1211 Geneva 4, Switzerland, Geneva, Switzerland, ³iGE3 Institute of Genetics and Genomics of Geneva, University of Geneva, 1211, Geneva, Switzerland.

Trisomy 21(T21), is a model disorder of altered gene expression. We have previously used a pair of monozygotic-twins discordant for T21 to study the global dysregulation of gene expression, eliminating genetic variation among individuals (Nature:508;345-350;2014). Majority of previous studies on aneuploidies were conducted on cell-populations or tissues. Studies on gene and allelic-expression of single-cells(SC) may reveal important biological insights regarding the cellular impact of aneuploidy elucidating the fundamental mechanisms of gene dosage. We estimated the allele-specific-expression(ASE) from RNAseq of ~1000 single-cells in different aneuploidies: 352 SC fibroblasts (172 Normal-179 T21 cells) from the pair of monozygotic-twins discordant for T21, 166 from a mosaic-T21, 176 mosaic-T18, 151 mosaic-T8, and 146 SC-fibroblasts from mosaic-T13. In the monozygotic-twins, considerable number of heterozygous sites genome-wide were expressed monoallelically (Normal: 73.5%-564,668 observations, and T21: 78.7%-549,799 observations). There was considerable monoallelic-expression for chr21 sites in Normal and, surprisingly, in T21 cells as well (Normal: 63.3%-5,009 observations, T21: 72.8%-6,456 observations). We classified chr21 genes in three classes according to the level of the aggregate monoallelic-expression of their corresponding sites (9-monoallelic, 29-intermediate, 2-biallelic). We hypothesize that each class of genes contributes in a specific way to the phenotypic variability of Down-Syndrome(DS). Similar results, (i.e. extensive monoallelic-expression of genes on the supernumerary chromosomes, were also observed in the other aneuploidies. Our analysis demonstrated that, for genes with monoallelic-expression, the altered gene dosage induced by the aneuploid chromosome is due to the number of cells expressing the gene on the supernumerary chromosome. This difference in the fraction of expressing cells could contribute to the development and variability of phenotypes in aneuploidies. This study provides a new fundamental understanding of gene dosage effects in aneuploidies.

C23.3

The landscape of polymorphic inversions and their functional impact in the human genome

J. Lerga-Jaso¹, M. Oliva¹, S. Villatoro¹, D. Izquierdo¹, L. Pantano¹, S. Casillas^{1,2}, M. Cáceres^{1,3};

¹Institut de Biotecnologia i de Biomedicina, Universitat Autònoma de Barcelona, Bellaterra (Barcelona), Spain, ²Departament de Genètica i de Microbiologia, Universitat Autònoma de Barcelona, Bellaterra (Barcelona), Spain, ³Institució Catalana de Recerca i Estudis Avançats (ICREA), Barcelona, Spain.

Recent advances in genomic techniques have generated an increasing interest in structural variants (SVs). However, there is still limited data on their functional impact. This is particularly true for inversions, in which their balanced nature and the complex repetitive regions where they appear make their study especially challenging. In this regard, we have designed a null model to elucidate the functional characteristics of these variants, taking as reference the most reliable set of human polymorphic inversions so far from the InvFEST database. Human inversions show the signature of natural selection, avoiding more often than expected not only genes, but also other functional elements such as enhancers, chromatin domain boundaries and highly conserved regions. Moreover, we measured the effect of 45 experimentally-genotyped polymorphic inversions on gene expression based on the transcriptome data from lymphoblastoid cell lines of 175 individuals from the Geuvadis project. Using a combination of well-established tools and further filtering criteria to minimize false positives, we found that although the majority of inversions do not appear to have any significant regulatory effect in this cell type, around half a dozen of them have a clear influence on specific genes, both in cis and in trans. Finally, we intersected SNPs reported as GWAS hits of different human phenotypes with the inversions in our dataset. All together, these results illustrate the potential impact of inversions on the human genome, and contribute to shed light on the molecular mechanisms responsible for phenotypic variability. Support: European Research Council (ERC) Starting Grant (INVFEST).

C23.4

Assessment of the GENCODE annotation through experimental validation

A. Ferreira^{1,2}, B. Uszczyńska³, J. Lagarde³, J. Chrast¹, A. Frankish⁴, J. Harrow⁴, R. Guigó³, A. Reymond¹;

¹Center for Integrative Genomics, Lausanne, Switzerland, ²Swiss Institute of Bioinformatics, Lausanne, Switzerland, ³Centre for Genomic Regulation, Barcelona, Spain, ⁴Wellcome Trust Sanger Institute, Cambridge, United Kingdom.

Within the ENCODE consortium, GENCODE aims to accurately annotate all protein-coding genes, pseudogenes and non-coding transcribed loci in the human genome through manual curation and computational analysis. Lower confidence transcribed loci, i.e. not supported by ENCODE or GTex RNA-seq data, were systematically experimentally evaluated in 8 tissues by RT-PCR amplification followed by highly multiplexed sequencing readout, a method we coined RT-PCR-seq. 78% of all assessed junctions are confirmed by this evaluation procedure demonstrating the high quality of the annotation reached by the GENCODE gene set. In a second phase unvalidated junctions were reevaluated by RT-PCR-seq in a second set of 8 tissues and with a novel pair of primers to account for tissue specificity and bad design of the oligos, respectively.

To assess the completion of the GENCODE annotation we then tried to amplify new exons and/or new splice junctions of 541 deeply annotated protein-coding genes that belong to the UK Genetic Testing Network list through individual 5' and 3' nested-RACEs in 8 different tissues (brain, testis, heart, kidney, liver, lung, spleen and skeletal muscle) paired with long-range Pacific Biosciences sequencing. Whereas these experiments failed to reveal a large number of new exons and splice sites, they further contributed to the improvement of the human genome annotation through identification of new splice junctions between already annotated exons, de facto new transcripts. While the results demonstrate that the human transcriptome annotation is far from complete, we are moving to accurately identifying all protein-coding loci of major interest to the clinical community.

C23.5

Single-cell RNA-seq analysis of human pancreatic islets

M. Garieri^{1,2}, C. Borel¹, T. Stoeger³, F. Santoni¹, C. Howald^{1,2}, P. Ribaux¹, L. Pelkmans³, P. Halban¹, S. Antonarakis¹, E. Dermizakis^{1,2};

¹Department of Genetic Medicine and Development, University of Geneva, Geneva, Switzerland, ²Swiss Institute of Bioinformatics (SIB), Geneva, Switzerland, ³Institute of Molecular Life Sciences, University of Zurich, Zurich, Switzerland.

Pancreatic islets consist of several endocrine cell types. We investigate the heterogeneity of this tissue using single-cell (SC) RNA-seq. Dissociated islet cells of 3 donors (n=241, 183 after quality control) were analyzed. We also sequenced sorted-beta SCs (n=60, 44 after quality control) from the same individuals.

Clustering analysis on islet SCs identified the follow populations of cells: beta SCs (mean INS expression 40777 RPKM, representing the 75% of all SCs), alpha (mean GCG expression 86443 RPKM, 12%), gamma (mean PPY expression 49928 RPKM, 3%), delta (mean SST expression 76061 RPKM, 2%) and a small population of exocrine SCs. In the sorted beta SCs we observed beta SCs (INS 32708 RPKM, 93%) and delta SCs (SST 135327 RPKM, 7%).

Interestingly we observed that insulin (INS) is expressed in all the islets SCs and not just in the subpopulation of beta SCs, in addition GCG has expression in 93% of all islets SCs. We controlled for the absence of transcript contamination of INS and GCG by sequencing 11 empty chambers. We are verifying the cellularity of the cell types and the presence of INS and GCG transcript in most of the SCs using another technology (branched-DNA single-molecule FISH) allowing for quantification and cellular localization of transcripts. Differential expression and differential splicing analysis has been performed among all different cell types.

SC transcriptome analyses provide an unprecedented opportunity to discover the heterogeneity of human pancreatic islets of Langerhans.

M.G and C.B. and the labs of SEA and ETD contributed equally to the work.

C23.6

Identifying novel long non-coding RNAs in the Human genome

M. P. Hardy, J. Harrow, J. Loveland, A. Frankish, HAVANA Group; Wellcome Trust Sanger Institute, Cambridge, United Kingdom.

Multiple lines of evidence are emerging that long non-coding RNAs (lncRNAs) can be crucial regulators and markers of disease. For example, the long intergenic RNA (lincRNA) MALAT1 has been shown to regulate cancer tumor growth in bone and has been identified as a potential therapeutic target in osteosarcoma*. As part of the GENCODE project, the HAVANA team at the Wellcome Trust Sanger Institute aims to identify and manually annotate all lncRNAs in the human and mouse genomes. Our most recent release for

human (GENCODE 24) identifies 15,941 lncRNA loci containing 28,031 transcripts. Historically, lncRNA annotation has been supported by ESTs and cDNAs submitted to INSDC databases. Recent developments in next generation sequencing technology provide a huge amount of transcriptome data, however, this data needs to be handled carefully if it is to be used for building high quality gene annotation**. We will discuss the incorporation of public RNAseq and SLRseq datasets into our annotation pipeline to identify novel loci and describe our PacBio Capture-seq pipeline to extend loci to their full length and identify alternative splicing (AS). Additionally, we will show how we use PhyloCSF and Mass Spectrometry data to check coding potential in lncRNA loci and confirm their non-coding status, or update their annotation. Combining multiple public and bespoke next-generation data sets allows us to identify novel lncRNA loci, extend and add AS transcripts to existing loci and validate their non-coding annotation in an effort to provide a more detailed picture of the human non-coding transcriptome.

C24 Rare Disease Gene Discoveries

C24.1

Studying the genetic basis of idiopathic short stature using whole exome sequencing

C. T. Thiel¹, N. N. Hauer¹, E. Schöller¹, S. Schuhman¹, M. T. Wittmann¹, B. Popp¹, S. Uebe¹, C. Büttner¹, A. B. Ekici¹, K. Kutsche², D. Wieczorek³, H. Sticht⁴, H. Dörr⁵, A. Reis¹;
¹Institute of Human Genetics, Friedrich-Alexander-University Erlangen-Nürnberg, Erlangen, Germany, ²Institute of Human Genetics, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, ³Institute of Human Genetics, University of Düsseldorf, Düsseldorf, Germany, ⁴Institute of Biochemistry, Friedrich-Alexander-University Erlangen-Nürnberg, Erlangen, Germany, ⁵Department of Pediatrics and Adolescent Medicine, Friedrich-Alexander-University Erlangen-Nürnberg, Erlangen, Germany.

Shortness of stature is a common medical concern in childhood with an incidence of 3%. After excluding common defects the underlying cause remains unknown in approximately 70-80%.

We now recruited and clinically characterized a group of >500 families with idiopathic short stature (ISS) and selected 200 individuals where common genetic causes were excluded for whole exome sequencing (100 Trios, 100 affected only).

Surprisingly, in 21 Trios we found mutations in known short stature genes where characteristic clinical features of the syndromes were missing. In 62 of the remaining 89 trios we found potential protein affecting variants in 126 novel candidate genes. A second variant was found for 4 of these 126 candidate genes in the affected only analysis. 2 further genes were recently reported for ISS in agreement with a dominant de novo model of inheritance. 31 / 126 genes show evidence for causation based on gene constraint, chondrocytes expression levels, animal models, short stature associated CNVs, functional GO terms and known protein interactions.

In conclusion, exome analyses of 200 patients with ISS identified a known cause of shorted stature in 11% of cases. Furthermore, we found 126 potential novel candidate genes in 62% of the individuals including 6 genes with independent mutations in two individuals each. Thus, our data strongly suggest that single gene defects may be a frequent cause for idiopathic short stature.

C24.2

Targeted Next Generation Sequencing in skeletal dysplasias: experience on 216 patients

C. Michot¹, S. Hanein², C. Haudry³, G. Baujat¹, S. Monnot³, A. Munnich¹, J. Bonnefont³, V. Cormier-Daire¹;

¹Genetics Department, INSERM UMR1163, Paris Descartes-Sorbonne Paris Cité University, Imagine Institute, Necker-Enfants Malades Hospital, Paris, France, ²Imagine Institute, Necker-Enfants Malades Hospital, Paris, France, ³Molecular Biology Department, Paris Descartes-Sorbonne Paris Cité University, Necker-Enfants Malades Hospital, Paris, France.

Short stature is a common reason for paediatric consultations. After having excluded digestive, renal, inflammatory, metabolic or endocrinologic aetiologies skeleton X-rays may orientate toward the diagnosis of skeletal dysplasias. Next generation sequencing (NGS), allowing simultaneous analysis of many genes, has improved the ability to perform genetic testings for such heterogeneous related conditions. The study reports the results of the analyses of 216 patient DNAs by targeted NGS.

Medical files and X-rays from all patients included were first reviewed by Centre of Reference for Constitutional Bone Dysplasias. A targeted NGS pa-

nel for skeletal dysplasias was designed to sequence 70 genes. Amplicons were captured by Sure-Select technology (Agilent technologies) and sequenced on HiSeq (Illumina). Alignment and detection of variants were realized thanks to Burrows-Wheeler and Genome Analysis Toolkit softwares before annotation and analysis by a homemade web interface (PolyWeb).

216 DNAs have been analyzed. For 61 patients (28%), a pathogenic variant was identified and confirmed by Sanger sequencing. Many variants of unknown significance (VOUS) were found. In 63 cases (30%) the VOUS were consistent with the phenotypes; familial segregation studies and cDNA analysis (for some) are still in progress. Finally, analyses were negative in 92 cases (42%).

Targeted NGS is efficient to establish the molecular diagnosis of skeletal dysplasias, especially in subgroups with high genetic heterogeneity, such as epiphyseal dysplasias. The important number of VOUS highlights the importance of clinico-biological staffs. Such expertise further emphasizes the need for Centre of Reference for rare diseases.

C24.3

NUP107 mutations cause autosomal recessive inherited early childhood-onset steroid resistant Nephrotic syndrome

N. Miyake¹, H. Tsukaguchi², E. Koshimizu¹, A. Shono², N. Matsumoto¹;

¹Yokohama City University, Yokohama, Japan, ²Kansai Medical University, Osaka, Japan, ³Kobe University Graduate School of Medicine, Kobe, Japan.

Introduction: Nephrotic syndrome is a renal disorder caused by disruption of the glomerular filtration barrier, resulting in massive proteinuria, hypoalbuminemia, and dyslipidemia. At least 27 genes have been reported to be associated with steroid resistant Nephrotic syndrome (SRNS), but approximately 70% of the patients with childhood-onset SRNS are genetically unknown.

Materials and Methods: To identify the novel responsible gene for SRNS, we performed WES for 18 families in whom the causative mutations have not been identified in the known SRNS genes.

Results: We identified biallelic NUP107 mutations in nine affected individuals from five unrelated families who showed early-onset SRNS. Seven of nine affected individuals had compound heterozygous mutation of one truncating mutation (c.1079_1083del or c.969+1G>A) and commonly shared missense mutation (c.2492A>C). They developed nephrotic syndrome from 2 to 3 years of age and progressed to end stage renal disease until 10 years old. The rest of two patients in one family had compound heterozygous mutation of two missense mutation (c.469G>T and c.2492A>C) and showed milder phenotype with later onset (10 to 11 years old). NUP107 encodes Nucleoporin 107kDa (NUP107) is a component of the nuclear pore complex embedded in the nuclear envelope, and ubiquitously expressed including in glomerular podocytes. NUP107 knockdown zebrafish generated by morpholino oligonucleotides displayed hypoplastic glomerulus structures and abnormal podocyte foot processes, which could recapitulate the renal changes in the patients with NUP107 mutations

Conclusions: Here, we identified biallelic NUP107 mutations caused early childhood-onset SRNS and highlighted the importance of nuclear pore complex in human renal disease.

C24.4

Whole-exome sequencing identifies mutations of TBC1D1 encoding a Rab-GTPase-activating protein in patients with congenital anomalies of the kidneys and urinary tract (CAKUT)

A. Kosfeld¹, M. Kreuzer², C. Daniel³, F. Brand¹, A. Schäfer⁴, A. Chadt⁵, A. Weiss¹, V. Riehmer¹, C. Jeanpierre⁶, M. Klintschar⁷, J. Bräsen⁸, K. Amann³, L. Pape², A. Kispert⁴, H. Al-Hasani⁵, D. Haffner², R. G. Weber¹;

¹Hannover Medical School, Department of Human Genetics, Hannover, Germany, ²Hannover Medical School, Department of Pediatric Kidney, Liver and Metabolic Diseases, Hannover, Germany, ³Friedrich-Alexander University of Erlangen-Nürnberg, Department of Nephropathology, Erlangen, Germany, ⁴Hannover Medical School, Institute of Molecular Biology, Hannover, Germany, ⁵Leibniz Center for Diabetes Research at the Heinrich-Heine-University Düsseldorf, German Diabetes Center, Düsseldorf, Germany, ⁶Institut National de la Santé et de la Recherche Médicale UMR1163, Hôpital Necker-Enfants Malades; Université Paris Descartes - Sorbonne Paris Cité, Institut Imagine, Paris, France, ⁷Hannover Medical School, Department of Legal Medicine, Hannover, Germany, ⁸Hannover Medical School, Department of Pathology, Hannover, Germany.

Congenital anomalies of the kidneys and urinary tract (CAKUT) are genetically highly heterogeneous leaving most cases unclear after mutational analysis of the around 30 causative genes known so far. Assuming that phenotypes frequently showing dominant inheritance, such as CAKUT, can be caused by de novo mutations, de novo analysis of whole exome sequencing data was done on two patient-parent-trios to identify novel CAKUT genes. In

one case, we detected a heterozygous de novo frameshift variant in TBC1D1 encoding a Rab-GTPase-activating protein regulating glucose transporter GLUT4 translocation. Sequence analysis of 100 further CAKUT cases yielded three novel or rare inherited heterozygous TBC1D1 missense variants predicted to be pathogenic. TBC1D1 mutations affected Ser237-phosphorylation or protein stability and thereby act as hypomorphs. Tbc1d1 showed widespread expression in the developing murine urogenital system. A mild CAKUT spectrum phenotype, including anomalies observed in patients carrying TBC1D1 mutations, was found in kidneys of some Tbc1d1^{-/-} mice. Significantly reduced Glut4 levels were detected in kidneys of Tbc1d1^{-/-} mice and the dysplastic kidney of a TBC1D1 mutation carrier versus controls. TBC1D1 and SLC2A4 encoding GLUT4 were highly expressed in human fetal kidney. The patient with the truncating TBC1D1 mutation showed evidence for insulin resistance. These data demonstrate heterozygous deactivating TBC1D1 mutations in CAKUT patients with a similar renal and ureteral phenotype, and provide evidence that TBC1D1 mutations may contribute to CAKUT pathogenesis, possibly via a role in glucose homeostasis.

Gemelli", Università Cattolica del S. Cuore, Rome, Italy, ¹³Clinica Sant'Anna, Cagliari, Italy.

Introduction: Crisponi syndrome (CS)/Cold-induced sweating syndrome type 1 (CISS1) is a rare autosomal recessive syndrome characterized by a complex phenotype with high neonatal lethality, hyperthermia and feeding difficulties in the neonatal period, scoliosis and cold induced sweating since early childhood. Mutations in the CRLF1 gene are implicated in CS/CISS1. A subset of CS/CISS1 cases remains yet genetically unexplained after CRLF1 sequencing.

Materials and Methods: To identify new gene(s) implicated in the clinical phenotype, we used a whole exome sequencing approach followed by targeted Sanger sequencing.

Results: We identified homozygous mutations in the KLHL7 gene in five cases. KLHL7 encodes a BTB-Kelch-related protein involved in the ubiquitination of target proteins for proteasome-mediated degradation. Mono-allelic mutations in KLHL7 have been reported in three cases affected by a late-onset form of autosomal dominant retinitis pigmentosa. A critical evaluation of the retinal phenotype in our probands revealed retinitis pigmentosa, so implying that KLHL7 mutations could show greater severity in recessive than in dominant cases.

Conclusions: Although these data further support the pathogenic role of bi-allelic KLHL7 mutations in a CS/CISS1-like phenotype, they do not explain all their clinical manifestations and highlight the high phenotypic heterogeneity associated to mutations in KLHL7. Uncovering whether KLHL7 and CRLF1 converge functionally can have important implications in the search for novel disease-associated genes and pharmacological targets.

This work was supported by TELETHON exploratory grant GEP13093 to L.C. and by a grant from Innovative Medical Research, Münster, Germany to I.B. and F.R.

C24.6

Loss-of-function mutations in ELMO2 impeding RAC1 signaling and cell migration cause intraosseous vascular malformation

Primary intraosseous vascular malformations are rare and almost exclusively described in sporadic cases involving bones that ossify intramembranously such as the skull. We previously reported an autosomal recessive form of such a disorder, intraosseous vascular malformation (VMOS) [MIM 606893], characterized by severe progressive life-threatening craniofacial vascular malformations and supraumbilical raphe. Homozygosity mapping and massively parallel sequencing identified mutations in ELMO2, which conveys extracellular signals to cytoskeleton, in five unrelated families with eight affected individuals with VMOS. These include two splice site mutations, a one-nucleotide deletion causing frameshift, and a complex rearrangement deleting the first exon. VMOS lesions had bones with abnormally expanded and malformed blood vessels lacking mature vascular smooth muscle layer. ELMO2 deficient cells had a significant downregulation of the associated partner DOCK1, resulting in deficient activation of RAC1 - a key factor in controlling cell migration. Primary fibroblasts from an individual with VMOS had impaired cell migration, an essential process during angiogenesis, which was rescued by external ELMO2 protein. Comparative phylogenetic analysis points out that Elmo2 first appeared with the divergence of jawed vertebrates from others, and might have acquired new functions in jawed vertebrates. Taken together, our study places ELMO2 in a critical position for maintenance of vascular stability in bone tissue, and sheds new light on the understanding of the regulatory mechanisms underlying angiogenesis in intramembranous ossification.

Trisomy/Tetrasomy 15q in two prenatal cases

E. Geán¹, D. Escué¹, M.A. Caamaño¹, A. Morales¹, R. Bohera¹, S. Rubio¹, A. Torrents¹, M. García², V. Moreno², F. Espejo², C. Garrido^{1,2};
¹Reference Laboratory, L'Hospitalet de Llobregat (Barcelona), Spain, ²Hospital de Mérida, Mérida, Spain.

Introduction: Tetrasomy 15q is a well-known clinical entity. Sometimes is found in prenatal study like a SMCs or derivative chromosome.

Case 1: Amniotic fluid for a 29-year-old woman was referred to our laboratory for atrio-ventricular dilatation, liver arterio-venous malformation and bilateral hydronephrosis of the fetus. Cytogenetic analysis showed 47,XX, + SAC in 65% of metaphases. ISCA array by Agilent of 60K, and we found an amplification of 15q25.2q26.3 region. It seems to be the origin of SAC. To confirm this hypothesis, we applied centromeric probe of chromosome 15 and telomeric probe of 15qtel by FISH, and the result was an i(15)(q25.2q26.3), without centromeric signal.

47,XX,+mar:ish i(15)(q25.2q26.3)(D15Z1x0,D15S936x2).arr[hg19] 15q25.2q26.3(81.795.278-102.383.473)x3

Parental cytogenetic studies were normal, indicating a de novo origin for the SMC.

Case 2: Amniotic fluid for a 27-year-old woman was referred to our laboratory for pleural effusion, ascites and hydrops of the fetus at 32 weeks of gestation. Cytogenetic studies in amniotic fluid showed a derivative of chromosome 7. CGH array confirm a terminal deletion on the short arm of chromosome 7 (with deletion of the genes in this region) and amplification of 15q23q26.3, that behaves double gene dosage of the genes contained in that region. No information about cytogenetic studies of the parents has been facilitated.

46,XX,der(7)t(7;15)(p22.3;q26.3).arr[hg19] 7p22.3(101.528-67.231)x1,15q23q26.3(68.759.755-102.383.473)x3

Conclusion: The increasing use of array CGH in clinical laboratories will provide an efficient method for more comprehensive characterization of SMCs and derivative chromosomes. We discuss clinical utility.

P01.002

Raising confidence threshold increases the positive predictive value of a SNP-based NIPT for the 22q11.2 microdeletion

A. Ryan, S. Iyengar, B. Jiorle, Z. Demko;
Natera Inc, San Carlos, CA, United States.

AIM: To examine whether raising the confidence threshold at which the algorithm for a SNP-based NIPT for the 22q11.2 microdeletion makes a positive call would increase the positive predictive value (PPV) without affecting test sensitivity.

METHODS: 20,776 NIPT samples received between Feb-Aug, 2014 were previously evaluated for the 22q11.2 deletion using primers targeting 672 SNPs in a 2.9 Mb segment of 22q11.2, and analyzed using a high-risk confidence threshold of 0.90. Follow-up information, including ultrasound findings, were collected for high-risk cases. Here, the algorithm's confidence threshold was raised to 0.95, and PPV recalculated for the entire cohort and for the subset of cases with prior-known directly-associated ultrasound anomalies (high a priori risk) and with no prior-known anomalies (low a priori risk).

RESULTS: At the original confidence cut-off, the test had a PPV of 18%, which increased to 42.3% upon reflex-sequencing of high-risk samples at a higher read depth (HDOR). Raising the algorithm's confidence level increased the PPV to 52.4% and reduced the false positive rate from 0.12% to 0.07%, with no loss in test sensitivity. The PPV was 100% for high a priori risk cases, and 20% for low a priori risk cases.

CONCLUSIONS: The updated methodology (raised confidence level + reflexing) eliminated 80% of the FP cases originally reported, yielding an improved PPV for this SNP-based NIPT (52.4% vs. 18%). Given the higher than previously-reported incidence of the 22q11.2 microdeletion and the benefits of early intervention, we expect this improved test to be highly beneficial in prenatal testing.

P01.003

5-methylcytosine and 5-hydroxymethylcytosine patterns in human spermatogenic cells

A. V. Tikhonov^{1,2}, O. A. Efimova^{1,2}, A. A. Pendina^{1,2}, I. D. Fedorova², S. E. Parfenyev¹, A. S. Koltsova^{1,2}, T. V. Kuznetsova^{1,2}, V. S. Baranov^{1,2};
¹Saint Petersburg State University, St.Petersburg, Russian Federation, ²D.O.Ott Research Institute of Obstetrics, Gynecology and Reproductology, St.Petersburg, Russian Federation.

We aimed to study 5-hydroxymethylcytosine (5hmC) and 5-methylcytosine (5mC) patterns in human spermatogenic cells. Samples were obtained by testicular biopsy of 15 patients diagnosed with azoospermia. Chromosome and nuclei preparations were made by "direct" technique using hypotonic (0.9% sodium citrate) and colchicines treatment and fixation with methanol:acetic acid, 3:1. Using indirect immunofluorescence, we have analyzed the localization of 5hmC and its co-distribution with 5mC in the nuclei and chromosomes from spermatogenic cells. To visualize nuclei and to identify chromosomes, we used QFH/ACD-staining. To determine nucleus ploidy, we used FISH with two centromeric DNA-probes.

5mC was detected in all nuclei from both diploid and haploid cells and in all chromosomes from both mitotic spermatogonia and meiotic spermatocytes. 5hmC showed a different pattern: it was present only in some nuclei and was totally absent in mitotic and meiotic chromosomes. By comparing hydroxymethylation and FISH patterns in 5000 nuclei from each sample, we established that 5hmC was present in 32-52% of diploid nuclei from spermatogonia and Sertoli cells. In contrast, among haploid nuclei from spermatids, only 0.6-1.9% was hydroxymethylated.

Thus, in contrast to 5mC, global 5hmC pattern changes during human spermatogenesis. The presence of 5hmC in a minor set of spermatids suggests active demethylation of their genome. The fate of these hydroxymethylated spermatids during spermiogenesis is to be elucidated in further studies. Supported by RFBR (16-34-00532_mol_a).

Application of a-CGH for preimplantation genetic testing (PGT) in young women and patients of advanced maternal age

O. A. Yacuts, J. V. Tsukerman, A. B. Zhabinskaya, A. V. Aliakseyeva, O. L. Tishkevich;
Centre of assisted reproduction «Embryo», Minsk, Belarus.

PGT was started in our center in 2012 with FISH diagnostics. In 2015 we began applying array comparative genomic hybridization (a-CGH) for preimplantation screening and diagnostics. Indications for PGT included: advanced maternal age (AMA) (>35), repeated implantation failure (>2), balanced chromosome rearrangements.

Materials and Methods: We conducted 14 cycles, IVF+ICSI. Patients were di-

vided into 2 cohorts: 1) young patients (<35) and 2) AMA (>35). Average age was 29,5 ±1,4 and 41,2±2,2, respectively. A-CGH (BlueGnome, Illumina) was used to detect whole chromosome aneuploidies. Trophoctoderm biopsy was performed on 5-6 day of embryo development. Blastocysts were vitrified and transferred in next cycle after PGT.

Results:

PGT was performed for 48 blastocysts and aneuploidy rates were 53,1% for young patients and 100% for AMA group. The reason for high aneuploidy rate in AMA group is age and small number of blastocysts. Complex chromosome abnormalities were more common in AMA group (Table 1). The most frequent aneuploidies were trisomies (37,5%) and monosomies (35,4%), Aneuploidies for X and Y chromosomes were detected in 8,3%.

	Young patients	AMA
Average number of blastocysts per cycle	4	2,7
Euploid blastocysts,%	46,9	0
Blastocysts with complex chromosome abnormalities,%	15,6	31,2
Failed amplification,%		4,2

Conclusion: In cohort of AMA the average number of blastocysts on day 5 and 6 was significantly lower than in patients of younger age. Complex chromosomal aberrations were double higher in this group.

P01.005

Male age is not related with high rates of spermatozoa and embryos aneuploidy

J. A. Ortiz¹, B. Lledo¹, R. Morales¹, A. M. Fabregat¹, E. Garcia-Hernandez¹, A. Rodriguez-Arnedo², J. Llacer², R. Bernabeu^{2,1};
¹IB Biotech, Alicante, Spain, ²Instituto Bernabeu, Alicante, Spain.

Introduction: The frequency of IVF embryo aneuploidies is estimated to be high and its occurrence is related to maternal and paternal factors. The main factor is female age, however paternal factor could play an important role, mainly in patients with abnormal seminal parameters and chromosomal segregation.

Materials and Methods: We performed a retrospective observational study (from January 2013 to December 2015). For PGSv2.0 trophoctoderm genome was amplified and aCGH performed using Agilent SurePrintG3 8x60K. The association between variables and male age was evaluated by logistic regression and chi-square (SPSSv20.0).

Results: The seminal parameters and sperm FISH from 428 patients (from 20 to 53 years old) were evaluated. 31% of the analysed patients had an abnormal sperm FISH. No significant differences were reported for male age and abnormal FISH (p=0.166), however patients older than 50y showed a tendency to higher sperm aneuploidies (50.0% vs 30.5%, p=0.081). To show the effect on embryo aneuploidy we analysed 155 blastocysts from 51 oocytes from donor cycles where the male partner had a normal sperm FISH in order to evaluate the effect of male age in embryo aneuploidies avoiding the confounding effect of female factor and the abnormal FISH. The embryo aneuploidy rate was 26%. In these cycles no significant difference was reported between male age and embryo aneuploidy rate (p=0.787) in oocyte donors.

Conclusions: Increased paternal age is not associated with sperm and embryos aneuploidies, therefore aging men do not have increased risk of producing chromosomally abnormal offspring.

P01.006

Novel mutations in the androgen receptor gene in four 46,XY females with complete androgen insensitivity syndrome

H. Ilgin-Ruhi¹, H. G. Karabulut¹, Z. Siklar², E. Gokpinar¹, M. Gokoglu¹, M. Berberoglu², A. Tukun¹;
¹Ankara University Medical Faculty, Department of Medical Genetics, Ankara, Turkey, ²Ankara University Medical Faculty, Department of Pediatric Endocrinology, Ankara, Turkey.

Androgen Insensitivity Syndrome (AIS) which is an X-linked disease, is one of the major cause of 46,XY disorders of sexual development (DSD). There is variable phenotypic expression of the disease, and therefore it is classified into complete (CAIS), partial (PAIS) and mild (MAIS) AIS. Female appearance is characteristic finding for a complete resistance to androgen in an affected person with a male karyotype. Here, we presented four cases with CAIS. Case 1 is a 28-year-old infertile woman. Cases 2, 3 and 4 were evaluated due to primary amenorrhea, 17, 16 and 15 years old, respectively. Patients' physical examination revealed an apparently normal female phenotype. Routine chromosomal analysis showed a 46,XY karyotype. All of them were SRY (+) by FISH and were negative for Y chromosome microdeletions. Clinical

and laboratory investigation confirmed the patients' diagnosis of CAIS. We performed DNA sequencing analysis of all eight exons and respective exon-intron boundaries of the AR gene. The four novel mutations detected in the AR gene were as follows: p.Y408* (c.1224T>A), p.Q68* (c.1314C>T) in exon 1 and p.D691E (c.2073C>A), p.G725R (c.3288G>C) in exon 4. To date, more than 1000 distinct mutations in the gene have been reported. We described two novel nonsense and two novel missense mutations. The identified mutations provides further evidence for the correlation between genotype and phenotype corresponding to AIS. This study adds the number of AR gene mutations identified so far.

The length of the CAG and GGN repeat stretches in the AR gene exert independent and combinatorial effects on reproductive hormones and sperm parameters

M. Grigороva¹, M. Punab², T. Kahre³, M. Ivandi², N. Tönisson³, O. Poolamets², V. Vihljajev², B. Žilaitienė⁴, J. Erenpreis⁵, V. Matulevičius⁶, M. Laan¹;

¹Institute of Molecular and Cell Biology, University of Tartu, Tartu, Estonia, ²Andrology Unit, Tartu University Hospital, Tartu, Estonia, ³Department of Genetics, United Laboratories, Tartu University Hospital, Tartu, Estonia, ⁴Lithuanian University of Health Sciences, Medical Academy, Institute of Endocrinology, Kaunas, Lithuania, ⁵Andrology Laboratory, Riga Stradins University, Riga, Latvia.

Introduction: Androgen receptor (AR) is a transcription factor regulating the expression of reproduction-related genes. We analysed independent and combinatorial effects of polymorphic CAG- and GGN-triplets within the AR transactivation domain on reproductive parameters in the Baltic young male cohort.

Materials and Methods: Baltic young male cohort (n=974, 20±2.1 yrs, sperm concentration 81.6±73.0 mln/mL); genotyping of CAG and GGN repeats by fragment analysis PCR; linear regression (CAG and GGN repeat lengths as continuous variables), CAG and GGN trichotomised as short, intermediate, and long (i.e., CAG≤21, 22≤CAG≤24, CAG≥25; GGN≤22, GGN=23, GGN≥24), and treated as categorical variables for Wilcoxon rank-sum and Kruskal-Wallis tests; tests for nine groups of the combinations of short (s), intermediate (i), and long (l) CAG and GGN repeats (i.e., ICAG-sGGN=long CAG-short GGN, etc.).

Results: The major findings of the study were: (1) Significant difference in serum FSH among the carriers of 'long-CAG' (≥24 repeats; median 2.51 IU/L) and 'short-CAG' variants (≤21 repeats, 2.92 IU/L; p=0.0007); (2) Independent associations of 'short-CAG' (71.6 mill/mL) and 'short-GGN' (68.4 mill/mL) stretches with the highest sperm concentration; (3) The lowest sperm concentration (<51.8 mill/mL) among men with the 'long-CAG' and 'long-GGN' combination; (4) A synergetic effect of 'long-CAG' and 'short-GGN' on reduced total testosterone (18.8-19.1 vrs 25.5-28.6 nmol/L for other variants).

Conclusions: Our results demonstrate for the first time that CAG and GGN repeats in the AR gene affect male reproductive parameters in a combinatorial way, and may have pharmacogenetic implications in modulating the outcome of hormonal therapy.

P01.008

Length of the androgen receptor CAG polymorphic repeat sequence is associated with ovarian response to Elonva-controlled ovarian hyperstimulation

M. Macek, Sr.¹, G. Griesinger², J. Chrudimska¹, T. Lerman³, T. Borgbo⁴, H. Kluckova¹, M. Macek Jr.¹, C. Y. Andersen⁴;

¹Department of Biology and Medical Genetics, Charles University, Prague, Czech Republic, ²Department of Obstetrics and Gynecology, Kinderwunschzentrum, Luebeck, Germany, ³Department of Obstetrics and Gynecology, Kinderwunschzentrum, Luebeck, Germany, ⁴Laboratory of Reproductive Biology, Rigshospitalet, Copenhagen, Denmark.

Introduction: Previously we have observed that "long" polymorphic CAG repeat sequence (henceforward CAG-RS; 23-26x) of the androgene receptor gene (AR) are associated with significantly decreased intrafollicular fluid testosterone levels, compared to "medium" (20-22x) and "short" (<20x) CAG-RS, as well as with higher conversion of testosterone into estradiol in small antral follicles (PMID: 26404660). The aim of this study was to assess the influence of the CAG-RS length on Elonva-controlled ovarian hyperstimulation (COH) in assisted reproduction.

Materials and Methods: The prevalence of the three categories of CAG-RS "length" was assessed in DNA samples from 48 "low", 191 "intermediate" and 34 "high" responders by Sanger sequencing.

Results: A significantly decreased prevalence of "short" CAG-RS was found

in 12.5% of low responders, compared to 30.0% and 32.3% in intermediate and high responders, respectively. High responders had significantly increased proportion of shorter CAG-RS and the difference of CAG-RS between alleles with low and higher CAG-RS repeats on both X chromosomes was significant (p<0.0001) between low and high responders. In addition, high responders with shorter CAG-RS were characterized by an association with FSH/receptor gene polymorphisms -29 A/G and p.Asn680Ser, i.e. by an integrated genotype: AG / AsnAsn.

Conclusion. Longer CAG-RS are linked to lower response to COH in association with other FSH-R,LH-R and LH polymorphisms, including other genes sensitive to the AR transactivation potential. Supported by 00064203, CZ.2.16/3.1.00/24022 and NF-CZ11-PDP-3-003-2014 to MM.

P01.009

A possible role of Androgen Receptor CAG/ GGN repeat polymorphisms in therapeutic response of infertile men with Hypogonadotropic Hypogonadism

A. Mohseni Meybodi¹, M. Sabbaghian², K. Farahmand¹, V. Firouzi¹, Z. Rokhsat Talab¹, H. Hosseinifar², M. Sadighi Gilani², H. Gourabi¹;

¹Department of Genetics, Reproductive Biomedicine Research Center, Royan Institute for reproductive Biomedicine, ACECR., Tehran, Iran, Islamic Republic of, ²Department of Andrology, Reproductive Biomedicine Research Center, Royan Institute for reproductive Biomedicine, ACECR., Tehran, Iran, Islamic Republic of.

Introduction: Male hypogonadism is a condition in which testicular function harms and decreased synthesis of sex hormones and incomplete sperm production occurs. Hypogonadotropic hypogonadism (HH) affects the hypothalamus and/or the pituitary gland, so secretion of gonadotropin releasing hormone (GnRH) is absent or insufficient. HH may also result from isolated lack of production or poor biosynthesis of pituitary gonadotropins. Accordingly, these patients required Gonadotropin treatment by means of administration of both FSH and β-HCG to have mature sperms in the ejaculate in order to reach fertility. Besides, testosterone is an androgenic hormone which contributes directly to maintaining and promoting spermatogenesis. Given that the actions of Testosterone are mediated by its interaction with Androgen Receptor (AR), the aim of this study was to evaluate the impact of CAG/ GGN three nucleotides repeats expansion in AR gene on the effectiveness of GnRH treatment.

Materials and Methods: Sixty-two HH subjects were subdivided according to their response to GnRH: 31 HH men had positive and 31 HH men had negative response to GnRH treatment. The numbers of CAG/ GGN in first exon of AR gene was analyzed using Hot Start PCR-Sequencing technique.

Results: The average of CAG repeats was statistically higher in patients who had positive response in comparison with patients who hadn't responded to GnRH (p<0.05), but the incidence of GGN repeats were not statistically different among these groups (p>0.05).

Conclusion: The results of this study suggest that in contrast to GGN, the length of AR gene CAG repeats polymorphism might affect the response to GnRH in HH men. Accordingly, it can be used as a predictive biomarker for response to GnRH in HH hormonal therapy.

Clinical implementation of a custom oligonucleotide array-CGH. Experience in a cohort of +2100 prenatal samples.

C. Hernando¹, O. Villa¹, N. Fornés¹, S. Cano¹, H. Mattlin¹, M. Garcia¹, L. Armengol¹, L. A. Pérez-Jurado²;

¹qGenomics Laboratory, Esplugues de Llobregat, Spain, ²Universitat Pompeu Fabra-Unitat de Genètica, Barcelona, Spain.

Introduction: The implementation of genomic array in prenatal diagnosis has demonstrated the ability of this technique to fulfil the longstanding need for a diagnostic test with a higher resolution and higher diagnostic yield than its predecessor, the conventional karyotype.

Materials and methods: Array CGH analysis was performed prospectively in +2100 prenatal samples with indication for invasive testing, using a custom 60k oligonucleotide-microarray (qChip CM), enriched in pericentromeric, subtelomeric and disease-associated genomic regions, in order to maximize the detection of clinically relevant copy-number alterations and minimize the detection of variants of unknown significance (VOUS). As a general rule, VOUS with no clear phenotypic effect (according to current knowledge) and some susceptibility variants were not reported.

Results: The genetic analysis of 2146 prenatal samples from different origins allowed us the identification of 151 pathogenic or probably pathogenic alterations (7.03%) and 57 VOUS (2.65%). As expected, the greatest pathogenic detection rate (71,52%, 108/151) was found in fetuses with ultrasound abnormalities. Regarding the VOUS detection, almost all of parental analysis (when available) were inherited from a non-affected parent

(88,46%, 23/26).

Conclusions: Our series demonstrates the utility of prenatal microarray testing, since it nearly doubles the diagnostic yield of conventional karyotyping (64/151 with CNVs <10Mb), without a significant increase in the frequency of VOUS. Based on this experience we highlight the importance of pre-test and post-test counselling of couples who are offered prenatal array analysis, and also to establish a fluid communication between the laboratory and the clinicians for the discussion of possible findings.

P01.011

Evaluation of the diagnostic performance of array CGH analysis in a large cohort of prenatal samples in a public health service

A. B. Lasierra, M. J. Alcaine, M. D. Miramar, A. Rodríguez, S. Izquierdo, J. I. González, D. Lerma;
Hospital Universitario Miguel Servet, Zaragoza, Spain.

Introduction: The application of array CGH (aCGH) in prenatal diagnostics enables the detection of submicroscopic copy number variants (CNVs) not detected by karyotyping that can be associated with clinically significant outcomes. However, its use in prenatal diagnosis is discussed and controversial yet. We report the yield of prenatal aCGH test in a public clinical setting. **Materials and Methods:** Since 2014, our Genetics Service included aCGH in prenatal genetic diagnosis routine, previous exclusion of common aneuploidy by QF-PCR/FISH and cytogenetic analysis performed concurrently on all samples tested. The criteria to realise aCGH was abnormal ultrasound scan findings (including NT>P99) in the first or second trimester with normal karyotype. A total of 1043 prenatal samples were analysed by conventional methods: 881 amniotic fluid (AF) and 162 chorionic villi samplings (CVS). aCGH was performed in 192 AF and 31 CVS using qChip Pre (60K).

Results: Conventional cytogenetics methods revealed chromosomal abnormalities (aneuploidy, translocations, mosaicism...) in 89/881(10.1%) LA and 44/162(27.2%) CVS. By aCGH, clinically significant CNVs were observed in 5/192(2.6%) AF and 2/31(6.5%) CVS and variants of unclear significance (VOUS) in 9/192(4.7%) AF and 3/31(9.7%) CVS.

Clinically significant CNVs					
Case	Age yrs	Weeks	Indication	aCGH	Parents study
1 AF	32	16	Incomplete AV canal, ostium primum atrial septal defect, hyperdense bowel	arr[hg18] 6q25.3q26(157,533,166-162,090,585)x1 dn	Karyotype and FISH aCGH dn

5 AF	17	26.2	NT>P99, pathological ductus venosus, megacystis, IUGR and cardiomegaly	arr[hg18] 20q13.1 2q13.2(42,759,013-49,503,589)x1 arr[hg18] 20q13.3 1q13.33(55,851,218-61,900,827)x3	Pending
6 CVS	18	13	NT>P99 and IUGR	arr[hg18] 7q32.2q33(129,098,029-132,492,196)x1 dn arr[hg18] 2q11.1q37.3(94,691,169-242,717,069)x2_3	aCGH dn MS-MLPA
7 CVS	36	13.1	Fetal death at 13 weeks	Mosaicism ~41.8%	Karyotype

Conclusions: The use of aCGH provides a 3.14%(7/223) incremental yield in prenatal cases with abnormal ultrasound scan findings and normal karyotype. However, the frequency of VOUS detected was superior, 5.4%(12/223), which complicates genetic counselling and increases parental anxiety providing doubts about pregnancy outcome.

Effects of partial AZFc microdeletions on micro TESE results in azoospermic infertile men

M. Zamanian¹, M. Seddighi Gilani², A. Miraghazdeh³, A. Ghaheri⁴;
¹Department of Genetics, Reproductive Biomedicine Research Center, Royan Institute for Reproductive Biomedicine, ACECR, Tehran, Iran, Islamic Republic of, ²Department of Andrology, Reproductive Biomedicine Research Center, Royan Institute for Reproductive Biomedicine, ACECR, Tehran, Iran, Islamic Republic of, ³Department of Molecular and Cellular Sciences, Faculty of Advanced Sciences & Technology, Science and research branch, Islamic Azad University, Islamic Azad Un., Tehran, Iran, Islamic Republic of, ⁴Department of Epidemiology and Reproductive Health, Reproductive Epidemiology Research Center, Royan Institute for Reproductive Biomedicine, ACECR, Tehran, Iran, Islamic Republic of.

Introduction: Microdeletions of Yq chromosome are the most frequent molecular genetic etiology for the male infertility which usually spans AZFa, AZFb and AZFc regions. Microdeletions are mostly seen in AZFc region and usually cover genes actively involved in spermatogenesis. Partial AZFc microdeletion may also happen with various spans namely gr/gr, b2/b3 and

b1/b3. It is known that the micro TESE outcomes as the surgical process for sperm retrieval from the testis in infertile azoospermic men can be predetermined based on the type of AZF microdeletion. Present study was aimed to evaluate the effect of partial AZFc microdeletions on micro TESE results. **Materials and Method:** 200 infertile azoospermic men referred to Royan institute were evaluated for the presence of partial AZFc microdeletions before they undergo micro TESE. Partial AZFc microdeletions were examined through multiplex PCR using seven different STS markers.

Results: Among 90 patients (45%) with positive micro TESE results 9 (10%) showed partial microdeletion in AZFc region. From 110 (55%) patients with negative micro TESE results 7 (6.3%) had AZC partial micro deletion.

Conclusion: Among 200 patients 16 (8%) showed AZFc partial microdeletions including 11 (5.5%) of gr/gr and 5 (2.5%) of b2/b3. Statistical analysis showed no significant difference on micro TESE results between the patients with and without partial AZFc microdeletions.

P01.013

Identification of Genetic Mutations Among Male Infertility Saudi Patients using Next Generation Sequencing panels

M. A. Al Balwi^{1,2}, A. AlAbdulrahman², M. Aldrees², A. Alasiri², M. Ballow², F. AlSalman¹, I. AlAbdulkareem²;
¹King Abdulaziz Medical City, Ministry of National Guard Health Affairs, Riyadh, Saudi Arabia, ²King Abdullah International Medical Research Center, Ministry of National Guard Health Affairs, Riyadh, Saudi Arabia.

Approximately half of male factor infertility cases have no known reasons in which genetic contribute up to 30% of Male infertility cases including chromosomal abnormality and chromosome Y microdeletion. Genetic expansion testing should be considered for men who exhibited non-obstructive spermatogenic failure such as azoospermia or oligospermia. Here, genetic study were conducted on 130 patients whom diagnosed with azoospermia or oligospermia and referred from IVF and Urology clinics at King Abdulaziz Medical City-Riyadh, Ministry of National Guard. Previously, we reported that about 21 patients (16%) of cases revealed presence of chromosomal abnormalities and 3 patients (2.3%) harboring male factor abnormality that associated with Y chromosome microdeletion(DDX3Y, DAZ1, DAZ2, DAZ3, USP9Y genes).

We designed infertility panel of 72 genes been reported or associated with male infertility using Next Generation Sequencing technology approach. Furthermore, about 81.5% (106 patients) of our cases still idiopathic were screened using this designed infertility panels. To date, there are little know or no molecular analysis studies of male infertility in Saudi Arabia. Using PGM next generation sequencing technology; We identify several novel mutations, SNPs and indels and their frequency among our patients. In this study, we correlated patient's clinical presentation with their mutations finding within the 72 male infertility genes.

P01.015

Severity of diseases in expanded carrier screening tests of commercial providers

L. Vidmar, M. Volk, B. Peterlin;
Clinical Institute of Medical Genetic, UMC Ljubljana, Slovenia, Ljubljana, Slovenia.

Introduction: As recently recommended by European Society of Human Genetics and American College of Medical Genetics, expanded genetic carrier screening (EGCS) should be focused on severe childhood diseases. The aim of our study was to evaluate and compare commercial providers of EGCS in regard to severity of diseases included in their panels.

Methods: We selected four providers and retrieved information on their disease panels from their websites on the 1st of February 2016. Disease severity was determined using a recently published algorithm.

Results: The analyzed panels included from 75 to 255 diseases, while only 29 diseases were screened by all four providers. Overall, providers screened for 303 diseases of which 35% (range:37-40%) classified as profound, 28% (range:29-38%) as severe, 31% (range:19-28%) as moderate and 6% (range:1-12%) as mild. The composition of panels regarding the severity of diseases differed significantly among the providers, mainly due to different frequencies of mild diseases (p=0.008). Nevertheless, it should be noted that the algorithm for disease classification had been designed based on medical professionals' opinions on disease severity, which might not necessarily reflect the lay public opinion.

Conclusions: Analyzed panels show great diversity in their composition and size. The majority (68-75%) of diseases included in the panels were classified as either profound or severe, while relative frequency of mild diseases differed significantly among the panels analyzed.

Noninvasive prenatal diagnosis experience in the Cukurova Region of Southern Turkey: detecting paternal mutations of sickle cell anemia and β -thalassemia in cell-free fetal DNA using high resolution melting analysis

E. Dündar Yenilmez, A. Tuli, C. Evrûke; Cukurova University, Adana, Turkey.

Introduction This study used a high-resolution melting (HRM) technique to detect paternal mutations for the noninvasive prenatal diagnosis (NIPD) of β -thalassemia and sickle cell anemia (HbS). We also determined the levels of cell-free fetal DNA and total cell-free DNA.

Materials and Methods We used the HRM technique for fetal genotyping of paternal mutations in maternal plasma from 32 pregnancies at risk of β -thalassemia and 57 pregnancies at risk of HbS. The DNA levels in maternal plasma were measured using real-time quantitative PCR. Multiples of the median (MoM) values were calculated in women at risk for β -thalassemia or HbS.

Results Twenty-two paternal mutations were detected in 89 pregnant women. Although we were successfully able to detect the paternal β -thalassemia mutations, the mutant HbS fetuses could not be distinguished from maternal background in the early weeks of pregnancy. The detection of DYS14 in male fetuses was 100%. The MoM values of women at high risk of having HbS-affected fetuses were higher than those for the other groups.

Conclusion High-resolution melting is a useful method for NIPD of β -thalassemias by detecting paternal mutations in the maternal plasma. Cell-free fetal DNA quantification and MoM values were not informative for HbS or β -thalassemias in early pregnancy.

Non-invasive prenatal testing for genome-wide detection of fetal copy number variants reveals aneuploidies in patients with repeated cell-free DNA testing failures

S. Bono, F. Fiorentino, F. Pizzuti, A. Polverari, S. Duca, M. Faieta, A. Nuccitelli, M. Sessa, M. Baldi, L. Diano, F. Spinella; GENOMA GROUP, Rome, Italy.

A potential issue with the use of cell-free fetal DNA (cfDNA) testing as a universal method of screening for aneuploidies, is the possibility of failure to provide a result. This is relevant to comparisons with conventional screening, which rarely reports test failures.

Data from pregnant women with repeated quality control (QC) failures (i.e., final analysis metrics do not meet internal QC standards) were retrospectively analysed using bioinformatics methods enabling genome-wide detection of chromosomal copy number variations, in order to ascertain if such failures are caused by biological factors.

Of the 11,584 samples analysed, 12 (0.1%) did not returned a result because of a quality metrics failure. In 9 of these samples a single trisomy (T) was identified, whereas the remaining 3 samples showed a double trisomy, one of which involving chromosome 21 (T2+T21). Pregnancy follow-up at birth revealed five chromosomal abnormalities that have been overlooked: three cases of fetal mosaicism, one case of UPD15, and one case of T21. All the other pregnancies resulted in a normal karyotype, suggesting confined placental mosaicism occurrences. A retrospective analysis of the 11,572 pregnancies with a normal result for common aneuploidies revealed further 22 (0.2%) samples with a single trisomy.

These results demonstrate that aneuploidies other than T21, T18, T13 and sex chromosome aneuploidies, might represent a biological cause of repeated QC failures. cfDNA testing for genome-wide detection of fetal chromosomal abnormalities has demonstrated a useful tool to reduce the incidence of test failures and to improve prenatal management, obtaining comprehensive information about the genetic makeup of the fetus.

P01.018

Clinical validation of a non-invasive prenatal test for genome-wide detection of fetal chromosomal abnormalities

F. Fiorentino, S. Bono, F. Pizzuti, A. Polverari, S. Duca, A. Nuccitelli, M. Sessa, M. Baldi, L. Diano, F. Spinella; Genoma Group, ROME, Italy.

Current non-invasive prenatal testing (NIPT) approaches, based on analysis of cell-free fetal DNA (cfDNA), involve screening only for common fetal aneuploidies. Such level of screening allows identification of ~83% of chromosomal abnormalities detected by karyotyping in a general screening population.

Hence, a significant proportion (~17%) of fetal chromosomal abnormalities are not detectable by current cfDNA testing methods. To overcome these limitations, NIPT should be extended to cover the entire genome.

Here we present the results of the clinical validation of a novel NIPT designed to detect genome-wide fetal chromosomal abnormalities. A large blinded clinical study was performed, including cfDNA testing of maternal plasma, collected from pregnant women at increased risk for fetal chromosomal abnormalities undergoing invasive prenatal diagnosis. Performance was assessed by comparing test results with findings from G-band karyotyping and/or microarray analysis.

Among 1419 samples analyzed, there were 100 trisomy (T)21 samples, 31 T18 samples, 14 T13 samples, 36 samples with sex chromosome aneuploidies (SCAs) and 37 samples that had positive results for a variety of CNV aberrations, including both sub-chromosomal copy number variants (CNVs) and whole chromosome trisomies. All euploid and chromosomally abnormal samples were classified correctly by NIPT. Clinical sensitivity and specificity within this study was determined to be 100% for T21, T18, T13, SCAs and genome-wide CNVs.

This study has demonstrated that genome-wide non-invasive chromosomal assessment can provide sensitive and specific detection of common and other aneuploidies, as well as a wide range of sub-chromosomal abnormalities, analogous to what can be detected by cytogenetic G-band karyotyping following invasive prenatal diagnosis.

P01.019

Clinical validation of the NeoBona test, a new paired-end MPSS approach for cfDNA based prenatal screening of common chromosome aneuploidies

V. Cirigliano, E. Ordoñez, L. Rueda, M. Grau, I. Castilla, M. P. Cañadas; Labco Diagnostics, Barcelona, Spain.

Objective: To assess the performance of the NeoBona test, based on a novel paired-end massive parallel shotgun sequencing (MPSS) approach for prenatal aneuploidy screening using cell-free DNA (cfDNA) analysis in maternal blood.

Methods: Retrospective study of 1730 plasma samples collected in the 1st trimester (11-13 weeks) including 66 confirmed trisomies 21, 34 trisomies 18, 13 trisomies 13 and 8 sex chromosome aneuploidies. The NeoBona test was carried out blindly on 1 ml of plasma using paired-end MPSS and a novel bioinformatics approach generating a unique trisomy score for each chromosome, based on fetal fraction, counting statistics, size distribution and sequencing depth.

Results: The NeoBona test provided valid results in 98,9% of cases. All trisomies 21 and 13 were detected (100% sensitivity and specificity) as also 33/34 trisomies 18. All 5 cases of 45,X and 3 with 47,XXY were also correctly identified without false positive results. Normal and aneuploid samples could be correctly scored even at low fetal fractions, in some cases below 1%.

Conclusions: Paired-end MPSS allowed simultaneous assessment of fetal fraction, size distribution and chromosome counting which, integrated into a new analysis algorithm allowed the NeoBona test to be successful on a high proportion of samples. Setting analysis cutoffs at the new multifactorial Tscore as evaluated in the course of this study, resulted in high specificity, while also eliminating the need of a lower limit for FF at 4%, thus potentially extending the benefits of cfDNA analysis to a larger proportion of pregnancies.

P01.020

Development of a high throughput workflow for genotyping CFTR mutations

T. Hartshorne, J. Lang, E. Swartzman, P. Brzoska, D. de Castro, G. Chow, L. Tracy; Thermo Fisher Scientific, South San Francisco, CA, United States.

Cystic fibrosis (CF) is an autosomal recessive genetic disease caused by mutations in the cystic fibrosis transmembrane conductance regulator (CFTR) gene. CF is the most common genetic disease of Caucasians, affecting 1 in 3000 newborns. To facilitate CFTR genotype analysis, we developed a panel of 200 TaqMan™ SNP Genotyping Assays to specific CF-causing mutations and a high throughput CFTR genotyping workflow. CFTR mutations were selected for TaqMan™ assay development from the CFTR1 and CFTR2 databases based on population frequency and predicted functional activity. Mutations include single nucleotide polymorphisms, small insertion deletions, large deletions, repetitive sequences, and triallelic polymorphisms. The diverse nature of the mutations presented challenges to developing assays that used a single chemistry and that could be run together on one platform. TaqMan SNP assays were initially tested on both 384-well and OpenArray™ (3072-well) plates, run on a real-time PCR system, with Coriell cell line gDNA samples carrying CFTR mutations. As CFTR mutations are

rare and control gDNAs are not always available, assays were also tested with synthetic DNA controls representing all three genotypes per variant to ensure robust allelic discrimination. Any assays that underperformed were redesigned to produce sufficiently robust assays. CFTR assays were additionally tested with DNA isolated from blood and buccal cell samples, and assay accuracy and concordance studies were performed. We present here our development of a complete sample-to-data analysis workflow for high throughput CFTR mutation detection, and provide example assay data and analysis methods for difficult targets such as the 5T/7T/9T polymorphism.

P01.021

Implementation of NGS methodology in prenatal testing of Cystic Fibrosis: a diagnostic tool upgrading the quality of genetic services.

V. Papanikolaou¹, V. Maroulis¹, E. Darmanis², M. Vergi², V. Georgiou³, M. Papadakis¹; ¹EUROGENETICA SA, Athens, Greece, ²EUROGENETICA SA, Thessaloniki, Greece, ³Woman's Health, Athens, Greece.

Introduction: Cystic fibrosis (CF) is a life-threatening genetic disorder associated with mutations within the CFTR [cystic fibrosis transmembrane conductance regulator (ATP-binding cassette sub-family C, member 7)] gene. Although >90% of CFTR mutations have already been identified, the severity of the disease, the absence of an effective treatment, and the great heterogeneity of mutations, raise the need for a more effective molecular characterization of CF mutations, especially in prenatal diagnosis.

Materials and Methods: We validated this approach in a cohort of 298 samples, the majority of participants were pregnant women or couples during screening. Sampling is ongoing. Genomic DNA was amplified using the Ion AmpliSeq™ CFTR panel. DNA libraries were pooled, barcoded, and sequenced using an Ion Torrent PGM sequencer.

Results: The NGS method helped identifying among known mutations and polymorphisms, 54 rare variants, each found in just 1/298 samples. Among them, 27 are known as pathogenic or causing mild symptoms or CBAVD and 8 are known to be non-pathogenic. We identified 19 new variants, not included in the known CF mutation databases. These variants, of unknown clinical significance include c.164+18G>A, c.164+1457 delT, p.Leu541Pro, p.Tyr577Cys, p.Glu826Lys, p.Asp836Tyr, p.Val1212Phe, p.Gln1476Glu, c.*325A>G.

Conclusions: The next-generation sequencing technology, fast and cost-effective, applied to the analysis of the CFTR gene on a larger scale of samples should allow a better identification of unknown variants and should be proven a useful tool for the update of the existing mutation databases and the improvement of genetic counseling.

P01.022

CGH-array and karyotyping analysis. Comparison in selected cases of prenatal diagnosis.

M. Costa¹, M. Aviles², S. Arévalo³, L. Espi¹, L. Trobo¹, E. Garcia-Arumi^{1,4}, C. Mediano¹;

¹Department of Clinical and Molecular Genetics and rare Disease Unit. Hospital Vall d'Hebron, Barcelona, Spain, ²Unitat Diagnòstic Prenatal. Hospital Vall d'Hebron, Barcelona, Spain, ³Unitat de Medicina Fetal. Hospital Vall d'Hebron, Barcelona, Spain, ⁴CIBERER. Hospital Vall d'Hebron, Barcelona, Spain.

CGH-array has had a major impact on genetic diagnosis over the last years. Comparing with conventional karyotyping, CGH-array offers higher resolution and faster results, which makes it the first approach for most of postnatal cases as well as selected prenatal diagnosis referral indications. However, conventional karyotyping should still be considered as a valuable tool to confirm a number of CGH-array pathological results or to elucidate the ethiological origin of some pathological findings for accurate genetic assessment.

Our Service in a public tertiary Hospital routinely offers QF-PCR and karyotype to all prenatal invasive tests. From 2012 onward, CGH-array has been progressively introduced to selected cases, such as fetal ultrasound abnormalities and genetic family history.

A total of 534 CGH-array prenatal cases were performed including amniocentesis (n=443) and chorionic (n=91) samples employing a 60 K custom oligonucleotide-based CGH-array (qChip Pre v1.1 Complete), that allows a resolution of 100-125 Kb in regions causing genomic disorders. Results were obtained at an average time of 7 days.

Pathologic results were detected in 40 cases (7.5%) 19 of which (47.5%) were confirmed by karyotype. Three different categories of cytogenetic ascertained abnormalities were defined: those that were surely detected by karyotype (n=10), those that were detected due to the CGH-array pathologic result (n=8) that included unexpected possible inherited translocations, and rare findings (n=1) that was defined as a ring of chromosome 15.

We conclude that although CGH-array is an increasing, powerful analysis for prenatal diagnosis procedures, conventional karyotyping is still useful to ascertain specific chromosomal rearrangements.

P01.023

Counseling for variants of uncertain significance (VOUS) in the setting of prenatal diagnosis

A. Bar-Shira¹, D. Brabbing-Goldstein², I. Kaplan-Ber¹, D. Barel¹, H. Kolog¹, T. Naiman¹, S. Simchoni¹, A. Orr-Urtreger^{1,3}, Y. Yaron^{1,3}, A. Reches^{1,2};

¹Genetic Institute, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, ²Lis Maternity Hospital, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, ³Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel.

Introduction: The increased sensitivity of chromosomal microarray (CMA) technology allows for improved detection of genomic alterations. Consequently CMA is now recommended as a first-tier test for evaluating multiple anomalies in the fetus. This technology has been embraced by low risk pregnant women in order to gain as much information about their fetus as possible. While there is an expected increase in the detection yield, there is also an increased risk of detecting VOUS.

Objectives: We describe our results within the unique setting of prenatal counseling, often complicated by the unknown phenotype and the paucity of information available.

Results: A total of 750 prenatal samples were processed using CMA. The indications for prenatal testing included: maternal age, abnormal ultrasound findings, family history and parental request. Clinical implication of detected CNV's was determined based on local guidelines and those described in the literature. Of samples tested, 32 (4%) were pathogenic variants, 6 (0.8%) were designated as likely pathogenic, and 55 (7.3%) were designated as VOUSs. Parental testing was done in some cases to determine whether the finding was inherited or *de novo*. All results were discussed in genetic counseling.

Conclusion: Physicians and patients alike crave certainty. However, CMA testing often lead to the detection of VOUS, which may be associated with a variable phenotype, reduced expressivity and incomplete penetrance. In such cases, expectant parents are often confused and perplexed. In our experience, proper genetic counseling may alleviate parental anxiety and avoid undue termination of a clinically unaffected fetus.

P01.024

Increased chromosome 16 disomy rates in human spermatozoa and recurrent spontaneous abortions

M. Neusser¹, N. Rogenhofer², S. Dürfl¹, R. Ochsenkühn³, M. Trottmann⁴, V. Jurinovic⁵, O. Steinlein¹, V. von Schönfeldt², C. J. Thaler², S. Müller¹;

¹Institute of Human Genetics, University Hospital, Ludwig-Maximilians-University, Munich, Germany, ²Division of Gynecological Endocrinology and Reproductive Medicine, Department of Obstetrics and Gynecology, Ludwig-Maximilians-University, Munich, Germany, ³Center for Reproductive Medicine, Munich, Germany, ⁴Department of Urology, Ludwig-Maximilians-University, Munich, Germany, ⁵Institute for Medical Informatics, Biometry and Epidemiology, Ludwig-Maximilians-University, Munich, Germany.

Introduction: Fetal aneuploidy caused by maternal meiotic chromosome segregation errors is an established cause of pregnancy loss. We investigated whether unexplained recurrent spontaneous abortions (RSA) are also associated with increased rates of aneuploidy in spermatozoa of RSA-partners ("RSA males").

Materials and Methods: Sperm samples of eleven "RSA males" were evaluated for elevated diploidy and disomy levels of chromosomes 1-22, X and Y by multicolour "sperm-FISH".

Results: Compared with base-line aneuploidy rates in healthy males, significantly elevated mean disomy rates (p<0.05) were observed for chromosomes 1, 2 and 16, while chromosomes 3, 7, 8, 14, 17 and X were inconspicuous in all eleven patients. We observed increased disomy rates for at least three chromosomes in more than 60% of our patients, but no significant increase of the overall mean sperm disomy or diploidy rate. Importantly, meiotic errors involving chromosome 16 contributed to increased sperm disomy in 7/11 of our patients.

Conclusions: The high relative contribution of maternal disomy 16 to aneuploidy related fetal loss is well established. Our data suggest that among paternal meiotic errors nondisjunction of chromosome 16 might have similar relative influence on fetal aneuploidy. Our findings argue against using the "standard clinical FISH probe set" 13/18/21/X/Y in "RSA males", because aneuploidy of chromosome 1, 2, and 16, and probably also 6, 15 and 21 appear to be prevalent in spermatozoa from this particular group of patients, and chromosome 16 appears to be the most promising biomarker for diagnostic and prognostic objects in RSA patients.

P01.025

De novo mutations in autosomal recessive congenital malformation

H. A. Black¹, D. Parry¹, S. S. Atanur¹, D. Ross¹, E. Rose¹, H. Russell², S. Stock³, J. Warner⁴, M. Porteous⁴, T. Aitman⁵, M. J. Evans⁵;

¹Centre for Genomic and Experimental Medicine, Institute of Genetics and Molecular Medicine, University of Edinburgh, Edinburgh, United Kingdom, ²NHS Fife Fetal Medicine Unit, Victoria Hospital, Kirkcaldy, United Kingdom, ³Tommy's Centre for Maternal and Fetal Health, MRC University of Edinburgh Centre for Reproductive Health, Edinburgh, United Kingdom, ⁴South East of Scotland Clinical Genetics Service, Western General Hospital, Edinburgh, United Kingdom, ⁵Department of Pathology, NHS Lothian, Edinburgh, United Kingdom.

Rare developmental disorders are genetically heterogeneous. Genetic testing following a termination of pregnancy, on account of congenital abnormalities, often fails to make a molecular diagnosis. In such circumstances, the recurrence risk for future pregnancies is based on the phenotype alone. For a suspected autosomal recessive syndrome, the risk to future pregnancies would be reported as 25%, assuming inheritance of one causative allele from each parent. We report here results from trio-based exome sequencing of two unrelated fetuses, each with a suspected recessively-inherited developmental disorder, within a larger series of nine trios. In both fetuses, a combination of a *de novo* loss of function mutation on one parental haplotype and an inherited loss of function variant on the other parental haplotype were identified, respectively, as the cause of the recessively-inherited developmental disorders, Ellis-van Creveld and Fraser syndromes. *De novo* mutation has only rarely been reported as a contributory cause of recessive disease, but it markedly reduces the recurrence risk for future pregnancies. Our results suggest that causative *de novo* mutations may contribute to the cause of autosomal recessive disease more frequently than has been considered hitherto.

P01.026

RYR1 related congenital myopathy in two sib fetuses conceived through artificial insemination with donor sperm (AID)

M. Romagnoli, E. Pompili, F. Palombo, E. Bonora, M. Seri; Medical Genetics Unit, Policlinico S. Orsola-Malpighi, University of Bologna, Bologna, Italy.

RYR1-related congenital myopathies present clinical, histological, and genetic heterogeneity: a subset of patients has an antenatal onset form of the disorder, characterized during pregnancy by decreased fetal movements, polyhydramnios and arthrogryposis.

We present a case of two sib fetuses, affected by antenatal onset myopathy, conceived through artificial insemination with donor sperm. The first sib presented a NT of 7,76 mm at combined first trimester screening test. At 12+0 gestational week, ultrasound examination revealed large nuchal septated cystic hygromas, mild ascitic effusion, absent fetal movements, contracted limbs and club feet. No cardiac or encephalic malformations were detected and biometric parameters were normal. The pregnancy was terminated. Karyotype formula was 46,XY. Testing for myotonic dystrophy (DM1) was negative.

In the second pregnancy, conceived by the same biological parents, first trimester ultrasound examination demonstrated comparable clinical features (cystic hygromas, absent fetal movements and contracted limbs) and the pregnancy was terminated. Karyotype formula was 46,XX. Exome sequencing performed on the second fetus revealed a compound heterozygosity for two novel mutations in RYR1: a frameshift mutation (g.38951153CG>C) and a splice acceptor site mutation (g.39019237G>A). Sanger sequencing confirmed these mutations and the healthy mother resulted heterozygous carrier of g.39019237G>A. Both variants are predicted to be pathogenic and clinical findings are suggestive of a RYR1-related congenital myopathy. However, co-segregation studies in the first fetus are needed.

This clinical case confirms the great diagnostic power of whole exome sequencing in autosomal recessive disorders and exemplifies the hard challenge of gamete donors' selection process related to ultra-rare diseases.

P01.027

Estimation of frequencies of 20 known recurrent pathogenic CNVs in prenatal and postnatal settings

I. Maya¹, L. Basel-Vanagaite^{2,3}, M. Shohat⁴, J. Jeshaya⁴, S. Kahana¹, T. Tene⁵, L. Cohen Vig⁶, S. Jakobson¹, I. Fishman¹;

¹Raphael Recanati Genetics Institute, Rabin Medical Center, Beilinson Campus, Petah Tikva, Israel, ²The Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel, ³Felsenstein Medical Research Center, Rabin Medical Center, Petah Tikva, Israel, ⁴The Sackler Faculty of Medicine, Tel Aviv University, tEL aVIV, Israel, ⁵Genetics Institute, Meir Medical Center, Kfar-Saba, Israel, ⁶Schneider Children's Medical Center of Israel, Petah Tikva, Israel.

Background: Chromosomal microarray (CMA) testing is widely used in prenatal and postnatal setting. Penetrance of many copy-number variants (CNVs) is incomplete; this poses challenges for genetic counseling. The purpose of our study was to compare the prevalence of 20 known recurrent pathogenic CNVs in prenatal and postnatal cohort.

Methods: During 2010-2016 our clinical hospital-based laboratory performed 8500 tests on index low-risk prenatal samples (3600), fetuses with congenital malformations (2750) and postnatal samples (2150). Recurrent pathogenic CNVs were classified as high-penetrance (>40%; 8 CNVs), moderate-penetrance (10-40%; 8 CNVs) and low-penetrance (<10%; 4 CNVs). We calculated the prevalence of these CNVs in: I) normal fetuses, II) fetuses with malformations, III) individuals with developmental disabilities/congenital malformations.

Results: CNVs were detected in 2% of prenatal samples (139/6350) and 6% (125/2150) of postnatal samples. Prevalence of high-penetrance CNVs was 0.3% in group I, 0.6% in group II and 2.4% in group III and of moderate-penetrance CNVs 0.5% in group I and II and 1.2% in group III. Prevalence of low-penetrance CNVs was similar in all groups - e.g for 15q11 microdeletion (NIPA1) it was 0.7% in all groups.

Conclusions: We show that the prevalence of low-penetrance CNVs is similar in low-risk prenatal and in postnatal cohort, pointing that these CNVs may have a minor contribution to the overall heritability of developmental disorders. Information on prevalence for different pathogenic CNVs, especially as it pertains to diagnostic yield in genetic testing, should be useful to clinicians considering chromosomal microarray analysis in fetuses with and without structural anomalies

P01.029

Offspring of a male 45,XY,der(22;22)(q10;q10) carrier

F. van Erp;

Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.

Introduction: In about 5% of the couples with multiple miscarriages a balanced chromosomal aberrations in one of the partners is detected.

Case: In our case, father is carrier of a der(22;22)(q10;q10) and as such can produce gametes with either two chromosomes 22 or none, both leading to a miscarriage due to a trisomy or a monosomy 22, respectively. The couple had had two miscarriages, however, they also had a healthy son who showed a 46,XY karyotype. This might indicate UPD22mat or the presence of a normal 46,XY cell line in the gametes of our patient. Results: Paternity testing confirmed that our patient indeed was the father. To look for a mosaicism with a normal cell line, karyotyping of a skin biopsy was performed and showed also in all cells a der(22;22). In buccal cells no normal cell line was found either, .

The question is whether the children have a maternal UPD22. In literature 4 cases have been described of a UPD22, all as a result of a trisomy rescue mechanism and never a monosomy rescue. No cases of multiple children with UPD22 in one family have been reported as yet.

Conclusion: Normally we tell carriers of a der(22;22)(q10;q10) that they can not have biological children. Our case show that this isn't always true.

Two explanations therefore could be: there is a normal cell line present in the gametes of the father leading to normal sperm cells, or the healthy children have a maternal UPD22. These studies are ongoing.

Discordant genotypic sex and concordant phenotypes in two Spanish siblings with 17α-hydroxylase/17,20-lyase deficiency carrying the most prevalent mutated alleles in Brazilian patients

M. Fernández-Cancio¹, L. Audí², E. García-García², I. J. Arnhold³, B. B. Mendonça³, E. García-Arumí⁴, E. F. Tizzano⁴, A. Carrascosa¹;

¹Paediatric Endocrinology Unit, Vall d'Hebron Research Institute and Hospital, CIBERER, Autonomous University, Barcelona, Spain, ²Paediatric Service, Hospital Virgen del Rocío, Sevilla, Spain, ³Division of Endocrinology, Hospital das Clinicas of the University of Sao Paulo, Sao Paulo, Brazil, ⁴Department of Clinical and Molecular Genetics and Rare Disease Unit, Hospital Vall d'Hebron and CIBERER, Barcelona, Spain.

Introduction: 17α-hydroxylase/17,20-lyase deficiency is a rare form of congenital adrenal hyperplasia caused by mutations in *CYP17A1*, characterized by reduction of androgens, estrogens and cortisol production and mineralocorticoid excess.

Patients and Methods: Two sisters, phenotypic females, aged 17 and 15, the oldest with 46,XY and the youngest with 46,XX karyotypes, presented with primary amenorrhea and absent secondary sexual characteristics; the eldest presented elevated blood pressure. Both had elevated levels of ACTH, gonadotropins, progesterone, corticosterone and deoxycorticosterone, and reduced estradiol, testosterone, androstendione, 17-OH-P, DHEA-S, cortisol, aldosterone and renin activity. Sanger sequencing was performed to detect

variants/mutations in *CYP17A1* gene.

Results: Mutational analysis showed that the two sisters were compound heterozygotes for p.Arg362Cys and Trp406Arg mutations, previously described as the most prevalent mutations in Brazilian families of Spanish (p.Trp406Arg) or Portuguese (p.Arg362Cys) descent. The present siblings were born from parents with origins near Sevilla (Spain). The analysis of 8 polymorphisms in *CYP17A1* in this family and in two Brazilian families, homozygote for each of the mutations, suggested that paternal allele with p.Arg362Cys may have a common origin with the Brazilian carriers while the maternal allele p.Trp406Arg did not.

The clinical and biochemical phenotypes agree with a complete lack of combined 17 α -hydroxylase/17,20-lyase activities. Estrogen therapy and hydrocortisone were given in both cases and gonadectomy was performed in the oldest.

Conclusions: Mutations in *CYP17A1* should be investigated in patients with mineralocorticoid excess and deficiency of cortisol, androgens and estrogens. Regardless of genotypic sex, patients with combined 17 α -hydroxylase/17,20-lyase deficiency are treated with glucocorticoids and estradiol.

Introduction: DNA methylation has been shown to influence tissue specific gene expression and differentiation. Taking advantage of tissue-specific methylation patterns, several groups focused their work on the identification of fetal-specific markers based on the methylation differences between maternal and fetal DNA for the development of non-invasive prenatal testing (NIPT) for fetal aneuploidies.

Materials and Methods: Initially, MeDIP-NGS was applied to characterize DNA methylation differences between 3 chorionic villus samples (CVS), 3 female peripheral blood (WBF) samples and 2 plasma samples. A subset of differentially methylated regions (DMRs) was confirmed using MeDIP in combination with a targeted enrichment method followed by NGS. Furthermore, the inter-individual methylation variability of the selected DMRs was investigated and the classification efficiency of the method was verified using normal and trisomy-21 spike-in samples. Finally, normal and aneuploid pregnancies (n=32) were used for the detection of fetal aneuploidies (26 normal, 4 T21, 1 T18, 1 T13).

Results: Initially, based on specific selection-criteria 331 hypermethylated fetal-specific DMRs were selected and confirmed in 24 samples (p<2x10⁻¹⁶). Twenty-nine CVS and twenty-eight plasma samples were used to assess inter-individual methylation variability. Trisomy-21 spike-in samples were detected with the z-scores increasing as spiked-in percentage increased. Finally, this method exhibited 100% sensitivity and specificity for all normal, trisomy-21 and trisomy-18 cases. The trisomy-13 case was marginally below threshold.

Conclusions: Results show that this approach can potentially be used for the enrichment of fetal DNA in maternal plasma and the development of a novel NIPT method for fetal aneuploidies.

Genetical study of patients with DSD from Ukraine

L. Livshits¹, S. Chernushyn¹, S. Kravchenko¹, G. Livshyts¹, V. Pampukha¹, L. Tavokina², A. Brovko²;

¹Institute of Molecular Biology and Genetics, Kiev, Ukraine, ²ISIDA-IVF, Kiev, Ukraine.

Disorders of sexual development (DSD) are a very important clinical issue with its different aspects relating to diagnosis, treatment and sex of rearing. The classification of ambiguous genitalia in patients is difficult because similar or identical phenotypes may have several aetiologies. In one of every 4500 births, the genital appearance is abnormal and it is not possible to decide at first glance the sex of the infant. To study the genetical aspects of DSD we have collected a cohort of 37 patients with different DSD phenotypes. Using GTG-banded chromosome analysis we identified 4 46,XX males and 32 46,XY females. The karyotype of one male was 45,X+mar. After PCR and FISH analysis of SRY gene location there of four 46,XX males were determined as SRY-positive with Xp;Yp translocations and two 46,XY females were SRY-negative. Rest of 46,XY female results of Sanger sequencing revealed that SRY gene was intact. rs279895, rs376062302, rs531364677, rs200423545

were determined in DMRT1 gene and rs915034 in NR5A1 gene. Exon analysis of one 46,XX SRY-negative male and two 46,XY SRY-positive females are in progress. The project "Genetics of Human Disorders of Sexual Development" is funded by Swiss National Science Foundation.

Ten-year trends in prevalence of Down syndrome in a developing country: impact of the maternal age and prenatal screening

A. Kurtovic-Kozaric¹, L. Mehinovic¹, R. Malesevic², S. Mesanovic³, M. Stomornjak-Vukadin¹, M. Mackic-Djurovic⁴, M. Peric³, I. Kurtovic-Basic¹, M. Kozaric¹;

¹Clinical Center of the University of Sarajevo, Sarajevo, Bosnia and Herzegovina, ²University Clinical Center Banja Luka, Banja Luka, Bosnia and Herzegovina, ³University Clinical Center Tuzla, Tuzla, Bosnia and Herzegovina, ⁴Medical Faculty, University of Sarajevo, Sarajevo, Bosnia and Herzegovina.

This study examines trends in total and live birth prevalence of trisomy 21 with regard to increasing maternal age and the introduction of prenatal diagnosis in Bosnia and Herzegovina. The postnatal detection of trisomy 21 has been available since 2005 and prenatal detection since 2008. All centers that diagnose DS prenatally and postnatally in the period from January 01, 2005 to December 31, 2015 were included. In this study, 93 fetuses and 329 babies were diagnosed in the 10-year period. On average, each year 33 DS individuals were born and 13 DS fetuses were diagnosed prenatally. The calculated incidence for the live born DS individuals in Bosnia and Herzegovina is 1:999. Between 2005 and 2015, the LB prevalence of T21 was 9.6 per 10000 births (range 6.3-12.3) and the total prevalence of T21 was 19.1 per 10000 births (range 10.8-25.0). The T21 prevalence per 10000 births increases exponentially with the advanced maternal age. Prenatal prevalence per 10000 births is ~1 for mothers younger than 35, but increases exponentially with advanced maternal age (32 for mothers older than 40 years). The most common indications for invasive prenatal testing were obstetric ultrasound screening combined with biochemical serum analysis followed by the advanced maternal age. There was an increase in total T21 prevalence, mainly explained by increasing maternal age. Live birth prevalence remained stable over time even after the introduction of prenatal diagnosis.

P01.034

Differentially expressed miRNAs between normal and trisomy-21 placenta - their potential involvement in Down syndrome pregnancy pathologies

I. Svobodová¹, P. Calda², M. Brestak³, M. Korabecna¹, E. Pazourkova¹, S. Pospisilova¹, M. Krkavcova⁴, M. Novotna², A. Horinek¹;

¹General faculty hospital in Prague, Prague 2, Czech Republic, ²Department of Obstetrics and Gynecology of the First Faculty of Medicine, Charles University and General University Hospital in Prague, Prague 2, Czech Republic, ³Screening center of Prague, Prague, Czech Republic, ⁴GENVIA genetic laboratories, Prague, Czech Republic.

Background: The Down syndrome (DS) etiology is still unknown. However, all data suggest that the mechanism is more complex than previously supposed. Epigenetic mechanisms, including miRNAs gene expression regulation, are one of potential influencing factors. The aim of this study was to compare miRNAs expressions in placentas with normal and trisomic karyotype and to associate differentially expressed miRNAs with concrete biological pathways.

Materials and Methods: In the pilot study, 754 miRNAs were profiled in 30 chorionic villi samples (CVS) - 14 normal and 16 DS, using real-time PCR technology and TaqMan Human miRNA Array Cards A and B. Twelve differentially expressed miRNAs between compared groups of samples were validated on 50 independent samples (25 normal and 25 DS) using TaqMan miRNA Assays. The Mann-Whitney test with a cutoff p-value < 0.05 was used for results evaluation. Functional annotation and diseases association of selected miRNAs were performed using several web-based software tools (miRWalk, DAVID, WebGestalt).

Results: Eight miRNAs were verified as upregulated in DS placentas; three of these miRNAs are located on chromosome 21 (miR-99a, miR-125b and let-7c). Many biological pathways associated with DS complications, as neurodegenerative diseases, leukemia, transcriptional regulation or apoptosis, were identified to be potentially disrupted. Moreover, miRNAs overexpressed in DS placenta apparently regulates genes crucial for placenta development (GJA1, CDH11, EGF, ERVW-1, ERVFRD-1, LEP or INHA).

Conclusion: Our findings suggest possible participation of miRNAs in etiology of Down syndrome including DS placenta ectopic development.

Polygenic profiles for predicting risk of early menopause

T. Laisk-Podar^{1,2}, A. Salumets^{1,2}, R. Mägi³;

¹Women's Clinic, University of Tartu, Tartu, Estonia, ²Competence Centre on Health Technologies, Tartu, Estonia, ³Estonian Genome Center, University of Tartu, Tartu, Estonia.

Introduction. Reproductive aging impacts female fertility and health, and involves a considerable genetic component as evidenced by recent genome-wide association studies (GWAS). Currently, no genetic markers are used for predicting menopausal age. The aim of this study was to evaluate the applicability of polygenic risk scores (PRS) to predict the risk for early menopause (before age 45).

Material and methods. PRS were generated using the publicly available ReproGen consortium menopausal age GWAS meta-analysis summary statistics including data for 2.4 million markers and involving approximately 70,000 women. Correlation between PRS and menopausal age was tested among 3,189 post-menopausal women in the Estonian Biobank. Receiver operating characteristic (ROC) curves were generated to evaluate the predictive value of PRS for discriminating women with early menopause.

Results. Polygenic risk profiles generated using different marker cut-offs were significantly correlated with age at natural menopause ($p < 0.05$). The same profiles were a good predictor of early menopause (AUC up to 0.70), outperforming the predictive value of smoking status (AUC=0.55), which is one of the most important lifestyle factors affecting menopausal age. When the extremes of the PRS were compared, up to 9-fold difference in risk for early menopause was observed.

Conclusion. Polygenic risk profiles show considerable discriminative power for detecting women at risk of early menopause and have the potential to become a valuable tool to increase the accuracy of ovarian reserve assessment, leading to more personalized counselling regarding family planning and patient management.

miR-346 and miR-582-3p regulate EG-VEGF-induced cell invasion and migration through repressing matrix metalloproteinases 2 and 9 in trophoblast cells.

M. Su;

Department of Obstetrics and Gynecology, National Cheng-Kung University Hospital, Tainan, Taiwan.

MicroRNAs (miRNAs) are noncoding small RNAs emerging as posttranscriptional regulators in various biological processes. Several miRNAs are expressed in human gestational tissue and play some role in embryo implantation and placental development. Some miRNAs are identified to be associated with placenta dysfunction and abnormal pregnancy status, such as intrauterine fetal restriction, preeclampsia, ectopic pregnancy and recurrent miscarriages (RM), but the underlying mechanism is not clear. Recently, EG-VEGF was regarded as a critical factor for embryo implantation and placental development; however, no EG-VEGF related micro-RNAs have been published yet. Two microRNAs (miR-346 and miR586-3p) were predicted to target on 3'UTR of EG-VEGF, and were confirmed to regulate EG-VEGF expression by a luciferase system. Moreover, miR-346 and miR-586-3p were shown to alter intracellular calcium influx and suppress cell invasion ability in trophoblastic cells (HTR-8/SV neo and JAR) through repressing the expressions and activities of MMP-2 and MMP-9 using western blotting and gelatin zymography. In conclusion, miR-346 and miR586-3p could regulate the expression of EG-VEGF and trophoblast cell invasion, which may therefore influence several EG-VEGF related pathophysiology of human pregnancy.

P01.038

Frequency of chromosomal abnormalities in 4539 Polish patients with fertility disorders. A retrospective data analysis

A. Strychalska, E. Martin, A. Podbiel-Palenta, W. Ratyńska, E. Budek, A. Czaja, M. Ptasinski, E. Hnatkiewicz, K. Czop, B. Sokolowska, J. Swadzba; Diagnostyka Sp. z o. o., Cracow, Poland.

Introduction: Fertility disorders have been a growing issue in modern societies. The successful treatment of these conditions depends on a thorough diagnosis, including karyotype assessment. This study is based on 3 years data and evaluates the prevalence of chromosomal abnormalities in 4539 patients with reproductive disorders.

Methodology: The study includes 4539 patients referred to our laboratory between 2013 and 2015 for routine karyotype assessment. Study groups were defined on the basis of three referrals: infertility, IVF failure and miscarriages. Cytogenetic analysis of peripheral blood lymphocytes was performed using GTG-banding technique, according to the standard algorithms.

Results: Out of 4539 patients (51,27% females, 48,73% males) 126 (2,78%)

carried chromosomal aberrations. There were no significant differences found in the prevalence of abnormalities or the types of aberrations between the groups. The most common chromosomal abnormalities were balanced translocations. Additionally no differences were found in the prevalence of aberrations between the genders. The statistical analysis was done using χ^2 -test ($p < 0,05$).

The results of karyotype assessment in patients with fertility disorders						
	Infertility		IVF failure		Miscarriages	
	3698 patients		264 patients		577 patients	
	number	%	number	%	number	%
Translocations	40	1,08%	4	1,51%	8	1,39%
Genosomal mosaics	30	0,81%	1	0,38%	7	1,21%
Numerical aberrations of genosomes	17	0,46%	0	0,00%	1	0,17%
Inversions	7	0,19%	1	0,38%	0	0,00%
Other	4	0,11%	1	0,38%	0	0,00%
Deletions	3	0,08%	0	0,00%	0	0,00%
Other mosaics	2	0,05%	0	0,00%	0	0,00%

Conclusions: This study shows 3,5-fold times higher frequency of chromosomal abnormalities in patients with fertility disorders in comparison to the general population. Since the exact reason for referral or the gender does not influence the prevalence of aberrations, all patients with reproductive disorders should be referred for karyotype assessment. It must be noted that balanced translocations can not be distinguished with any other currently used diagnostic method.

A non-invasive bioinformatic method for the analysis of fetal aneuploidies in maternal blood by NGS

K. Ibáñez¹, D. Prieto^{2,3}, J. Silla-Castro¹, V. F. Montañó⁴, E. Vallespín^{4,5}, P. Lapunzina^{5,3}, E. Mansilla^{2,3}, M. Mor^{2,3}, R. Rodríguez⁶, Á. Del Pozo^{1,3}, F. García-Santiago^{2,3};

¹Bioinformatics Section, Institute of Medical and Molecular Genetics (INGEMM), Madrid, Spain, ²Cytogenetics Section, Institute of Medical and Molecular Genetics (INGEMM), Hospital Universitario La Paz, Madrid, Spain, ³Centro de Investigaciones Biomédicas en Red de Enfermedades Raras (CIBERER), Madrid, Spain, ⁴Structural and Functional Genomics section, Institute of Medical and Molecular Genetics (INGEMM), Hospital Universitario La Paz, Madrid, Spain, ⁵Institute of Medical and Molecular Genetics (INGEMM), Madrid, Spain, ⁶Department of Gynecology & Obstetrics, Hospital Universitario La Paz, Madrid, Spain.

Fetal aneuploidies constitute over 80% of chromosomal abnormalities at birth. Currently, the

majority are detected using invasive screening tests, involving both risk to the mother and fetus. Recent studies propose non-invasive methods to detect fetal chromosomal aneuploidies in maternal plasma using common NGS technologies; whole genome sequencing or the selection of various chromosomal loci using a proprietary methodology (DANSRTM), not available to the general scientific community. Hence, we here present a novel custom bioinformatic NGS design for non-invasive prenatal testing.

Our strategy employs the dosage detection of a unique set of markers along chromosomes 13, 18, 21, and X, compared to a control (chromosome 1). The design also incorporates chromosome Y markers for sexing, and numerous SNPs for fingerprinting and for the determination of the fractional fetal DNA concentration. Approximately 1,500 very reliable markers have been selected, with lengths ranging from 100 to 300 bp. The sequences have been captured using Roche NimbleGen EZ library and have been sequenced on a MiSeq Illumina platform. A total of 16 samples, including trisomies and normal controls have been used in the validation.

Due to an error in the library generation, experimental modifications are still under development, and thus, the performance of the validation has been lower than expected. Nevertheless, the results demonstrate a 67% of sensitivity and 70% of specificity.

In conclusion, our design would provide a sensitive and robust method for the fetal aneuploidies detection in maternal blood, and could decrease as well the number of invasive tests.

Uniparental Disomy of Chromosome 8 unmasks a homozygous mutation in the Thyroglobulin gene causing a rare form of fetal goiter

K. Steindl¹, R. Müller², P. Joset¹, B. Oneda¹, M. Zweier¹, A. Rauch¹;

¹Institute of Medical Genetics, University of Zurich, Zurich-Schlieren, Switzerland, ²Private outpatient clinic, Winterthur, Switzerland.

A solid mass within the fetal neck on second trimester ultrasound scan is a

rare finding and can be due to either a teratoma or to a goiter. A goiter is characterized by its typical morphological features, i.e. a homogeneous structure symmetric in shape with increased vascularity within the anterior neck. Fetal goiter can be associated with hyperthyroidism, most frequently caused by maternal antibodies, hypothyroidism due to maternal antithyroid treatment (e.g. Graves' disease) or with a defect within the fetal thyroid gland hormone biosynthesis. We report a rare case of fetal goitrous hypothyroidism in a mother without thyroid gland pathology. TSH, FT3 and FT4 concentrations in the amniotic fluid were determined with amniocentesis. Chromosomal SNP-array analysis on fetal DNA detected isodisomy of chromosome 8 with a long stretch of LOH on the whole chromosome 8. Since UPD 8 may unmask recessive mutations we searched for genes causing autosomal recessive congenital hypothyroidism and found two, the TG and TRHR genes mapping on the long arm of chromosome 8q24.22 and 8q23.1, respectively. At this point we opted for NGS of the Mendeliome which revealed a homozygous nonsense mutation in the TG-Gene [c.4588C>T]. Our data support the importance of UPD as an underlying mechanism of rare autosomal recessive disorders. Till now not more than 50 different mutations in the TG gene had been described and thyroglobulin defects due to biallelic mutations have an estimated incidence of 1 in 100.000.

P01.041

Prenatal screening shows a remarkably high FMR1 premutation prevalence in the Balearic Islands

D. Heine-Suñer, R. Alfaro Arenas, J. Rosell, Group for the study of FXS in the Balearic Islands;

Hospital Universitari Son Espases, Palma de Mallorca, Spain.

We conducted a pilot screening study in 3731 pregnant and non-pregnant women in childbearing age of the Balearic Islands. The aims of this study were to determine Fragile X syndrome (FXS) CGG repeat alleles and frequencies in our population and to determine if TP-PCR is an adequate method to perform generalized population prenatal screening. The molecular results of the study are: 1) a prevalence of premutation (PM) carriers of 1 in 106 which is the highest described to date in any population; 2) Information on the AGG interruptions and CGG repeat numbers that showed that the most frequent alleles are 10A9A9 (38,4 %), 9A9A9 (15,1 %) and 10A9 (10, 5 %). Furthermore, alleles with 0 AGG interruptions or with a pure (uninterrupted) CGG repeat run larger than 34 (presumably more unstable), were highest among PM alleles (10 % and 100 % respectively) compared to normal alleles (0, 7% and 0, 07 %, respectively). Collected geographic origins of participants make it very unlikely that the high prevalence observed in this study is originated by founder effects. As for the psychosocial aspects of the study, we found a very high voluntary participation, self-reported high level of satisfaction and low levels of added stress. In addition, we detect low knowledge of the FXS (25%) and irrelevancy of the self-reported health data. The high level of acceptance and unexpected high frequency of expanded PM alleles in females in the Balearic Islands makes a very compelling argument for prenatal and/or preconceptional FXS screening.

P01.042

Evaluating the correlation between AGG interruptions in the FMR1 gene promoter and allele stability in the population that was evaluated in the Institute of Human Genetics at two large hospitals in Israel during the years 2011-2015

L. Waldman Radinsky¹, E. Manor^{1,2}, I. Menashe¹, R. Sukenik-Halevy³, L. Fridman³, A. Shtorch-Asor³, A. Koifman^{1,2};

¹Ben-Gurion University of the Negev, Beer-Sheva, Israel, ²Soroka University Medical Center, Beer-Sheva, Israel, ³Meir Medical Center, Kfar Saba, Israel.

The promoter region of the FMR1 gene is characterized by various lengths of CGG repeats. AGG triplicate can be found every 9 CGG repeats in average, usually 1-3 in total. Those triplicate suggested to stabilize carriers of 59-199 repeats. It was previously suggested that a reduction of AGG interruptions is correlated to an increased number of CGG repeats and expansion from carrier to mutated state (>200 repeats).

Aim: to determine the correlation between AGG triplets interruption and allele stability in the Israeli population.

Materials and methods: we conducted a retrospective case-control study assessing AGG interruptions within the promoter of FMR1 gene and the correlation of CGG repeats. **Results:** No correlation was found between maternal AGG interruptions and allele stability (pv=0.59). A correlation between CGG repeat numbers to allele instability was shown (pv- 0.003). Maternal ethnicity (Ashkenazi versus non- Ashkenazi) does not affect the chance for unstable transmission (pv=0.285). We showed a correlation between younger maternal age and a less stable transmission (pv=0.021, OR-0.734,

CI (0.564-0.954)). Two cases in which the fetus inherited a mosaic of the allele were found. We also found a woman who was not a pre-mutation carrier and transmitted the allele in an expanded length to her fetus.

Conclusions: No correlation was found between AGG number abnormalities and allele instability in the tested population. Younger women were found at greater risk for unstable transmission to their fetus. A case of non pre-mutation carrier that can transmit a CGG expansion was recorded. This unusual finding requires further evaluation.

P01.043

Elevation of GATA-6 and StAR, steroidogenesis pathway genes, in prenatally androgenized rats

M. Salehi Jahromi¹, A. Zadeh-vakili¹, F. Ramezani Tehran², M. Norouz-zadeh², M. Zareksh¹;

¹Cellular and Molecular Endocrine Research Center, Reseach Institute for Endocrine Sciences, tehran, Iran, Islamic Republic of, ²Reproductive Endocrinology Research Center, Reseach Institute for Endocrine Sciences, tehran, Iran, Islamic Republic of.

Introduction: Hyperandrogenism, a hallmark of polycystic ovarian syndrome, caused by fetal androgen exposure, is suspected to act via altered expressions of related genes. The aim of this study was to evaluate the expression of GAGT-6 and StAR genes, involved in steroidogenesis pathway, in adult female rats prenatally exposed to androgen excess by comparing them in different phases of estrus cycle with non-treated rats.

Materials and Methods: Eight pregnant Wistar rats in the experimental group were treated by subcutaneous injection of 5 mg free testosterone on day 20 of pregnancy, while controls (n = 8) received 500 mL of solvent. Adult female off-springs of each mother were divided into four groups based on observation of their vaginal smear. Along with measurement of serum steroidogenic sexual hormones and gonadotropins levels using ELISA, RNAs were extracted from ovarian theca cells and relative expression levels were measured using Cyber-green Real-Time PCR.

Results: Comparing intervention and control group, relative expression of GATA-6 and StAR increased by 2.08 (p<0.001) and 1.4 (p<0.05) fold, respectively. Despite changes in expression of each gene in different phases, their trend of expression was almost similar, with the maximum change being observed in diestrus.

Conclusions: This investigation on gene expression changes in ovarian theca cells in prenatally androgenized rats demonstrated elevated expression of the genes studied. Further studies on genes from steroidogenesis and other reproduction related pathways are recommended to confirm these findings and to further explore prenatal effects of excess androgens.

P01.044

A single-tube tetradecaplex panel of highly polymorphic STR markers for preimplantation genetic diagnosis of hemophilia A by combined mutation detection and linkage analysis

S. S. Chong^{1,2}, M. Zhao¹, P. C. Wong^{1,2}, F. S. H. Cheah², J. Mathew², M. Chen¹, A. S. C. Tan^{1,2};

¹National University of Singapore, Singapore, Singapore, ²National University Health System, Singapore, Singapore.

Introduction: Preimplantation genetic diagnosis (PGD) to detect the common hemophilia A (HEMA) inversion mutations represents a major technical challenge. Indirect linkage analysis using polymorphic markers is possible, but is dependent on availability of informative markers. We have developed a single-tube tetradecaplex panel of highly polymorphic microsatellite markers for simplified PGD of HEMA by haplotype linkage analysis with/without mutation detection.

Materials and Methods: Twenty-eight markers <1Mb from F8 were selected for initial testing. Compatible markers were optimized into a single-tube panel and genotyped in 135 Chinese females. The panel was also tested on single cell whole genome amplification (WGA) products. PGD was performed on a couple at risk of transmitting a point mutation, consisting of single-tube multiplex-PCR of fully informative markers and the mutation-site amplicon, followed by GeneScan analysis. Minisequencing was performed on an aliquot of PCR product to detect the point mutation.

Results: Thirteen markers were optimized into a single-tube PCR panel together with AMELX/Y. Observed marker heterozygosities ranged from 0.45 to 0.84, and 80% of the studied population were heterozygous for ≥5 markers, while 95% were heterozygous for at least one marker on either side of F8. In the IVF-PGD case, the point mutation was successfully detected from single embryo blastomeres and perfectly correlated with a specific marker haplotype.

Conclusions: The single-tube tetradecaplex marker panel provides a common platform containing sufficient marker redundancy for general application to potentially any PGD of HEMA, through haplotype linkage analysis either alone or in combination with mutation detection.

P01.046

Genetic variation in leptin and leptin receptor genes as a risk factor for idiopathic male infertility

A. Hodžič¹, M. Ristanović², B. Zorn³, C. Tulić⁴, A. Maver¹, I. Novaković², D. Plaskeša-Karañfilska⁴, B. Peterlin¹;

¹Clinical Institute of Medical Genetics, University Medical Centre Ljubljana, Ljubljana, Slovenia, ²Institute of Human Genetics, Medical Faculty, University of Belgrade, Belgrade, Serbia, ³Andrology Unit, Reproductive Unit, Department of Obstetrics and Gynecology, University Medical Centre Ljubljana, Ljubljana, Slovenia, ⁴Research Centre for Genetic Engineering and Biotechnology, Skopje, Macedonia, The Former Yugoslav Republic of.

Introduction: The current data support an important role of leptin system in the pathophysiology of male infertility in animals and humans. The aim of this study was to examine whether genetic variability in leptin and leptin receptor genes influence male infertility.

Methods: We performed a case-control study and were searching for an association between polymorphisms of leptin and leptin receptor genes and male infertility. The study group consisted of 317 patients with idiopathic infertility and a control group of 241 fertile men from Slovenia. Four SNPs in leptin gene and four SNPs in leptin receptor gene were chosen and genotyped. Statistically significant SNP was further validated in additional 255 infertile patients and 168 controls from Serbia and Macedonia.

Results: In the Slovenian population we found a statistically significant difference in genotype distribution for rs10244329 polymorphism in leptin gene (recessive genotype model, p value =0.048). The trend toward statistically significant difference in genotype distribution for rs10244329 polymorphism was found also in the Serbian and Macedonian populations (p value=0.09).

Conclusions: Our data suggest that genetic variability in the leptin gene might be associated with male infertility warranting further confirmation and mechanistic investigations.

This study was supported by grant P3-0326 from the Slovenian Research Agency.

Incremental yield of Genomic Microarray in Early Growth Restricted Fetuses Over Karyotyping

A. Borrell¹, M. Grande¹, J. Sabrià², E. Meler³, A. Muñoz³, E. Mazarico², L. Rodríguez-Reventós¹, F. Figueras¹;

¹BCNatal. Hospital Clínic Barcelona, Barcelona, Spain, ²BCNatal. Hospital Sant Joan Déu, Barcelona, Spain, ³Hospital Universitari Quirón Dexeus, Barcelona, Spain, ⁴Centre Diagnòstic Biomèdic. Hospital Clínic Barcelona, Barcelona, Spain.

Introduction: Fetal intra-uterine growth restriction, particularly when early (< 24 weeks) and severe (< 3rd percentile on estimated fetal weight) is associated with fetal genetic disease. However, scarce information is available about this association with microdeletion and microduplication syndromes. The aim of this multicenter study is to assess the incremental yield of genomic microarray over karyotyping in early and severe growth restriction.

Material and Methods: This multicenter study included 139 consecutive early and severe growth restricted fetuses, studied during a 3-year period (January 2013 - December 2015) in 3 centers of Barcelona. QF-PCR and BAC (Bacterial Artificial Chromosome) array-CGH (CytoChip Focus Constitutional, BlueGnome, Illumina) were performed in DNA extracted from amniotic fluid after amniocentesis. The incremental yield was defined by the rate of fetuses presenting with a pathogenic copy number variant below 10 Mb in normal QF-PCR results, stratified by the presence of fetal malformations.

Results: In our series 9 pathogenic copy number variants were found. Among non-malformed growth-restricted fetuses, a 5.7% (95%CI:1.3 to 10.1)(6/16) incremental yield of genomic microarray was observed over karyotyping, while this rate was 9.1% (95% CI: -0.7 to 18.9) (3/33) in malformed fetuses.

Conclusion: The use of genomic microarray provides a 5.7% incremental yield in non-malformed restricted fetuses with a normal karyotype, increasing up to 9.1% in malformed fetuses. These results confirmed previous findings of the single large series on growth restricted fetuses (3% and 10% respectively). Our findings support the use of genomic microarray after a normal QF-PCR or/and karyotype.

An innovative test for non-invasive Kell genotyping on circulating fetal DNA by means of the allelic discrimination of K1 and K2 antigens

F. Cro¹, C. Lapucci¹, E. Vicari¹, G. Salsi², N. Rizzo², A. Farina²;

¹Geneticlab, Noventa Vicentina, Italy, ²Division of Prenatal Medicine Department of Medicine and Surgery (DIMEC) University of Bologna, Bologna, Italy.

Introduction: Blood incompatibility between mother and fetus causes he-

molytic disease of the fetus and the newborn (HDFN), a potentially fatal condition. The blood groups mainly responsible for the most severe form of HDFN are RhD and Kell. Nowadays fetal Kell genotype can only be detected through invasive procedures, increasing the chance of maternal alloimmunization. Detection of fetal Kell genotype in circulating cfDNA in maternal plasma would enable prevention of HDFN avoiding risks associated to invasive procedures. In this study, an innovative test for Kell genotyping was designed and optimized on cfDNA to create a non-invasive prenatal test for prevention of HDFN caused by Kell incompatibility.

Materials and Methods: 17 samples: 1 alloimmunized pregnant woman plasma presenting anti-K antibodies, 6 dilution of Kell positive DNA in Kell negative DNA and 10 control blood samples were collected and analyzed. Real-time PCR was developed for the allelic discrimination of K1 and K2 and Kell genotype determination.

Results: The K1/K2 genotype was correctly determined in all control samples. Results on the Kell positive dilution allow to verify the linearity and efficiency of the method. Results on cfDNA from a Kell-negative pregnant woman confirmed the Kell-positive genotype of the fetus. Fetal fraction was determinate using the Kell-positive DNA quantification.

Conclusions: An efficient and reliable strategy for Kell genotyping is herein presented. The method was optimized on cfDNA in order to create a non-invasive prenatal test which could be routinely used for the prevention of hemolytic disease of the fetus and the newborn.

³Ginecology Departament, Hospital Puerta de Hierro, Madrid, Spain.

Introduction: prenatal diagnoses of microdeletion syndromes, which don't show ultrasound alterations until the third trimester, are always difficult, especially if we want to correlate phenotype-genotype. The introduction of microarray based technology enabled genome in prenatal diagnosis resulting in the detection of recurrent microdeletions in fetuses. We try to correlation between these ultrasound alterations and Koolen-de Vries syndrome. This syndrome is characterized by developmental delay, hypotonia, facial dysmorphisms, epilepsy, heart defects and kidney/urologic anomalies.

Materials and Methods: We present 4 fetuses with 17q21.31 microdeletion. All of them showed anomalies in the third trimester, 3 ventriculomegaly leve-moderate and one of them T.N. 4.2 mm at first trimester, VI. hyperecogenicity, severe CIR and disgenesis of corpus callosum at birth. Array-SNPs performed on uncultured amniocytes. Array-SNPs were performed by HiScan Illumina, ES CYTOSNP850k.

Results: All of them revealed a 17q21.31 microdeletion.

Conclusions: The appearance of minor malformations in prenatal diagnosis, especially in pregnancies over 22 weeks, is a source of uncertainty when it comes to genetic analysis. However, these findings are the only prenatal expression of many genetic syndromes, as many of them do not present major malformations in this period. From our point of view, it is important to evaluate each case individually and make these genetic studies given the impossibility of another form of screening and its consequences in postnatal life. To our knowledge, this kind of malformations should be a high marker of this syndrome.

Genetic screening for chromosomal abnormalities, Y chromosome microdeletions and copy number variation in infertile male patients living in the Trakya region of Turkey

H. Gurkan, S. Demir Ulusal, H. Tozkur, E. Atlı, E. I. Atlı, D. Eker;

Trakya University, Medical Faculty, Department of Medical Genetics, Edirne, Turkey.

Introduction: Male factor plays important role in the infertility of 40-50 % of infertile couples. Genetic factors such as Y microdeletions associated to testicular function, chromosomal abnormalities and copy number variations (CNVs) of genes have been reported to be risk factors or causes of male infertility.

Materials and Methods: In this study 141 male patients (mean age : 33,7) included who have been referred to Trakya University Faculty of Medicine Department of Medical Genetics because of infertility between February 2013- November 2015. 93 of patients (66%) were azoospermic, 48 (34 %) of patients were severe oligozoospermic. Karyotype analysis (GTG banding with a resolution of 450-500) and Y chromosome microdeletion analysis have been performed for all patients. In addition, CNVs were investigated of 39 azoospermic patients (42%) without any structural or numerical chro-

mosome abnormalities and Y microdeletion

Results: Y chromosome microdeletion or chromosomal abnormality were not found in the severe oligozoospermic patient group. Numerical chromosome abnormalities were found 20.4% (19/93), when structural chromosome abnormalities have been found 3.2% (3/93) and Y chromosome microdeletions have been found 8.6% (8/93) of azoospermic patients. CNVs have been found in the 7 (18%) out of 39 azoospermic patients investigated for CNVs.

Conclusions: Chromosome abnormality ratios have been reported to be between 1.9-20.86 % in different populations of infertile male patients. Chromosomal abnormality frequency was 15.6% (22/141) in our study. Y microdeletion frequency has been reported between 3.15-20.4% in different studies. One of the CNVs defined in this study was associated with Williams Beuren Syndrome.

P01.052

MAMLD1 mutations seem not sufficient to explain a 46,XY DSD phenotype

N. Camats¹, M. Fernández-Cancio¹, L. Audí¹, P. E. Mullis², C. E. Flück²;
¹Vall d'Hebron Institut de Recerca, Barcelona, Spain, ²University Children's Hospital Bern, Bern, Switzerland.

Introduction: The MAMLD1 gene (Xp28) is thought to cause disorder of sex development (DSD) in 46,XY patients, mostly presenting with hypospadias, and, recently, gonadal dysgenesis. However, there is some controversy about its role in sex development because some MAMLD1 variants are also detected in normal individuals, several MAMLD1 mutations have wild-type (WT) activity, male Mamld1 knockout mouse have normal genitalia and reproduction; and other species with or without DSD harbor also MAMLD1 variants in the genome. We aimed to analyse MAMLD1 sequence variations in individuals presenting with a wide spectrum of DSD phenotypes.

Patients and Methods: Sanger sequencing was performed in 108 46,XY DSD individuals to detect MAMLD1 gene variations/mutations. Functional experiments were completed in non-steroidogenic and steroidogenic cell lines. We assessed transcriptional activity (on Hes3 and CYP17A1 promoters) and expression of WT and mutant MAMLD1. Besides, we tested the MAMLD1 effect on androgen production by testing the CYP17A1 activity.

Results: We found 9 MAMLD1 mutations (7 novel) in 9/108 46,XY DSD patients. In vitro assays revealed that most MAMLD1 variants acted similarly to the WT. Only the L210X mutation showed loss of function in all tests, while variants L724V and S730S showed a decrease in CYP17A1 promoter activation. We found no effect of either WT or any MAMLD1 variant on CYP17A1 enzyme activity. Also, no difference for MAMLD1 protein expression was found, except for a shorter L210X.

Conclusion: Our data support the notion that MAMLD1 sequence variations may not suffice to explain the DSD phenotype in carriers.

MiR-335-5p, miR-203a and miR-204-5p expression study in fetal and maternal tissues of women with spontaneous abortion in the first trimester of pregnancy

E. P. Omelchuk, E. V. Butenko, K. A. Kovalenko, E. V. Mashkina;
 Southern Federal University, Rostov-on-Don, Russian Federation.

Introduction. Coordinated work of gene cascades in maternal and fetal cells is crucial for mother-placenta-fetus system formation and functioning. Reasons for up to 60% of spontaneous abortions remain unknown. Micro RNAs act as post-transcriptional gene regulators, and affect gene expression directly in the cells of their origin or take part in intercellular signaling through vesicular transport. In current work, we investigated the expression of three micro RNAs in embryonic, chorionic and decidual tissues after spontaneous abortion compared to normal first trimester pregnancies.

Materials and methods. Bioinformatic study was conducted and miR-335-5p, miR-203a and miR-204-5p were chosen for further investigation. Samples of chorionic, embryonic tissue and decidua were taken after surgical termination of normally progressing pregnancies (n = 14) and spontaneous abortion (n = 10) in 5-9 week of gestation. Micro RNA expression was analyzed using quantitative real-time PCR method. MiR-92a-1-5p was used as a reference gene. All experiments were conducted in triplicates. Data were analyzed using the 2- $\Delta\Delta$ CT method.

Results. The expression of miR-203a-3p was decreased in decidual and embryonic tissues in spontaneous abortion compared to normal pregnancy. Expression of miR-204-5p and miR-335-5p was equal in all studied tissues and in spontaneous abortion compared to normal gestation.

Conclusion. The results demonstrated that low miR-203a-3p expression level in decidual and embryonic tissues could be associated with spontaneous

abortion in first trimester of pregnancy. This study was supported by the federal assignment № 6.98.2014/K from Russian Ministry of Science and Education.

Integrated analysis of miRNA- and mRNA expression profiles in preeclampsia

O. Biro, B. Nagy, J. Rigo;
 Semmelweis University, 1st Dept. of Obstetrics and Gynecology, Budapest, Hungary.

Background: Preeclampsia is the leading cause of maternal and fetal morbidity and mortality, affecting 3-8% of all pregnancies worldwide. Unfortunately, the pathogenesis of preeclampsia is still not clear. miRNAs are small, non-coding RNA molecules, which negatively regulate gene expression. They are associated with several pathological conditions, including pregnancy complications such as preeclampsia. The aim of our study was to find preeclampsia-related miRNA regulatory mechanisms using bioinformatics approaches.

Methods: We analyzed miRNA (GSE57050) and mRNA (GSE73374) expression datasets, which were created under similar experimental circumstances. Differently expressed miRNAs were identified for the estimation of their inhibitory effect. We integrated miRNA and gene expression profiles with the MAGIA web tool, and created a bipartite network from the significant miRNA-mRNA pairs using the Cytoscape software. Two subnetworks were expanded by protein-protein interactions from the HPRD database. We analyzed the network elements using different bioinformatics tools and through literature research.

Results: We created a network, which consists of 85 nodes and 80 edges signaling the connections between 52 regulated genes and 33 miRNAs. 11 of the genes are preeclampsia-related and 9 of them were targeted by multiple miRNAs. 8 miRNAs are associated with preeclampsia, and 13 miRNAs regulated more than one mRNA. Hsa-mir-210 was the highest degree node in the network and its role in preeclampsia is well-known.

Conclusions: We identified several miRNA-mRNA interactions, which may contribute to the pathogenesis of preeclampsia. Further investigations are needed to validate these mechanisms and to unfold the possibilities of developing potential therapeutic targets.

P01.055

Contribution of chromosome rearrangements to the etiology of miscarriages

A. Soler^{1,2,3}, C. Morales⁴, I. Mademont-Soler⁵, E. Margarit^{1,2,3}, M. Papiol¹, A. Borrell^{1,2,3}, V. Borobio¹, A. Sánchez^{1,2,3};

¹Hospital Clínic, Barcelona, Spain, ²CIBER de enfermedades raras (CIBERER), Barcelona, Spain, ³IDIBAPS (Institut d'Investigacions Biomèdiques August Pi i Sunyer), Barcelona, Spain, ⁴ThePGDlab Reproductive Genetic Medicine, Jabriya, Kuwait, ⁵Institut d'Investigació Biomèdica Josep Trueta, Girona, Spain.

Introduction: Around 10-15% of clinically recognized pregnancies result in miscarriage and about 50% of early pregnancy losses has chromosome abnormalities. Most of them are numerical abnormalities such as autosomal trisomies, poliploidies and monosomy X. However, structural chromosome abnormalities are also found in around 5% of the cases, most of them unbalanced, and identified through karyotyping.

Materials and Methods: We describe the chromosome rearrangements detected in a series of 1119 consecutive first trimester spontaneous miscarriages, obtained through CV sampling before evacuation and semi-direct cytogenetic analysis. When an unexpected rearrangement was found in the CV sample, chromosome analysis of parents was performed.

Results: Cytogenetic result was achieved in 1011 samples, from which 711 showed an abnormal karyotype (70.3%). Thirty-six chromosome rearrangements were detected (5.1% of the abnormal cases), 5 balanced (0.7%) and 31 unbalanced (4.7%). Three of the balanced rearrangements presented with an additional trisomy. Among the unbalanced rearrangements there were 10 reciprocal translocations, 5 were previously unknown: 3 of them turned out to be inherited, 1 de novo and 1 with no information. Two inversions were unexpected and turned out to be inherited. Only 2 out of the 12 Robertsonian translocations were previously known; among the unexpected ones, 8 were de novo, 1 inherited and 1 with no information.

Conclusions: Karyotyping allows the detection and interpretation of such unexpected chromosome rearrangements and adds valuable information for the genetic counseling of the couple and their family.

This work was partially supported by grant PI11/01841 from F.I.S. of Spanish Ministerio Sanidad y Consumo.

P01.056

Placental chromosomal mosaicism in first trimester spontaneous abortions

A. Sánchez^{1,2,3}, C. Morales⁴, I. Mademont-Soler⁵, E. Margarit^{1,2,3}, M. Rubio¹, A. Borrell^{1,2,3}, M. Muñoz¹, A. Soler^{1,2,3},

¹Hospital Clinic Barcelona, Barcelona, Spain, ²CIBER de enfermedades raras (CIBERER), Barcelona, Spain, ³IDIBAPS (Institut d'Investigacions Biomèdiques August Pi i Sunyer), Barcelona, Spain, ⁴ThePGDlab Reproductive Genetic Medicine, Jabriya, Kuwait, ⁵Institut d'Investigació Biomèdica Josep Trueta, Girona, Spain.

Around 10-15% of clinically recognized pregnancies result in miscarriage and about 50% of early pregnancy losses has chromosome abnormalities. Chromosomal mosaicism in chorionic villi samplings (CVS) is detected in 1-2% of the cases and can involve different numerical and structural chromosome abnormalities. Depending on the distribution of the abnormal cells lineage among the placental tissues, there are different classes of mosaicism. The purpose of this work is to identify the rate and spectrum of placental chromosomal mosaicism involved in first trimester miscarriages in our population.

We present the placental chromosomal mosaicism found in a series of more than one thousand of arrested pregnancies obtained through chorionic villi sampling before evacuation. The chromosomal analysis was carried out by semi-direct/short-term (STC) and long-term culture (LTC).

Of 1011 CVS samples analysed we obtained results in both cultures in 592 (58.5%). Among them 21 (3.5%) showed discrepant karyotypes. The chromosome abnormality was present in STC in 9 cases (43%) while the karyotype obtained in LTC was normal only in two cases (9.5%). In all cases except four, chromosomal abnormality was numerical, and the structural abnormalities were present only in LTC. In 33% of cases we found discrepant abnormal karyotypes between both cultures.

These data underline the importance of karyotyping both placental layers, also in spontaneous abortions, to obtain a reliable result and a predictive value for fetal involvement and provides clinical elements to offer an accurate genetic counselling.

Is mitochondrial DNA content in euploid blastocysts established by next generation sequencing (NGS) on Ion Torrent platform applicable as a predictor of successful implantation?

M. Hrubá¹, R. Vlková¹, M. Pittrová¹, L. Hradecký¹, J. Zemanová¹, P. Nováková¹, V. Petriková¹, P. Martinek², B. Wirleitner³, M. Schuff⁴, A. Stecher³, M. Murringer²,

¹IVF Centers Prof. Zech - Pilsen, Pilsen, Czech Republic, ²Biopsticka laborator, Pilsen, Czech Republic, ³IVF Centers Prof. Zech - Bregenz, Bregenz, Austria.

Introduction: Mitochondrial DNA (mtDNA) content in preimplantation embryos, assessed predominantly by qPCR, was recently suggested as a potential novel biomarker for selection of the most competent euploid embryo (Fragouli E et al, 2015; Diez-Juan A et al, 2015). The embryos with lower mtDNA content were reported to show significantly better implantation rates. Most importantly, embryos with mtDNA amount exceeding a certain threshold (0.003% by qPCR, 0.070% of total reads by NGS; Fragouli E et al, 2015) did not implant.

Materials and methods: We reanalyzed 56 trophoctoderm samples from euploid embryos (determined previously by aCGH) by NGS using the Ion Torrent platform allowing simultaneous CNV analysis of both nuclear and mitochondrial DNA. 18 embryos were transferred (10 SETs, 4 DETs with known mtDNA level and transfer outcome for both embryos). We analyzed a putative correlation of the implantation outcome and the level of mtDNA. Results: NGS confirmed euploidy and established mtDNA amount in all 56 cases (mean 0.064%, median 0.054%). 33% (6/18) of the transferred embryos implanted, while 67% (12/18) did not. Interestingly, mtDNA amount did not differ between implanted and non-implanted embryos (P 0.285). Moreover, in 2 successfully implanted embryos the suggested 0.070% threshold was substantially exceeded (0.368%, 0.146% respectively).

Conclusions: Although the results obtained by qPCR in two previous studies indicated the application of mtDNA content as a predictor of embryo competence to produce viable pregnancy, the results obtained by NGS using the Ion Torrent platform should be further cautiously studied and verified in a larger cohort of samples.

Investigating the Role of Mitochondria in the Preimplantation Stages of Human Embryonic Development

R. S. Jawdat¹, W. Parson², N. Lane³, S. Sengupta¹;

¹Institute for Women's Health, London, United Kingdom, ²Institut für Gerichtliche Medizin der Medizinischen Universität Innsbruck (GMI), Innsbruck, Austria, ³Research

Department of Genetics, Evolution and Environment, UCL, London, United Kingdom.

Introduction: Maternal factors that may lead to abnormal preimplantation development include mitochondria, which are the most abundant organelles in the oocyte. Genes required for mitochondrial function are encoded by both mitochondrial DNA (mtDNA) and the nuclear DNA (nDNA) necessitating the coordination between the two genomes. Mitochondrial-nuclear mismatch has been proposed as a cause of embryonic cell death. Changes in ATP synthesis and metabolic reactions in the mitochondrial electron transport chain (ETC) have been linked to female infertility. This study explores the effect of differences in mtDNA and nDNA haplotypes in genes involved in the ETC by assessing preimplantation embryo development.

Methods: Maternal and paternal mitochondrial DNA was analysed from 11 fertile and 12 infertile couples by Long range PCR and NGS. The selected nuclear genes were sequenced using SureSelect QXT from Agilent. Each sample was assigned to a mitochondrial haplogroup using HaploGrep and confirmed by the EMMA software. PGD cycles from the fertile group were compared for the proportions of both oocytes that fertilised and embryos that developed to blastocyst.

Results: Several mitochondrial haplogroups were identified reflecting the diverse ethnic population in London. Overall more couples from the infertile (4/12) had identical mtDNA haplotypes compared to the fertile group (1/11). Within the fertile group the presence of the T haplogroup was associated with poor blastocyst formation. Analysis of the selected nuclear gene sequences as well as investigation of the interaction of the T haplotype SNPs remains to be investigated before mitochondrial nuclear mismatch can be correlated to embryo development.

Interdisciplinary clinical workup increases diagnostic yield in increased nuchal translucency

D. Niedrist¹, J. Wisser², K. Frontzek³, H. Budka³, N. Rupp⁴, R. Caduff¹, M. Zweier¹, B. Oneda¹, P. Joset¹, R. Asadollahi¹, A. Rauch¹;

¹Institute of Medical Genetics, University of Zurich, Zurich - Schlieren, Switzerland, ²Department of Obstetrics, University Hospital Zurich, Zurich, Switzerland, ³Institute of Neuropathology, University Hospital Zurich, Zurich, Switzerland, ⁴Institute of Pathology, University Hospital Zurich, Zurich, Switzerland.

Increased nuchal translucency is an early sonographic marker in pregnancies for chromosomal abnormalities. In case of a normal karyotype, increased nuchal translucency may be associated with fetal malformations and monogenetic syndromes such as Noonan syndrome.

We now report on a 37-year old healthy woman at 13 weeks of gestation. The nuchal translucency was increased, there was growth retardation and oedema of the skin. The chromosomes were found to be normal (Affymetrix HD 2.65M, resolution of about 100kb). As the sonographic markers became worse, NGS (TruSight™ One Sequencing panel, 4613 Gene, illumina Inc.) was performed, but still did not reveal the underlying cause. At week 22 the couple decided for termination of pregnancy. The pathological examination revealed a male fetus with low birth weight, microcephaly and severe contractions with webs. The fetal brain was premature with agenesis of corpus callosum and hydrocephalus internus.

The result of an interdisciplinary case discussion was the clinical suspicion of Neu-Laxova Syndrome.

Reevaluation of NGS data showed only one deleterious missense mutation in the PHGDH-gene, and reevaluation of microarray data showed a downward pattern of makers, indicating the possibility of a deletion affecting PHGDH. By MLPA the deletion of exon 12 and 3'UTR of the PHGDH-gene was confirmed in the fetus and the mother. The healthy father was carrier of the mutation in the PHGDH-gene.

This case highlights the importance of interdisciplinary clinical discussions. The clinical suspicion may drive the new genetic technologies in finding even rare diagnoses in a time and cost saving way.

P01.060

First clinical application of paired-end MPSS for cfDNA based prenatal screening of aneuploidies

V. Cirigliano^{1,2}, E. Ordoñez^{1,2}, L. Rueda^{1,2}, I. Castilla¹, M. Grau¹, C. Fuster², M. P. Cañadas¹;

¹Labco Diagnostics, Barcelona, Spain, ²Universitat Autònoma de Barcelona, Bellaterra, Barcelona, Spain.

Objective: To evaluate the performance of the NeoBona test, a new paired-end MPSS based assay for cfDNA aneuploidy screening, in an average risk population.

Methods: A total of 2855 consecutive samples were collected from pregnant women above 10w of gestation (102 twins), regardless their risk category. Samples were analysed using the NeoBona test, a new paired-end MPSS ap-

proach allowing simultaneous assessment of fetal fraction, DNA fragment size distribution and chromosome counting statistics and providing a novel Tscore value which quantifies the likelihood for chromosome aneuploidy. Results: Patients choose to only assess risk for autosomal trisomies in 43,2% of cases, screening for XY aneuploidies was requested for 56.8% of samples. Twelve cases were not suitable for analysis, 2843 were tested and results obtained for 2779 (97,8%). Patient redraw following test failure provided valid results in 88% of cases. A total of 71 aneuploidies were detected, 63 autosomal trisomies, 8 involving the sex chromosomes. High-risks results were confirmed by invasive procedures in all but 7 cases of autosomal trisomies and 1 false positive trisomy 21 result was observed (0.03%). Invasive procedures were performed in 5/8 cases of XY chromosomes aneuploidies (3 45,X, 1 47,XXY and 1 47,XXX) and no false positive results were observed. No follow up available on normal pregnancies, the majority of which are still ongoing.

Conclusions: The new analysis algorithm of the NeoBona test, including fetal fraction, size distribution, chromosome counting and sequencing depth, proved highly efficient allowing detecting chromosome aneuploidies with extremely low false positive and failure rates.

P01.061

Non-invasive prenatal testing (NIPT) may detect unexpected diagnosis of CAIS/PAIS

F. Falatta¹, D. Quagliarini², V. Nicotra³, S. Salmona⁴, S. Guerneris⁵, L. Colombo⁶, C. Ciavoli⁷, G. Manzoni⁸, V. Pasterski⁹;

¹Clinical genetics Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Milano, Italy, ²Obstetrics Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Milano, Italy, ³Centro di Riferimento Regionale diagnosi e cura delle malattie genetiche, Università degli Studi di Catania, Catania, Italy, ⁴Obstetrics, Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Milano, Italy, ⁵Genetic Laboratory Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Milano, Italy, ⁶Department of Neonatology, Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Milano, Italy, ⁷Endocrinology and Metabolic Diseases Unit, University of Milan, Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Milano, Italy, ⁸Pediatric Urology Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Milano, Italy, ⁹Department of Psychology, University of Cambridge, Cambridge, United Kingdom.

Introduction: From the first trimester of pregnancy, free DNA of fetal origin (cell free fetal DNA, cfDNA) is present in maternal blood and can be recovered non-invasively. NIPT is increasingly utilized to screen for the most common fetal aneuploidies, including those involving sex chromosomes. Here we report a case in which we resolved a discrepancy between the foetal genotype and phenotype detected using NIPT.

Case description: a 32-year-old primigravida was referred to our unit at 20 weeks to further investigate a 46,XY karyotype concurrent with female-typical genitalia as visualized in routine ultrasound. Considering possible complete/partial androgen insensitivity syndrome (PAIS/CAIS), the AR was analysed, identifying a novel mutation. Disclosure of the CAIS diagnosis took place at 22 weeks and included participation of specialists in paediatrics, genetics and a paediatric urology. At 30 weeks, a psychological assessment was carried out for both parents. There was evidence of elevated somatization and anxiety in the mother and both parents showed notable traumatic stress. However, both expressed a degree of relief at going into the birth with knowledge of the diagnosis and requested a "birth plan" allowing for privacy with respect to (public) discussion of the diagnosis. The pregnancy was carried to term and the birth was uncomplicated.

Conclusions: Both parents reported satisfaction with the prenatal diagnostic process and were relieved to have a sense of knowledge and control in planning for the child's birth and clinical management. Nevertheless, notable levels of traumatic stress were observed as they acclimated to the diagnosis.

P01.062

Discordant results between fetal karyotyping and non-invasive prenatal testing by maternal sex chromosomal mosaicism (45, X and 46, XX)

S. Jung¹, K. Lee², K. No¹, K. Lee¹;

¹Molecular Diagnostics Testing Center, Seegene medical foundation, Seoul, Korea, Republic of; ²Department of Physics, Kangwon National University, Chuncheon, Korea, Republic of.

Background: Non-invasive prenatal testing (NIPT) is a novel accurate screening technology for early detection of fetal chromosomal aneuploidies, but the test performance of NIPT for sex chromosomal abnormality (SCA) is not as good as it is for trisomy 21, 18, and 13. For the diagnosis of SCA, the maternal or fetal mosaicism, maternal chromosomal abnormalities, and multiple pregnancies have been considered as a confounding factor in NIPT.

Here, we present a false positive fetal SCA (45, X) result caused by maternal sex chromosomal mosaicism.

Case: A 36-year-old primigravida was offered NIPT due to advanced maternal age. The NIPT result was available at 13⁺¹ weeks and negative for trisomy 21, 18, and 13. However, Turner syndrome (45, X) was reported in NIPT. She underwent an amniocentesis at 15⁺⁵ weeks in order to confirm the identification of 45, X obtained through the analysis of NIPT and the result of amniocentesis showed that the fetus was normal (46, XY). For discordant result between fetal karyotyping and NIPT, full karyotyping analysis of her peripheral blood was additionally performed. Among the 178 G-banded karyotypes randomly selected, 173 (97.2%) were normal (46, XX), but 5 (2.8%) were abnormal (45, X), indicating that maternal mosaicism for aneuploidy could result in discordant NIPT results.

Conclusion: Our findings indicated that maternal mosaicism of sex chromosome could cause discordant SCA associated with NIPT. We highly recommend that maternal karyotype should be confirmed for the cases with abnormal results in NIPT.

Implementation of a targeted enrichment method for the detection of microdeletion and microduplication syndromes for NIPT

M. Neofytou¹, K. Tsangaras², E. Kyprisi^{1,2}, L. Charalambos¹, P. Mina², M. Ioannides², A. Achileos², G. Koumbaris^{1,2}, P. C. Patsalis^{1,2};

¹The Cyprus Institute of Neurology and Genetics, Nicosia, Cyprus, ²NIPT Genetics LTD, Nicosia, Cyprus.

Introduction: Novel targeted enrichment technologies have been recently developed and applied for the detection of chromosomal aneuploidies. However, only few studies have examined the possibility of applying targeted technologies for the detection of clinically relevant copy number variants (CNVs). The purpose of this study was to develop and validate a targeted enrichment method in combination with NGS to enable the detection of CNVs using cell free DNA from maternal plasma.

Materials and Methods: Synthetic microdeletion and microduplication syndrome samples were created by spiking DNA from affected samples into cfDNA derived from non-pregnant female samples. We created 63 samples simulating 5%, 10% and 20% fetal fraction pregnancies. Enrichment probes spanning the critical region of twelve microdeletion and microduplication syndromes were developed and used to perform targeted enrichment using in-solution hybridization. A statistical analysis pipeline that simultaneously tests for aberrations in any of the syndromes was also developed.

Results: The overall preliminary detection rate ranged from 59% at ff 5% to 95% at ff 20%.

Conclusion: These preliminary results, illustrate the feasibility of this novel targeted technology for the detection of pathological CNVs in cfDNA from maternal plasma.

P01.064

Prenatal detection of tetrasomy 12p using Non-Invasive Prenatal Testing (NIPT)

Y. Torres¹, X. da Silva¹, J. C. Cigudosa^{1,2}, J. Suela¹;

¹NIMGenetics, Madrid, Spain, ²Centro Nacional de Investigaciones Oncológicas, Madrid, Spain.

INTRODUCTION: Non invasive prenatal testing (NIPT) is a recent prenatal screening procedure that estimates the risk of several fetal cytogenetic aberrations by means of analyzing the circulating cell-free fetal DNA (ccfDNA) present in maternal blood. Although NIPT have been used to mainly detect chromosomal aneuploidies such as trisomy 21, 18 or 13, the implementation of deeper and more robust next generation sequencing (NGS) protocols and algorithms are showing that other chromosomes and genomic regions can be analyzed with a reasonable sensitivity and specificity.

METHODS: Fetal DNA was extracted from plasma obtained in a BCT DNA free tube (Streck). Library preparation and sequencing proceedings were performed according to BGI NIFTY protocol. NIFTY algorithm was used to analyze the risk for fetal trisomies and other aneuploidies. Genomic results were validated with DNA extracted from 16th gestational week amniotic fluid using a custom Agilent 60k array-CGH platform designed for prenatal diagnosis.

RESULTS: NIFTY algorithm informed of a high risk for duplication of the whole short arm of chromosome 12 (dup12p). Array-CGH confirmed the aberration and informed of a tetrasomy 12p, compatible with a Pallister-Killian syndrome. Further ultrasound scanning confirmed the presence of diaphragmatic hernia and other abnormalities compatible with the syndrome. CONCLUSION: Although NIPT was initially designed for the estimation of fetal trisomies T21, T18 or T13, whole genome sequencing can successfully

detect other microscopical aberrations such as tetrasomy 12p. Further studies and reports must be done in order to dilucidate the role of this technique in prenatal care

P01.065

Non Invasive Prenatal Testing by digital counting of fluorescently labeled DNA molecules

F. Dahl;

Vanadis Diagnostics, Sollentuna, Sweden.

Several countries have implemented Non Invasive Prenatal Testing (NIPT) to analyze chromosomal abnormalities in high-risk pregnancies. The majority of these tests are performed using sequencing technologies that provide both superior specificity and sensitivity compared to traditional first trimester screening. However, in order to provide all women with high performance prenatal screening, the NIPT assay cost and complexity need to be dramatically reduced. We present a platform that reduces the cost of the analysis by an order of magnitude making the assay available for high throughput diagnostic laboratories.

Our solution, called Smart NIPT technology, provides a very high assay precision by counting individual fluorescently labeled DNA molecules. The technology uses DNA probes to specifically convert chromosomal targets of interest into DNA circles. These circles are then clonally expanded into discrete fluorescently labeled DNA objects. The DNA objects are immobilized on a transparent nanopore filter and finally imaged and counted through the bottom of the well. By capturing thousands of DNA targets from each chromosome, PCR amplification can be avoided with increased assay precision and reduced contamination risks as a result.

We applied the technology to analyze 183 blinded plasma samples of which 15 were from women pregnant with a trisomy 21 fetus. All positive samples were classified correctly, separated from the normal samples with a minimum of 6.6 standard deviations. No false positives were called.

In conclusion, the Smart NIPT platform, supported by convincing clinical data, is a new solution that holds promise to provide NIPT to all pregnant women.

Nowadays, genome-wide approaches are part of Non Invasive Prenatal Testing (NIPT), analyzing fetal cell-free DNA (cfDNA) through a maternal blood sample. Technical issues are not the keypoint anymore. Ethical questions, about their large-scaled implementation and potential diagnosis of sub-chromosomal imbalances, do occupy a major place. Another critical issue is about unexpected finding on maternal cfDNA, which is screened altogether with fetal cfDNA, far away from the original test aim.

We report the case of Mrs R., a French forty-year-old pregnant woman, without any medical history. She underwent NIPT, prescribed because of maternal age in Luxembourg where she lives, and performed in Belgium. By massive parallel sequencing of cfDNA, an abnormal genome-wide representation profile was detected with a gain of 1q, 6p, and chromosome 15 and the loss of 13, 14 and 22q. This specific abnormalities association, reminiscent of acquired chromosomal imbalances, indicated a possible Multiple Myeloma (MM). Clinical, biological and radiological assessments confirmed a smouldering lambda-type free light chain MM. Array Comparative Genomic Hybridization and Fluorescent In Situ Hybridization were performed on tumor plasma cells from bone marrow puncture : they revealed the same anomalies as those detected by NIPT.

This case-report reminds that global medical and ethical thinking is highly required to plan safeguards against possible abuses allowed by these new techniques. It shows the potential power of this tool, whose consequences should be anticipated so as to enrich prior information given to patients. The real medical benefit of incidental findings that may arise out needs careful assessment.

Clinical potential of effective non-invasive exclusion of KEL1 positive fetuses in KEL1 negative pregnant women

R. Vodicka¹, J. Böhmová¹, M. Lubusky¹, R. Kratochvilová¹, E. Krejciriková¹, M. Janiková¹, L. Dusek², R. Vrtel¹, M. Prochazka¹;

¹University Hospital and Palacky University Olomouc, Olomouc, Czech Republic,

²Masaryk University Institute of Biostatistics and Analyses, Brno, Czech Republic.

Objective: The clinical importance of assessing the fetal KEL genotype is to exclude "K" positive fetuses (genotype KEL1/KEL2) in "K" alloimmunized pregnant women (genotype KEL2/KEL2). Non-invasive assessment of the fetal KEL genotype is not yet available in the Czech Republic. The aim of this study is to assess the fetal KEL1/KEL2 genotype from cell-free fetal DNA in the plasma of KEL2/KEL2 pregnant women.

Methods: The fetal genotype was assessed by minisequencing (a dilution series including control samples). A total of 138 pregnant women (between the 8th and the 23th gestational week) were tested by minisequencing. The fetal genotype was further verified by analysis of a buccal swab from the newborn.

Results: Minisequencing proved to be a reliable method. In 2.2 % of the examined women (3/138), plasma sample testing failed; 94.8 % of women (128/135) had the KEL2/KEL2 genotype, and a total of 3.1 % fetuses (4/128) had the KEL1/KEL2 genotype. Sensitivity and specificity reached 100 %, p < 0.0001.

Conclusion: Minisequencing is a reliable method for the assessment of the fetal KEL1 allele from the plasma of KEL2/KEL2 pregnant women.

Introduction: There is a great need for the development of highly accurate, cost effective technologies, which can facilitate the widespread adoption of Non Invasive Prenatal Testing (NIPT). We hereby present a novel cost effective assay of unparalleled accuracy which overcomes the limitations of current technologies.

Materials and Methods: This method enables the targeted analysis of selected genomic regions at very high sequencing depth and allows highly accurate fetal fraction determination to ensure extremely accurate aneuploidy detection. The analytical performance of the assay was evaluated in a blind study, which comprised 631 samples derived from pregnancies of at least 10 weeks of gestation that had also undergone invasive testing.

Results: The blind study exhibited 100% sensitivity and specificity and correctly classified 52/52 (95% CI: 93.2-100%) cases of trisomy 21, 16/16 (95% CI: 79.4-100%) cases of trisomy 18, 5/5 (95% CI: 47.8-100%) cases of trisomy 13, and 538/538 (95% CI: 99.3-100%) normal cases. The test also correctly identified fetal sex in all cases (95% CI: 99.4-100%). One sample failed pre-specified assay quality control criteria, and 19 samples were non-reportable due to low fetal fraction.

Conclusions: The clinical impact of free fetal DNA (ffDNA) testing has been significant as indicated by its quick adoption in prenatal care. Our novel technology overcomes limitations of current technologies and exhibits near diagnostic performance. We believe that this method enables accurate and cost-effective non-invasive fetal aneuploidy detection of trisomy 21, 18 and 13, which is critical for wide-spread adoption of NIPT.

Non-invasive prenatal testing or microarray? Additional benefit of microarray analysis in prenatal diagnosis of fetuses with increased risk of common aneuploidies

Z. Vlachová, J. Graakjaer, D. Svaneby, A. Bojesen; Lillebaelt Hospital, Vejle Hospital, Vejle, Denmark.

Introduction: Microarray analysis enables detection of copy number variations, aneuploidies and unbalanced translocations. In prenatal diagnostic, microarray analysis is considered most beneficial in pregnancies with ultrasound abnormalities. We report chromosomal abnormalities detected

by single-nucleotide polymorphism (SNP) array in fetuses with increased risk of common aneuploidies without ultrasound abnormalities. We focus on chromosomal abnormalities that would not be detected by non-invasive prenatal testing (NIPT).

Materials and Methods: We performed SNP-array analysis in 358 pregnant women, who underwent chorionic villus sampling or amniocentesis between July 2013 and January 2016. The high risk (HR) group (n=165) included fetuses with abnormal ultrasound findings as defined by Danish Society of Fetal Medicine. The group with increased risk (IR) (n=193) consisted of fetuses without ultrasound abnormalities with risk assessment for common aneuploidies (Astraia) higher than 1/300. SNP-array analyses were performed by using Illumina CytoSNP-12 version 2.1.

Results: Abnormal SNP-array results were more prevalent in the HR group 14.5% (n=24) compared with IR group 5.7% (n=11) (p-value 0.007). Within the IR group, nine cases were evaluated as pathogenic. Four of the nine pathogenic chromosomal abnormalities detected by SNP-array, would not be detected by NIPT or other diagnostic methods (aneuploidy screening, traditional karyotyping). However, all four conditions resulting from these chromosomal abnormalities are known to have variable penetrance.

Conclusions: In comparison with NIPT, SNP-array can potentially identify additional genetic abnormalities in fetuses with increased risk of common aneuploidies without ultrasound abnormalities. However, the variable penetrance of the additionally detected chromosomal abnormalities by SNP-array makes genetic counseling challenging.

P01.070

A free fetal DNA - Real Time PCR based - approach for prenatal diagnosis of beta globin gene mutations in embryos at risk for Thalassaemia

F. Strikou, L. Ikononopoulos, A. Floratos, C. Chassanidis, E. Voskaridou, A. Balassopoulou, E. Boutou;

Laiko Hospital, Athens, Greece.

Thalassaemias, the most common genetic disorders worldwide, are inherited in a recessive autosomal manner. Therefore, prenatal diagnosis of embryos at risk presents the most common method of disease prevention and is predominantly based on genetic analysis of cells of fetal origin. This material is mainly obtained through invasive procedures with 1-2% probability of miscarriage. Therefore, non-invasive prenatal testing (NIPT) approaches, based on analyzing fetal DNA circulating in the maternal plasma, were developed.

Here, we present a novel approach for detecting beta globin gene mutations present in free fetal DNA (ffDNA). This method is based on High Resolution Melting (HRM) combined with quantitative analysis.

ffDNA was isolated from maternal serum (Qiamp method) and screened for the presence of β globin gene parental mutations based on an in-house HRM developed approach. In addition, previously described SNPs in the vicinity of β globin gene, for which parents presented distinct haplotypes, were also determined.

Preliminary results from 12 cases of male embryos carrying the paternal mutation succeeded in obtaining the same diagnosis with the preceded analysis of corresponding chorionic villus sampling. Interestingly, the presence of SRY gene was clearly detected in mixtures of 0,5% of male with female genomic DNA while ffDNA is estimated to be no less than 3% of the maternal free DNA.

The described approach may be directly applied for NIPT of cases where the embryo is male and has inherited the paternal β globin gene mutation. Further development of the method is expected to cover the rest of the cases.

P01.071

Non-invasive prenatal testing (NIPT) in unusual aneuploidy cases: partial trisomies and low-level mosaicism

R. Michaelson-Cohen;

Shaare Zedek Medical Center, Hebrew University, Jerusalem Israel, Jerusalem, Israel.

Background: NIPT for aneuploidies is extremely efficient, particularly for trisomy 21(t21) and t18, with sensitivity and specificity >99%. Clinical utilization of NIPT has grown rapidly.

Patients and methods: In our referral center, women undergo NIPT for several indications. We describe performance in 3 cases.

Three rare aneuploidies were diagnosed combining NIPT (USA-based-laboratories), karyotyping.

First case: 42-year-old woman, integrated-first-second-trimester screening: high t18 risk. Ultrasound: atrioventricular septal defect and hydrone-

phrosis. NIPT: high t18 probability.

Second case: 36-year-old primigravida, IVF-ICSI-pregnancy, mildly-increased nuchal-translucency. NIPT: normal male. Later sonogram demonstrated thickened nuchal-fold.

Third case: 28-year-old, normal first, second trimester screening. 15 week ultrasound: cardiac-echogenic-focus and choroid-plexus-cyst. NIPT: t21.

Results: First case: declined invasive testing, at delivery baby showed minor t18 signs, however lacked classic features. Neonate died of respiratory complications at 3 weeks. Cord-blood-karyotype: 46,XX,der(14)t(14;18)(p10;q10) (Partial t18).

Second case: Karyotype and CMA (amniocytes): atypical Klinefelter syndrome, with isochromosome-X.

Third case: amniocyte QF-PCR: normal, however, full-karyotyping: low level t21 mosaicism (50%).

Conclusions: Many factors limit NIPT accuracy. One main limitation is genetic discrepancy between fetal and placenta tissue. This is true in simple aneuploidies, moreover in incomplete/mosaic trisomies.

In the first case, although chromosome 18 only partially-duplicated, it was correctly identified by NIPT.

However, rare isochromosome Xq Klinefelter induced false-negative NIPT, consistent with lower performance of NIPT for detection of rare sex-aneuploidies. Xq-duplication probably causes even lower detection-rate than complete duplication.

For low-level mosaicism, NIPT detected a level of mosaicism of t21, below QF-PCR detection-threshold.

These unusual cases are examples that demonstrate NIPT strengths and weaknesses.

P01.072

False positive result of trisomy 13 by non-invasive prenatal testing (NIPT) due to confined placental mosaicism

C. C. Hung¹, Y. N. Su^{1,2}, H. W. Su³;

¹Sofiva Genomics, Co., Ltd., Taipei, Taiwan, ²Dianthus Maternal Fetal Medicine Clinic, Taipei, Taiwan, ³Department of Obstetrics and Gynecology, Taichung Veterans General Hospital, Taichung, Taiwan.

Introduction: Recently, non-invasive prenatal testing (NIPT) has been proposed to be a powerful alternative to screening of aneuploidy with its high sensibility and specificity. However, there is a small chance of false positive results due to placental mosaicism.

Methods: A 31-year old woman went for NIPT at 19 weeks of gestation. The positive NIPT result was noted and Z-score value was 7.36 for chromosome 13. After informing the elevated risk for fetal trisomy 13, the pregnant woman accepted invasive diagnosis by amniocentesis to confirm the result. Amniotic fluid cells were used for karyotyping by GTG-banding and oligo array comparative genomic hybridization (aCGH).

Results: The karyotype was 46,XY and aCGH result showed arr[hg19] (1-22)x2, (X)x1, (Y)x1 on amniocentesis for the fetus. Following an abnormal NIPT result, both of the karyotype and aCGH genotype were inconsistent. Then the case underwent genotyping for the placenta and cord blood after childbirth. Interestingly, the genotype was arr[hg19] 13q12.11q34 (20,407,324-115,092,619)x3, (X)x1, (Y)x1 which is compatible with trisomy 13 for placenta, and had normal genotype for cord blood.

Conclusion: The American College of Obstetrics and Gynecology (ACOG) recommended that abnormal NIPT results should be confirmed by invasive procedures. This study shows a false positive NIPT finding due to confined placental mosaicism because the fetal cell-free DNA present in maternal plasma is mainly derived from placenta.

Fetal hydrops in combination with gonadoblastoid testicular dysplasia may represent a lethal type of Noonan syndrome

T. Reischer¹, M. Schmid¹, M. Nista², S. Balendran³, J. Vodopivec⁴, E. Krampfl-Bettelheim^{4,5}, N. Popitsch⁶, S. Liebmann-Reindl⁷, B. Streubel⁸;

¹Department of Obstetrics and fetal-maternal Medicine, Medical University of Vienna, Vienna, Austria, ²Department of Pathology, Hospital La Paz, Universidad Autónoma de Madrid, Madrid, Spain, ³Department of Pathology, Medical University of Vienna, Vienna, Austria, ⁴Department of Pediatrics, Medical University of Vienna, Vienna, Austria, ⁵Fetomed - Center for Fetal Medicine, Doebling Private Hospital, Vienna, Austria, ⁶Wellcome Trust Centre for Human Genetics, University of Oxford, Oxford, United Kingdom, ⁷Core facility genomics, Medical University of Vienna, Vienna, Austria.

Objectives: Fetal gonadoblastoid testicular dysplasia is a rare finding. The combination with typical features of Noonan syndrome has never been described so far. We performed genetic testing including whole exome sequencing in two cases with fetal hydrops, congenital heart disease and gonadoblastoid testicular dysplasia.

Methods: Exome sequencing was performed in the index case, where high quality DNA was isolated from fetal blood. In the second case and in five

further gonadoblastoma samples, conventional Sanger sequencing was performed on DNA isolated from formalin fixed, paraffin embedded tissue.

Results: Whole exome sequencing of the index case revealed a pathogenic mutation in the RIT1 gene (c.270G>A (p.Met90Ile)), leading to the diagnosis of Noonan syndrome type 8. In case 2, Sanger sequencing of RIT1 did not show any disease causing mutations. Sequencing of PTPN11 revealed a heterozygous frameshift mutation (c.1098delA, p.K366Nfs*12). Successful sequencing of four gonadoblastoma samples revealed mutations in RIT1 in two cases.

Conclusions: Here we present a lethal form of Noonan syndrome in two fetuses with typical features combined with severe hydrops and gonadoblastoid testicular dysplasia. Gonadoblastoid testicular dysplasia may be an additional feature of Noonan syndrome, which has not been described so far, but analysis of more cases is needed. Moreover, we have demonstrated a potential role of RIT1 in the pathogenesis of gonadoblastoma.

P01.074

Azoospermia and Varicocele in Noonan Syndrome

F. Hazan¹, E. Pariltay², B. S. Ada³, E. Ataman², A. Tukun³;

¹Medical Genetics, Dr. Behcet Uz Children's Hospital, Izmir, Turkey, izmir, Turkey, ²Ege University Faculty of Medicine, Medical Genetics, izmir, Turkey, ³Duzen Laboratories Group, Division of Medical Genetics, Ankara, Turkey.

Noonan Syndrome (NS) is a syndrome having autosomal dominant inheritance, characterized by typical facial dysmorphic features, short stature and cardiac abnormalities. PTPN11, SOS1, RAF1, KRAS, NRAS, and BRAF are the genes responsible for this syndrome, in which genetically heterogeneity is considered. PTPN11 gene mutation is seen approximately in 50% of the patients. Although fertility seems normal in females, males have decreased fertility. The incidence of undescended testes (UT) ranges between 60-77% that is the most responsible cause of impaired male fertility. Besides the studies reporting the functional impairment of sertolian cells, according to the hormonal evaluation of NS during adulthood; there are studies remarking the functional impairment of leydig cells. The seminal analysis of male patients with NS was reported in 3 studies (8 patients). Three of these cases were normal, whereas half of them having azoospermia and one with severe oligospermia. Here we present a father having PTPN11 mutation, screened after having a child diagnosed as NS. Father had normally placed testicles, azoospermia and bilateral varicocele in his history. He had a child with intra-cytoplasmic sperm injection (ICSI) practice, after varicocele operation. As far as we know, this is the only NS case had the ICSI practice in the literature. In this page we report the clinical presentation of the father and his girl case with literature review.

P01.075

Findings of Oligo array CGH study of de novo small supernumerary marker chromosomes detected prenatally

H. Zolghadr, A. Rajaei, A. Moshtagh, N. Sadatian, G. Abbasi, m. bazregar, s. gholami, A. Kariminejad, R. Kariminejad;

Kariminejad-Najmabadi Pathology & Genetics Center, Tehran, Iran, Islamic Republic of.

One of the most problematic findings in prenatal chromosomal studies is the presence of non-hereditary small supernumerary marker chromosomes. It is common practice to identify the status of these chromosomes by performing routine C- and NOR banding. Recently we have encouraged all couples to have oligo array comparative genomic hybridization testing for all not bisatellited markers.

Overall we have done it for eleven samples in the past two years. All eleven had markers that were not present in chromosomal study of either parent, the presence of genomic material was hard to detect and would fall into the category of sSMCs. In all these cases the sSMC was present in more than 15% of the studied cells.

We performed oligo array cgh testing on DNA extracted from chorionic villi samples or in many cases cultured amniotic fluid cells. Oligo array was performed on Illumina Cytochip 4X44 or 8X60 ISCA platforms according to manufacturer's protocol.

The results show normal genomic content in all but two cases that we detected pericentromeric genomic duplication. One showed a 13 Mb gain and the other, a 2 Mb gain on chromosome 8. Considering the size of the imbalance in the first case, the parents opted for abortion. In the second case only four genes were present in the region and the pregnancy is ongoing.

Our findings suggest that despite the small size of the marker chromosomes and their cytogenetically similar appearance, genomic analysis is necessary to help predict their possible role and phenotypic contribution.

P01.076

An intronic variant in TP73 is not associated with ovarian reserve or response markers in females undergoing assisted reproduction

D. Tohlob^{1,2}, P. Pemberton², L. Mohiyiddeen¹, W. G. Newman²;

¹Mansoura faculty of medicine, Mansoura, Egypt, ²Manchester Centre for Genomic Medicine, University of Manchester, Manchester, United Kingdom, ³Department of Clinical Biochemistry, Manchester Royal Infirmary, Manchester, United Kingdom,

⁴Department of Reproductive Medicine, Central Manchester University Hospitals NHS Foundation Trust, Manchester, United Kingdom.

The p53 family members are involved in many important biological processes, including cell regulation and apoptosis. TP73 has been associated with the size of the follicular pool, ovulation rate and maintenance of genomic stability. In a recent Brazilian study, homozygosity for an intronic variant in TP73 (c.283-5855G>A, rs4648551) was associated with diminished ovarian reserve during the assessment of females undergoing *in vitro* fertilization (IVF) [1].

The aim of our study was to investigate whether this intronic TP73 variant was associated with the ovarian reserve markers: follicle stimulating hormone (FSH), antral follicle count (AFC), and anti-Mullerian hormone (AMH), and early outcome measures: number of eggs retrieved, and gonadotropin dose required to controlled ovarian hyper-stimulation and late outcome measures, including live birth rate.

We genotyped the TP73 variant by Taqman allelic discrimination assay in 603 females, attending a reproductive medicine unit for their first cycle of controlled ovarian hyper-stimulation for IVF/ICSI. We did not detect any significant differences (p<0.05) in FSH, AFC, AMH, the number of eggs retrieved, the gonadotropin dose used or the live birth rate in women with different TP73 variant genotypes.

Our results indicate that there is insufficient evidence to support genotyping this variant to individualize the treatment protocols of females undergoing IVF/ICSI.

P01.077

Novel sequence of Pregnancy-Associated Glycoprotein-like family (PAG-L) identified in the human genome

M. Majewska¹, A. Lipka², G. Panasiwicz², M. Gowkielewicz², M. Jozwik³, A. Bossowska¹, B. Szafranska²;

¹Department of Human Physiology, Faculty of Medical Sciences, University of Warmia and Mazury, Olsztyn, Poland, ²Department of Animal Physiology, Faculty of Biology and Biotechnology, University of Warmia and Mazury, Olsztyn, Poland, ³Department of Gynecology and Obstetrics, Faculty of Medical Sciences, University of Warmia and Mazury, Olsztyn, Poland.

Introduction: The PAG-L genes encode chorionic proteins belonging to aspartic proteinases (AP), together with pepsin A,C,F, renin and cathepsin D. Conservative structure of the AP genes comprises promoter, 9 exons and 8 introns named A-H. The aim was to identify unknown nucleotide sequences of the PAG-L gene family in the human genome.

Material and Methods: Human gDNA templates (N=6) were isolated from leucocytes. The gDNA templates were used for PCR of the PAG-L sequence with primers that should amplify the region from 5'UTR to exon 2 (with exon 1 and intron A), according to AP gene structures (769-1556 bp). After electrophoresis and UV-visualization, dominant amplicons (approx. 700bp) were gel-out purified, precipitated and sequenced in both directions. All chromatograms were analyzed with Geneious software. Obtained gDNA sequences were compared to PAG-L cDNAs identified by NGS (Illumina).

Results: Sequencing of amplicons (197-680bp) permitted to identify novel sequence of the human PAG-L (named hPAG-L). This region of exon 1 revealed homology (88-99%) only to the pepsinogen family (especially PepA) in the primates. The identified sequence of the entire intron A (486bp) shared high homology (72-100%) to different gDNA clones of homo sapiens and PepA in some other mammals, including 76% homology (exon 1) and 51%

homology (intron A) to the porcine PAG2 gene.

Conclusions: This is the first report describing sequence identification of the hPAG-L/PepA gene fragment (exon 1 and intron A). Further complex studies are required to discover the entire structure of the hPAG-L gene, as potential useful novel marker for genotyping.

EvE: Reducing the cost of array-based preimplantation genetic diagnosis for chromosome rearrangements

A. R. Jones¹, A. Corrigan², S. Bint^{2,3}, A. Davies^{2,3}, P. Renwick^{3,4}, C. Mackie Ogilvie^{3,4}, J. Ahn¹; ¹Clinical Bioinformatics, Guy's & St Thomas' NHS Foundation Trust, London, United Kingdom, ²Genetics Laboratories, Viapath, London, United Kingdom, ³Guy's and St Thomas' Centre for Preimplantation Genetic Diagnosis, London, United Kingdom, ⁴Genetics Department, Guy's & St Thomas' NHS Foundation Trust, London, United Kingdom.

Introduction: The Guy's and St Thomas' Centre for Preimplantation Genetic Diagnosis (PGD) offers PGD for carriers of balanced chromosome rearrangements.

Currently, the service uses an array CGH platform to detect imbalances, hybridising DNA derived from embryo biopsies against Promega DNA as a reference sample, prepared in the same way as the biopsy. As only a few cells are biopsied, whole genome amplification is required to generate sufficient detectable signal; however, this introduces noise, which is compounded by differences between quality and nature of biopsy and reference material.

We have developed the embryo versus embryo algorithm (EvE) which enables the use of an in silico reference, and removes the need to prepare a reference sample for each embryo, significantly reducing labour and consumable costs.

Method: Two embryos are hybridised to an array. EvE takes the fluorescence intensity data for each embryo and for a stored reference embryo and performs an in silico hybridisation, which can be analysed within standard array CGH analysis software.

Results: EvE was validated by retrospective analysis of 74 abnormal embryos. Subsequently, EvE was trialled prospectively for three months (46 embryos). Overall, EvE demonstrated sensitivity >99% (95% CI 97.6-100) and specificity >99% (95% CI 98.4-100).

Conclusions: We have validated and successfully completed a prospective trial using EvE for chromosome rearrangement PGD, which increases efficiency and reduces costs for this test. Furthermore, as an optimal reference can be used for each embryo, there is potential to improve quality and analytical sensitivity.

Preimplantation genetic diagnosis by aCGH in woman with familial complex translocation - 46,XX,t(3;6;7)

S. P. Hadjidekova^{1,2}, G. S. Stamenov², S. Y. Yaneva Staykova², B. B. Rukova^{1,2}, R. G. Staneva^{1,2}, K. S. Nikolova², D. I. Toncheva¹;

¹Department of Medical Genetics, Medical University-Sofia, Sofia, Bulgaria, ²"Nadezhda" Women's Health Hospital, Sofia, Bulgaria.

Introduction: Complex chromosome rearrangements (CCRs) are very rare in humans. In three-breaking-point translocations the hexavalent meiotic configuration allows four patterns of segregation: 3:3, 4:2, 5:1 and 6:0. 64 different gametic chromosomal combinations can arise of which only 2 are normal/balanced. Carriers have an increased risk of producing embryos with unbalanced karyotype. PGD enables the selection of balanced/normal embryos for transfer, enhancing the possibility for a healthy child.

Materials and methods: A couple suffered from two early miscarriages. The woman was found to carry CCR:

46,XX,t(3;6;7)(3pter→3q13.2::7p22→7pter;6pter→6q21::3q13.2→3qter;7qter→7p22::6q21→6qter). Her first cousin had the same translocation. The couple went through stimulated and Natural-Cycle-IVF. Embryo biopsy was carried out on Day 5, collecting 5-7 trophectoderm cells. The cells were amplified by whole-genome amplification through SurePlex. The amplification products were processed by 24sure+ microarrays (Illumina) and analyzed by BlueFuseMulti software.

Results: In total 36 ova were retrieved and two ICSI-PGD procedures were performed. From the first cycle 9 ova were aspirated and 4 embryos were biopsied, none was normal/balanced. The second ICSI-PGD procedure has started with 27 eggs, 11 embryos were biopsied. We found three normal/balanced embryos. Two were transferred on Day 6 after fertilization. The third normal/balanced embryo was frozen for future transfer. The women conceived with one embryo. She refused prenatal diagnosis but after birth the cytogenetic analysis confirmed normal male karyotype 46,XY.

Conclusion: The application of aCGH for PGD is an efficient test for CCRs carriers. It reduces the risk of chromosomally imbalanced offsprings, miscarriages and enhances the baby take home rate.

P01.080

An efficient protocol for the detection of junction fragments in PGD (preimplantation genetic diagnosis) for gross deletion mutations

S. Peleg-Schalka, V. Gold, T. Frumkin, A. Carmon, S. Assaf, A. Amit, M. Malcov; Racine IVF Unit, Lis Maternity Hospital. Sourasky Medical Center, Tel Aviv, Tel Aviv, Israel.

Introduction: In PGD for monogenic disorders the causal mutation is usually diagnosed by restriction enzymes or GeneScan analyses. However, in familial gross deletions, primarily diagnosed by MLPA or SNP arrays, the exact breakpoints location is unknown and identifying the deleted region is challenging.

Aim: To present an effective and simple protocol to detect gross deletions in PGD by amplifying junction fragments.

Methods: Four couples carrier of gross deletions in chromosomes 11, 16, FANCA and MSH2 opted for PGD. Deletions ranged between 6-241kbp. In order to confine the junction fragments 6-25 primers, flanking the deleted regions, were purchased. The closest primers were designed 500bp from the positive probe/ SNP, followed by several primers in a similar distance. Following amplification of a junction fragment, amplicons' sizes were restricted by moving toward the breakpoints. **Results:** In 3 cases we managed to create a junction fragment and applied it to PGD. Amplification failure in one

case was due to extended duplication regions homologues to the deletion. Six PGD cycles were performed. One couple with deletion in chromosome 16 achieved pregnancy and another couple with simultaneous detection of 2 FANCA mutations and HLA matching has delivered one healthy child and BMT was performed successfully. **Discussion:** For maximal accuracy in PGD, direct detection of mutations along with haplotype analysis is required. Whenever informative polymorphic markers are absent in the deleted regions, we applied an effective protocol for junction fragments detection by scanning large DNA regions. This turns PGD for gross deletions a reliable and simple procedure.

Benefits of combined preimplantation genetic screening and endometrial receptivity assessment on IVF outcome for complicated reproductive history patients

L. Volozonoka^{1,2}, L. Kornejeva², N. Novikova^{2,3}, V. Fodina²;

¹Riga Stradins University, Riga, Latvia, ²"IVF Riga" Reproductive Genetics Clinic, Riga, Latvia, ³Latvian University, Faculty of Medicine, Riga, Latvia.

Introduction: The mechanism of recurrent implantation failure (RIF) still remains a mystery in many cases of IVF treatment. Embryonic factor exclusion by preimplantation genetic screening (PGS) is relevant step in achieving considerably good results; however failure rates do not fade away. Testing of endometrial transcriptome (ERA-test) has been launched recently to catch skewed implantation window.

The aim of our study was to evaluate the endometrial receptivity as an implantation failure factor in infertile couples after negative post-PGS embryo transfer (ET).

Materials and methods: IVF was performed by ICSI technology. PGS was applied to 80 families. Trophectodermal cells were analyzed according to 24Sure protocol (Illumina). Endometrial biopsies for ERA-testing were performed according to manufacturer's (Igenomix) instructions.

Results: 19 couples (23%) had no euploid embryos after PGS (female age 41.06±3.42). 20 families are waiting for ET; 41 ET has been performed, 25 of them resulted in clinical pregnancies (61%, female age 33.77±5.14, BC amount 5.58±3.22, euploid embryo amount 2.33±1.55). In control group (679 couples, female age 38.25±5.4, no PGS, no ERA) clinical pregnancy rate was 37.86%. Half of the patients with negative ET post factum showed non-receptive endometrium.

Conclusions: Results suggest that PGS analysis can exclude one of the leading infertility causes - embryo chromosomal incompetence. Great amount of RIF patient has skewed implantation window, assessment of which is crucial in successful implantation establishment. RIF patient subgroup is heterogeneous and options such as PGS should be applied carefully based on embryo amount and quality, managing infertile couples in individual patient-tailored manner.

Uniparental disomy of chromosome 12 which leads to a phenylketonuria case

S. Azadmehri¹, T. Shirzad¹, E. Davoudi-Dehaghani¹, S. Dabbagh-Bagheri¹, Z. Sharifi¹, A. Bandehi Sarhadi¹, L. Rejali¹, F. Mollazade¹, F. Golnabi¹, H. Bagherian¹, M. Fallah^{1,2}, Z. Zeinali^{1,3};

¹Dr. Zeinali's Medical Genetics Lab, Kawsar Human Genetics Research Center (KHGRC), Tehran, Iran, Islamic Republic of; ²Cellular and Molecular Endocrine Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran, Islamic Republic of; ³Department of Molecular Medicine, Biotech Research Center, Pasteur Institute of Iran, Tehran, Iran, Islamic Republic of.

Introduction: Phenylketonuria (PKU) is one of the most prevalent amino acid metabolism disorders caused by deficiencies in the PAH gene located on chromosome 12(12q23.2). Affected persons are born from carrier parents with autosomal recessive pattern of inheritance.

Material and method: A 9-year-old boy who was identified to be affected through newborns screening for PKU referred to our laboratory. Sanger sequencing of PAH gene was performed by extracted DNA from peripheral blood sample. Linked STRs and VNTR analysis were done in parallel. MLPA (Multiplex ligation-dependent probe amplification) technique was utilized to detect probable deletion in PAH gene. Performance of DNA fingerprinting by evaluation of 16 different DNA markers for the child and his mother.

Result: PAH: c.782G>A mutation was detected in patient. His father was heterozygote for the same mutation while surprisingly his mother was normal. DNA fingerprinting confirmed maternity with over 99.9% certainty. MLPA results did not show any deletion for the affected child and also his mother. No common haplotype in STR analysis and same number of repeats in VNTR was found for the affected child and his mother. The probability of uniparental disomy of chromosome 12 was verified observing homozygous haplotype in STR analysis linked to two other genes on chromosome 12, VWF gene 12p13.3 and MMAB gene 12q24.

Conclusion:

Paternal uniparental disomy of chromosome 12 is a rare chromosomal anomaly. This study highlighted the importance of STRs and VNTRs analysis along with mutation detection to specify necessity of prenatal diagnosis.

P01.083

Study of the genetic etiology of primary ovarian insufficiency (POI): FMR1 and FMR2 genes

M. Barasoain¹, G. Barrenetxea², I. Huerta^{1,3}, M. Téletz^{1,3}, E. Ortiz-Lastra², J. González², B. Criado⁴, M. Arrieta¹;

¹Department of Genetics, Physical Anthropology and Animal Physiology, Faculty of Science and Technology, University of the Basque Country, Bilbao, Spain, ²Department of Medical-Surgical Specialities, Faculty of Medicine, University of the Basque Country, Bilbao, Spain, ³Virgen de Begoña Clinical Analysis Laboratory (Medikosta), Erandio, Spain, ⁴Cooperativa de Ensino Superior Politécnico e Universitario (CESPU), Porto, Portugal.

Primary ovarian insufficiency (POI) is an ovarian dysfunction defined as irregular menses and elevated gonadotrophin levels before or at the age of 40 years. The FMR1 intermediate (35-54 CCGs) and premutation (55-200 CCGs) alleles have been related with the development of this condition. The FMR2 alleles with 11 or less CCG repeats are also a possible genetic cause of POI. A group of 68 women with ovarian dysfunction of unknown etiology, divided into three groups concerning their ovarian condition, and 47 control women from the Basque Country were analyzed. The FMR1 gene, including the length of the repeat and the AGG interspersed pattern, and the number of CCG repeats of the FMR2 gene were evaluated. Considering the FMR1 gene, the frequency of alleles with 35-200 CCG repeats was statistically higher in the patient group and in the three subgroups. Moreover, these alleles appeared to have two interruptions, the first AGG located in the 10th position and more than 15 CCG at the 3' end with the predominant structure 9+9+n. The patient group presented, in general, more unstable alleles and therefore the FMR1 gene appeared to play a role in the etiology of POI in the patient group. Regarding the FMR2 gene, we have not found a clear association with the development of an ovarian dysfunction.

This work has been supported by the Vicerectorate for research of The University of the Basque Country (GIU 10/05 and UFI 11/32).

Isomerism, intellectual disability and clinical features associated with mutations in the Polyglutamine-binding protein 1 (PQBP1) gene

L. Martínez Ribot¹, P. Fernández Álvarez¹, M. Sánchez Duran², S. Arévalo Martínez³, T. Vendrell Bayona¹, A. Cueto González², M. Borregan Prats³, F. Lopez Grondona¹, E. Tizzano Ferrari¹;

¹Department of Clinical and Molecular Genetics and Rare Disease Unit, Hospital Vall d'Hebron Barcelona, Spain, Barcelona, Spain, ²Prenatal Diagnosis Unit, Hospital Vall d'Hebron Barcelona, Spain, Barcelona, Spain, ³Fetal Medicine Unit, Hospital Vall d'Hebron Barcelona, Spain, Barcelona, Spain.

Introduction: A 31-year-old woman was referred to our center at 20 weeks of gestation because of a male fetus presented congenital heart defect, left isomerism and ventriculomegaly. No consanguinity was reported but as family history, her brother and a maternal uncle had mental retardation of unknown cause and similar physical characteristics.

Methodology: Genetic prenatal studies performed in the fetus (karyotype and CGH-array) were normal. The differential diagnosis of the fetus was interpreted not only based in the autopsy findings but also mental retardation present in the two males. PQBP1, an X-linked gene, was considered to be a potential candidate cause. Sanger sequencing of the coding region of PQBP1 (six exons, GenBank accession no. NM_005710.2) as well as the flanking intronic sequences were performed from fetal genomic DNA and after in DNA of the consultant, her brother, mother, maternal uncle and aunt.

Results: A 5'UTR mutation (c.-20A>C; NG_015967.1:g.5579A>C) was identified in the fetus, the patient, her mother and both males affected with mental retardation.

The mutation identified was not described before in the scientific literature. It is considered as possible pathogenic because its location in the promoter region of the gene could affect the transcription/translation of the protein. Apart from cognitive impairment, physical similarities were found in both males. All these features are described in patients with other PQBP1 mutations.

Conclusions: PQBP1 should be considered as a candidate to study when an X-linked unknown cause of mental retardation is associated with clinical features such as isomerism, short stature and microcephaly.

Since the first cases of PGD-HLA in 2001, >1000 cases have been performed, making it a well-established procedure. However, limited publications preclude evaluation of parameters (assisted-reproduction, embryology, genetic probability) influencing positive outcomes: donor-live-born babies and haematopoietic stem-cell transplantation (HSCT). This retrospective multicentre cohort study, co-ordinated by the ESHRE PGD-Consortium, aims to address this. In 2014, 30 PGD centres with published/known PGD-HLA activity were invited to participate. Fourteen centres submitted data between February-September 2015, using a custom-designed secure database (Redcap). Data parameters covered assisted-reproduction procedures, embryology, genetic diagnosis, donor-babies born and HSCT for 704 PGD-HLA cycles (364 couples), analysed using STATA SEv.11. HLA-matching with concurrent exclusion of monogenic disease accounted for 81%. Mean maternal age was 33years, 7.5% couples were infertile, with 1.93 PGD-HLA cycles/couple. 9751 oocytes were retrieved (13.89/cycle), 5552 embryos (7.88/cycle) were analyzed (85% on day-3), using PCR-based protocols (97% cycles). Of 4392 embryos diagnosed (79% of analyzed), 644 were genetically suitable (16.2% of those analysed for HLA alone; 10% of those ana-

lysed for HLA with monogenic disease exclusion). 56.6% of couples had an embryo-transfer (598 embryos in 382 cycles), producing 163 HCG-positive pregnancies (pregnancy-rate/embryo-transfer: 42.67%, pregnancy-rate/initiated cycle: 24.3%). To September 2015, 127 babies were born and 30 pregnancies ongoing. HSCT was performed in 55 cases (7.8% cycles initiated), 76.1% without complications. This first multicentre study evaluates clinical utility of PGD-HLA. Genetic probability remains a major limitation to overall success, but further data analysis is expected to highlight other factors. Acknowledgement: ESHRE funded database customization and data analysis.

Identification of mutated genes in consanguineous families with premature ovarian failure

S. Caburet^{1,2}, F. Fauchereau^{1,2}, A. Todeschini^{1,2}, B. Legois^{1,2}, M. Fellous^{3,4}, R. A. Veitia^{1,2};
¹Institut Jacques Monod, Paris, France, ²Université Paris Diderot-Paris VII, Paris, France, ³Institut Cochin, Paris, France, ⁴Université Paris Descartes-Paris V, Paris, France.

Premature ovarian failure is the endpoint of premature ovarian insufficiency (POI) and represents the complete loss of ovarian function. Although POI is a multifactorial condition, the existence of familial cases shows that it can be inherited as the result of a genetic defect. The genetic analysis of families, particularly very informative consanguineous families, is therefore invaluable to identify genes involved in the pathology.

We analysed two consanguineous families from Middle-East, respectively with 4 and 2 affected sisters. Combining linkage analysis, homozygosity mapping and exome sequencing, we identified in the first family a 1-bp deletion in the STAG3 gene, leading to a truncated coding sequence. STAG3 encodes a meiotic component of the synaptonemal complex, a ring that entraps sister chromatids and is required for proper pairing of homologous chromosomes during meiosis. STAG3 loss of function as the cause of POI was confirmed by the Stag3-deficient mouse model, in which both sexes were infertile due to loss of germ cells and degenerative gonads. In the second family, this approach highlighted a premature stop codon in MCM9, encoding the minichromosome maintenance complex component 9, recently implicated in POI associated with short stature. Furthermore, Mcm9-deficient mice were sterile with empty ovaries. Therefore, our results provided the first confirmation of the implication of MCM9 mutations in POI, expanding the phenotypic spectrum to females with normal height.

The genetic analysis of consanguineous families combining linkage analysis and exome sequencing is a powerful way to unravel genetic etiologies, especially in highly heterogeneous conditions such as POI.

Current dilemmas in prenatal diagnosis revealed through new genomics applications and a single center's 30 years' experience and 90,000 cases

C. Konialis, C. Pangalos;
 InterGenetics-Diagnostic Genetics Center, Athens, Greece.

Introduction: Recent developments in genomics and the wealth of data accumulated from the application of various diagnostic molecular approaches in prenatal diagnosis, combined with the advent of novel non-invasive prenatal screening tests (NIPT), have introduced new challenges in this highly sensitive field. We provide a perspective of prenatal diagnosis derived from a single center's evolving experience from more than 90,000 consecutive prenatal cases and we highlight important issues and current dilemmas.

Materials and Methods: Prenatal cases were referred for various indications and more than 90,000 clinical investigations were performed by a combination of standard karyotype, multiplex ligation-dependent probe amplification (MLPA), standalone array comparative genomic hybridization (aCGH) and exome sequencing.

Results: Classic karyotype revealed 1.7% and 7.9% of pathological cases in amniotic fluid and CVS samples, respectively, common aneuploidies accounting for 59.6% and 64.3% of the total abnormal. Molecular approaches increased the diagnostic yield by 0.6% for MLPA and 1.6% for aCGH, uncovering pathogenic chromosomal abnormalities undetectable by karyotype analysis. Finally, exome sequencing provided a further beneficial increase in our diagnostic capabilities.

Conclusions: Current molecular diagnostic capabilities and the recent introduction of NIPT point to one current major dilemma in prenatal diagnosis, with serious implications in genetic counseling of parents, relating on the one hand to reaping the benefits from the high detection rate afforded through new powerful diagnostic techniques, but accepting an invasive risk, and, on the other hand, offering a lower detection rate practically for Down syndrome only, with minimal invasive risk.

P01.089
Walker-Warburg syndrome as a cause of prenatally detected hydrocephalus in two Roma families

J. Laštůvková¹, A. Klímová¹, M. Tóthová², T. Nix², M. Fišer², V. Čejnová¹, V. Harmaš¹;
¹Masaryk Hospital, Ústí nad Labem, Czech Republic, ²GENvia, s.r.o., Praha, Czech Republic.

Walker-Warburg syndrome is a rare autosomal recessive inherited condition characterised by brain and eye abnormalities and severe congenital muscular dystrophy. Most of affected individuals die before the third year of age. Disorder is caused by mutations in several different genes, one of them is ISPD gene.

Our patients are two unrelated young women of Roma origin. Both of them were referred to genetic examination because of ultrasound detection of hydrocephalus of foetus in the second trimester of gravidity. Diagnosis was also confirmed by magnetic resonance imaging. Both women decided to terminate their pregnancy. Karyotype of both fetuses was normal, but Array CGH identified homozygous a 290kb deletion of ISPD gene at chromosome 7, which is one of causes of Walker-Warburg syndrome. Mothers and their partners are heterozygous carriers of this deletion. Genetic counselling was provided in affected families. They were informed about possibility of assisted reproduction and PGD and about possibility of early prenatal detection of Walker-Warburg syndrome from CVS. Unfortunately, in the subsequent gravidity of both our patients the foetal hydrocephalus was again confirmed in the second trimester.

The overall incidence of Walker-Warburg syndrome is unknown, but for example in the Ashkenazi Jewish population it is 1 in 60500 with frequency of heterozygous carriers 1 in 149. There is no study about frequency of Walker-Warburg syndrome in Roma population.

Walker-Warburg syndrome should be considered in a differential diagnosis of prenatal detected hydrocephaly and it would be useful to assess frequency of ISPD gene deletion in Roma population.

P01.091
A QF-PCR/aCGH strategy for the diagnosis of chromosome imbalance in products of conception (POC) and fetal tissues

C. Donaghue¹, N. Davies¹, J. Ahn², H. Thomas¹, C. Mackie Ogilvie², K. Mann¹;
¹Genetics, VIAPATH, London, United Kingdom, ²Genetics, Guys and St Thomas Hospital, London, United Kingdom.

In the UK, karyotype analysis of couples with recurrent miscarriage has been replaced by genetic investigation of POCs and fetal tissues. As a consequence, sample numbers for these tissues have increased by 69% in our laboratory since 2012. We have replaced karyotype/MLPA testing of miscarriage products with QF-PCR for chromosomes 13, 14, 15, 16, 18, 21, 22, X and Y, followed in the case of normal results by aCGH. All array imbalances >1Mb and any fully penetrant clinically significant array imbalances <1Mb are reported. In an 18 month period, 1391 samples were tested using this approach. 25.9% of samples were found to be abnormal on QF-PCR and aCGH identified a further 9.4% of samples with clinically significant imbalance, giving an overall abnormality rate of 35.3%. The initial QF-PCR test is rapid, cost-effective and clinically indicated, detecting triploidy (4%) and maternal cell contamination in addition to the common aneuploidies. The aCGH analysis approach minimises the number of unknown and reduced penetrance CNVs that are reported; 0.7% of samples were reported to have an imbalance of uncertain clinical significance. Overall, our QF-PCR/aCGH strategy has a lower failure rate and higher detection rate than karyotype or MLPA strategies. Detection of chromosome imbalance provides reasons for pregnancy loss and fetal abnormalities, minimising further investigations and informing risk of recurrence of both miscarriage and fetal abnormality.

P01.092
Recurrent miscarriage and implantation failure-Could the etiology be maternal intolerance itself?

P. Ata¹, S. Soysal², A. Turkyilmaz¹, K. Delil¹, G. Ilhan³, B. Geckinli¹, M. VuraF¹;
¹Dept of Medical Genetics, Marmara University Faculty of Medicine, Istanbul, Turkey, ²Dept of Obstetrics and Gynecology, Marmara University Faculty of Medicine, Istanbul, Turkey, ³Dept of Obstetrics and Gynecology, Marmara University Faculty of Medicine, Istanbul, Turkey.

Recurrent miscarriage and recurrent implantation failure (RIF) is one of the most controversial issues in assisted reproduction. Herein our aim is to search the factors affecting maternal tolerance to pregnancy.

We investigated 34 infertile couples with recurrent miscarriage, admitted to assisted reproduction between July 2014 to January 2016. Male factor is excluded. Karyotyping and thrombophilic mutations (Prothrombin, Factor V Leiden, MTHFR 677, 1298 mutations) were analyzed. HLA and KIR typing

of the couples and Panel Reactive Antibody (PRA) level of the females were performed. For HLA and KIR typing Sequence Specific Primer (SSP) technique is used. Natural Killer Cell quantitation and PRA levels are determined by Flowcytometric analysis.

Of the 34 couples we had 10 couples who had three and more miscarriages and implantation failure and the remaining 24 couples had one or two miscarriages after assisted reproduction. There were more patients with MTHFR mutations at the second group than the first ($p < 0,05$). There were no patients with Factor V Leiden and Prothrombin mutations. Five couples had chromosomal rearrangements of three inversion chromosome 9 and two translocations. Patients at the second group having more miscarriages had maternal KIR typing as AA haplotype and paternal HLA-C2 typing as predisposing factor for the "fetal rejection" compared to the first group patients (8/10 versus 5/24 respectively,) ($p < 0,05$).

Herein our results support that there is a worse effect of KIR and HLA-C mismatch on fertility and those patients with MTHFR mutations had more miscarriages compared to wild type MTHFR carriers.

P01.093

Change to guidelines for investigations for recurrent miscarriage - effect on solid tissue referrals

N. Davies, C. Donaghue, R. Pain, L. Allan, A. Bergbaum, K. Mann, K. Pawliczak; Viapath, Guy's Hospital, London, United Kingdom.

In April 2011 the Royal College of Obstetricians and Gynaecologists (RCOG) published new recommendations for investigation and treatment of couples with recurrent miscarriages; cytogenetic analysis should now be performed on products of conception rather than the couple's blood samples. Inheritance studies are only recommended if an unbalanced structural chromosomal abnormality is detected in the products of conception.

These recommendations were implemented in the SE Thames region in April 2012.

We experienced an increase in the total number of products of conception samples from 2011/12 to 2012/13 (42.3%) and a further increase from 2012/13 to 2013/14 (18.4%), with concomitant increase of products with sample quality insufficient for analysis.

Gestation was given for 1126 (61%) samples; the first trimester samples increased from 109 in 2011/12 (39.4%) to 181 in 2012/13 (51%) to 239 in 2013/14 (52.1%). Of the samples received, with a known gestation, following the release of the new guidelines, 207 (11.3%) samples were classed as unsuitable, of which 71 were from the first trimester. Overall, the number of tests which did not yield a result rose from 9.6% in 2012/13 to 12.3% in year 2013/14.

Poor morphology, or lack of fetal or placental material in these early gestation samples are the likely causes of the increase in failure to obtain a diagnosis. Nevertheless, cause of miscarriage was identified in 35.3% of cases, in the period following the new recommendations.

P01.094

Relevance of SNP on p53, IL-11, IL-10, VEGF and APOE in patients with repeated implantation failure (RIF) and pregnancy loss (RPL)

B. Lledo¹, J. Ortiz¹, R. Morales¹, A. Turienzo¹, J. Llaca², R. Bernabeu¹; ¹Instituto Bernabeu Biotech, Alicante, Spain, ²Instituto Bernabeu, Alicante, Spain.

INTRODUCTION: In a population of RIF and RPL patients a high incidence on different gene polymorphisms was observed. The aim of this work was investigate whether single nucleotide polymorphism on p53, IL-11, IL-10, VEGF and APOE have a higher prevalence among women with a history of recurrent implantation failure (RIF) and pregnancy loss (RPL).

MATERIAL AND METHODS: SNPs genotyping (rs1042522-p53-R72P; rs1800896-IL-111082AG; rs1570360-VEGF-1154AG; rs11668344-IL-10; rs429358-APOE-R112C; rs7412-APOE-R158C) using TaqMan-assays has been studied in 255 women. The control group included 89 oocyte donors. In the study group included 166 women: 77 with RIF and 89 with RPL. RIF was defined as a total of four transferred cleaved good quality embryos with negative hCG. RPL was defined as two or more miscarriages.

RESULTS: The frequency of P72/P72 genotypes on p53 gene among women experiencing RIF was 9.5% compared with 13.5% for those with a history of RPL and 6% in controls ($p < 0,05$). The frequency of E4 isoform on APOE gene among RIF was 18.6% compared with 28.9% for those with RPL and 13.5% in controls ($p < 0,05$). A tendency between the frequency of genotypes distribution with respect to VEGF and IL-11 was shown with no statistical significance difference. As for IL-10 no differences were reported.

CONCLUSION: This investigation reveals that in RIF and RPL patients P72 on p53 gene and E4 isoform on APOE are more prevalent than fertile population. This information together with some additional markers will allow developments of diagnostic tests for detect risk for RIF and RPL before infertility treatment is initiated.

P01.096

Fetal imaging in the diagnosis of skeletal dysplasias and craniosynostosis - a case series

V. Ward¹, M. Irving¹, A. Belezza¹, S. Sankaran², P. Kyle², G. J. Lee³, C. Walsh⁴, S. Allouini⁴, C. Ogilvie⁵, K. Mann⁵, D. Shears⁶, J. Carmichael⁷, M. Holder-Espinasse¹; ¹Clinical Genetics, Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom, ²Maternal-Fetal Medicine, Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom, ³Neonatology, Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom, ⁴Molecular Genetics, Viapath, Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom, ⁵Genetics laboratories, Guy's Hospital, Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom, ⁶Clinical Genetics, Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom, ⁷Paediatric Radiology, Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom.

There are more than 450 skeletal dysplasias ranging in severity and degree of associated complications, and although individually rare, collectively they have a birth incidence of around 1 in 5000. Prenatal diagnosis is often prompted by the finding of short long bones on ultrasound scanning or in cases with a family history of skeletal dysplasias. Specific diagnosis can be difficult and relies on clinical, radiological and molecular criteria.

Craniosynostosis, the premature fusion of cranial sutures, has a prevalence of 1 in 2000 and around 15% of these are syndromic and associated with other anomalies. Prenatal ultrasound diagnosis of craniosynostosis can be difficult and so a definite diagnosis relies on DNA testing.

The use of fetal MRI and CT scan imaging has advantages over ultrasound imaging and can provide excellent tissue resolution and a greater field of view. Detailed imaging allows for a clear differential diagnosis to be established as early as possible, enabling further investigations such as molecular diagnostic testing to be considered. This can allow for the distinction between lethal and non-lethal dysplasias, and permit further discussions with parents around prognosis and management.

We report 4 prenatal cases of Saethre-Chotzen and Carpenter syndromes, Hypochondrogenesis, and Metatropic dysplasia with their clinical, radiological and molecular features. We show the first UK case where fetal CT scan was performed as well as MRI images. The findings demonstrate the importance of fetal imaging in helping to reach a prenatal diagnosis and the impact it has on subsequent clinical management.

QF-PCR and SNP array offer a superior method for detection of copy number variant and copy number neutral abnormalities in a consanguineous family

G. A. M. Nimmo¹, N. Martin², A. Staines², N. Watkins³, A. Noor³, D. Chitayat^{1,2}, E. Kolomietz³;

¹Division of Clinical and Metabolic Genetics, The Hospital for Sick Children, The University of Toronto, Toronto, ON, Canada, ²The Prenatal Diagnosis and Medical Genetics Program, Department of Obstetrics and Gynecology, Mount Sinai Hospital, Toronto, ON, Canada, ³The Department of Pathology and Laboratory Medicine, Mount Sinai Hospital, Toronto, ON, Canada.

Background: Chromosome microarray analysis can identify submicroscopic genomic imbalances that may not be detectable by karyotyping. Because of this increased yield, microarray analysis is emerging as a first-line test for prenatal diagnosis in pregnancies with fetal anomalies or with invasive testing for another indications. Furthermore, single nucleotide polymorphism (SNP)-arrays offer the ability to detect copy neutral chromosomal aberrations such as uniparental disomy and absence of heterozygosity. Our centre offers combined rapid aneuploidy screening, by quantitative fluorescence-PCR (QF-PCR), with SNP-array as a first line test in women undergoing invasive prenatal testing. **Report:** We describe a consanguineous couple, known to be carriers for a recessive disease by family history, presenting with multiple fetal abnormalities at 12 weeks gestation. The fetal abnormalities were not in keeping with disease known to segregate within this family. Combined aneuploidy screening performed on chorionic villus sampling was suggestive of monosomy 21. SNP-array subsequently demonstrated normal chromosome copy-number and near complete absence of heterozygosity (AOH) of chromosome 21. Further testing revealed homozygous mutations in the *MKS1* gene known to cause Meckel-Gruber Syndrome. **Discussion:** The initial QF-PCR result of monosomy 21 would have predicted a low recurrence risk for this family. SNP-array demonstrated a significant proportion of the genome with AOH. This information, along with the findings from additional molecular testing identified that this couple was a carrier for a second recessive disease. The combination of both tests allowed for more accurate counselling in this and future pregnancies.

P01.098

Prenatal diagnosis of a de novo, interstitial duplications of 10q24.32, associated with split hand and foot malformation by array comparative genomic hybridization

M. Smyk¹, P. Węgrzyn², K. Sobiecka¹, M. Kędzior¹, E. Obersztyń¹, B. A. Nowakowska¹;
¹Dep. of Medical Genetics, Institute of Mother and Child, Warsaw, Poland, ²Dep. of Obstetrics and Gynecology of the Medical University of Warsaw, Warsaw, Poland.

Introduction: Split hand and foot malformation (SHFM) is a condition characterized by hypoplasia or aplasia of central digital rays, clefts of hands and feet and variable fusion of remaining digits and occurs in 1:20000 newborns. In 2004 Roscioli et al. characterized a large autosomal dominant pedigree segregating split-hand/foot linked to chromosome 10q24. Since then postnatal cases with duplication of this region and SHFM phenotype have been described. Herein we present for the first time two prenatal cases of a de novo interstitial duplication of 10q24.32 and SHFM.

Materials and Methods: In both cases amniocentesis was performed at 16 weeks gestation, due to the presence of fetal SHFM, detected by ultrasound scan. Chromosome analyses were performed on cultured amniotic cells at approximately 350 band resolution. Array CGH was performed using commercially available array (CytoSure, OGT, UK). Confirmatory FISH analyses were performed in cultured amniotic cells and peripheral blood lymphocytes from parents, using BAC clone specific for the 10q24.32 region.

Results: G-band chromosome analyses revealed normal karyotypes, whereas the array CGH detected duplication at chromosome 10q24. In the common duplicated region 3 genes are mapped: BTRC, POLL and FBXW4, the results were confirmed by FISH.

Conclusions: The detailed second trimester ultrasound scan can detect major fetal malformations and is offered for routine prenatal care. Array-CGH allowed a precise chromosomal diagnosis, confirming this analysis as a first tier approach to clarify molecular bases of fetal malformations.

This work was granted from Ministry of Science and Higher Education (3942/E-215/S/2014 to BAN).

Preimplantation diagnostics after genomic analysis in spontaneous abortions

I. Dimova¹, T. Milachich², M. Savova², T. Timeva², M. Yunakova², A. Shterev²;
¹Medical University Sofia, Sofia, Bulgaria, ²SAGBAL Hospital „Dr.Shterev“, Sofia, Bulgaria.

Spontaneous abortions, defined as embryonic or fetal loss before 20 weeks of gestation, occur at a frequency of 10-15% of confirmed pregnancies. Establishing their etiology is essential for proper clinical decision in each case. About 10% of women with one miscarriage are at risk of recurrent spontaneous abortions, which is a great physical and emotional burden. The most common causes of this condition are fetal genetic abnormalities. In the present study we performed whole-genome analysis by array CGH in 10 abortive tissues. We detected the following genomic anomalies: 2 cases with 47,XY,+22 [arr(22)x3]; 1 case with 47,XX,+20 [arr(20)x3], 47,XY,+16 [arr(16)x3] and 46,XY,arr(7p)x3. Since the last case represents a structural aberration we assumed a carriership of balanced chromosomal aberration and performed cytogenetic analysis of the parents. The karyotype of the mother showed balanced translocation with breakpoints 7q11 and 10p13 - 46,XX,t(7;10)(q11;p13), explaining the observed fetal anomaly. Based on this result we performed preimplantation diagnostics in the family using array CGH and only balanced embryo was transferred. The patient has successful ongoing pregnancy.

Conclusion: We detected chromosomal aberrations in 50% of the analyzed cases. Among them were present both frequent (such as trisomy 16 and 22) and less common (trisomy 20) anomalies. The structural anomaly revealed constitutional aberration which needs PGD for patient's safety and successful pregnancy. We conclude that genomic analysis is an effective tool in the complex diagnostic approach in spontaneous abortions and could be first line analysis with grate impact on decision making.

Recurrent de novo translocation trisomy 21 in the same family

I. Soldatova, J. Horáček, E. Zemánková, M. Kláková, D. Stejskal, M. Koudová;
 GENNET, Prague, Czech Republic.

Rapid detection of aneuploidies of chromosomes 13,18, 21, X and Y (RAD) using Quantitative Fluorescent Polymerase Chain Reaction (QF-PCR) has been routinely performed in our laboratory since 2002.

Here we present a case of recurrent translocation trisomy 21 (Down syndrome) in one family resulting from two different maternal meiotic division errors. In both cases origin and mechanism of non-disjunction was elucidated by the QF-PCR.

The first pregnancy of unrelated healthy parents (25 and 24 years) was referred to invasive prenatal diagnosis due to significant aneuploidy risk calculated from multi-marker screening results in 2010. Diagnostic procedure was declined by the family and the newborn karyotype was 46,XX,+21,der(21;21)(q10;q10). Both parental karyotypes were normal (46,XX and 46,XY). QF-PCR using peripheral blood of the newborn proved maternal origin of trisomy with non-disjunction in meiosis I.

In the consecutive pregnancy 2014 chorionic villi sampling (CVS) was performed due to history and high risk for trisomy 21 of first-trimester combined screening. Fetal karyotype was again 46,XX,+21,der(21;21)(q10;q10) and the pregnancy was electively terminated. However, in this case the trisomy of chromosome 21 was proved to be of the maternal origin resulting from meiosis II error. So the derivative chromosome 21 turned out to be most likely an isochromosome 21 with a corresponding karyotype description 46,XX,i(21)(q10).

Due to the plausible high recurrence risk of maternal meiotic errors the family meets the criteria for preimplantation aneuploidy screening (PGS) in prospective reproduction.

Prenatal diagnosis of trisomy 2 mosaicism: discrepancy between FISH study on uncultured amniocytes and karyotyping of cultured amniocytes

N. Marle¹, A. Mosca-Boidron¹, C. Thauvin², T. Rousseau², D. Lehalle², J. Thevenon⁴, N. Jean-Marçais², F. Harizay², N. Laurent², L. Faivre², P. Callier¹;

¹Laboratoire de Cytogénétique, Plateau Technique de Biologie, CHU Dijon, Dijon, France, ²Centre de Génétique et Centre de référence „Anomalies du Développement et Syndromes Malformatifs“, Hôpital d'Enfants, CHU Dijon, Dijon, France, ³Maternité du Bocage, CHU Dijon, Dijon, France, ⁴Centre de Génétique et Centre de référence, Dijon, France, ⁵Laboratoire d'Anatomo-Pathologie, Plateau Technique de Biologie, CHU Dijon, Dijon, France.

True trisomy 2 mosaicism is rare and has been reported in only one in 58 000 cases of second-trimester amniocenteses. We report on a healthy 38-year-old G2P1 woman who underwent chorionic villus sampling (CVS) at 14 weeks of gestation because she presented an abnormal first trimester maternal serum screening (1/196). A non-mosaic 47,XX,+2 karyotype was found on direct cytogenetic analysis and on long-term CVS culture. Amniocentesis was performed at 16 weeks of gestation. FISH analysis on uncultured amniocytes revealed the trisomy 2 at a non-significant level. However, conventional cytogenetic and FISH studies on cultured amniocytes detected mosaic trisomy 2 in two independent cultures. Detailed ultrasonographic examination at 18 weeks of gestation showed an eutrophic fetus, without malformation. The patient declined the option to conduct a fetal ultrasound follow-up and decided to terminate the pregnancy.

Genetic counseling for mosaic trisomy 2 remains delicate because of the rarity of published cases and the difficulty to determine if the trisomy involves fetal tissues or only the amniotic epithelium. Moreover, it has been established that presence of autosomal trisomy in amnion correlates with poor outcome even when the fetus appears to carry only diploid cells.

To date, 19 cases of mosaic trisomy 2 detected by amniocentesis have been reported. Of these, 10 cases were associated with prominent phenotypic abnormalities. There were only four births with a normal phenotype.

Here, we conduct an exhaustive analysis of all published observations plus the present case in search of elements with prognostic value that may facilitate genetic counseling.

P01.102

Mosaicism of trisomy 21 due to an isochromosome 21 with the normal cell line resulting from a two-step rescue

B. S. Kristiansen¹, J. R. Fagerberg², C. R. Fagerberg¹;

¹Odense University Hospital, Dept. of Clinical Genetics, Odense, Denmark, ²Odense Katedralskole, Odense, Denmark.

Introduction: In a pregnancy with NT of 6,7mm and maternal serum markers indicating high risk of aneuploidy, the aneuploidy screening with QF-PCR on chorion villus sample (CVS) showed trisomy 21 and chromosomal analysis showed isochromosome 21 to be the cause. However, in the aborted fetus, QF-PCR seemed compatible with normal quantities of chromosome 21.

We present how additional QF-PCR analysis reveals the structural anomaly. **Materials and Methods:** CVS, different tissue samples from the fetus, and blood samples from the parents.

Rapid aneuploidy screening with quantitative fluorescence PCR (QF-PCR). (Devyser Compact kit)

Standard chromosomal analysis

Results: Trisomy 21 based on an isochromosome 21 was found in CVS. QF-PCR analysis of DNA from different tissues from the aborted fetus showed

normal or borderline normal results by QF-PCR, the pattern of markers being slightly different between different tissues. Chromosomal analysis was not available for the aborted fetus. The parents had normal karyotypes. The pattern of markers in the QF-PCR-analyses was compatible with mosaicism of trisomy 21, the normal cell line resulting from a two-step rescue with loss of the maternally derived isochromosome 21 and doubling of the paternal chromosome 21. The ratio between the two cell lines in different tissues was calculated.

Conclusions: In a fetus with trisomy 21 mosaicism, QF-PCR results could wrongly be interpreted as normal. We show that the QF-PCR results reflected mosaicism of a cell line with a maternally derived isochromosome 21 and a normal cell line resulting from a two-step rescue of the trisomy 21.

P01.103

Detection aneuploidies in trophoblast cells in the model experiment

E. Musatova, A. Martynov, Z. Markova, N. Shilova;

Federal State Budgetary Institution «Research Centre for Medical Genetics», Moscow, Russian Federation.

Introduction: Non-invasive prenatal testing implies obtaining information about the genetic status of developing fetus without damage of the fetal membranes. Trophoblast cells circulate in blood of pregnant women. It should be noted, that trophoblasts, in contrast with other fetal cells in maternal blood, are epithelial cells that are characterized by large size and distinctive morphology. For assessment opportunities of trophoblasts' isolation from the peripheral blood of pregnant women followed by analysis of these cells the model experiment was performed.

Materials and methods: There were used 11 samples of artificially created mixtures. The artificial mixtures were prepared by mixing samples of peripheral venous blood of adult with cells' samples of chorionic villus with known karyotype. There were selected two artificial mixtures for followed analysis of genetic material: for preparation these samples were used chorionic cells with karyotypes 47,XX,+13, and 47,XY,+21. There was used filtration through polycarbonate filters with a pore diameter of 8 µm to isolate trophoblasts from artificial mixtures. Detection of trophoblasts on the filters was carried out by immunocytochemical staining with monoclonal antibodies to the cytoplasmic protein cytokeratin 7. Isolation of single cytokeratin7-positive cells was performed by laser microdissection followed by a whole genome amplification step. Analysis of genetic material isolated cytokeratin7-positive cells was performed by comparative genomic hybridization.

Results: The profiles of hybridization of the genetic material isolated cells corresponded karyotype chorionic cells that were used for the preparation of an artificial respective mixtures.

Conclusion: The obtaining results show that isolated cells were fetal origin.

P01.104

Ethnic patterns of Y chromosome microdeletions in Iranian infertile men with azoospermia/severe oligospermia

F. Asadi, M. Seddighi Gilani, A. Ghaheri, F. Reihani-Sabet, J. Roodgar Saffari, M. Zamani;

Royan Institute, Tehran, Iran, Islamic Republic of.

Introduction: Y chromosome microdeletion (Yq) is the most common molecular genetic cause for severe male infertility and covers three regions of AZFa, AZFb and AZFc, each of which contain various genes involved in spermatogenesis. Ethnic pattern of Yq microdeletions has not been widely studied in Iranian population. The present study aimed to reveal these patterns in Iranian infertile men with azoospermia/severe oligospermia.

Materials and Methods: 3636 infertile men referred to Royan institute with azoospermia/severe oligospermia were examined for Yq microdeletions in using multiplex PCR and different STS markers. The patients were categorized into ethnic groups based on their origin of birth and spoken language in three male generations namely Azeri, Fars, Kurd, Gilak/Mazani, Lor and Arab.

Results: Among 3636 infertile men, 177 cases of Yq microdeletions (4.8%) were diagnosed, including 60 from Azeri origin (33.8%), 55 from Fars origin (31%), 23 from Kurd origin (12.9%), 10 from Gilak/Mazani (5.6%), 18 from Lor origin (10.1%), and 2 from the Arab origin (1.1%). There were also 6 cases of non-Iranian (Afghan & Iraqi) origin. In 177 Iranian infertile men with AZF microdeletions we detected 157 microdeletions in AZFc (70%), 57 in AZFb (25.4 %) and 10 in AZFa (4.6%) regions.

Conclusion: Statistical analysis did not reveal any difference in the frequency and pattern of Yq microdeletions among various Iranian ethnic groups. Furthermore, the frequency and pattern of Yq microdeletions in Iranian population seems to be similar to the other world regions with AZFc as the most common type.

The ABCA4 c.5461-10T>C substitution in intron 38, frequently seen in Stargardt disease patients, is a splice site mutation causing skipping of exon 39-40 and reduced protein level

I. Aukrust¹, R. W. Jansson², C. Bredrup², S. Berland¹, H. E. Rusaas¹, A. Jørgensen³, M. G. Haug⁴, E. Rødahl^{2,5}, G. Houge¹, P. M. Knappskog^{1,6};

¹Center for Medical Genetics and Molecular Medicine, Haukeland University Hospital, Bergen, Norway, ²Department of Ophthalmology, Haukeland University Hospital, Bergen, Norway, ³Division of Child and Adolescent Health, Medical Genetics Department, University Hospital of North Norway, Tromsø, Norway, ⁴Department of Pathology and Medical Genetics, St. Olav's University Hospital, Trondheim, Norway, ⁵Department of Clinical Medicine, University of Bergen, Bergen, Norway, ⁶Department of Clinical Science, University of Bergen, Bergen, Norway.

Introduction: One intronic *ABCA4* substitution, c.5461-10T>C in intron 38, with a minor allele frequency of 0.039% (non-Finnish, European population), is the third most common *ABCA4* variant observed in patients with Stargardt disease, but its functional effect is unknown.

Materials and methods: Fibroblast samples from patients carrying the *ABCA4* variant c.5461-10T>C were analyzed by isolating total RNA, followed by RT-PCR using specific primers spanning the variant. For detection of *ABCA4* protein, fibroblast samples were lysed and analyzed by SDS-PAGE followed by immunoblotting using a monoclonal *ABCA4* antibody.

Results: The *ABCA4* variant c.5461-10T>C causes a splicing defect resulting in reduction of full-length mRNA in cells from patients and the presence of alternative spliced mRNAs where exon 39-40 is skipped. The splicing defect is causing a reduced level of full-length *ABCA4* protein compared to controls not carrying the variant.

Conclusions: This study describes the functional effect and the molecular mechanism of the pathogenic *ABCA4* variant c.5461-10T>C. The variant is functionally important as it leads to splicing defects and reduced level of *ABCA4* protein.

Introduction: LAT2 (*SLC7A8*) is a neutral amino acids transporter expressed in inner ear and it has been associated with non syndromic deafness locus *DFNA53*. Here we demonstrate that *SLC7A8* is involved in age-related hearing loss phenotype.

Materials and Methods: A null mouse model (*Slc7a8*^{-/-}) was generated. *SLC7A8* transporter has been localized in the basal layer cells of the *Stria Vascularis* and in the organ of Corti, both essential structures for proper auditory function. Auditory Brainstem Response (ABR), has been used to measure the integrity of hearing process. Human *SLC7A8* mutations screening was done in 325 individuals aged more than 50 years old. *In vitro* functional characterization of mutations found has been done overexpressing *SLC7A8* mutants in HeLa cells and quantifying the alanine uptake.

Results: ABR analysis confirmed that *Slc7a8*^{-/-} mice suffer hypoacusis earlier than C57Bl/6 old wild type mice, which suffer age-related hearing loss (ARHL). Concomitant with the phenotype observed in *Slc7a8*^{-/-} mice, four different *SLC7A8* missense mutations had been found in ARHL patients. *In vitro* mutations functional studies demonstrated a total or partial loss of LAT2 activity.

Conclusion: Characterization of *Slc7a8*^{-/-} mice revealed how unbalanced amino acid content in cochlea could affect auditory system and proved that LAT2 is involved in hearing mechanism. The finding of ARHL patients' carriers of *SLC7A8* mutation and the functional studies are robust evidences that

point out the significance of *SLC7A8* in auditory system. These data open new perspective where amino acid transporters could be new potential targets to unravel uncharacterized congenital deafness.

P02.03

Modifiers of gene expression as potential mechanism underlying incomplete penetrance and variable expressivity in retinal dystrophies

P. Llavona¹, S. Kohl¹, M. Pinelli², M. Mutarelli², V. Singh Marwah², S. Schimpf-Linzenbold¹, K. Nieselt³, D. di Bernardo², S. Banff², B. Wissinger¹;
¹Institute for Ophthalmic Research, Tuebingen, Germany, ²TIGEM, Naples, Italy, ³Center for Bioinformatics, Tuebingen, Germany.

Hereditary retinal dystrophies are frequently associated with incomplete penetrance and variable expressivity phenomena. Underlying mechanisms may include environmental, epigenetic and genetic factors with the latter being independent or linked to the primary disease causing gene such as variants involved in gene regulation. Therefore, identification of retinal disease genes that show allelic expression imbalance (AEI) in general population is a powerful approach for the identification of cis-acting expression quantitative trait loci (cis-eQTL). Our aim is to determine which cis-eQTLs could act as disease behavioral modifiers. We performed RNA-Seq from retinal RNA obtained from 52 healthy eye donors of European background. After filtering SNPs displaying extreme imbalanced allelic ratios, that are defined as lower than 0.3 and higher than 3.4 based on top 5% values, we validated heterozygosity by Sanger sequencing and AEI by pyrosequencing. Our RNA-Seq results revealed that among 301 known retinal disease genes, 64 showed evidence for AEI. *CDHR1* and *EMC1*, displaying some of the highest AEI frequencies (100% and 67% respectively), have already been positively validated by pyrosequencing. In both cases AEI is a feature exclusively present in specific gene isoforms. Comparative sequencing revealed an intronic SNP, rs4562752, strongly associated with AEI in *CDHR1*-002. *In silico* analysis predicts an impact of this variant on splice site selection and thus, explains the AEI observed for this isoform. Our results indicate that allelic transcriptional alterations caused by cis-eQTLs can indeed be traced by RNA-Seq analysis. Validation of further relevant retinal genes is still ongoing. FP7-PEOPLE-2012-ITN under grant agreement 317472.

Deep next generation sequencing of the whole mitochondrial genome in Polish patients with aminoglycoside-induced hearing impairment

M. Ryzdzanicz¹, A. Pollak², U. Lechowicz², P. Stawinski^{2,1}, M. Wrobel³, I. Wojsyk-Banaszak⁴, R. Ploski¹;
¹Department of Medical Genetics, Warsaw Medical University, Warsaw, Poland, ²Department of Genetics, Institute of Physiology and Pathology of Hearing, Warsaw, Poland, ³Department of Otolaryngology and Laryngological Oncology, Poznan University of Medical Sciences, Poznan, Poland, ⁴Department of Pulmonology, Pediatric Allergy and Clinical Immunology, Poznan University of Medical Sciences, Poznan, Poland.

Introduction: Mutations in mitochondrial DNA (mtDNA) are associated with aminoglycoside-induced hearing impairment (AIHI). However, in many studies only *MTRNR1* gene is analyzed. We performed whole mtDNA sequencing for identification of known and novel AIHI mutations, mtDNA heteroplasmy assessment and haplotype prediction.

Materials and Methods: Hearing impairment patients with aminoglycoside exposure history (n=130) and normal hearing controls treated with aminoglycosides without ototoxic effect (n=100) were enrolled into the study. All participants were Caucasian. MtDNA was enriched by long-range PCR and sequenced. MToolBox was used for haplogroup assignment, functional and prioritization analysis of identified variants, and heteroplasmy fraction assessment.

Results: Mean coverage per mtDNA genome was >1000x in each subject. We found homoplasmic AIHI m.1555A>G mutation in *MTRNR1* (5/130) and several putative AIHI-related candidates, including m.7445A>G in *MTTS1* precursor (1/130, familial case) previously not associated with AIHI. Heteroplasmy analysis through the whole mtDNA genome and haplotype prediction revealed higher heteroplasmy frequency in HI patients and recurrent haplotypes not observed in control subjects (H7c - 3/130, HV10 - 2/130, ROa - 3/130, W3a - 3/130, W6a - 2/130). We also identified patient harboring low level heteroplasmy of m.3243A>G mutation in *MTTL1* associated with MELAS syndrome. This mutation was missed in previous Sanger sequencing screening and patient was misclassified to our AIHI group.

Conclusions: NGS technology is a powerful tool for mtDNA analysis in AIHI patients allowing for known and novel mutations detection. Heteroplasmy frequency and specific haplogroups observed in AIHI patients may be an additional factors modifying personal susceptibility to AIHI.

Microdeletions in patients with aniridia and other eye anomalies

V. I. Damyanova¹, M. Mihaylova¹, A. Popova², R. Vajarova³, S. Ivanov³, L. Balabanski³, S. Hadjidekova¹, R. Staneva¹, D. Avdjieva-Tzavella⁴, R. Tincheva⁵, M. Malinov³, D. Toncheva¹;
¹Department of Medical genetics, Medical university of Sofia, Sofia, Bulgaria, ²Department of Ophthalmology, Medical University of Sofia, Sofia, Bulgaria, ³Genomic laboratory, SBALGAR "Malinov", Sofia, Bulgaria, ⁴Department of Clinical genetics-University Pediatric Hospital, Medical University of Sofia, Sofia, Bulgaria, ⁵Department of Clinical genetics-University Pediatric Hospital, Medical University of Sofia, Sofia, Bulgaria.

Introduction: Aniridia is a rare, bilateral, congenital ocular disorder causing incomplete formation of the iris, usually characterized by iris aplasia/hypoplasia. In the majority of cases, it is caused by mutation in the *PAX6* gene, but it can also be caused by microdeletions that involve the 11p13 region. One-third of cases are sporadic and result from de novo mutations.

Materials and methods: We tested 6 patients with aniridia (full and partial forms), glaucoma and myopathia, and 1 patient with dysgenesis mesodermalis oculi with SNP microarray Illumina Human CoreExome-12.

Results: Aberrations were observed in 4 patients. Two patients with full aniridia were found to harbor heterozygous deletion in 11p13 sized 167.108 kb encompassing genes *PAX6* and *ELP4*. One patient with partial aniridia had loss of heterozygosity in part of 20p11.1p11.21 sized 1.266678 Mb, containing *VSX1* gene. *VSX1* mutations have been previously reported in patients with abnormalities of the anterior segment and keratoconus. A heterozygous deletion in 6q22.31q22.32 sized 659.704 kb, including genes: *HEY2*; *NCOA7*; *HINT3* was found in one patient with dysgenesis mesodermalis oculi. Gene *HEY2* is involved in the signal transduction pathway of *PAX6*, *FOXC1* and *PITX2* genes, associated with the disease.

Conclusion: In our study of patients with eye disorders we found in addition to a microdeletion of *PAX6*, two new deletions encompassing *HEY2* and *VSX1* genes.

P02.06

Whole exome sequencing (WES) and downstream analysis in a family with suspected "x-linked" cone rod dystrophy (CORD) reveals two disorders caused by compound heterozygote mutations in *CERKL* and *CRB1*

J. C. Gardner¹, V. Plagno², M. Aguilà¹, A. R. Webster^{1,3}, M. Michaelides^{1,3}, A. J. Hardcastle¹;
¹UCL Institute of Ophthalmology, London, United Kingdom, ²UCL Genetics Institute, London, United Kingdom, ³Moorfields Eye Hospital NHS Foundation Trust, London, United Kingdom.

Molecular genetic analysis of a family with apparent X-linked inheritance of CORD was performed in order to establish the cause of visual impairment. Negative mutation screening of X-linked genes *RPGR* and *RP2* in the male proband was followed by WES which revealed possible compound heterozygous mutations in two autosomal candidate genes: *CERKL* and *CRB1*.

Segregation analysis in the extended pedigree demonstrated the proband and his affected brother were compound heterozygotes for the *CERKL* variants, ENST00000410087:c.[863_864del];[1160-1G>A] that could account for their condition, however the *CRB1* variants were both on the same (maternal) haplotype, *CRB1* :ENST00000367399:c.[exon2:493_501del;exon4:1024G>A]. An affected male cousin did not inherit either *CERKL* variant, but had inherited the variant *CRB1* haplotype. The cause of his condition was therefore unresolved. Sanger sequencing of the coding regions of *CRB1* in this individual did not reveal any additional mutations in other *CRB1* exons, however, cloning and sequencing of exon 2 revealed a heterozygous frameshift deletion ENST00000367399:c.[613_619del] on the paternally derived haplotype, that had been masked by the deletion variant of the maternally derived haplotype. The phenotype in the cousin was therefore caused by compound heterozygous mutations of *CRB1*.

Our analysis has identified novel disease-causing compound heterozygous variants in *CERKL* and *CRB1* and shows two autosomal recessive retinal disorders masquerading as an X-linked condition in this pedigree, thus creating issues for genetic counselling. This illustrates the importance of segregation analysis in the extended family for the successful interpretation of WES data. This work was supported by Moorfields Special Trustees.

Next generation sequencing discovers novel splice variants causing deafness in the Middle Eastern population

N. Danial-Farran^{1,2}, L. Tamer², Z. Brownstein³, F. T. A. Martins², M. Khayat¹, G. Ast², S. Allon-Shalev¹, K. B. Abraham¹;

¹Genetics Institute, Ha'Emek Medical Center, Afula, Israel and Rappaport Faculty of Medicine, Technion-Israel Institute of Technology, Haifa, Israel, ²Department of Human Molecular Genetics and Biochemistry, Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel, ³Department of Human Molecular Genetics and Biochemistry, Sackler Faculty of Medicine, Tel Aviv University, Afula, Israel.

The numbers of reported pathogenic variants causing genetic disorders have increased dramatically since Next Generation Sequencing has become available. The Middle Eastern population, known to exhibit high rates of consanguinity and comprised of isolated ethnic groups, has contributed dramatically to the discovery of pathogenic variants causing deafness. We applied targeted genomic enrichment (TGE), along with massively parallel sequencing (MPS), of 284 genes on unrelated Middle Eastern families. Our results doubled the number of genes associated with deafness in this population. A number of these required functional validation to determine the consequences of the variants. One of these was a synonymous alteration located in the 5' splice site of the MYO15A gene. Our challenge was to prove the consequences of this variant, since we could not check the splicing in the patient's RNA, due to the inaccessibility of human inner ear tissue and lack of MYO15A expression in lymphoblasts. As a result, a functional splicing assay was performed to determine the consequences of the variant on splicing. Due to the high GC content surrounding the splice site, we created a modified human cell line expressing the wild type and mutant forms of the genomic region. Our results indicate that the mutation abolishes intron retention, an event that is likely to be a functional alternative splicing event. Considering the importance of providing evidence for pathogenic variants, our study demonstrates the use of a robust tool for investigating splicing variants, particularly for genes expressed in inaccessible tissues.

P02.08

Exon-skipping allows passing complete CEP290 loss-of-function in an individual with unusually mild retinal disease

X. GERARD¹, I. Perrault¹, A. Munnich², C. Hamel³, J. Kaplan¹, J. Rozet¹;

¹Institut Imagine - Lab of Genetics in Ophthalmology - Inserm U1163 - Université Paris Descartes, Paris, France, ²Institut Imagine - Genetics department - Inserm U1163 - Université Paris Descartes, Paris, France, ³Maladies Sensorielles Génétiques, CHRU - INSERM U1051, Institute for Neurosciences, Montpellier, France.

Introduction. CEP290 is pivotal in the assembly/maintenance of primary and motile cilia in a wide range of cell systems. Biallelic CEP290 mutations cause a wide spectrum of devastating ciliopathies ranging from mono-symptomatic retinal dystrophy to multi-visceral sometimes embryo-lethal syndromes. The CEP290 retinal disease manifests invariably as a congenital and dramatically severe cone-dominant disease with visual function reduced to light perception. Using targeted-NGS in individuals with retinal dystrophies, we identified a homozygote CEP290 1pb deletion (c.1666del; p.Ile 556Phefs*17) in a 15 year-old girl having a rod dominant disease with preserved cone function (visual acuity = 6/10). The present study aimed at understanding the molecular bases of this observation.

Material and Methods. RT-PCR, RTqPCR, Western blot and cilia analyses were performed from patient and control fibroblasts.

Results. Analysis of the CEP290 mRNA in patient fibroblasts revealed low levels of an altered splice form in which exon 18 was skipped (5% of the amount of the wildtype mRNA in controls) and Western blot detected low levels of a CEP290 protein around 290 KDa. The number of patient fibroblasts producing a cilium under serum starvation was in the normal range.

Conclusions. The mutation identified in the patient is predicted to encode a premature stop codon in exon 18, downstream of the 1bp deletion in exon 17. The skipping of exon 18 with the upstream 1bp deletion allows producing low levels of CEP290 mRNA with an intact open reading frame and of a minimally shortened protein which expression may explain the preservation of central vision.

P02.09

Unravelling human complex traits: the case of hearing function and age related hearing loss

D. Vuckovic¹, A. Morgan², M. P. Concas³, M. Ciullo⁴, T. Nutile⁴, M. Pirastu³, M. J. Huentelman⁵, I. Schrauwen⁵, R. A. Friedman⁶, E. Franssen⁷, G. Van Camp⁷, P. Gasparini^{1,2}, G. Grotto^{2,1};

¹Sidra Medical and Research Centre, Doha, Qatar, ²University of Trieste, Trieste, Italy, ³Institute of Population Genetics, CNR, Sassari, Italy, ⁴Institute of Genetics and Biophysics A. Buzzati-Traverso, CNR, Naples, Italy, ⁵Translational Genomics Research Institute,

Phoenix, AZ, United States, ⁶Keck Medicine of USC, Los Angeles, CA, United States, ⁷University of Antwerp, Antwerp, Belgium.

In order to overcome the lack of knowledge on the molecular bases of complex hearing traits (Normal Hearing Function-NHF, Age-Related Hearing Loss-ARHL), a fruitful gene discovery strategy is proposed: new candidate genes/variants identified through GWAS/metanalysis are then validated by targeted re-sequencing (TRS) and functional studies in animal models.

GWAS on NHF (quantitative) and ARHL (qualitative) on 4150 subjects from different cohorts (Italian isolates, Belgium, Caucasus and Central Asia) were performed. Two strongly significant loci (p-value~2e-8) were identified, one of which (top-SNP:rs11520167) includes a gene causing hearing loss in mice and affecting cochlear outer hair cells. Interestingly, it is the first example of a hearing-loss gene modulating NHF.

To further investigate the role of candidates identified we developed a custom TRS panel of 46 genes and analysed ~500 ARHL patients from our cohorts. 56 mutations of interest were identified: 5 frameshift indels, 2 nonsense and 49 missense affecting 22 different genes and 128 patients. According to the complex genetic structure of ARHL, three scenarios were detected: 1) different mutations in the same gene, 2) the same mutation in different patients and 3) different mutations in the same patient. Finally genes were prioritised and included for expression analysis in the otic vesicle of Zebrafish larvae and for the generation of Knock-Out/In models and their accurate phenotypic characterisation. Results from the first series of genes (e.g. SLC44A2 and SLC9A3R1) will be presented and discussed.

These results strongly support the usefulness of our approach to detect and validate new genes involved in NHF and ARHL.

P02.10

Evaluation of a progressive diagnostic strategy to identify the genetic etiology of hearing loss

J. S. Crettaz¹, R. Muguerza¹, L. Otaolea¹, Z. Martinez², M. Abrego², Y. Ramirez¹, R. Saez¹;

¹Genetics Department, Donostia University Hospital, San Sebastian, Spain, ²Otorhinolaryngology Department, Donostia University Hospital, San Sebastian, Spain.

Introduction: Hearing loss is the most prevalent sensory deficit and is caused by genetic, environmental or multifactorial etiologies. It traditionally presented a challenge for genetic testing due to its heterogeneity.

Materials and Methods: Seventy-one patients with early-onset sensorineural hearing loss were enrolled. First Tier approach includes the study of m.1555 and m.1494 mitochondrial mutations and MLPA study for identification of duplications/deletions and common point mutations in GJB2 and GJB6 genes. Second Tier was performed using a custom NGS panel of 92 genes on 16 negative patients. Haloplex technology (Agilent Technologies) was used for exons and flanking intronic sequences enrichment and sequencing was performed on a MiSeq (Illumina).

Results: First-tier strategy detected 1 homoplasmic m.1555 mutation in MT-RNR1 gene (1,5%) and 8 pathogenic conditions in GJB2 and GJB6 genes (12%). Second-tier produced a coverage of targeted exons for >20 reads of 96,3% and a mean depth coverage of 454x. By our filtering strategy, the patients were classified as follow: 5 resulted with a pathogenic variant (31%), 5 with uncertain variants (31%) and 6 with irrelevant findings (38%). All relevant variants were confirmed by Sanger sequencing and characterization of novel variants is in course.

Conclusions: Diagnostic capacity of NGS is indubitable although the progressive approach presented here may be useful to maintain a cost-effective strategy and to cover all the technically excluding needs (mitochondrial, large copy number variants, single nucleotide variants). Preliminary results of our testing strategy reached an overall diagnostic yield of 44%.

P02.11

Distribution of pathogenic variants in non-SLC26A4/PDS hearing impaired patients with inner ear abnormalities: initial results from a Czech cohort

R. Pourová¹, J. Paděrová¹, J. Sabová¹, R. Katra², M. Jurovčík², M. Havlicová¹, M. Macek, jr.¹;

¹Department of Biology and Medical Genetics, University Hospital Motol, Prague, Czech Republic, ²Department of ENT, 2nd Faculty of Medicine, Charles University in Prague and University Hospital Motol, Prague, Czech Republic.

Hereditary hearing loss (HHL) is the most common inborn sensory deficit affecting about 1 in 300 neonates with a strong genetic aetiology (up to 75%) and is mainly associated with AR- and non-syndromic pattern inheritance. However, de novo AD pathogenic variants may also be found, while syndromic features could be rather mild or even misleading during childhood.

Five families from the cohort of SLC26A4/PDS negative patients with HHL

compounded by inner ear abnormalities (IEA) were analysed. One family has AR-, another AD trait; in three cases the occurrence of HHL was apparently sporadic. Four cases did not have syndromic signs, while one case had a syndromic form of HHL.

Extended gene panel next generation sequencing (NGS) was carried out in all studied cases (TruSight One, Illumina, USA), verified by Sanger DNA sequencing in detected variants.

We have identified likely pathogenic variants in all examined families. Most commonly compound heterozygous pathogenic variants were found in MYO15A (2 families) associated with AR NSHL, while compound heterozygous MYO7A variants linked to Usher syndrome 1B and de novo AD EYA1 and CHD7 variants causing BOR- and CHARGE syndromes respectively, were observed.

In conclusion, this pilot study provided evidence that the genetic aetiology of inner ear disorders is heterogeneous. Although BOR- and CHARGE syndromes are well documented causes of HHL with IEA, pathogenic variants in MYO15A and MYO7A have not been reported, thus far. Further studies utilising NGS are thus warranted.

Supported by FNM00064203, CZ.2.16/3.1.00/24022, NF-CZ11-PDP-3-003-2014, LD14073 and GAUK_165815.

POU3F4 mutations (DFNX) are the most prevalent cause of hearing loss among all the X-linked loci. The aim of the study was to screen for POU3F4 mutations in a large group of hearing loss patients, analyze audiological and radiological features in patients with HL caused by POU3F4 defects and to present our experience on cochlear implantation in these patients. Mutations in the POU3F4 gene were first analyzed in a selected group of patients with gusher or gusher-like incidence (n= 26) through sequencing of the whole gene. Subsequently, the identified mutations were screened for in a cohort of two thousand males with HL. The molecular techniques used to detect POU3F4 mutations included whole exome sequencing, Sanger sequencing and real-time PCR. Three novel (p.Glu187*, p.Leu217*, p.Gln275*) and one known p.Ala116fs141* POU3F4 mutations were detected. One of the novel mutations was revealed to be a de novo event. All probands with POU3F4 defects suffered from bilateral prelingual severe to profound HL. Morphological changes of the temporal bone in these patients presented a similar pattern, including malformations of the internal auditory canal, vestibular aqueduct, modiolus and vestibule. Two of the patients with POU3F4 mutations received cochlear implants with good outcome. In summary, extensive clinical and genetic investigations show that POU3F4 mutations frequently occur in patients with particular temporal bone malformations. In this group of patients sequencing of the entire POU3F4 gene is necessary due to specific requirements and an increased risk of complications during otologic surgery.

Molecular findings from 537 individuals with inherited retinal disease

J. M. Ellingford¹, S. Barton², S. Bhaskar², J. O'Sullivan¹, S. G. Williams¹, J. A. Lamb¹, B. Panda³, P. I. Sergouniotis¹, R. L. Gillespie¹, S. P. Daiger⁴, G. Hall², T. Gale², C. Lloyd¹, P. N. Bishop¹, S. C. Ramsden¹, G. C. M. Black¹;
¹University of Manchester, Manchester, United Kingdom, ²Central Manchester University NHS Foundation Trust, Manchester, United Kingdom, ³GANIT Laboratories, Institute for Bioinformatics and Applied Biotechnology, Bangalore, India, ⁴University of Texas, Texas, TX, United States.

Background: Inherited retinal diseases (IRD) are a clinically and genetically heterogeneous set of disorders, for which diagnostic next-generation sequencing (NGS) services have been developed worldwide.

Methods: We present the molecular findings for 537 individuals referred to

a 105-gene diagnostic NGS test for IRD. We assess the diagnostic yield, the spectrum of clinical referrals, the variant analysis burden, and the genetic heterogeneity of IRD. We retrospectively analyze disease-causing variants, including an assessment of variant frequency in ExAC.

Findings: Individuals were referred from 10 clinically distinct classifications of IRD. Of the 4,542 variants clinically analysed, we have reported 402 mutations as a cause or a potential cause of disease in 62 of the 105 genes surveyed. These variants account or likely account for the clinical diagnosis of IRD in 51% of the 537 referred individuals. 144 potentially disease-causing mutations were identified as novel at the time of clinical analysis, demonstrating a clear advantage of diagnostic NGS approaches for IRD but also highlighting the need for further evidence to assist clinical interpretation. Only 15% of molecular diagnoses are accounted for by mutations in the 33 genes identified as a cause of IRD post-2005, suggesting that whilst the continued addition of new disease-causing genes will of course improve diagnostic services, there is a need to survey intronic and regulatory regions of genes known as a cause of IRD.

Interpretation: Our findings illustrate the continued powerful utility of custom-gene panel diagnostic NGS tests for IRD in the clinic, but suggest clear future avenues which will increase diagnostic yields.

Whole genome sequencing findings in Spanish families affected with Retinal Dystrophies

R. Sanchez-Alcudia¹, N. Bedoni², B. Royer-Bertrand², **M. Corton¹**, A. Avila-Fernandez¹, R. Perez-Carro¹, N. Sanchez-Bolivar¹, O. Zurita¹, K. Nikopoulos², S. Balzano², C. Rivolta², C. Ayuso¹;
¹Department of Genetics, IIS-Fundacion Jimenez Diaz University Hospital, Madrid, Spain, ²Department of Medical Genetics, University of Lausanne, Lausanne, Switzerland.

To study the genetic basis and to identify pathogenic mechanisms of Retinal Dystrophies (RD), a total of 10 Spanish families, remaining uncharacterized by Whole Exome Sequencing (WES), were analyzed by Whole Genome Sequencing (WGS). The WGS data were processed following an expert in-house in silico pipeline developed by the University of Lausanne. We were able to characterize 4 out of 10 (40%) of the families. Biallelic single nucleotide variations (SNV), undetected by WES due to the low-depth coverage of the specific region, were detected in an X-linked Retinitis Pigmentosa and two autosomal recessive RD families with mutations in the NYX, DFNB31 and ACBD5 genes, respectively. The identification of a nonsense mutation in the NYX gene, responsible for congenital stationary night blindness, led to the reassessment of the clinical diagnosis. Interestingly, the WGS analytical pipeline in combination with homozygosity mapping analysis were able to identify a novel homozygous mutation in the ACBD5 gene in a maternal isodisomy case, leading to a new phenotype-genotype association. A combination of a non biallelic SNV and a structural variation was found in an additional arRD family. Affected members of this family were compound heterozygous for a missense variant and a ~56kb deletion involving exons 32 and 33 in the EYS gene. In this study, we show the power of WGS coupled with homozygosity mapping in solving recessive cases. Moreover, we demonstrate not only that WGS allows the detection of structural events, but it also has a more uniform and reliable sequencing coverage compared to WES.

Introduction: Molecular diagnosis of Inherited Retinal Dystrophies (IRD) has long been challenging due to their extensive clinical and genetic heterogeneity. Here, we describe an efficient next generation sequencing (NGS)-based diagnostic tool for the identification of causative mutations in a Spanish cohort with diverse IRD.

Methods: We used a custom NGS panel comprising 64 IRD-associated genes in our population, and three disease-associated intronic regions for the molecular diagnosis of 32 families with a wide range of IRD. Targeted bases were captured and sequenced on the Illumina MiSeq platform. Subsequently, bioinformatics and co-segregation analyses were performed to identify causative variants.

Results: A total of 37 pathogenic mutations (14 novels) were found in 73% of IRD patients ranging from 50% for autosomal dominant cases, 75% for syndromic cases, 83% for autosomal recessive cases, and 100% for X-linked cases. Additionally, unexpected phenotype-genotype correlations were found in 6 probands, which led to the refinement of their clinical diagnoses. Furthermore, intra- and interfamilial phenotypic variability was observed. Finally, two cases unsuccessfully analysed by exome sequencing were resolved by applying this panel.

Conclusions: Our results demonstrate that this hypothesis-free approach based on frequently mutated, population-specific loci is highly cost-efficient for the routine diagnosis of this heterogeneous condition and allows the unbiased analysis of a miscellaneous cohort. The molecular information found here has aid clinical diagnosis and has improved genetic counselling and patient management.

P02.17

Unraveling the genetic basis of simplex cases of Retinitis Pigmentosa

N. Bravo-Gil^{1,2}, M. González-del Pozo^{1,2}, C. Méndez-Vidal^{1,2}, M. Martín-Sánchez¹, S. Borrego^{1,2}, G. Antiñolo^{1,2};

¹Department of Genetics, Reproduction and Fetal Medicine, Institute of Biomedicine of Seville, University Hospital Virgen del Rocío/CSIC/University of Seville, Seville, Spain, ²Centre for Biomedical Network Research on Rare Diseases (CIBERER), Seville, Spain.

Introduction: The purpose of this study was to elucidate the genetic cause of the disease in Spanish patients with simplex (isolated) Retinitis Pigmentosa (RP), allowing to determine the proportion of these cases with autosomal recessive, *de novo* autosomal dominant or X-linked RP.

Materials and Methods: A capture panel containing 68 genes associated with Inherited Retinal Dystrophies (IRD) in Spanish population was used for the molecular diagnosis of 24 simplex cases of RP. Targeted bases were sequenced on the Illumina MiSeq platform.

Results: Gene panel sequencing generated a mean coverage of 915x and a mean of reads on target of 96.98%. A total of 19 pathogenic mutations, including point mutations, frameshift mutations and large deletions, were found in 13 out of 24 patients, obtaining a diagnostic rate of 54.17%. Of families solved, 69.2% were autosomal recessive cases, 15.4% carried mutations in X-linked IRD genes and 15.4% were autosomal dominant cases with *de novo* mutations.

Conclusions: Our results indicate that the most common pattern of inheritance of simplex cases of RP is autosomal recessive but, due to family impact, other options should not be overlooked. To our knowledge, this is the first study to apply next-generation sequencing to seek for causative mutations in Spanish simplex RP cases, deciphering the prevalence of the different modes of inheritance behind these types of pedigrees and improving the subsequent clinical management of patients and respective families.

Funded by: PI11-02923 and PI15-01648 (ISCIII), CIBERER, CTS-1664 (Government of Andalusia). NB-G is supported by fellowship FI12/00545 from ISCIII.

P02.18

Panel-based NGS reveals: a new mutation in the LTBP2 gene causing Isolated Ectopia Lentis in a Spanish consanguineous family

S. Bernal¹, J. Crespi², L. Aliás^{1,3}, L. González-Quereda^{1,3}, P. Gallano^{1,3}, M. Baiget²;

¹Genetics Department. Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, ²Ophthalmology Department. Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, ³U705-CIBERER, Barcelona, Spain.

Introduction: The ectopia lentis is a rare disease characterized by the presence of crystalline bilaterally smaller and more spherical than the normal size (microspherophakia). The lens subluxation can lead refractive error, glaucoma due to pupillary block and vision loss. Although it is generally associated with systemic disorders (Marfan, Weill-Marchesani syndromes or homocystinuria), it is also described an isolated form (IEL) showing an autosomal recessive inheritance, and characterized by a high phenotypic variability and genetic heterogeneity (ADAMTSL4, FBN1, LTBP2, ADAMTSL10 and ADAMTSL17). Material: All members of a Spanish consanguineous family were studied, of which two sons were affected by IEL without megalocornea. Methods: 1) Next generation Sequencing (NGS) by TruSight One panels (Illumina) of the patient samples. 2) Validation of the NGS results by Sanger sequencing method. 3) Confirmation of a common origin of the detected mutation in the LTBP2 gene using the polymorphic markers D14S43 and D14S999. Results: Several genetic variants were identified by NGS, only one showed a pathogenic effect. This mutation involves the insertion of an ade-

nine in the exon 36 of the LTBP2 gene (c.5439_5440insA). Familial study by the polymorphic markers confirmed a common haplotype associated with this mutation previously not described. Conclusion: The LTBP2 gene has been described in non-European families as a responsible of IEL associated with megalocornea or congenital glaucoma (OMIM#251750). Panel-based NGS approach has allowed the identification of a new mutation in the LTBP2 gene, which confers a different phenotypic variation to IEL: no megalocornea or congenital glaucoma.

Keratoconus (KTCN) is a protrusion and thinning of the cornea, resulting in impairment of visual function. The extreme genetic heterogeneity makes it challenging to identify factors unambiguously influencing the KTCN phenotype. To identify a potential genetic susceptibility component which may be involved in familial KTCN, we used linkage analysis, whole exome sequencing (WES), and Sanger sequencing in an Ecuadorian family with KTCN. We applied WES in two affected KTCN individuals from the family that showed a suggestive linkage between the KTCN phenotype and the 5q31.1-q35.3 locus. Putative rare variants identified in WES analysis were confirmed and further evaluated for segregation in this family using Sanger sequencing. Exome capture discovered a total of 173 rare (MAF <1% in control population) nonsynonymous variants in both affected individuals. Among them, 16 SNVs were selected for further study. Segregation analysis revealed that variants c.475T>G (p.Cys159Gly) in *SKP1*, c.671G>A (p.Gly224Asp) in *PROB1*, and c.527G>A (p.Cys176Tyr) in *IL17B* in the 5q31.1-q35.3 linkage region co-segregated with the phenotype. We demonstrate that a combination of linkage analysis, WES, and Sanger sequencing, significantly narrowed reduced the list of the putative variants. Moreover, since the analyzed locus overlapped two other chromosomal regions previously recognized in distinct KTCN studies, our findings further suggest that this 5q31.1-q35.3 locus might be linked with KTCN.

P02.20

A targeted-resequencing gene panel for the genetic diagnosis of Leber congenital amaurosis

M. Plumari¹, A. Asaro¹, S. Zucca¹, M. Valente¹, G. S. Grieco¹, S. Signorini², C. Cereda¹;

¹Center of Genomics and post-Genomics, C. Mondino National Neurological Institute, Pavia, Italy, ²Child Neurology and Psychiatry Unit, C. Mondino National Neurological Institute, Pavia, Italy.

Introduction: Leber congenital amaurosis (LCA) is a group of early-onset childhood retinal dystrophies characterized by vision loss, nystagmus and severe retinal dysfunction. Currently, mutations in over 20 genes have been reported to cause LCA, mostly with an autosomal recessive pattern of inheritance, although a genetic diagnosis is hard to achieve because of the genetic heterogeneity. The aim of this study was to obtain a fast and accurate strategy for genetic diagnosis of LCA.

Materials and Methods: coding regions of 24 genes implicated in LCA were analyzed in a cohort of 27 unrelated patients referred to our laboratory, by performing a TruSeq Custom Amplicon (Illumina) assay for targeted-resequencing.

Results: two and one mutations were detected in 16 and 6 patients, respectively. Sanger sequencing of uncovered regions identified further mutations in 4 patients. The segregation analysis was performed on the available parents. Twenty cases were fully diagnosed: 7 homozygotes and 12 compound heterozygotes (recessive genes), and one heterozygous subject (dominant genes). Overall, 32 different pathogenetic variants were identified (half of which were new mutations); nonsense, missense, frameshift and

splicing mutations were found mostly in 6 genes (AIPL1, CEP290, GUCY2D, NMNAT1, RRG1, SPATA7).

Conclusions: in a high percentage of confidently diagnosed LCA patients, mutations may be found in known recessive genes; our targeted-resequencing gene panel allows to detect a high number of described and new mutations, turning out to be a valid method for genetic diagnosis of LCA.

P02.21

Genetic heterogeneity in autosomal dominant familial Meniere Disease

C. Martín-Sierra¹, T. Requena¹, A. Gallego-Martinez¹, A. Lysakowski², J. Lopez-Escamez¹; ¹GENYO, Granada, Spain, ²Dept. of Anatomy and Cell Biology, Univ. of Illinois at Chicago, Chicago, IL, United States.

Introduction: Meniere's Disease (MD) is a complex disorder characterized by recurrent attacks of spontaneous vertigo associated with sensorineural hearing loss and tinnitus, with a strong familial aggregation (prevalence of 8-10% of familial cases). We have performed whole-exome sequencing (WES) analysis in three different families with autosomal dominant inheritance pattern of MD, to study the genetic causes of this disorder, identifying the candidate variants segregating the MD phenotype.

Materials and Methods: WES data were processed in SOLiD 5500xl platform. We filtered the Single Nucleotide Variants (SNVs) by dbSNP 142, ExAC databases and our in house control database, using a minor allelic frequency MAF > 0.0001. To prioritize candidate variants we used the following bioinformatics tools: Pathogenic Variant -PAVAR score, an in house scoring system based upon seven tools (SIFT, PolyPhen2, Grantham's Matrix, GERP+, Mutation taster, PhastCons and PhyloP) estimating the effect in protein structure and phylogenetic conservation; and bioinformatics tools that include phenotype information such as Exomiser v2 and Variant Annotation Analysis and Search Tool (VAAST) + Phevor. All variants were validated by Sanger sequencing technology in a 3130 Genetic Analyzer.

Results: After filtering and prioritizing, we have generated a list of candidate pathogenic SNVs, and we confirmed the expression of these genes in inner ear human tissue. The top candidate genes are PRKCB, SEMA3D and DPT.

Conclusion: Our results support genetic heterogeneity in familial MD.

Acknowledgments: Funded by PI-0496-2014 (Consejería de Salud), Meniere's Society UK and NIH DC013181.

P02.22

WES and mutation analysis in 26 families reveal a new founder MYO15A frameshift duplication as the major cause of Genetic Hearing Loss in Oman

F. Palombo¹, T. Pippucci¹, N. Al-Wardy², M. Oppo^{3,4}, M. Al Kindi⁵, A. Angius^{3,5}, K. Al Lamki², G. A. Gnechchi Ruscone⁶, T. Giangregorio¹, M. Benelli⁷, F. Cucca^{3,4}, A. Magi⁸, M. Seri¹, M. Sazzini⁹, M. Al Khabori⁹, G. Romeo¹;

¹Medical Genetics Unit, Policlinic Sant'Orsola-Malpighi, Bologna, Italy, ²College of Medicine and Health Sciences, Sultan Qaboos University, Muscat, Oman, ³Istituto di Ricerca Genetica e Biomedica, Consiglio Nazionale delle Ricerche, Cagliari, Italy, ⁴Dipartimento di Scienze Biomediche, University of Sassari, Sassari, Italy, ⁵Center for Advanced Studies, Research, and Development in Sardinia (CRS4), Parco Scientifico e Tecnologico della Sardegna, Pula, Italy, ⁶Laboratory of Molecular Anthropology, University of Bologna, Bologna, Italy, ⁷Department Laboratory, Careggi University Hospital, Firenze, Italy, ⁸Department of Experimental and Clinical Medicine, University of Florence, Firenze, Italy, ⁹Department of ENT, Al Nahda Hospital, Ministry of Health, Muscat, Oman.

The prevalence of Genetic Hearing Loss (GHL) in Oman is estimated to be 6/10000 and mutations in *GJB2* are known to be absent; however a thorough molecular genetic assessment of GHL in Oman is lacking. Families of children with GHL have high consanguinity rates, indicating a major role for autosomal recessive forms. We recruited 43 GHL patients from 26 North Omani consanguineous families and analyzed one of these by Whole Exome Sequencing (WES), identifying a novel homozygous frameshift duplication (c.1171_1177dupGCCATCT) in *MYO15A*, a gene associated with autosomal recessive deafness (DFNB3). This was then found in 8/26 (28%) families, in heterozygous state in 2/190 subjects from North Oman and absent in 94 subjects from South Oman. The duplication was within a 849 Kb founder haplotype and using SNPs located on a 1Mb genomic interval including *MYO15A* to infer haplotypes in disease individuals and in around 2,500 healthy worldwide subjects we reconstructed a median joining network to get insights into the origins and evolutionary history of the *MYO15A* duplication. We then performed WES in 12 families out of the 18 non *MYO15A*-mutated and identified mutations in different genes which are likely to be causative of GHL in 7/12 families with an overall diagnostic rate of 58% (15/26). In conclusion, the *MYO15A* duplication, found in 28% of families and with a carrier population frequency of 1%, emerges as the major cause

of GHL in North Oman and the strategy described could have primary implications for an efficient design of GHL diagnosis in Oman.

P02.23

Targeted/Whole Exome Sequencing plus Animal Models for the molecular characterisation of Hereditary Hearing Loss (HHL)

A. Morgan¹, D. Vozzi², E. Rubinato¹, M. Khalifa Al-Kowari², M. Di Stazio¹, R. Badi³, K. Abdulhad³, M. La Bianca⁴, P. Gasparini¹, G. Giroto¹;

¹University of Trieste, Trieste, Italy, ²Sidra medical research, Doha, Qatar, ³Hamad Medical Corporation, Doha, Qatar, ⁴IRCCS Burlo Garofolo, Trieste, Italy.

HHL is characterised by clinical and genetic heterogeneity. Here, 70 Italian and Qatari HHL families were screened by analysis of 113 HHL-genes by Targeted Re-Sequencing (TRS) followed, in negative cases, by Whole Exome Sequencing (WES) to discover HHL-candidate genes and by in vitro and in vivo validation of them.

Ion Torrent PGM™(4.356 amplicons ensuring approximately 92,6% coverage of the target region) and Ion Proton™(293.903 amplicons ensuring approximately >99% coverage of the target region) were used for TRS and WES, respectively. Genomic variants were annotated by ANNOVAR and filtered according to: a) pedigree pattern of inheritance, b) allele frequency data, c) pathogenicity prediction. Functional studies were carried out in Zebrafish (expression and generation of K/O-K/I).

TRS allowed us to characterise 9/25 Italian and 8/15 Qatari families (overall detection rate of 43%) while for other 30 TRS-studies are in progress.

As regards to WES, 19 cases entered the pipeline. Some new genes (i.e. BDP1; PSIP1) and several strong candidates (e.g. TBL1Y, PIEZO1, LAMC1, PLS1) for which final functional validation is in progress were identified. Preliminary data include: 1) expression studies for PLS1 in Zebrafish larvae revealing a strong gene-expression in the hair cells of the otic vesicle; 2) RT-PCR on TBL1Y showing a cochlear expression in the Human cDNA and transfection of HEK cells displayed that the mutation alters the stability of the protein itself. These findings highlight the relevance of the combined approach based on NGS and animal model validation in understanding the genetics of HHL. Updated data will be presented and discussed.

Introduction: Congenital eye malformations are highly heterogeneous conditions displaying a wide spectrum of overlapping phenotypes. Mutational load is not well known due to lack of systematic molecular characterization of large cohorts. Our aim is to perform comprehensive molecular screening for eye developmental causal genes using a next-generation sequencing (NGS) gene panel.

Methods: 82 uncharacterized patients with several ocular phenotypes (A/M, aniridia, ocular coloboma, anterior segment dysgenesis and nerve optic malformations) were analysed. Six positive cases carrying previously known mutations or CNVs were included for validation. A custom targeted enrichment system for 121 genes was used, followed by sequencing on Illumina platforms. Sanger validation and custom Agilent CGH arrays were used to validate candidate variants and CNVs, respectively.

Results: Currently we have findings for 44 patients. Targeted NGS identified pathogenic mutations or novel potentially damaging variants in 44% of patients. After segregation analysis and phenotyping, we characterized the 30% of cases, mainly those suffering from A/M. A total of 19 different causal mutations, being 63% of them novel, were found in 17 genes. Complete heterozygous deletion of *OTX2* and *SIX6* was also been identified by NGS in a patient with syndromic bilateral anophthalmia. Further aCGH analysis confirmed a 6.2Mb microdeletion at 14q22.3-q23.2 encompassing both genes.

Conclusions: Our custom NGS gene panel represents an accurate tool for genetic analysis of eye developmental diseases, allowing for a better understanding of pathogenic mechanisms, deciphering of novel phenotypic associations and improving molecular diagnosis of these rare conditions.

P02.25

The importance of NGS in the diagnosis of syndromic deafness

T. Likar¹, N. Teran¹, A. Maver¹, M. Hasanhodžić², B. Peterlin¹, K. Writzl¹;

¹Institute of Medical Genetics, Ljubljana, Slovenia, ²UKC Tuzla, Tuzla, Bosnia and Herzegovina.

Objective: 30% of patients with hereditary hearing loss have the syndromic form thereof. This means, that they have clinical signs of illness in at least one other organ system. Hearing loss has been described in more than 400 different syndromes but its severity varies widely. Our aim was to demonstrate the importance of NGS in the diagnosis of syndromic deafness when the patient's phenotype is atypical.

Methods: We enrolled 19 patients with HL who had previously been screened to exclude pathogenic mutations in the GJB2 gene and whose clinical symptoms indicated a form of syndromic deafness. Exon library construction and enrichment were performed using the Illumina TruSight One targeted panel and sequencing was subsequently carried out on the Illumina MiSeq Sequencer. Variant analysis and filtering were performed using a bioinformatic pipeline designed at our Institute.

Results: Our exome sequencing study led to the identification of 9 causative pathogenic variants among the 19 patients giving us a diagnostic yield of 47%. Variants were found in 8 different genes including CHD7, NEFL, MITE, HDAC8, SF3B4, USH2A, TSHZ1, and RYR1.

Discussion: Our results coincide well with previous findings that NGS has a high potential in the diagnosis of syndromic HL. We demonstrate that NGS is especially useful in the diagnosis of patients with atypical phenotypes and in cases of uncertainty of whether the HL is part of a syndromic case or a separate condition altogether.

Noonan syndrome (NS) is a multiple congenital malformation disease whose incidence is evaluated from 1/1000 to 1/2500 living births, quite frequent among the rare diseases. Characteristic features are short stature, facial dysmorphism, heart defects and cryptorchidism. Orthopedic, renal malformations, development delay and intellectual disability are also observed. Eyes complications are less described but very common since 95% of patients with NS displayed at list one or more ophthalmologic findings. Most of those findings are external features belonging to the characteristic facial dysmorphism of NS (hypertelorism, ptosis, down slanting palpebral fissures and epicanthic folds). Strabismus and refractive errors (myopia, hypermetropia and astigmatism) are also frequent. Fundus changes are reported less frequently. Few cases of iris and/or optic disc coloboma in patients with NS or related disorders have been described since 1987. Only one study focused on eye abnormalities in NS had found coloboma in 4% (2 cases among 51 patients). None of the previously NS cases with coloboma was confirmed by molecular analysis.

We describe 7 new cases of NS (or related disorders) with iris and/or optic disc coloboma and review the 10 previously reporter cases. Elevated incidence of NS could let thought this association would be fortuitous but the 2 familial cases (one family previously reported and one new family) may suggest that coloboma is a rare complication of Rasopathy.

P02.27

Experimental pain threshold and tolerance analysis points to ROCK2 as a novel gene involved in nociception

M. Kirin¹, A. Miljković¹, A. Relja¹, A. Gelemanović², C. Hayward², M. Brašć¹, I. Rudan⁴, I. Kolčić¹, O. Polasek¹;

¹Medical School, University of Split, Split, Croatia, ²Institute for Genetics and Molecular Medicine, University of Edinburgh, Edinburgh, United Kingdom, ³Medical School, University of Zagreb, Zagreb, Croatia, ⁴Usher Institute, University of Edinburgh, Edinburgh, United Kingdom.

Introduction: The aim of this study was to investigate the genetic basis of acute pain.

Materials and methods: We measured experimentally-induced mechanical

pain threshold (least stimulus intensity) and pain tolerance (maximum tolerance stimulus intensity) in 1,114 previously genotyped subjects from the 10,001 Dalmatians cohort. The subjects were genotyped with either HumanHap 300v1 or 370CNV-Quad. QC protocol included removal of individuals with less than 97% genotyping rate, call rate below 98%, minor allele frequency below 2% and P-value for Fisher's exact test of Hardy-Weinberg equilibrium below 10E-10. Since subjects originated from three different groups, we performed a fixed effects meta-analysis.

Results: The results suggested one marginal hit for pain tolerance on chromosome 2, belonging to ROCK2 gene (rs4260216, P=5.3x10⁻⁷). The effect size of this SNP was comparable among all subsets, with similar allele frequencies and with very low heterogeneity (I²=0, P=0.540). This SNP also showed nominal significance association with pain threshold (P=6.8x10⁻⁴). There were no other SNPs in this region with suggestive significance, due to very low regional LD patterns.

Conclusion: This gene was previously implied in cytokinesis, smooth muscle contraction and focal adhesion, thus suggesting a plausible biological role in nociception, which was also recently implied in mice study. Replication efforts on humans should focus on independent population, larger sample sizes and possibly even patients with chronic pain.

Funding: Medical Research Council UK, Croatian Science Foundation grant 8875 and EFIC-EGG grant for young investigators. We gratefully acknowledge contribution from the Institute for Anthropological Research, Croatia.

P02.28

Three major mutations and their rapid detection of the SLC26A4 gene in East Asian patients with Pendred syndrome/enlarged vestibular aqueduct syndrome

T. KANAME¹, K. Yanagi¹, A. Ganaha², M. Higa², M. Iso¹, Y. Matsui¹, F. Koiwa¹, Y. Kuroki¹, M. Suzuki², Y. Matsubara¹;

¹National Center for Child Health and Development, Tokyo, Japan, ²University of the Ryukyus Graduate School of Medicine, Okinawa, Japan.

Pendred syndrome (PS) and hearing loss associated with enlarged vestibular aqueduct (EVA) are caused by mutations in the SLC26A4 gene. We examined the SLC26A4 gene in 30 patients with PS or EVA in Okinawa Islands, whose clinical history, findings of physical and otoscopic examinations, hearing test, and computed tomography (CT) scan of the temporal bones were recorded, by Sanger sequencing and/or next-generation sequencing. We found that a mutation of IVS15+5G>A was the major allele in Okinawan patients and the 2nd was p.H723R, which was the major mutation allele in main Islands of Japan and in Korea. As ancestral differences have been reported between people from Okinawa Islands and those from the main islands of Japan, the mutation type of SLC26A4 was also different. According to our results and previous reports, the three mutations, IVS15+5G>A, p.H723R and IVS7-2A>G, accounted for more than 60% of SLC26A4 mutations in the East Asian patients. Thus, we constructed a simple and rapid detection system based on high resolution melting method for the three mutations. The detection system will be able to detect more than 95%, 60%, 90%, 65%, and 80% of SLC26A4 mutations in the Okinawan, Japanese, Korean, Chinese and Taiwanese patients, respectively. The system will be cost effective and will be applied to first screening/genetic testing of PS/EVA.

P02.29

Molecular study of 14 families with Perrault syndrome: genotype / phenotype correlations

L. Jonard¹, S. Marlin¹, J. Lerat¹, A. Munnich¹, D. Lacombe², S. Christin-Maitre³, C. Goizet², L. Van Maldergem⁴, S. Gherbi¹, P. Touraine⁵, J. Bonnefont¹;

¹Necker Hospital, APHP, Paris, France, ²Bordeaux Hospital, Bordeaux, France, ³Saint Antoine Hospital, APHP, Paris, France, ⁴Besancon Hospital, Besancon, France, ⁵Pitié Salpêtrière Hospital, APHP, Paris, France.

Perrault syndrome is an autosomal recessive disorder characterized by the association of bilateral sensorineural hearing loss and female gonadal dysgenesis. The prevalence of this syndrome is probably underestimated due to the discovery of secondary ovarian failure and no sign associated with deafness in boys.

Recently five different genes: c10ORF2, CLPP, HARS2, HSD17B4, and LARS2 were involved in Perrault syndrome. A sixth candidate gene has been suggested: LONP1.

Thanks to NGS technique, we analyzed the five known genes and the additional candidate gene in a cohort of 17 patients (14 families) with a clinical picture suggestive of Perrault syndrome, 6 patients presented with neurological signs. This is the first study of all the genes involved in Perrault syndrome in a cohort of patients.

We showed mutations in 8 families. LARS2 seems to be the most frequently

implicated gene and we haven't found any mutation in the candidate gene LONP1. 8 of the 10 mutations found in our study had not been described previously.

Thanks to our results and literature data (18 mutations, 31 patients, 12 families), we found correlations between the presence of neurological manifestations and mutations in HSD17B4 and c10ORF2 genes.

The absence of mutation in the studied genes in several families could be due either to a fortuitous association between ovarian dysgenesis and deafness in sporadic cases, or the existence of other genes involved. In favor of this hypothesis, a linkage study of a large family of patients allowed to exclude the six known loci.

P02.30

Genetics of Congenital Glaucoma in Saudi Arabia, phenotype-genotype correlation

L. Abu Safieh, L. Aljasim, O. Owaydha, D. Edward,
King Khaled Eye Specialist Hospital, Riyadh, Saudi Arabia.

Purpose: Primary congenital glaucoma (PCG) is an autosomal recessive disorder, affects children between birth and 3 years old and causes improper development of the eye's aqueous outflow system that results in optic nerve damage and significant vision loss. PCG is predominantly caused by mutations in the CYP1B1 gene. Aim was to understand more about the genetic factors versus the phenotypic presentation that affect the development and PCG in Saudi patients for proper diagnosis and patients care.

Methods

In this study we screened CYP1B1 in 75 PCG families at KKESH. DNA was extracted from affected individuals and available relatives. We performed PCR and sequence analysis to detect mutations and perform genotype/phenotype correlation.

Results: This study describes a missense mutation to be responsible for disease in less than 1% of the cases, the previously reported p.G61E mutation was found to be responsible for approximately 40% of all cases, emphasizing on the founder effect expected from a consanguineous population like the Saudi population. Screening our cohort against the previously reported p.R469W mutation showed that it is responsible for approximately 1% of the cases. Approximately 34% were negative for CYP1B1 mutations, disease in these cases would be either due to regulatory or deep intronic mutations in CYP1B1 gene or other glaucoma known genes.

Conclusion: These results with the clinical evaluations are being used in genotype phenotype correlation and genetic counselling for family with PCG. We analysed age of onset, vision severity, myopia and other clinical features, significance was found between the 3 mutations group.

P02.31

Clinical and molecular characterization of the ABCA4-associated dystrophies: novel genotype-phenotype correlations

M. Riera, A. Bures-Jelstrup, J. C. D'Antin, P. Mendez, B. Corcostegui, R. Navarro, E. Pomaes,
Institut de Microcirurgia Ocular, Barcelona, Spain.

Purpose: Mutations in ABCA4 gene cause a wide range of recessive retinal disorders that can lead not only to macular dystrophies, but also more diffuse and peripheral atrophy patterns. To date, over 800 pathogenic variants have been associated to this gene, showing an extremely high allelic heterogeneity. The aim of this study was to evaluate whether certain ABCA4 alleles correlate with specific clinical features.

Methods: Clinical assessment was performed to characterize and classify a cohort of 55 families into five different phenotypes: Stargardt Disease (STGD), fundus flavimaculatus (FF), bull's eye maculopathy, cone dystrophy and cone-rod dystrophy (CRD). These families were genetically analyzed by a combination of highthroughput analyses, Sanger sequencing, genotyping microarrays, MLPA techniques, and cosegregation studies. When a new variant was detected, the pathogenic effect was validated using bioinformatic predictions, human polymorphism databases and molecular assays.

Results: In 62% of the families the two disease-causing alleles were found. Overall, 61 different ABCA4 variants were identified, including 18 novel ones. Our results showed a strong correlation between particular ABCA4-associated dystrophies and certain genotypes. Thus, the presence of two missense variants were mainly related with diffuse retinal disturbances such as FF and CRD, whereas STGD patients carried one missense mutation together with a null or splicing variant.

Conclusions: The clinical outcome of ABCA4-associated dystrophies may be determined by the type of the causative mutations. Our findings support that two missense variants are responsible for much more severe and diffuse phenotypes, suggesting that protein mislocalization or misfolding would cause more deleterious effects.

P02.32

Linkage analysis of Pakistani families with autosomal recessive retinal dystrophies

Z. Ravesh^{1,2,3}, B. Wissinger², V. Yassaee^{1,4}, M. Ansari³;

¹Genomic Research Center, Shahid Beheshti University of Medical Sciences, Tehran, Iran, Islamic Republic of, ²Institute for Ophthalmic Research, Tübingen, Germany, ³Department of Biochemistry, Lab of Genomics, Quaid-i-Azam University, Islamabad, Pakistan, ⁴Dept. of Medical Genetic, Faculty of Medicine, Shahid Beheshti University of Medical Sciences, Tehran, Iran, Tehran, Iran, Islamic Republic of.

Introduction: Hereditary retinal dystrophies (RD) are a group of heterogeneous disorders caused by mutations in over 200 genes. RDs can be subdivided into different groups based on the primary degeneration of rod or cone photoreceptor cells. This study was conducted to investigate the underlying RD genes and mutation in consanguineous families from Pakistan.

Material and Methods: Families were recruited after informed consent. Peripheral blood was collected and genomic DNA was extracted according to standard procedures. Homozygosity mapping was performed using Affymetrix Gene Chip Human Mapping 250 K-NspI arrays. The data were analyzed using Homozygosity Mapper software. Primers for amplifying all exons and intron boundaries of all genes were designed with Primer3plus software followed by PCR and Sanger sequencing. Minigene splicing assay and DNA walking were performed on respective samples.

Results: Homozygosity mapping identified a novel locus in family A, one novel gene (C8ORF37) in family B and a large novel genomic deletion of the (LCA5) gene in family C.

Conclusion: Our study indicates the heterogeneous nature of retinal dystrophies in Pakistan. The amalgamation of traditional and modern molecular techniques is required for accurate identification of mutations. It is anticipated that these findings will contribute to future genetic testing in Pakistani families to minimize the risk of recessive disorders.

P02.33

Generation of retinal dystrophy mouse models by CRISPR/Cas9 genome editing

M. López-Iniesta^{1,2,3}, P. Escudero-Ferruz¹, G. Marfany^{1,2,3}, R. González-Duarte^{1,2,3};
¹Dept. de Genètica, Fac. Biologia, Universitat de Barcelona, Barcelona, Spain, ²Institut de Biomedicina (IBUB), Universitat de Barcelona, Barcelona, Spain, ³CIBER-ER (Instituto Carlos III), Barcelona, Spain.

Introduction: Mutations in over 200 genes are associated to inherited monogenic retinal degenerative diseases (prevalence 1:3000 worldwide), but we are still far from completely understanding their ethiopathology. Therefore, animal models are an essential tool to complement in vitro and cell culture assays. We aimed to generate two different mouse models by genome editing of CERKL and NR2E3, two retinal dystrophy genes, to dissect and characterize their precise role in photoreceptor cells.

Methods: We have generated mouse models by the new approach RNA-guided endonuclease CRISPR/Cas9 system. For CERKL, we performed a full gene deletion of nearly 100 kb. For NR2E3, we aimed to delete some of the functional domains. After zygote injections and embryo transfer, mosaic pups were genotyped to characterize the modified alleles, and were used as founder animals to obtain heterozygous homozygous mice in subsequent matings.

Results: As no viability problems were observed, experiments to assess the effect of CERKL and NR2E3 deletions in retinal phenotype are currently being carried out on wildtype, heterozygous and homozygous littermates. Retinal morphology and functionality is being assessed and compared to other knock-out and knock-down animal models. These new genetically modified strains will provide further insights into the role of these two genes in visual disorders.

Grants: MJLI is in receipt of a FI-DGR 2015 fellowship (Generalitat de Catalunya). This work was supported by SAF2013-49069-C2-1-R (Ministerio de Economía y Competitividad, Spain), La Marató TV3 (project 201417.30), SGR2014-0932 (Generalitat de Catalunya), and CIBERER (Instituto Carlos III, Spain)

P02.34

Deubiquitinating enzyme genes as candidates for retinal disorders

M. Esquerdo^{1,2}, V. Abad-Morales^{1,2}, V. Toulis^{1,2}, G. Marfany^{1,2,3};

¹Dept. de Genètica, Fac. Biologia, Universitat de Barcelona, Barcelona, Spain, ²Institut de Biomedicina (IBUB), Universitat de Barcelona, Barcelona, Spain, ³CIBER-ER (Instituto Carlos III), Barcelona, Spain.

Introduction: Post-translational modifications, such as conjugation of ubiquitin, are crucial for the differentiation of specific retinal neurons and may play a role in photoreceptor cell fate. Ubiquitination is dynamic and reversible since the ubiquitin moiety is deconjugated from protein targets by deubiquitinating enzymes (DUBs). Many DUBs are implicated in human

pathological disorders from cancer and neurodegeneration to hereditary visual disorders. Besides, knockout or knockdown animal models of specific DUB genes show severe neuronal and eye phenotypes.

Methods: We aimed to characterize the gene expression pattern of several DUBs in the mouse retina. To this end, we detected mRNA and protein localization by in situ hybridization and fluorescent immunodetection. As a proof of principle, we also performed knockdown of selected DUB genes by morpholino microinjection in zebrafish embryos to study the resulting phenotype.

Results: Several expression patterns emerge, from ubiquitous expression to DUBs mostly detected in the photoreceptor layer or axonal processes, pointing to specific functions for different DUBs in the retina. Zebrafish knockdown morphants of selected DUBs show moderate to severe eye morphological defects, with defective formation of retinal structures: no lamination, no observable plexiform layers nor differentiated photoreceptors. These results support the relevance of some DUBs in the formation and differentiation of the vertebrate retina, making them good gene candidates for inherited retinal dystrophies or other visual disorders.

Grants: V.T. is in receipt of a FPI fellowship (BES-2014-068639, MINECO). Work is supported by SAF2013-49069-C2-1-R (Ministerio de Economía y Competitividad, Spain), La Marató TV3 (project 201417.30), SGR2014-0932 (Generalitat de Catalunya)

P02.35

CNVs and mosaic are not an uncommon cause of retinal blindness in children

I. Perrault¹, S. Hanein², N. Delphin³, J. Kaplan¹, J. Rozet¹;
¹INSERMU1163, Lab of Genetics in Ophthalmology, IMAGINE Institut, Paris Descartes University, Paris, France, ²INSERMU1163, NGS molecular diagnosis, IMAGINE Institut, Paris Descartes University, Paris, France, ³Lab of Molecular diagnosis, Necker Hospital, Paris, France.

Introduction: Leber congenital amaurosis (LCA) and early-onset and severe retinal dystrophies (EOSRD) are a leading cause of incurable blindness in children. The visual outcome is variable, ranging from light perception to low but measurable visual acuity in the first two decades. LCA/EOSRD can be the presenting symptom in a range of devastating ciliopathies with skeletal, neurologic and/or renal involvement. Both the visual and extraocular outcomes strongly correlate with the gene. Here, we assessed targeted NGS (T-NGS) as a tool to improve the care of infants with severe visual deficiency.

Methods: 300 index LCA/EOSRD cases were sequenced using a T-NGS array comprising 45 genes causing monosymptomatic and/or syndromic EOSRD and 10 genes of differential diagnoses. Mutations and familial segregation analysis were confirmed by Sanger sequencing.

Results: T-NGS allowed identifying disease-causing mutations in 184/300 (60 %) of the index cases: 10/184 had mutations that could not be detected by Sanger sequencing, including 9 heterozygote rearrangements (8 deletions, 1 duplication) and one mosaic (54 /395 reads), 6/184 had homozygous large deletions.

Conclusion: The molecular diagnosis in LCA/EOSRD neonates is crucial to predict the visual outcome, and to decide whether vital functions should be monitored. Yet, the genetic heterogeneity of these blinding conditions long challenged routine molecular testing. The identification of the mutation underlying the disease in 60% of the cases and the detection of second disease alleles missed by PCR-based Sanger sequencing in 5 % out of them support the relevance of implementing routine T-NGS for LCA/EOSRD.

P02.36

Functional role of CERKL, a Retinitis Pigmentosa gene, in mRNA transport in retinal cells

R. Andres^{1,2,3}, E. B. Domènech^{1,2,3}, A. Pons-Pons¹, M. J. López-Iniesta^{1,2,3}, F. Sava¹, G. Marfany^{1,2,3}, R. González-Duarte^{1,2,3};

¹Barcelona University, Barcelona, Spain, ²Institut de Biomedicina (IBUB), Barcelona University, Barcelona, Spain, ³CIBERER, Instituto de Salud Carlos III, Barcelona, Spain.

Introduction: CERKL mutations cause retinitis pigmentosa and cone-rod dystrophy in human. The CERKL gene is a paradigm for high transcriptional complexity, with many isoforms produced by alternative splicing and the use of alternative promoters. The protein displays several protein domains, such as lipid kinase, nuclear localization and nuclear export signals. Although the precise physiological function is still unknown, CERKL overexpression protects cells from apoptosis triggered by oxidative stress.

Results: In vitro studies on cultured cells showed that CERKL binds mRNA and contributes to stress granule complexes. These in vitro results have been further confirmed in isolated retinal neurons (retinal ganglion cells and photoreceptors), where CERKL co-localizes with RNA and RNA-binding proteins and is a component of the stress granules produced under oxida-

tive-stress conditions. Moreover, differential localization of CERKL isoforms in rods and cones has been shown using a panel of in-house antibodies.

Conclusions: This differential isoform specificity is highly suggestive of specific functional roles for CERKL in different photoreceptor cell types. Future work will address the impact of CERKL mutations in rods and cones related to human visual pathophysiology.

Grants: This work has been supported by SAF2013-49069-C2-1-R (Ministerio de Economía y Competitividad, Spain), La Marató TV3 (project 201417.30), SGR2014-0932 (Generalitat de Catalunya) and CIBER-ER (Instituto Carlos III, Spain).

P02.37

The molecular diagnosis of two large deletions in genes causing Retinitis Pigmentosa by WES

M. de Castro-Miró^{1,2,3}, R. Tonda^{4,5}, B. Cormand^{1,2,3}, R. González-Duarte^{1,2,3};

¹Departament de Genètica, Facultat de Biologia, Universitat de Barcelona, Barcelona, Spain, ²Institut de Biomedicina (IBUB), Universitat de Barcelona, Barcelona, Spain, ³CIBERER, Instituto de Salud Carlos III, Barcelona, Spain, ⁴CNAG-CRG, Centre for Genomic Regulation (CRG), Barcelona Institute of Science and Technology (BIST), Barcelona, Spain, ⁵Universitat Pompeu Fabra (UPF), Barcelona, Spain.

Massive exome sequencing (WES) has revolutionized genetic diagnosis of highly heterogeneous monogenic disorders, as is the case of Retinitis pigmentosa (RP), the most frequent retinal disorder.

A heterozygous stop mutation was identified by WES in the *EYS* gene in an isolated RP patient. A subsequent dosage study of the *EYS* exons in the family was suggestive of a large deletion encompassing at least 10 exons, which was later supported by SNP cosegregation analysis. The identification of the second mutation confirmed *EYS* as the causative gene with autosomal recessive inheritance in the family. The second case was a large autosomal dominant RP pedigree with no plausible mutations revealed by WES in 5 affected members. Cosegregation of a rare *FGF21* variant with the disease in this family highlighted a closely linked RP gene (*CRX*) as a promising candidate. Coverage and SNP studies of the *CRX* genomic region in the patients, followed by genomic mapping with specific PCR primers, identified the boundaries of a heterozygous 10-kb deletion, spanning exons 3 and 4 of *CRX*. The benefits of WES for the molecular diagnosis of highly heterogeneous mendelian disorders are well established. However, the main drawback is the identification of gross structural genomic alterations at heterozygosity by using standard variant calling strategies. In such cases, the genetic data can be decisive to attain the genetic diagnosis by pointing to the disease candidates.

Grants: This work was supported by SAF2013-49069-C2-1-R (Ministerio de Economía y Competitividad, Spain), SGR2014-0932 (Generalitat de Catalunya) and CIBER-ER (Instituto Carlos III, Spain).

P02.38

Towards rapid genetic diagnosis of developmental eye anomalies: design and implementation of a large diagnostic and research gene panel

J. L. Bruty¹, Y. Wallis¹, D. McMullan¹, S. Clokic¹, M. Griffiths¹, R. Holt², D. Bax², J. Hoffman³, S. Hadfield³, N. Ragge^{2,3};

¹West Midlands Regional Genetics Laboratory, Birmingham, United Kingdom, ²Oxford Brookes University, Oxford, United Kingdom, ³Clinical Genetics Unit, Birmingham Women's Hospital, Birmingham, United Kingdom.

Developmental eye anomalies, including anophthalmia, microphthalmia and coloboma, affect ~1 in 3,500 individuals worldwide. At least 150-200 genes are implicated in these conditions, with many other genes known to be important in eye development pathways, and still more to be identified. Currently 4-5 genes are tested routinely in the UK, meaning only 28% of developmental eye anomalies patients receive genetic diagnosis; often following a lengthy research input.

A diagnostic gene panel containing 351 genes known to be involved in eye development and 195 genes of potential interest was developed, using the Illumina Nextera Rapid Capture Custom Enrichment kit, and sequenced using the MiSeq platform. Sequence data was processed using an in-house bioinformatics pipeline. A validation cohort of 10 patients who have previously undergone research testing, along with 16 new patients have been tested so far, with a further 16 patients planned.

So far mutations have been identified in 15 genes including *SOX2*, *PAX6*, *FOXE3* and *BEST1*, including all known mutations from the validation cohort and definite causative pathogenic mutations in 2/16 new patients (12%). Several other gene alterations are undergoing further analysis. A large amount of research data has also been collected, and is linked to an adjunctive research programme for further analysis.

A large panel for sequencing mutations in patients with developmental eye

anomalies is a valid and viable approach, and helps reduce the time taken for diagnosis. Including research genes linked to a research programme also gives huge potential benefit for further understanding of developmental eye anomalies.

P02.39

Splicing defects caused by rare *OPN1LW/MW* haplotypes associated with X-linked cone dysfunction disorders: *de novo* intrachromosomal gene conversion from *MW* to *LW* in the male germline results in Blue Cone Monochromacy

E. Buena Atienza¹, K. Ruether^{2,3}, B. Baumann¹, R. Bergholz², N. Weisschuh¹, S. Kohl¹, B. Wissinger¹;

¹Institute of Ophthalmic Research, Tübingen, Germany, ²Charité Campus Virchow-Klinikum, Berlin, Germany, ³Sankt Gertrauden-Krankenhaus, Berlin, Germany.

X-linked cone dysfunction disorders such as Blue Cone Monochromacy and X-linked Cone Dystrophy are characterized by absent or reduced L- and M- cone function due to defects in the *OPN1LW/OPN1MW* gene cluster. We studied 24 affected males from 16 families with either a structurally intact gene cluster or at least one intact single (hybrid) gene, but carrying rare combinations of common SNPs in exon 3 in single or multiple *OPN1LW* and *OPN1MW* gene copies. We applied a semi-quantitative minigene splicing assay to assess twelve different *OPN1LW/MW* exon 3 haplotypes. Nine haplotypes resulted in aberrant splicing of equal or more than 20% of transcripts including the known pathogenic haplotypes (i.e. 'LIAVA', 'LVAVA') with absent or minute amounts of correctly spliced transcripts, respectively. In one family with strikingly different phenotypes we observed *de novo* occurrence of the 'LIAVA' haplotype derived from an ancestral less deleterious 'LIAVS' haplotype. We could establish an intrachromosomal gene conversion in the male germline as the underlying mechanism driving the phenotype change from macula dystrophy with deuteranopia into Blue Cone Monochromacy. The converted sequence was narrowed to a region of ~1300 bp originating from a downstream *OPN1MW* gene. Although gene conversion shaping the *OPN1LW/OPN1MW* genes has been postulated and inferred from new arising mutations, we are the first to demonstrate a *de novo* gene conversion within the lineage of a pedigree.

The research leading to these results has received funding from the European Union Seventh Framework Programme [FP7-People-2012-ITN] under grant agreement 317472 (EyeTN).

Identification and functional assessment of deep-intronic and non-canonical splice defects in *ABCA4* associated with Stargardt disease

R. Sangermano^{1,2}, S. Albert^{1,2}, M. Bauwens³, N. Bax¹, S. Cornelis¹, V. Richelle¹, L. I. van den Born⁵, A. Garanto^{1,2}, C. B. Hoyng⁴, R. W. J. Collin^{1,2}, E. De Baere³, F. P. M. Cremers^{1,2};

¹Department of Human Genetics, Radboud University Medical Center, Nijmegen, Netherlands, ²Radboud Institute of Molecular Life Sciences, Nijmegen, Netherlands, ³Center for Medical Genetics, Ghent University and Ghent University Hospital, Ghent, Belgium, ⁴Department of Ophthalmology, Radboud University Medical Center, Nijmegen, Netherlands, ⁵Rotterdam Eye Hospital, Rotterdam, Netherlands.

Purpose: Non-canonical *ABCA4* splice variants are frequent in Stargardt disease (STGD1), but their effect is poorly understood. Deep-intronic variants have also been shown to affect RNA splicing. About 30% of STGD1 patients carry one or no *ABCA4* variant, and we hypothesize that the missing mutations reside in the non-coding parts. Transcript analysis is not straightforward as *ABCA4* is specifically expressed in the retina. The purpose of this study is to (1) identify intronic variants in unsolved patients by *ABCA4* locus sequencing, and (2) to prove their functional effects as well the effect of non-canonical splice variants, by *in vitro* splice assays.

Methods: Haloplex-based locus sequencing was performed in 70 mono-allelic maculopathy cases. After applying splice site prediction programs, the effect of intronic variants was tested *in vitro* by cloning ~1.5-kb fragments into minigenes, transfecting them into HEK393T cells and performing reverse transcription-PCR.

Results: Haloplex sequencing revealed > 80 rare deep-intronic variants which potentially activate cryptic exons. At least 12 are being analyzed by minigene splice assays. The non-canonical c.5461-10T>C and c.6729+5_6729+19del variants were shown to result in exon 39/40 or 48 skipping, respectively, effectively resulting in null alleles.

Conclusions: Two non-canonical splice variants, among which the most frequent severe *ABCA4* variant, c.5461-10T>C, were shown to completely inactivate *ABCA4* function. Minigene splice assays are effective to investigate variants predicted to have an effect on splicing. Some of these variants might be amenable for antisense oligonucleotide-based therapy.

Molecular genetic analysis of *COL2A1* gene in a group of Czech patients with Stickler syndrome

J. Sabova^{1,2}, V. Sucha¹, M. Simandlova², V. Horinova², R. Pourova², A. Krepelova²;

¹Laboratory for Molecular Diagnostics, Synlab Genetics s.r.o., Prague, Czech Republic, ²Department of Biology and Medical Genetics, 2nd Faculty of Medicine, Charles University and Motol University Hospital, Prague, Czech Republic, ³Sanatorium Helios, Brno, Czech Republic.

Stickler syndrome (STL) is an AD progressive disorder of connective tissue and it is one of the most frequent genetic syndromes associated with deaf-blindness with incidence 1:7500-1:9000 newborns. STL is characterized by midfacial underdevelopment and cleft palate (either alone or as part of the Robin sequence); eye abnormalities; hearing loss (both conductive and/or sensorineural); and mild spondyloepiphyseal dysplasia and/or precocious arthritis. Eye findings include high myopia, cataract, retinal detachment leading to impaired vision or blindness. The degree of hearing loss varies among affected individuals and may become more severe over time. There are several types of STL, which are distinguished by their genetic cause and their characteristic signs and symptoms. The most common type I (STL1) is responsible for approximately 70% of reported cases and presents with a wide variety of symptoms affecting the eye, ear, facial appearance, palate and musculoskeletal system and occurs due to mutations over the entire *COL2A1* gene on chromosome location 12q13.11. In our pilot study we investigated 29 patients from 15 families with STL from the Czech Republic (CR). We analysed the *COL2A1* gene using Sanger sequencing as a prescreening and here we present the first 3 families in the Czech Republic with 2 detected known heterozygous frameshift mutations c.2382delT and one novel splice-site mutation c.1123-2A>G. Identification of these mutations confirmed the diagnosis of Stickler syndrome. NGS screening of *COL2A1* negative patients will follow.

Supported by a project for conceptual development of research organization 00064203 and 64204 and GAUK 165815.

P02.42

TMPRSS3 mutation as a cause of non-syndromic hearing impairment among Polish hearing loss patients

U. Lechowicz¹, A. Pollak¹, A. Podgorska¹, P. Stawinski¹, M. Oldak¹, H. Skarzynski², R. Ploski²;

¹Institute of Physiology and Pathology of Hearing, Department of Genetics, Warsaw, Poland, ²Institute of Physiology and Pathology of Hearing, Warsaw, Poland, ³Medical University of Warsaw, Department of Medical Genetics, Centre of Biostructure, Warsaw, Poland.

Recessive mutations of the *TMPRSS3* gene cause non-syndromic hearing impairment (HI) but little is known about their spectrum among Polish population. The purpose of the study was to search for pathogenic *TMPRSS3* variants in Polish HI patients, determine the pathogenicity of those variants and genotype-phenotype correlations.

Using WES (Illumina HiSeq1500) in one patient two mutations in the *TMPRSS3* gene were found. Previously, mutations in the *GJB2* gene, common deletions in the *GJB6* gene and mitochondrial m.3243A>T and m.1555A>T mutations were excluded in this patient. A large cohort of HI patients (n=2277) and a control group (n=500) were studied to assess the prevalence of *TMPRSS3* mutations with real-time PCR. Sanger sequencing was used to confirm the presence of the detected *TMPRSS3* variants and to search for the second mutation in the *TMPRSS3* gene.

We found 43 (1.88%) probands with 14 different *TMPRSS3* variants. The most frequent mutation was the already known variant p.H70Tfs*19, the second one was p.A138E. Truncating *TMPRSS3* mutations cause a more severe HI with an earlier onset than missense mutations. The p.A90T variant previously linked with HI had a high prevalence in controls (~6%) indicating that is non-pathogenic change.

Mutations in *TMPRSS3* gene are not a common cause of HI in patients with autosomal recessive hearing loss, but considering the group of patients with a partial deafness HI and postlingual age of onset, *TMPRSS3* gene mutations may be an important component.

This study was supported by NCN grants: NCN 2012/05/N/NZ5/02629 and NCN 2011/03/D/NZ5/05592.

P02.43

Pathogenic Role of the USH2A mutation (p.Cys759Phe) among Spanish families with Retinitis Pigmentosa or Usher syndrome

R. Perez-Carro¹, A. Avila-Fernandez², F. Blanco-Kelly¹, A. Gimenez-Pardo¹, I. Martin-Merida¹, M. Corton¹, N. Reyes¹, E. Aller², J. Millan², C. Ayuso¹;

¹Instituto de Investigación Sanitaria-Fundación Jimenez Diaz, Madrid, Spain, ²Instituto de Investigación Sanitaria IIS-La Fe, Valencia, Spain.

Mutations in USH2A have been associated with non-Syndromic Retinitis Pigmentosa (RP) and Usher syndrome (USH), being the p.Cys759Phe one of the most frequent mutation. A recent study (Gonzalez-del Pozo et al) has questioned the pathogenicity of this variant detected homozygously in two asymptomatic individuals. However, the high prevalence of the p.Cys759Phe mutation in our cohort of patients supports its pathogenicity. The aim of this study was to establish the implication of p.Cys759Phe mutation as a cause of syndromic or non-syndromic RP.

A total of 81 Spanish families affected with RP or USH, carrying the p.Cys759Phe mutation, either in homozygosity or heterozygosity, were analyzed using classical molecular techniques. Among them, 15 heterozygous cases were further studied by different targeted-NGS approaches in order to identify the second causative allele.

We could characterize 68 families being 12 of them homozygous for the p.Cys759Phe variant. Furthermore, fifty-three compound heterozygous for USH2A were also found. In three out of 68 characterized patients, causative mutations in a different gene were identified being also carriers of the p.Cys759Phe. The remaining 13 uncharacterized families with the p.Cys759Phe in heterozygosity are being analysed by NGS for detecting disease-causing mutation.

All these data together seem to point to the pathogenic causative role for p.Cys759Phe, although another modifier effect for RP cannot be excluded. Overall, a comprehensive study of the molecular basis of these diseases allows us to provide an accurate diagnosis, a prognosis of the disease and proper genetic counseling to the patients.

Different ethnic distribution of the aberration splice mutation in intron 2, c. 293-13A/C>G, at CYP21A2 gene in Macedonian patients with classical form of 21-hydroxylase deficiency

V. Anastasovska, M. Kocova;
Genetic Laboratory, Department of Endocrinology and Genetics, University Children's Clinic, Skopje, Macedonia, The Former Yugoslav Republic of.

Introduction: 21-hydroxylase deficiency is an autosomal recessive endocrine disorder due to mutations in the CYP21A2 gene. Severe enzyme deficiency can present as a classical salt wasting (SW) and simple virilizing form (SV). The In2G (c.293-13A/C>G) mutation provides ~ 2% enzyme activity. It encompasses 25% of the classic 21-hydroxylase deficiency alleles and 51% of the SW alleles.

Materials and Methods: We have performed molecular analysis of the In2G (c.293-13A/C>G) mutation in 49 Macedonian patients with clinical and laboratory signs of severe form of 21-hydroxylase deficiency, 26 SW and 23 SV form, evaluated at the Department of Endocrinology and Genetics, University Children's Clinic, Skopje, Republic of Macedonia, using differential PCR/ACRS. Of the patients, 27 had Macedonian, 14 Albanian, and 8 Roma ethnic origin.

Results: The In2G mutation was detected in 57.1% of the patients, 40.8% were homozygotes and 16.3% were heterozygotes. It was revealed in 65.4% (34/52) of the SW alleles, and 30.4% (14/46) of the SV alleles. Interestingly, In2G was detected in all Roma patients on 93.8% of the alleles (7 homozygotes and 1 heterozygote), followed by 57.1% of the Albanians on 53.6% alleles (7 homozygotes and 1 heterozygote), and 44.4% of the Macedonian patients on 33.3% of the alleles (6 homozygotes and 6 heterozygote).

Conclusions: We found different ethnic distribution of the In2G mutation in the Macedonian patients with severe 21-hydroxylase deficiency. High In2G frequency detected in our patients, that is comparable to the most of the other European countries, supports its role in classical phenotype of the 21-hydroxylase deficiency.

P03.02

Dysregulation of NR5A1 is a novel and recurrent cause of 46,XX (ovo) testicular disorder of sex development

D. Baetens¹, A. L. Todeschini², F. Peelman³, H. Stoop⁴, F. Coppieters¹, T. Rosseel¹, T. Van Laethem¹, L. H. Looijenga⁴, R. A. Veitia², M. Cools⁵, E. De Baere¹;

¹Center for Medical Genetics, Ghent University, Ghent, Belgium, ²Institut Jacques Monod, Université Paris Diderot, Paris, France, ³Department of Medical Protein Research, Faculty of Medicine and Health Sciences, Flanders Institute for Biotechnology, Ghent, Belgium, ⁴Department of Pathology, Erasmus MC-University Medical Center Rotterdam, Rotterdam, Netherlands, ⁵Department of Pediatrics, Division of Pediatric Endocrinology, Ghent University Hospital and Ghent University, Ghent, Belgium.

Background: While many causes of 46,XY disorders of sex development (DSD) have been elucidated, the mechanisms leading to 46,XX (ovo) testicular DSD are poorly understood. Both conditions may represent a phenotypic spectrum resulting from a common underlying genetic defect.

Methods: Whole exome sequencing was applied to identify the molecular cause in ten unrelated patients with 46,XX (ovo) testicular DSD. Transcriptional activation of the variant of interest was assessed using luciferase assays. RNA-seq was performed on patient-derived lymphocytes. Immunohistochemistry was done on gonadal specimens for markers of gonadal development.

Results: We identified a novel heterozygous NR5A1 variant c.274C>T p.(Arg92Trp) in three unrelated cases with 46,XX (ovo) testicular DSD. This variant is absent in genomic databases and is predicted to be deleterious. The Arg92 residue is conserved up to zebrafish and located in the RGGR motif before the C-terminus helix in the conserved Ftz-F1 box, likely affecting DNA-binding stability and specificity. Immunohistochemistry confirmed SRY-independent SOX9 expression and absence of FOXL2 in testicular parts of XX gonads and vice versa in ovarian regions. No consistent changes in transcriptional activation were seen. RNA-seq showed upregulation of MAMLD1, a direct target of NR5A1.

Conclusions: Previously, loss-of-function mutations in NR5A1 were found in a spectrum of male undervirilization. Here, a novel NR5A1 mutation was found in three out of ten cases with 46,XX (ovo) testicular DSD, an ultra-rare condition. We hypothesize that this variant results in gain-of-function and triggers testicular differentiation in 46,XX individuals. We propose NR5A1 mutation p.(Arg92Trp) as a novel and recurrent cause of 46,XX (ovo) testicular DSD.

Dissecting the genetic complexity of Addison's disease by using targeted resequencing data of a large Swedish cohort

M. Bianchi¹, D. Eriksson², J. Wahlberg³, O. Ekwall⁴, P. Dahlqvist⁵, A. Hulting⁶, K. Lindblad-Toh⁷, S. Bensing⁸, O. Kämpe², G. Rosengren Pielberg¹;

¹Science for Life Laboratory, Department of Medical Biochemistry and Microbiology, Uppsala University, Uppsala, Sweden, ²Center for Molecular Medicine, Department of Medicine, Karolinska Institutet, Stockholm, Sweden, ³Department of Endocrinology, and Department of Medical and Health Sciences, and Department of Clinical and Experimental Medicine, Linköping University, Linköping, Sweden, ⁴The Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden, ⁵Department of Public Health and Clinical Medicine, Umeå University, Umeå, Sweden, ⁶Department of Molecular Medicine and Surgery, Karolinska Institutet, and Department of Endocrinology, Metabolism and Diabetes, Karolinska University Hospital, Stockholm, Sweden, ⁷Broad Institute of Harvard and Massachusetts Institute of Technology (MIT), Cambridge, MA, United States.

Addison's disease (AD) is a rare autoimmune disorder characterized by the failure of the adrenal cortex. Besides HLA and a few shared autoimmunity-predisposing associated loci, the genetics underlying AD is largely unknown. The Swedish Addison registry consists of 700 AD patients accurately characterized regarding their clinical phenotype and autoimmune serological parameters. 83% of the patients have 21-hydroxylase autoantibodies and 62% have at least another autoimmune disease. We resequenced 1,900 target genes involved in immune function and autoimmunity in all AD patients and in 1,500 healthy controls. Targets included coding sequences, full UTRs and conserved intronic and intergenic regions. GATK, LASER and KING software were used to call variants, pinpoint predicted non-Europeans and identify related samples, respectively. Single SNP and aggregate association tests, as well as pathway analysis will be performed in order to confirm known and unravel novel loci associated with AD and its co-inherited autoimmune diseases in the Swedish population.

We expect that our study of a slightly unconstrained Swedish population isolate will enable to improve global diagnostic and medical AD treatments by finding disease variants likely to be causative across different populations.

Background: In around 30% of families with colorectal adenomatous polyposis, no germline mutation in the known genes APC, MUTYH, POLE, POLD1, or NTHL1 can be identified, although a hereditary etiology is likely. **Methods:** To uncover new high-penetrance causative genes, exome sequencing of leukocyte DNA from 104 unrelated patients with unexplained adenomatous polyposis was performed. For data analysis and variant filtering, an established bioinformatics pipeline including in-house tools was applied. **Results:** We identified two unrelated patients with differing compound-heterozygous loss-of-function germline mutations in a DNA repair gene. The pedigrees, genotypes, and the frequency of mutations of this gene in the general population are consistent with an autosomal recessive mode of inheritance. By transcriptional analysis, by functional analysis of the tumor tissue and by use of various in-silico tools we found strong evidence for a loss-of-function effect. No germline mutation in any other gene known to cause polyposis was identified in these patients. Both index patients had an affected sibling carrying the same mutations. Besides colorectal and duodenal adenomas, colorectal cancer, gastric cancer, and early onset astrocytoma were reported in the two patients and their affected siblings. In addition, we identified one unrelated patient with a biallelic PMS2 germline mutation, representing Constitutional Mismatch Repair Deficiency Syndrome (CMMR-D). **Conclusions:** The present study is the first to identify biallelic pathogenic germline mutations of the given DNA repair gene in patients with a suspected hereditary tumor syndrome. Our data suggest that the reported cases represent a novel recessive subtype of colorectal adenomatous polyposis.

Molecular analysis of AR gene in fourteen female patients with 46,XY - advances of two generations of sequencing

S. Andonova¹, R. Vazharova^{2,3}, L. Grozdanova⁴, R. Robeva⁵, I. Bradinova⁶, E. Stefanova⁶, L. Balabanski³, S. Ivanov³, D. Toncheva⁷, P. Kumanov⁵, M. Sirakov⁸, A. Savov¹;

¹National Genetic Laboratory, UHOG „Maichin dom“, Sofia, Bulgaria, ²Sofia University “St. Kliment Ohridski”, Sofia, Bulgaria, ³GARH Malinov, Genomic Laboratory, Sofia, Bulgaria, ⁴Department of Pediatrics and Medical Genetics, Medical University Plovdiv, Plovdiv, Bulgaria, ⁵Clinical Center of Endocrinology and Gerontology, Medical University – Sofia, Sofia, Bulgaria, ⁶Pediatric Endocrinology, Diabetes and Genetics Clinic, University Pediatric Hospital, Medical University-Sofia, Sofia, Bulgaria, ⁷Department of Medical Genetics, Medical University - Sofia, Sofia, Bulgaria, ⁸Department of Gynecological endocrinology and Pediatric and Adolescent Gynecology, UHOG “Maichin dom”, Medical University – Sofia, Sofia, Bulgaria.

Disorders of sex development (DSD) are group of heterogeneous conditions that usually present with atypical genitalia and/or delayed puberty. One of the most common disorders in this group is the Androgen Insensitivity Syndrome (AIS) - the affected individuals are phenotypically females with resistance to androgen action and 46,XY karyotype. More than 600 mutations associated with the variable phenotype of the disorder are known in Androgen Receptor (AR) gene (Xq12). Fourteen XY female patients were referred to our team due to primary amenorrhea and/or discordance between phenotypic and chromosomal sex. Molecular analysis of AR gene was conducted using Sanger sequencing (9 patients) and targeted Next-generation sequencing (5 patients). Mutations in 6 patients were found: p.Q147Ter, p.R616H, p.R780W and p.I842N. The mutation was inherited from the heterozygous mother in 4 of the cases. The mother of the one patient was not a carrier and the mutation was de novo. DNA sample from relatives of the last patient were not available. Further analyses revealed mutations in SRY, SRD5A2 and NR5A1 genes in three of the remaining eight cases.

Conclusion: Sanger sequencing of AR is indicated for patients with strong suspicions for AIS while use of targeted next-generation sequencing of known genes associated with DSD could be beneficial in cases with atypical

phenotype and clinical data. The combination of routine and new genetic technologies could be crucial for the molecular diagnosis in such genetically heterogeneous diseases as 46,XY DSD.

P03.06

Identification by exome sequencing and functional characterization of nonobvious pathogenic variants responsible for Alport syndrome

C. Chierighin^{1,2}, M. Robusto^{1,2}, P. Castorina³, M. Gianì³, S. Duga^{1,2}, R. Asselta^{1,2}, G. Solda^{1,2};

¹Humanitas University, Rozzano (Milan), Italy, ²Humanitas Clinical and Research Center, Rozzano (Milan), Italy, ³Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Milan, Italy.

Introduction: Alport syndrome (AS) is a progressive inherited renal disease caused by mutations in three large collagen-IV genes (COL4A3, COL4A4, COL4A5), comprising about 50 exons each. Recently, the introduction of next-generation sequencing allowed the analysis of all three AS genes in a single step. Despite that, the total mutation detection rate has been estimated between 55-80%.

Materials and Methods: We selected three Italian families with clear clinical evidence of AS but no molecular diagnosis, despite having been subjected to extensive candidate gene analyses. The probands were screened by whole-exome sequencing (WES) using the Nextera Rapid Capture kit on a Next-Seq500 platform. All exons of AS genes were adequately covered. **Results:** Analysis of variants within AS genes identified pathogenic mutations in all families. In Family-1, we identified an homozygous 24-bp in-frame deletion in COL4A3 (p.Val11_Leu18del), segregating with autosomal recessive AS. The variant is predicted to disrupt the signal peptide, possibly altering COL4A3 protein secretion. In Family-2 proband, a COL4A5 hemizygous missense mutation (p.Gly491Asp) was found in exon 33, which was not covered by previous targeted resequencing. In Family-3, we detected an heterozygous intronic variant (c.2245-40A>G) altering COL4A5 exon-29 branch site, as we confirmed by in-vitro studies. Analysis of the pattern of X-chromosome inactivation (XCI) on DNA from blood revealed a correlation between unbalanced XCI and phenotypic manifestations in mutant females. **Conclusions:** WES was fundamental to provide a molecular diagnosis in 3 AS families, highlighting non-obvious pathogenic variants that escaped previous screenings.

We thank: Italian Telethon Foundation (grant#GGP11177) and Fondazione Cariplo (grant#2013-0825).

P03.08

The role of DNA analysis in diagnosis of autosomal recessive polycystic kidney disease

L. Obeidova¹, V. Elisakova¹, T. Seeman², J. Reiterova³, J. Stekrova¹;

¹Institute of Biology and Medical Genetics of the First Faculty of Medicine, Charles University in Prague and General University Hospital in Prague, Prague, Czech Republic, ²Department of Paediatrics, 2nd Faculty of Medicine, Charles University in Prague and Motol University Hospital in Prague, Prague, Czech Republic, ³Department of Nephrology, First Faculty of Medicine, Charles University in Prague and General University Hospital in Prague, Prague, Czech Republic.

Introduction: Autosomal recessive polycystic kidney disease (ARPKD) is a severe form of chronic kidney disease, frequently diagnosed prenatally. ARPKD is caused by mutations in the PKHD1 gene, nevertheless, the same phenotype is part of many other disorders. Thus, the molecular genetic analysis can be very useful in differential diagnosis of ARPKD.

Herein, we present the results of molecular genetic analysis in 52 families with clinically suspected ARPKD.

Materials and methods: The analysis of PKHD1 was carried out using next-generation sequencing and subsequent MLPA (multiplex ligation-dependent probe amplification). In some of the families, genetic analysis of HNF1β, PKD1/2 was carried out. The cohort of probands was divided into 2 groups (Group A and B) on the basis of their fulfillment of clinical criteria of ARPKD. Patients fulfilling all criteria were placed in Group A (n=24). Group B consisted of 30 patients.

Results: The detection rate in PKHD1 amounted to 81% in Group A, and 27% in Group B. Six families within Group B without mutation in PKHD1 harbored mutations in other genes (HNF1β, PKD1/2 and NPHP11).

Conclusions: The detection rate of PKHD1 mutations in children fulfilling all clinically diagnostic criteria of ARPKD is high, reaching 81%. However, mutations of PKHD1 were also detected in some of the patients without having met all three clinical criteria, especially in patients who died perinatally. The important sign of ARPKD in children proved to be congenital hepatic fibrosis.

Introduction of a routine NGS-based genetic screening into the universal screening programme for hypercholesterolemia in Slovenian 5-years old children

J. Kovač¹, G. Klančar¹, T. Tesovnik¹, U. Grošelj², T. Battelino^{2,3}, K. Trebušak Podkrajšek^{1,3},
¹Unit of Special Laboratory Diagnostics, University Children's Hospital, UMC, Ljubljana, Slovenia, ²Department of Pediatric Endocrinology, Diabetes and Metabolic Diseases, University Children's Hospital, UMC, Ljubljana, Slovenia, ³Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia.

Introduction:

Untreated familial hypercholesterolemia (FH) increases the risk for developing atherosclerosis and cardio-vascular disease in early adulthood for up to 100-fold. Slovenia launched the program of universal screening for hypercholesterolemia in 5-year-old children in 1995 with routine measurement of fasting serum cholesterol. Additionally, the routine genetic screening using NGS technology was introduced in 2011 to identify causative genetic variants in individuals with positive result of the screening.

Materials and Methods:

272 individuals (149 females) were sent to a tertiary paediatric outpatient clinic due to the increased level of serum cholesterol and referred to genetic testing. Genomic DNA was isolated from whole-blood samples according to established laboratory protocol. Samples for NGS were prepared using ADH MASTR assay (Multiplicom, Belgium) for detection of variants in 4 genes associated with FH (LDLR, PCSK9, APOE and exon 26 of APOB) and sequenced on a MiSeq platform with MiSeq reagent kit v2 (Illumina, California) following the manufacturer's protocol.

Results:

105 (38.6%) of individuals had causative variant identified in LDLR gene followed by 55 individuals (18.4%) with causative variant in APOB and none in PCSK9. Additionally, 51 participants (18.7%) were carriers of APOE E4 isoform genotype. The results of genetic analysis were negative for 66 participants (24.3%).

Conclusions:

Results clearly demonstrated the efficacy of universal screening programme with most participants having genetically confirmed FH. Additionally, data for family history may not suffice for reliable identification of FH patients. This work was supported by Slovenian National Research Agency grants P3-0343, J3-4116, J3-6800, and J3-6798.

Differential gene expression in chronic obstructive pulmonary disease cases and controls

M. Soler Artigas^{1,2}, A. Esteve², G. Thun², C. Newby³, L. V. Wain¹, M. D. Tobin¹, S. Heath², I. Gut², D. Singh⁴, L. Ziegler-Heitbrock⁵, C. Brightling³,
¹Genetic Epidemiology Group, Department of Health Sciences, University of Leicester, Leicester, United Kingdom, ²Centro Nacional de Análisis Genómico (CNAG-CRG), Center for Genomic Regulation, Universitat Pompeu Fabra (UPF), Barcelona, Spain, ³Department of Infection, Inflammation and Immunity, Institute for Lung Health, University of Leicester, Leicester, United Kingdom, ⁴University of Manchester, Medicines Evaluation Unit Limited, Manchester, United Kingdom, ⁵The EvA Study Center, Comprehensive Pneumology Center, Helmholtz-Zentrum München, Gauting, Germany.

Chronic obstructive pulmonary disease (COPD) is a leading cause of morbidity and mortality worldwide. However, the biological mechanisms underlying the development and progression of COPD are not yet well understood. We analysed sequence-based transcriptomics data in COPD cases and controls from the EvA study, as part of the AirPROM project. Cell material was obtained by airway epithelial brushing (305 cases/232 controls) and bronchoalveolar lavage (182 cases/174 controls).

Case-control differential expression was tested using an exact permutation test, and lasso regression was used to assess whether differentially expressed genes were able to predict case-control status. The dataset was divided into training and testing sets of randomly selected individuals, and average predictive values across 50 iterations of ~80% for brushing and ~70% for lavage were obtained. A small number of genes were selected in more than 40 out of the 50 iterations suggesting their potential relevance in biological processes relevant to COPD. Additionally, genes were clustered into modules according to their co-expression across individuals, and the association of these modules with COPD status and other related traits were tested using weighted gene co-expression network analysis. This approach highlighted some of the genes selected by the lasso regression analysis. Genome-wide data has now been generated for this set of individuals and integrative analysis is in progress.

Overall, these analyses will highlight genes relevant to biological processes present in COPD patients and have the potential to improve our understanding of this complex disease.

This research received funding from the European Union (grant n°270194).

Targeted NGS improves the identification of genetic determinants in Combined Pituitary Hormone Deficiency and Septo-Optic Dysplasia

J. Rodríguez-Contreras¹, C. Polo-Vaquero¹, A. Del Pozo^{1,2}, K. Ibáñez-Garikano¹, J. Silla¹, V. E. F. Montano¹, I. González-Casado³, B. Lecumberri-Santamaría⁴, P. D. Lapunzina^{1,2}, E. Vallespín^{1,2}, K. E. Heath^{1,2}, A. Campos-Barros^{1,2},
¹INGEMM, IdiPAZ, Hospital Universitario La Paz, Madrid, Spain, ²CIBERER (U753), ISCIII, Madrid, Spain, ³Pediatric Endocrinology, Hospital Universitario La Paz, Madrid, Spain, ⁴Endocrinology, Hospital Universitario La Paz, Madrid, Spain.

Introduction: Molecular diagnosis of combined pituitary hormone deficiency (CPHD) and septo-optic dysplasia (SOD) by classical gene screening cascade has a poor success rate due to the increasing number of implicated genes, the genetic overlap with other clinical entities such as congenital hypogonadotropic hypogonadism (CHH) and the recently postulated oligogenic inheritance.

Aim: To design, implement and validate a targeted NGS panel to identify the genetic determinants of CPHD and SOD.

Subjects and Methods

A cohort of 82 CPHD or SOD patients were analysed with the HYPOPIT.V1 panel, including a total of 73 genes: 50 found to be mutated in pituitary disorders and 23 genes in associated signalling pathways. Variants were validated by Sanger sequencing, MLPA or aCGH.

Results: After having completed the analysis of 26 patients (CPHD n=19; SOD, n=7), we have identified likely pathogenic variants in 11 (42%); 7 of which presented potentially relevant variants in more than one gene, some of them in genes known to be implicated in CHH, such as *FGFR1*, *FGF8*, and *PROKR2*, and in holoprosencephaly associated genes (*CDON*, *GLI2*, *ZIC2*, *PTCH1*, *EYA4*). Interestingly, in 3/11 patients, we also detected variants in *CHD7*, a gene implicated in CHARGE syndrome.

Conclusions: Targeted NGS identified disease relevant variants in 42% of analyzed CPHD and SOD cases, supporting the hypothesis of digenic/oligogenic inheritance in 27% of the examined patients. These results confirm the utility of the targeted NGS approach for improving the molecular diagnosis of CPHD and SOD.

Genetic variants underlying congenital cystic adenomatoid malformations

M. Garcia-Barcelo¹, J. S. Hsu¹, R. Zhang², F. Yeung¹, C. Wong¹, M. Yu¹, M. So¹, M. Li¹, P. Sham¹, H. Xia², P. K. Tam¹,
¹The University of Hong Kong, Hong Kong, Hong Kong, ²Guangzhou Women and Children's Medical Center, Guangzhou, China.

Introduction: A congenital cystic adenomatoid malformation (CCAM) is a congenital hamartomatous pulmonary lesion that results from abnormal overgrowth of tracheal, bronchial, bronchiolar, or alveolar tissue. The clinical presentation is variable, ranging from the most serious phenotype which may result in hydrops fetalis to mild phenotype with possible resolution. Affected new-borns present with severe respiratory distress or remain asymptomatic until later in life. Surgical resection is the definitive treatment. The disorder is rare (1/8300-1/35,000 live births) and occurs mainly sporadically. The condition is due to a defective branching morphogenesis of the lung at different developmental stages. What triggers this developmental defect is unknown, yet alteration of the signalling pathways controlling lung development are thought to be the cause.

Methods: Whole exome sequencing was conducted on 15 CCAM trios following the standard protocol.

Results: Damaging de novo mutations in four genes known to be involved in airway epithelium response to cigarette smoking and lung cancer (*SPG11*, *MICAL2* and *LRRC16A*) or soft tissue sarcoma (*SCYL1*) found in 4/15 patients. Importantly, damaging mutations forming compound heterozygotes were detected in *SLC15A1*, a gene involved in lung peptide clearance in bronchial airway epithelial cell lines. Likewise, mutations in interacting genes co-existed in several patients and its relevance is being assessed. Copy number analysis is underway.

Conclusion: CCAM is genetically heterogeneous with different mutated genes in different patients and it is likely to require mutations in more than one gene to give rise to the developmental anomaly.

Integration of genomic analysis and transcript expression in focal form of congenital hyperinsulinism

I. Wieland¹, I. Dallmann¹, S. Vogelgesang², W. Barthlen², K. Mohnike⁴, M. Zenker¹;
¹University Hospital, Institute of Human Genetics, Otto-von-Guericke University, Magdeburg, Germany, ²Institute of Pathology, University Greifswald, Greifswald, Germany, ³Clinic for Ped. Surgery, University Greifswald, Greifswald, Germany, ⁴University Hospital, Dept. of Pediatrics, Otto-von-Guericke University, Magdeburg, Germany.

Introduction: In congenital hyperinsulinism (CHI) insulin secretion is dys-regulated leading to severe hypoglycaemia in neonates and infants. Focal forms of CHI have been reported in 20-50% of mutation positive patients. The focal form is caused by a paternally transmitted recessive mutation in ABCC8 or KCNJ11 on chromosome 11p15 and a second somatic event in the affected islet of Langerhans. In pancreatic lesions we investigated the genetic mechanisms underlying focal form of CHI.

Methods: Patients with proven ABCC8 or KCNJ11 mutations and receiving therapeutic surgery were included. Loss of heterozygosity (LOH) and gene expression were analysed by PCR and Sanger sequencing. Deletions, duplications and uniparental isodisomy (UPD) were tested by methylation-specific MLPA. The effect of UPD on gene expression levels was analysed by massive analysis of cDNA ends (MACE) and real-time quantitative PCR.

Results: LOH was found in 10/11 focal lesions, in contrast to surrounding pancreatic tissue or blood cells. Monoallelic expression of mutant ABCC8/KCNJ11 alleles occurred in all lesions, whereas unaffected pancreatic tissue showed biallelic expression. Both, ABCC8 and KCNJ11, are located in proximity to the Beckwith-Wiedemann imprinting control region on chromosome 11p15 that is prone to UPD. Paternal UPD 11p15 was specifically found in samples showing LOH, neither deletion nor duplication was detected. Paternal UPD in focal lesions resulted in expression changes of 11p15 imprinted genes and upregulation of endocrine transcription factors.

Conclusions: Focal form of CHI is caused by somatic paternal UPD 11p15 leading to monoallelic expression of mutant ABCC8/KCNJ11 and affects gene expression of lesional endocrine cells.

Molecular analysis of CYP21A2 gene in Argentine patients with Congenital Adrenal Hyperplasia

C. S. Fernandez¹, M. Taboas², C. D. Bruque^{1,2,3}, N. Buzalino¹, L. Espeche¹, M. Delea¹, A. Nadra⁴, N. Ceballos⁴, L. Alba¹, L. Dain^{1,3,4};

¹National Center of Medical Genetics, ANLIS, Ministry of Health, Buenos Aires, Argentina, ²Regenerative Medicine Laboratory, Department of Orthopaedics and Traumatology, Juan Fernandez Hospital, Buenos Aires, Argentina, ³Institute of Biology and Experimental Medicine, CONICET, Buenos Aires, Argentina, ⁴School of Sciences, University of Buenos Aires, Buenos Aires, Argentina.

Introduction: Congenital adrenal hyperplasia, the most frequent inborn metabolism error, is caused in 90-95% of the cases, by mutations in the 21-hydroxylase gene (*CYP21A2*). The deficiency can present as severe, or classical form (C), and non-classical one (NC). *CYP21A2* and *C4* genes constitute the RCCX module. About 70% of haplotypes have a bimodular arrangement, with one module carrying *CYP21A2* and the other the highly homologous pseudogene *CYP21A1P*. A regulatory region of the *CYP21A2*, named Z promoter (ZP), is located 5.6 kb upstream. **Materials and Methods:** 628 patients (137 C, 491 NC) diagnosed as 21-hydroxylase deficient were studied. In 380/628 we studied the most frequent mutations. In 248/628 the entire *CYP21A2* gene was sequenced. Gene dosage was analyzed by MLPA. In 80/628 the ZP was sequenced. The RCCX region was studied by Southern-blot, MLPA and long range PCR. *In vitro* and/or *in silico* analyses, developed in our laboratory, were performed to determine the biological implications of novel mutations. **Results:** 100% of C and 86% of NC patients were fully genotyped. We have identified 10 novel mutations in the coding region and one in the ZP. All novel variants showed pathogenicity. We identified 3 novel haplotypes among 16 different conformations of the RCCX module. **Conclusions:** The *CYP21A2* gene is located in one of the most complex regions of the genome. Our results represent one of the larger series of patients in Latin America. We demonstrated the presence of novel mutations and haplotypes found for the first time in patients from our population.

Evaluation of human epididymis protein 4 as a novel serum inflammatory biomarker in cystic fibrosis

B. Nagy Jr.¹, L. Fila², L. A. Clarke³, Z. Fejes¹, P. Antal-Szalmás¹, J. Kappelmayer¹, M. Amaral², M. Macek Jr.², I. Balogh¹;
¹University of Debrecen, Debrecen, Hungary, ²Charles University, Prague, Czech Republic, ³University of Lisboa, Lisboa, Portugal.

Introduction: A biomarker that can be used for the evaluation of disease progression and the treatment efficacy in cystic fibrosis (CF) would be of a great importance. Increased expression of the human epididymis protein 4 (HE4) was previously described in CF lung biopsies, but it is unknown whether serum HE4 concentrations are elevated in CF.

Materials and Methods: 77 young and 57 adult CF patients were enrolled together with 117 normal controls. Serum HE4 was measured by an immunoassay and its expression was investigated using RT-qPCR in CF versus non-CF respiratory epithelium biopsies. The expression of the potential regulator miR-140-5p was analyzed using an UPL-based RT-qPCR assay. HE4 was measured in the supernatants from unpolarized and polarized CF bronchial epithelial CFBE cells expressing wt- or F508del-CFTR.

Results: Serum HE4 levels were significantly elevated in affected children and in adult CF patients (median 99.5 and 115.7 pmol/L, respectively) compared to controls (36.3 pmol/L). In CF patients, HE4 levels positively correlated with disease severity and CRP concentrations, while an inverse relationship was found between HE4 and the spirometric FEV1 value. HE4 mRNA levels were significantly upregulated with a decreased miR-140-5p expression in the CF airway biopsies. There were 2-fold higher HE4 concentrations in the supernatant of polarized F508del-CFTR CFBE cells compared to wt cells.

Conclusions: HE4 serum levels correlate with the overall severity of CF and the degree of pulmonary dysfunction. HE4 may thus be utilized as novel inflammatory biomarker and possibly also as measure of treatment efficacy in CF lung disease.

Genes underlying inherited cystic kidney disease in Arabian fetuses and neonates

M. H. Al-Hamed¹, W. Kurdi¹, M. Tulbah¹, N. Alsanah¹, Q. Ambosaidi¹, J. Sayer², B. Meyer¹;
¹King Faisal Specialist Hospital and Research Centre, Riyadh, Saudi Arabia, ²Newcastle University, Newcastle upon Tyne, United Kingdom.

Introduction: Inherited cystic kidney disorders are a common cause of end-stage renal disease. These diseases are common in the Saudi population and are associated with significant morbidity and mortality. Over 50 ciliopathy genes, which encode proteins that influence the structure and function of the primary cilia, are implicated in cystic kidney disease.

Materials and Methods: In order to define the phenotype and genotype of cystic kidney disease in fetuses and neonates, we correlated antenatal ultrasound examination and postnatal renal ultrasound examination with targeted exon sequencing, using a renal gene panel. A cohort of 50 families in whom antenatal renal USS findings in affected cases included either bilateral cystic kidney disease, echogenic kidneys or enlarged kidneys was investigated.

Results: In this cohort, causative mutations and inferred causative mutations using parental DNA were detected in 35 families (70%). Extra renal malformations, including encephalocele, polydactyly and heart malformations, consistent with ciliopathy phenotypes, were frequently detected. Mutations were found in 14 different genes with a total of 15 novel pathogenic variants. Mutations in CC2D2A followed by PKHD1 were the most common cause of an antenatally suspected ciliopathy in our cohort.

Conclusion: In families with ciliopathy phenotypes, mutational analysis using a targeted gene panel allows a rapid molecular diagnosis and provides important information for patients, parents and their physicians.

Hypothyroidism during fetal life impaired carbohydrate metabolisms in young and aged offspring rat: Role of glucose transporters in insulin-sensitive tissue

H. Gholami¹, S. Jeddī², F. Rouhollah¹, M. Zarkesh³, A. Zadeh-Vakilī², A. Ghasemī²;
¹Department of Biology, Tehran Medical Branch, Islamic Azad University, Tehran, Iran, Tehran, Islamic Republic of, ²Endocrine Physiology Research Center and Endocrine Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran., Tehran, Islamic Republic of, ³Cellular and Molecular Endocrine Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran., Tehran, Islamic Republic of.

Introduction: Both thyroid hormone deficiency during fetal life and aging decreases insulin secretion capacity and lead to glucose intolerance in the

later life; the underlying mechanisms however are unknown. This study aimed to determine whether fetal hypothyroidism (FH) affects GLUT1 and GLUT4 gene expressions in insulin-sensitive tissue of young (3 months) and aged (19 months) offspring rats.

Materials and Methods: Pregnant Wistar rats were divided into two groups: The FH group received water containing 0.025% 6-propyl-2-thiouracil during gestation and the controls consumed tap water. Offspring from both groups (n=6 in each group) were followed until month 3 and month 19. GLUT1 and GLUT4 mRNA expression in isolated heart, adipose tissue, and soleus muscle were measured using real-time polymerase chain reaction in 3 and 19 months offspring.

Results: Compared with controls, in FH rats, GLUT1 expression was lower in all tissues in both the young (34%, 41% and 84% for heart, adipose and soleus, respectively) and aged rats (51%, 64% and 78% for heart, adipose and soleus, respectively). In addition, FH rats had lower expression of GLUT4 in adipose tissue (84% for young and 88% for aged rats) and higher expression in heart (104% for young and 388% for aged rats) and soleus (290% for young and 591% for aged rats) tissues.

Conclusion: Hypothyroidism during fetal life affects mRNA expression of glucose transporters during later life in both young and aged rats; these changes may contribute to impaired carbohydrate metabolism.

Novel mutations in the MODY genes HNF4 α , GCK, HNF1 α in a Castilla y Leon population

M. De Pedro Muñoz^{1,2}, M. Fernández Prieto^{1,2}, E. Ruiz Pérez³, F. Gómez Peralta⁴, G. Díaz Soto⁵, J. Garrate Adrados⁶, R. Aguado García⁷, J. Miralles García⁸, R. González Sarmiento^{1,2};

¹Unidad de Medicina Molecular, Departamento de Medicina. Facultad de Medicina. Campus Miguel de Unamuno, Salamanca, Spain, ²Instituto de investigación biomédica de Salamanca (IBSAL), Salamanca, Spain, ³Servicio de Endocrinología y Nutrición, hospital militar de Burgos, Burgos, Spain, ⁴Servicio de Endocrinología y Nutrición, hospital general de Segovia, Segovia, Spain, ⁵Servicio de Endocrinología y Nutrición, hospital clínico universitario de Valladolid, Valladolid, Spain, ⁶Servicio de Análisis Clínicos, hospital universitario Rio Hortega, Valladolid, Spain, ⁷Servicio de Endocrinología y Nutrición, hospital universitario de León, León, Spain, ⁸Servicio de Endocrinología y Nutrición, hospital universitario de Salamanca, Salamanca, Spain.

Introduction: Maturity onset diabetes of the young (MODY) is a rare monogenic form of diabetes mellitus. This disease is characterized by autosomal dominant mode of inheritance and an early onset being frequently diagnosed before 25 years of age. The aim of this study was to identify novel mutations in the most prevalent MODY genes (HNF4 α , GCK and HNF1 α) in patients from Castilla y Leon.

Patients and Methods: We have studied 232 patients with clinical diagnosis of MODY from Hospitals from Castilla y Leon. The HNF4 α , GCK and HNF1 α genes were analyzed by direct sequencing. In silico predictions of the pathogenicity were carried out using: PolyPhen, pMut and SIFT.

Results: We have identified a total of 46 patients with mutations in HNF4 α , GCK or HNF1 α genes (20%) and 15 from these were novel mutations (32,60%). A missense mutation and a nonsense mutation had not been previously reported in the HNF4 α gene (p.T117I, p.R131X), both in exon 4. The following novel variations were identified in GCK gene: IVS7+1G>A, p.M57I, p.T116P, p.K205N, p.Trp257_Leu266delinsPLLLfSx27, p.F316fsX352, p.C371X, p.V374M, p.G385A, p.Y413X. Three more unreported mutations were identified in HNF1 α gene (p.T137fsX17, c.865 INSC, p.T458I). In silico analysis predicted all of the novel mutations to be pathogenic.

Conclusions: Recurrent mutations have not been detected in our cohort of MODY patients. It implies that there is still a high incidence of novel mutations. It is necessary to study all the coding region and adjacent intronic regions of prevalent MODY genes for improving the diagnosis.

A new submicroscopic duplication of the 8q24.3 region is a potential candidate for disorders of sex development

F. N. Dilek^{1,2}, F. E. Perçin¹, H. Kayseril^{3,4}, M. A. Ergün¹, N. Saka⁵;

¹Gazi University School of Medicine, Department of Medical Genetics, Ankara, Turkey, ²Diyarbakır Maternity and Child Hospital, Diyarbakır, Turkey, ³Istanbul Medical Faculty of Istanbul University, Department of Pediatrics & Medical Genetics, Istanbul, Turkey, ⁴Koc University School of Medicine, Department of Medical Genetics, Istanbul, Turkey, ⁵Istanbul University Faculty of Medicine, Department of Pediatric Endocrinology, Istanbul, Turkey.

Introduction: Some of the disorders of sex development (DSD), including 46,XX testicular DSD formerly called "XX maleness" and 46,XY DSD with partial or complete gonadal dysgenesis primarily affect the gonads. but can also result in non-syndromic XY-GD. The causative mutations in known ge-

nes have not been identified in more than 50% of 46,XY DSD cases. Among the detectable causative factors, deletions or nucleotide mutations of the SRY gene account for about 10-15 %. This implies that the vast majority of patients with gonadal DSD do not have an underlying molecular etiopathogenesis as of yet.

Material and methods: Ten unrelated patients diagnosed as complete 46,XY GD were selected to be included in the study. All patients with the diagnosis of XY complete GD met the clinical criteria for the inclusion. Sequence analysis of SRY, WT1 and CBX2 genes were performed in all patients and the genomic DNA from 10 unrelated females with complete 46,XY GD were processed on the Affymetrix Cyto2.7M array consistent with the manufacturer's protocol.

Results: The analysis result suggested that the most significant region maps to chromosome 8q24.3 which was previously reported by another independent study with a similar patient cohort and this region being probable candidate related to complete 46,XY GD.

Conclusion: Duplication of 8q24.3 region may be responsible for DSD etiology, because of in total three different cases with either partial or complete gonadal dysgenesis have been identified.

This study was funded by the Gazi University Scientific Research Foundation.

Hemolytic uremic syndrome in children-our experience

M. Gafencu¹, A. Lungu², O. Limoncu², C. Stoica², Z. Prohaszka³, A. Jianu⁴, M. Puiu¹, G. Doros¹;

¹Emergency Children Hospital, Victor Babes University of medicine and Pharmacy, Timisoara, Romania, ²Fundeni Clinical Institute, Bucuresti, Romania, ³Semmelweis University, 3rd Department of Medicine, Research Laboratory, Budapest, Hungary, ⁴University of Medicine & Pharmacy, Timisoara, Roumania, Timisoara, Romania.

Aims. Hemolytic uremic syndrome (HUS) is characterized by hemolytic anemia with fragmented erythrocytes, thrombocytopenia and acute renal failure. The aim of the study is to present the renal replacement therapy methods in our groups, genetic changes linked with the type of HUS, complications and mortality rate.

Methods. A retrospective analysis was supported on 49 children patients, aged 2 months to 17 years, with the diagnosis of HUS. We analyze the cases using the classic classification and evaluate the cases using data linked to renal replacement therapy need and mortality. Genetic testing was performed by Semmelweis University Budapest for 3 aHUS patients.

Results. More than 80% of patients were dialyzed. Mortality was correlated with the severity of extra renal involvement (less than 20%). One patient was found to be homozygous for a common deletion of CFHR1 and CFHR3 genes, no other copy number alterations were identified (although in parents). The second patient was found to be heterozygous for a substitution in exon 23 of the CFH gene (c.3592G>C) causing a glutamic acid to glutamine change at codon 1198 of the complement factor H protein (p.E1198Q) and heterozygous for a substitution in exon 7 of the CFHR5 gene (c.1067G>A). Other patient was found to be heterozygous for a mutation causing amino acid change (Q950H) in scr16 of complement factor H, and heterozygous for the rare allele of the CFH E936D polymorphism.

Conclusions. Different mutations were discovered in our cases, some expected to have a pathogenic role in the development of aHUS.

P03.21

Genetic testing in hypogonadotropic hypogonadism using next generation sequencing

K. Trebušak Podkrajšek^{1,2}, T. Obreza¹, M. Pfeifer³, A. Dankovčiková⁴, J. Kovač¹, T. Battelino^{1,2}, M. Avbelj Stefanija¹;

¹University medical centre Ljubljana, University Children's Hospital, Ljubljana, Slovenia, ²University of Ljubljana, Faculty of medicine, Ljubljana, Slovenia, ³University medical centre Ljubljana, Division of internal medicine, Ljubljana, Slovenia, ⁴University children's hospital, Kosice, Slovakia.

Introduction: Congenital hypogonadotropic hypogonadism (HH) is a rare but clinically and genetically heterogeneous disease caused by pathogenic mutations in several genes leading to impaired production and secretion of gonadotropin hormones and consequently sex hormones. HH is characterized by an absence or delay of puberty and infertility. The association of HH with hyposmia or anosmia is defined as Kallmann syndrome. Molecular genetic testing of HH is important, as it can prompt the treatment.

Materials and Methods: 11 subjects (10 males, one female) aged between 16 and 67 years with suspicion of congenital HH were included. Seven males had Kallmann syndrome, 3 males had normosmic HH. The female had suspicion of Kallmann syndrome. Three subjects had other congenital anomalies associated with HH (colour blindness, anomalies of heart, learning

disabilities, long limbs, sensorineural deafness, bimanual synkinesis, hyper-telorism). Targeted next generation sequencing (NGS) of 24 genes known to be associated with HH was used to identify genetic variants that were subsequently confirmed by Sanger sequencing.

Results: Six mutations in five genes (PROK2, GNRHR, PROKR2, FGFR1 and CHD7) were detected in six patients. Among them, three variants namely PROK2 NM_001126128.1: c.171_172delTT (p.Ile57MetfsTer17), FGFR1 NM_023110.2: c.196T>C (p.Tyr66Arg) and CHD7 NM_017780.3: c.5759A>G (p.Tyr1920Cys) have not yet been described.

Conclusion: NGS enables fast and reliable identification of causal mutations in several genes related to HH simultaneously. Presented subject group with HH was genetically very diverse and the results expand the spectrum of mutations implicated in HH.

P03.22

Clinical utility of a kidney disease gene panel for genetic diagnosis of cystic and glomerular inherited kidney diseases

G. Bullich¹, I. Vargas¹, P. Ruiz¹, L. Lorente¹, D. Trujillano², X. Estivill¹, J. Ballarín¹, R. Torra¹, E. Ars¹;

¹Fundació Puigvert, Barcelona, Spain, ²Centre for Genomic Regulation, Barcelona, Spain.

Introduction: Molecular diagnosis of cystic and glomerular inherited kidney diseases (IKD) is complicated by their high genetic heterogeneity and phenotypic variability. Clinical manifestations of these diseases cover a broad range of phenotypes that can be mimicked by mutations in several genes. We aimed to develop a more comprehensive approach for genetic diagnosis of these IKD.

Materials and methods: Massive parallel sequencing of 124 genes causative or associated with cystic or glomerular IKD was performed in 216 patients, a validation cohort (114 patients) and a diagnostic cohort (102 patients).

Results: We identified 136 of the 140 mutations in the validation cohort including several CNVs, demonstrating similar sensitivity than Sanger sequencing with the advantage of detecting CNVs in a single approach. Moreover, the kidney panel allows a more comprehensive analysis by identifying 1) mutations in low-frequency mutated genes, such as *NPHP3* mutations in patients with clinical suspicion of autosomal recessive polycystic kidney disease and *CUBN* mutations in nephrotic syndrome; 2) complex inheritance patterns, such as autosomal dominant polycystic kidney disease patients with two pathogenic mutations in *PKD1* and/or *PKD2* genes or Alport syndrome patients with mutations in two different collagen IV genes; 3) coinheritance of mutations in two genes causative of different IKD.

Conclusions: Massive parallel sequencing of this kidney-disease gene panel is a comprehensive, efficient and cost-effective tool for genetic diagnosis of cystic and glomerular IKD.

P03.23

Targeted NGS panel improves mutation detection rate in congenital hypogonadotropic hypogonadism and Kallmann syndrome patients and confirms the implication of further genes in these pathologies

C. Polo-Vaquero¹, J. Rodríguez-Contreras¹, M. Aza-Carmona^{1,2}, E. Vallespin^{1,2}, K. Ibañez-Garikano¹, J. Silla¹, P. Lapunzina^{1,2}, B. Lecumberri-Santamaria¹, I. González-Casado³, A. Campos-Barros¹, K. E. Heath^{1,2};

¹Institute of Medical & Molecular Genetics, Hospital Universitario La Paz, Madrid, Spain, ²CIBERER, ISCIII, Madrid, Spain, ³Dept. Pediatric Endocrinology, Hospital Universitario La Paz, Madrid, Spain.

Introduction: The large number of implicated genes and their oligogenic inheritance complicates the genetic diagnosis of patients with congenital hypogonadotropic hypogonadism (CHH) and Kallmann syndrome (KS).

Aim: We set out to identify the molecular defect in a cohort of CHH, HH and KS patients using a targeted NGS panel. Subsequently we evaluated the number of cases with monogenic or oligogenic inheritance.

Methods. Cohort of 58 probands: 39 CHH, 16 KS, 2 CHARGE with HH and 1 CAH with HH. All were screened for mutations using the NGS panel, HY-POPIT.V1, which includes a total of 73 genes: 50 found to be mutated in pituitary disorders and 23 genes in associated signalling pathways. Variants were validated by Sanger sequencing, MLPA or arrayCGH.

Results: Pathogenic or likely pathogenic mutations were identified in 19/58 probands (33%). The phenotype could be explained by the identified mutations in 8 of these (42%). In the remaining 11 probands, only one mutation was identified; 9 in genes with reported oligogenicity, and two are individuals with heterozygous variants in *GNRHR* and *GNRH1* suggesting the possibility of oligogenic inheritance for these genes. Interestingly, a heterozygous mutation in *POU1F1* was observed in an adult patient with KS.

Conclusions: Targeted NGS has increased our mutation detection rate and has also demonstrated the implication of further genes in the etiology of these pathologies.

Aim and Introduction: Identification of abnormal kidneys in the fetus may lead to termination of the pregnancy and raises questions about the underlying cause and recurrence risk in future pregnancies.

In this study, we investigate the effectiveness of targeted next generation sequencing in fetuses with prenatally detected kidney anomalies in order to uncover genetic explanations and assess recurrence risk. Also, we aim to study the relation between genetic findings and post mortem kidney histology.

Methods: The study comprises fetuses diagnosed prenatally with bilateral kidney anomalies that have undergone postmortem examination.

The approximately 110 genes included in the targeted panel were chosen on the basis of their potential involvement in embryonic kidney development, cystic kidney disease, or the renin-angiotensin system.

DNA was extracted from fetal tissue samples or cultured chorion villus cells, aminocytes, or fibroblasts. Data analysis was performed using CLC Genomics workbench, publicly available databases, and prediction tools.

The Regional Ethical Committee approved the study.

Results: Samples from 61 fetuses from 57 families were included in the study.

Two fetuses had mutations in the nephronophthisis associated gene, *TMEM67* and six fetuses had mutations in kidney developmental genes. For these fetuses kidney histology is presented.

Conclusion and Perspectives: In eight (14%) fetuses we identified a likely genetic cause of the kidney anomalies.

Ten fetuses from eight families, in which no mutations were identified, have been selected for exome sequencing in order to uncover novel genes associated to fetal kidney anomalies.

P03.25

Development of a comprehensive workflow for analysis of LPL gene, identification of LPLD patients eligible to receive AAV1- LPLS447X gene therapy.

I. Valaskova^{1,2}, J. Krizova^{1,2}, R. Gaillyova^{1,2};

¹University Hospital, Brno, Czech Republic, ²Masaryk University, Brno, Czech Republic, ³Mendel University, Brno, Czech Republic.

Lipoprotein lipase (LPL) deficiency (LPLD) is characterized by severe hypertriglyceridaemia. The most debilitating clinical manifestation of the disease is recurrent, severe and potentially life-threatening acute pancreatitis. LPLD is caused by loss-of-function mutations in the gene encoding LPL, regulated the plasma levels of triglyceride. Variant of the *LPL* gene Ser447stop called *LPL*^{S447X} is the only variant associated with increased LPL enzyme activity leading to reduced triglyceride levels.

It was developed a LPL gene therapy product, Alipogene tiparvovec (Glybera, AMT-01, AAV1- LPLS447X), an adeno-associated virus serotype 1-based gene therapy that results in the expression of gain-of-function S447X variant of the human LPL gene.

The aim of this work was to establish a molecular genetic screening program of patients with LPLD caused by loss-of-function mutations in LPL gene, suitable for AAV1- LPLS447X gene therapy.

Method: The examined group has consisted of patients with severe or multiple pancreatitis attacks. Genomic DNA has been extracted from whole blood. Screening algorithm in LPLD patients has been: 1. HRM-based LightSNiP assay to detect the most common LPL mutation Asn291Ser (cooperation with TIBMOlBio), 2. MLPA (P218 MRC Holand) confirmed using QF PCR, 3. sequencing LPL promoter and 10 exons.

Results: In LPLD patients, synonymous and nonsynonymous LPL sequence variants have been detected. In silico analysis have been performed to determine the pathological status of sequence variants with uncertain significance.

Conclusion: It is currently possible to identify patients with LPLD caused by loss-of-function mutations in LPL gene, eligible for the introduction of treatment of the therapeutic *LPL*^{S447X} gene.

P03.26

Crohn's disease associated with a higher rate of mevalonate kinase somatic mosaicism in circulating monocytes.

Y. Shinar¹, R. Cohen¹, V. Marcu-Malina¹, I. Goldstein¹, A. Menza-Vilaro², A. Menza-Vilaro², E. Gonzalez-Roca², J. I. Arostegui², A. Livneh^{1,3}, V. Oron-Karni⁴;
¹Sheba Medical Center, Ramat Gan, Israel, ²Hospital Clinic, Barcelona, Spain, ³Te Aviv University, Tel Aviv, Israel, ⁴Rhenium LTD, Modi'in, Israel.

Introduction The role of somatic mutations in the development of complex autoinflammatory diseases has barely been studied. We performed genetic testing for familiar monogenic autoinflammatory diseases in the case of an adult with late onset recurrent fever and severe upper abdominal pain. The patient was eventually clinically diagnosed with Crohn's disease based on capsule endoscopy and was treated successfully with an anti-TNF blocker.

Aim Study the rate and distribution of a novel and somatic mevalonate kinase (MVK) gene mutation detected by Sanger sequencing, in a patient with Crohn's disease.

Methods Massive parallel sequencing (MPS) of all MVK exons (2000 reads of target) was performed on DNA isolated from peripheral blood cells, and followed by exon 3 fusion-PCR MPS (10,000 reads per target) in DNA from neutrophils, and from FACS sorted T (CD3+), B (CD19+) and monocyte (CD14+) cells.

Results The somatic mutation was detected in 22% of the MVK exon 3 reads and was confirmed to be the only mutation in the entire MVK coding region. The mosaicism rate was twice higher in DNA of CD14+ monocytes (50%) than in neutrophils (23%), B (17.6%) or T cells (21.7%).

Conclusion This may be the first report of a somatic MVK mutation in the context of Crohn's disease. The mutation source was traced as far as a multi-potential hematopoietic stem cell. However the mutation appeared to expand in circulating CD14+ monocytes despite effective anti-TNF treatment. The pathogenic and auto-inflammatory significance of this monocyte sub-population remains to be studied.

P03.27

Rapid screening for mutations in MODY genes by next generation sequencing

M. Losekoot¹, L. Vijhuizen¹, W. S. Frankhuizen¹, C. M. J. Spruijt¹, A. H. B. Bollen¹, I. F. H. C. Fokkema², N. van der Stoep¹;
¹Department of Clinical Genetics, Leiden, Netherlands, ²Department of Human Genetics, Leiden, Netherlands.

Introduction: Maturity onset diabetes of the young (MODY) is a monogenic form of diabetes with an autosomal dominant pattern of inheritance. It is characterized by early onset (<25 years of age), non-obese and non-auto-immune mediated associated diabetes and accounts for 1-5% of all diabetic patients. Differentiation of the various subtypes allows an optimal treatment and delay of diabetes related complications. Mutations in at least 13 genes are responsible for MODY and therefore mutation analysis of all genes in one next generation sequencing experiment seems an optimal diagnostic strategy.

Materials and Methods: All coding exons and at least 20 bp of flanking intronic sequences were enriched using the Agilent SureSelectXT Inherited Disease Panel, followed by sequencing on Illumina HiSeq2000. Data analysis was performed using a home-made pipeline for MODY related genes.

Results: High-quality sequence data was obtained. Variant analysis using a low stringency analysis pipeline revealed a pathogenic mutation in 10 out of 69 patients in GCK, HNF1A, HNF4A or HNF1B. In addition, 4 possibly pathogenic mutations were found in ABCC8 and KLF11, genes that are not routinely tested in MODY patients.

Conclusions: This approach gives a mutation detection ratio comparable to Sanger Sequencing. The procedure is fast and efficient and reveals mutations in genes that otherwise might not have been tested in a gene-by gene approach.

P03.28

Variable clinical expressivity in patients with HNF1B mutations

A. Tranchina¹, C. Graziano¹, R. Minardi^{2,3}, C. P. Cristalli^{2,3}, S. Bin³, A. Mattiaccio³, M. Pariali³, G. Lanzoni¹, M. Romagnoli¹, G. Severi¹, G. La Manna², M. Seri¹, V. Mantovani^{1,3};
¹Medical Genetics Unit, S. Orsola-Malpighi University Hospital, Bologna, Italy, ²Nephrology Dialysis and Transplantation Unit, S.Orsola-Malpighi University Hospital, Bologna, Italy, ³Center for Applied Biomedical Research (CRBA), S.Orsola-Malpighi University Hospital, Bologna, Italy.

HNF1B heterozygous mutations are the cause of "Renal Cysts and Diabetes Syndrome", a clinically heterogeneous disorder characterized by maturity onset diabetes of the young, renal disease (cysts, small kidney, hyperuricemic nephropathy), liver test anomalies (cholestasis) and abnormalities of the genital tract.

In the last 4 years, we tested 29 patients for a suspected HNF1B-related disorder. Through sequencing and MLPA analysis, we identified a mutation in 14 patients from 11 unrelated families. Six patients carried large deletions involving the whole gene (de novo in three patients with available parental DNA). One carried an intragenic deletion (exon 1 to 4). One had a splicing mutation. One had a promoter variant of uncertain significance. Five patients from 2 unrelated families carried missense mutations.

No typical clinical presentation can be described. Patients with loss of function mutations (gene deletions and splicing) tend to have an earlier onset of symptoms, with hyperechogenic kidneys detected in the antenatal period and congenital urinary and/or genital malformation. Progression of kidney disease appears to be slow. All adult patients had diabetes mellitus or glucose intolerance. Two had cholestasis and two developed unexplained liver cirrhosis at a relatively young age (39 and 44 years). A 21-year-old woman also had mild developmental delay: after MLPA analysis that identified an HNF1B deletion, array-CGH was performed and a large (1.3 Mb) deletion was found.

In conclusion, we confirm the wide phenotypic heterogeneity of HNF1B-related disorders, but we point out that liver disease can be a major complication in patients.

P03.29

Whole-exome sequencing (WES) identifies rare mutations in two pedigrees with recurrent familial Nephrolithiasis

M. Jabalameli, V. Walker, S. Ennis;
 University of Southampton, Southampton, United Kingdom.

Introduction: Nephrolithiasis is a prevalent condition with high morbidity. Heritability accounts for 56% of the disease incidence. Patients often present with acute flank pain and dysuria that necessitates surgical intervention. High concordance rate among monozygotic twins suggest a strong genetic component. Recent studies on monogenic cause of nephrolithiasis identified that dominant mutations are more frequent in adult onset kidney stones. We sought to identify pathogenic mutations underlying late-onset nephrolithiasis in two pedigrees with recurrent stone formers.

Materials and Methods: 6 adults from two pedigrees with multiple stone formers were recruited. Biochemical markers of renal function were comprehensively analysed and genetic diagnosis carried out by whole exome sequencing.

Results: Based on segregation pattern, deleteriousness (PhyloP and Gerp++ scores) and scarcity of variant (MAF≤0.02) both in the reference population and in the in-house database, two missense mutations in *ADCY10* (p.P1200L) and *SLC25A25* (p.Q349H) were identified to underlie the condition in pedigree 1 and 2 respectively.

Conclusion: *ADCY10* encodes a unique class of adenylyl cyclases. Variation at this gene has been already proposed to underlie absorptive hypercalciuria. We identified a rare missense mutation in exon 26 of *ADCY10* (c.C3599T) that co-segregate with nephrolithiasis in pedigree-1. Furthermore, WES analysis revealed that a missense mutation in exon 8 of *SLC25A25* (c.G1047C) co-segregate with nephrolithiasis in pedigree-2. *SLC25A25* encodes a calcium-binding carrier that regulates uptake or efflux of adenine nucleotides into or from mitochondria. Our in-silico analysis suggested that variants involved in Ca²⁺/PO₄³⁻ metabolism and purine metabolism contribute to hereditary nephrolithiasis and their functional impact merit further investigation.

P03.30

Whole exome sequencing identifies a novel mutation in ACTN4 gene in a Brazilian patient with steroid resistant nephrotic syndrome

M. S. Guaragna, A. Lutaif, A. Maciel-Guerra, V. Belangero, L. Prates, G. Guerra-Júnior, M. de Mello;
 UNICAMP, Campinas, Brazil.

Introduction: Nephrotic syndrome (NS) is defined by heavy proteinuria, hypoalbuminemia, edema and hyperlipidemia. Approximately 20% of the patients do not respond to treatment with steroids and are classified as steroid-resistant (SRNS). A significant number of SRNS cases are caused by inherited mutations in proteins that form the glomerular filtration barrier. The aim of this study was to search for mutations in a SRNS familial case, using whole exome sequencing (WES), as this method has become a tool of choice for genetic screening in diseases with high genetic heterogeneity and phenotypic variability such as SRNS.

Material and Methods: WES was performed in one familial SRNS case. *NPHS1*, *NPHS2* and *WT1* mutations had been already excluded after Sanger sequencing. We used strict genetic criteria for reduction of variants. Sanger sequencing was performed in order to confirm the mutation identified.

Results: We identified the novel heterozygous p.Phe153Leu mutation in the *ACTN4* gene in the patient and in his father, who is also affected with the disease. The residue Phe153 localizes in the N-terminal region of α -actinin-4 protein and is conserved down to *Danio Rerio*. Mutations in the N-terminal region are described as increasing the affinity to actin filaments and affecting their intracellular localization.

Conclusions: We identified a novel mutation in *ACTN4*. The patient here presented and his family will benefit of the unequivocal etiology of the disease and of genetic counseling, as mutations in *ACTN4* are associated with late onset autosomal-dominant familial FSGS.

Extensive molecular analysis suggested the strong genetic heterogeneity of idiopathic chronic pancreatitis

V. Sofia¹, L. Da Sacco², C. Surace¹, A. Tomaiuolo¹, S. Genovese¹, S. Grotta³, M. Gnazzo¹, S. Petrocchi¹, L. Ciocca¹, F. Alghisi¹, E. Montemitro⁴, L. Martemucci⁵, A. Elce⁶, V. Lucidi⁴, G. Castaldo⁷, A. Novelli¹, A. Angioni¹;

¹Laboratory of Medical Genetics, "Bambino Gesù" Children's Hospital, Rome, Italy, ²Multifactorial Diseases and Complex Phenotypes Research Area, "Bambino Gesù" Children's Hospital, Rome, Italy, ³Laboratory of Medical Genetics, "Bambino Gesù" Children's Hospital/S. Pietro Fatebenefratelli Hospital, UOSD Medical Genetics, Rome, Italy, ⁴Cystic Fibrosis Unit, "Bambino Gesù" Children's Hospital, Rome, Italy, ⁵Pediatria Sistemica, A.O. Santobono-Pausilipon, Naples, Italy, ⁶Ceinge-Biotecnologie avanzate, Naples, Italy, ⁷Ceinge-Biotecnologie avanzate/Dipartimento di Medicina Molecolare and Biotecnologie Mediche, Università di Napoli Federico II, Naples, Italy.

Introduction: Genetic features of Chronic Pancreatitis (CP) have been extensively investigated mainly testing genes associated to the trypsinogen activation pathway. However, different molecular pathways involving other genes may be implicated in the pathogenesis of CP.

Materials and Methods: 81 patients with Idiopathic CP have been investigated using Next Generation Sequencing approach with a panel of 70 genes related to six different pancreatic pathways: premature activation of trypsinogen; modifier genes of Cystic Fibrosis phenotype; pancreatic secretion and ion homeostasis; Calcium signalling and zymogen granules exocytosis; autophagy; autoimmune pancreatitis related genes.

Results: We found mutations in 34 out of 70 genes examined. 65/81 patients (80.2%) were positive for mutations in one or more genes, 16/81 patients (19.8%) had no mutations. Mutations in the *CFTR* (Cystic fibrosis transmembrane conductance regulator) gene were detected in 33/81 patients (40.7%) and 23 of them exhibited at least one mutation in genes of other pancreatic pathways. Of the remaining 48 patients, 13/81 (16%) had mutations in genes involved in premature activation of trypsinogen and 19/81 (23.5%) had mutations only in genes of the other pathways: 40/65 patients positives for mutations showed variants in two or more genes (61.5%).

Conclusions: Our data suggest a high rate of genetic heterogeneity in chronic pancreatitis and that trans-heterozygosity may predispose to the Idiopathic CP phenotype.

P03.32

Genetic diagnosis by specific sequencing of PKD1 gene in a (spanish) cohort of 100 ADPKD families

M. Molero, C. Ruiz, A. Gomez, A. Arteche, L. Rausell, M. Lazaro, M. Bermejo, J. Garcia-Planells, M. Garcia-Hoyos; Instituto de Medicina Genómica (IMEGEN), Paterna, Spain.

Autosomal dominant polycystic kidney disease (ADPKD;# 173900 and #613095) is the most common inherited kidney disease and is characterized by the development and progressive enlargement of cysts in kidneys and other organs, eventually leading to end-stage renal disease and usually a late-onset multisystem disorder characterized by bilateral renal cysts. ADPKD is caused by mutations in the PKD1 gene (*601313) in approximately 85% of the cases and in the PKD2 gene (*173910) in the remaining 15%. The genetic diagnosis of this disease is very difficult due to the existence of 5 pseudogenes with high resemblance (98%) to the PKD1 gene.

We have developed, validated, and carried out a methodology based on a long PCR followed by several internal PCRs that allows specific and accurate analysis of the entire PKD1 gene while avoiding the amplification of the pseudogenes.

We used this long PCR approach for the analysis of the PKD1 gene in more than 100 ADPKD families. This procedure allowed the identification of the disease-causing mutation in 75,3% of our patients. The vast majority of the mutations detected are null variants (nonsense, frameshift, and canonical splice sites).

According to the results produced in this study, a high percentage of ADPKD cases is associated with mutations in the PKD1 gene. Specific sequencing of

the PKD1 is the most efficient approach to determine the molecular cause of the disease in ADPKD patients. An accurate genetic diagnosis is essential to provide reproductive options to ADPKD patients and their families in addition to appropriate genetic counselling.

P03.33

Molecular characterization of genetic variants in patients with primary ciliary dyskinesia from Serbia

M. Z. Andjelkovic¹, V. Spasovski¹, M. Vreca¹, P. Minic^{2,3}, A. Sovtic², M. Rodic², S. Pavlovic¹; ¹Institute of Molecular Genetics and Genetic Engineering, Belgrade, Serbia, ²Mother and Child Health Care Institute of Serbia „Dr Vukan Cupic“, Belgrade, Serbia, ³School of Medicine, University of Belgrade, Belgrade, Serbia.

Primary ciliary dyskinesia (PCD) is a rare, autosomal recessive disorder with extensive genetic heterogeneity and is estimated to affect 1 in 15,000 to 30,000 individuals. It usually comes to medical attention because of recurrent pneumonia, otitis media and upper respiratory tract infections early in the life, or, in the adult male, infertility. Respiratory infections are caused by defective mucociliary clearance due to immotile or dysmotile respiratory cilia with or without ultrastructural defects.

In this study, we analyzed 6 patients from Serbia with diagnosis of PCD according to clinical presentation. We used a NGS panel with 4813 genes to detect disease-causing mutations in this patients. We have detected variants in 6 different genes. In each patient only one gene was affected. Variants were detected in the genes previously associated with PCD: *DNAL1* (c.347A>T, c.350T>G and c.485G>A), *LRRC6* (c.27T>G and 1397T>C), *DNAH11* (c.7798C>T, c.8555C>G), *DNAH5* (c.1137C>T, c.7624T>C, c.4356-2A>G) and *CCDC40* (c. [248delC]; [248delC]), from first to the fifth patient, respectively. In the last patient we detected homozygous variant in *SCN11A* gene (c. [1654T>C]; [1654T>C]). So far, *SCN11A* gene was not associated with PCD, but it was associated with Cystic Fibrosis-Like Disease.

This study provided the first data about molecular genetics of patients from Serbia presenting with PCD clinical symptoms, thus paving a path to molecular genetic diagnostics and genetic counseling of this disease in the country. Acknowledgements

P03.34

The prevalence of GNAS deficiency-related diseases in a large cohort of patients characterized by the EuroPHP network

F. M. Elli¹, A. Linglart^{2,3}, I. Garin⁴, L. de Sanctis⁵, P. Bordogna¹, V. Grybek^{2,3}, A. Pereda⁴, F. Giachero⁵, E. Verrua¹, P. Hanna^{3,2}, G. Mantovani¹, **G. Perez de Nanclares¹**; ¹Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Department of Clinical Sciences and Community Health, University of Milan, Endocrinology and Diabetology Unit, Milan, Italy, ²APHP, Reference center for rare disorders of the mineral metabolism and Plateforme d'expertise Paris Sud Maladies Rares, Le Kremlin Bicêtre, France, ³INSERM U1169, Hôpital Bicêtre, Le Kremlin Bicêtre, et Université Paris-Saclay, Le Kremlin Bicêtre, France, ⁴Hospital Universitario Araba, Vitoria-Gasteiz, Spain, ⁵Department of Public Health and Pediatrics, University of Turin, Regina Margherita Children's Hospital, Health and Science City, Turin, Italy.

Context: The term pseudohypoparathyroidism (PHP) was coined to describe the clinical condition resulting from end-organ resistance to parathormone (rPTH), caused by (epi)genetic alterations within or upstream GNAS. Though knowledge is growing, there are few data on the prevalence of underlying (epi)genetic defects.

Objective: To ascertain the relative prevalence of PHP-associated molecular defects.

Design: With a special questionnaire, we collected data from patients (n=407) clinically and molecularly characterized by the EuroPHP network. **Results:** Isolated rPTH (31%) was caused only by epigenetic defects, 70% of patients showing loss of imprinting affecting all four GNAS differentially methylated regions (DMRs) and 30% loss of methylation restricted to the GNAS A/B:TSS-DMR. Multihormone resistance without Albright's hereditary osteodystrophy (AHO) (15%) was essentially due to epigenetic defects, although 10% had point mutations.

In patients with rPTH and AHO (10%), the rate of point mutations was higher (28%) and methylation defects lower (70%). Patients with multihormone resistance and AHO (38%), presented all types of molecular defects with different frequencies. Finally, isolated AHO (4%) and progressive osseous heteroplasia (2%) were exclusively caused by point mutations.

Conclusion: We have established the prevalence of various genetic and epigenetic lesions in PHP-affected patients. Using these findings, we will develop criteria to guide cost-effective strategies for genetic testing and explore the implications for management and prognosis.

Acute pancreatitis recurrence transcriptome profiling in chylomicronemia

K. Tremblay, D. Brisson, D. Gaudet;

Université de Montréal and ECOGENE-21 Research Center, Chicoutimi, QC, Canada.

Introduction: Recurrent acute pancreatitis (RAP) is defined as more than two crisis of acute pancreatitis not meeting the criteria of chronic pancreatitis. Extreme hypertriglyceridemia (fasting triglycerides >10 mmol/L) is associated with chylomicronemia (CM) and increased risk of RAP. The recurrence of pancreatitis episodes varies significantly between CM patients. We have investigated the gene expression profiles of adult patients with CM in a spectrum of RAP.

Materials and Methods: A total of 62 subjects participated in this study: 15 healthy controls and 47 CM subjects divided into three groups: 0 (n=21), 1-3 (n=10) or ≥4 (n=16) acute pancreatitis episodes. Whole blood RNA samples were hybridized on Affymetrix Human Gene 2.0 ST Array. After RMA normalization, differential expression moderated T-tests (Bioconductor package Limma) and Ingenuity Pathway Analyses were performed.

Results: At a p-value <0.01, a FDR of 5% (Benjamini-Hochberg method) and a >2-fold change expression significance levels, a set of 41 probes have been found differentially expressed in CM subjects with no pancreatitis, 103 in the CM group with 1 to 3 pancreatitis, and 94 in the group with ≥4 pancreatitis compared to controls. Of the identified annotated probes, 14 are shared by all CM groups; 3 are specific to CM with no pancreatitis; 11 are specific to CM with 1 to 3 pancreatitis, and 17 are specific to CM with ≥4 pancreatitis. Most of the annotated probes are involved in inflammatory, immune, lipoprotein kinetics or signalling biological pathways.

Conclusions: These results reveal gene expression signatures of RAP in patients with CM.

P03.36

Two novel RFX6 variants in siblings with Mitchell-Riley syndrome with childhood onset diabetes

M. Skopkova¹, M. Cijakova², Z. Havlicekova², J. Vojtkova², L. Valentinova¹, D. Danis¹, D. Murgas³, R. Szepeova², J. Stanik^{1,4,5}, P. Banovcin², I. Klimes¹, D. Gasperikova¹;

¹Institute of Experimental Endocrinology BMC SAS, Bratislava, Slovakia, ²Department of Children and Adolescents, University Hospital in Martin, Jessenius Faculty of Medicine, Comenius University, Martin, Slovakia, ³Department of Pediatric Surgery, University Hospital in Martin, Jessenius Faculty of Medicine, Comenius University, Martin, Slovakia, ⁴First Department of Pediatrics, Medical Faculty of Comenius University and Children Faculty Hospital, Bratislava, Slovakia, ⁵Center for Pediatric Research, Hospital for Children & Adolescents, University of Leipzig, Leipzig, Germany.

Introduction: Two sisters from a Caucasian family were diagnosed with multiple gastrointestinal tract (GI) malformations (duodenal atresia, Meckel diverticulum, gallbladder hypoplasia, and multiple gastric heterotopy loci in ileum) and childhood onset diabetes (in 2y 10m and 2y 7m). The aim of our study was to search for the genetic etiology.

Materials and Methods: The whole exome (SureSelect V4+UTR, Agilent) sequencing was performed (HiSeq2000, Illumina) in the two patients and their parents. Variant filtering included MAF<0.01, autosomal recessive mode of inheritance conditions and pedigree analysis. Candidate variants were confirmed by Sanger sequencing and their pathogenicity was tested by in silico analyses.

Results: In both affected sisters, two novel heterozygous RFX6 variants were identified: c.1316_1319delTCTA (p.I439Tfs*13) and c.1154G>A (p.R385Q). Each was inherited from another unaffected parent. Both variants were found to be pathogenic by in silico analyses. Mutations in the gene RFX6 are associated with neonatal diabetes, pancreatic and biliary hypoplasia and duodenal/jejunal atresia - classified as the Mitchell-Riley syndrome (MRS) with autosomal recessive type of inheritance.

Conclusions: From 11 previously reported patients with MRS, all but two of them developed diabetes in first days of life. We report here two sisters with two new compound heterozygous RFX6 variants with phenotypes consistent with MRS, but with diabetes onset in the third year of life. This supports the need of extending the diabetes definition in MRS to „neonatal or childhood“ onset and suggests that glycaemia should regularly be checked in patients with GI tract malformations typical for Mitchell-Riley syndrome. Supported by APVV 0187-12.

Role of Klotho genetic polymorphisms in salt-sensitivity: a link between salt and aging?

L. Citterio¹, C. Lanzani¹, S. Delli Carpini¹, S. Lupoli², E. Brioni¹, M. Simonini¹, G. Gatti¹, S. Tentori¹, L. Zagato¹, E. Messaggio¹, C. Barlassina², D. Cusi², P. Manunta¹;

¹University "Vita-Salute", Milano, Italy, ²Department of Health Science, University of Milan, Milano, Italy.

Rational: Previous data in transgenic mice showed that one-half Klotho deficiency resulted in extensive premature aging, increased salt sensitivity and caused salt-sensitive hypertension. Moreover, a recent gene expression study confirmed the expression of Klotho in renal distal tubular cells. Aim of the study: To evaluate the role of Klotho polymorphisms in human essential hypertension and salt sensitivity.

Design and Methods: 32 SNPs in Klotho gene identified with a previous GWA were used in the genetic analysis. Selected SNPs were studied in three different clinical settings: 1. Pressure-natriuresis relationship (PNat) in 580 naive essential hypertensive patients, never treated before, (NHP) by Acute salt load (NaLoad: 310 mMol in 2 h iv), 2. Low salt diet (137 pts, Low SD: <100 mEq/die for 15 days), and 3. Follow-up cohort (FUP, median 150 months) of 230 hypertensive patients.

Results: 15 SNPs (with tagging r²=0.80) out of 32 were selected in the identified gene region. Six of these resulted significantly associated to BP variation after NaLoad and/or LowSD and/or FUP. Particularly, the genotypes in a missense mutation in exon 2 were associated to salt sensitivity (SBP variation and PNat after Na load) and decrease in kidney function in FUP confirming the similar effect in the two different clinical settings.

Conclusion: Selected Klotho gene SNPs for first time resulted involved in salt homeostasis, hypertension development and long term kidney damage. Our findings support the proposed Klotho as key gene in salt sensitivity and aging in humans.

P03.38

Computational strategy to predict pathogenic variants in SERPINA1 gene led to the identification of new functional mutations

E. Giacomuzzi, M. Laffranchi, R. Berardelli, G. Borsani, A. Fra;

Department of Molecular and Translational Medicine, University of Brescia, Brescia, Italy.

Introduction: The SERPINA1 gene encodes for Alpha-1-Antitrypsin (AAT), an acute phase glycoprotein that inhibits Neutrophil Elastase (NHE). Mutations in this gene cause reduced levels of AAT in the plasma, Alpha-1 Antitrypsin Deficiency (AATD), and reduced inhibition of NHE leads to emphysema. Moreover, mutated forms of AAT can aggregate in the endoplasmic reticulum of hepatocytes causing hepatotoxicity and liver disease. AATD is characterized by high allelic heterogeneity, asking for a way to discriminate functionally impaired alleles as new missense variants are observed in the gene.

Methods: By combining CADD score, amino acid conservation, protein structure modeling and alignment with other SERPIN polypeptides, we have developed a computational strategy to identify missense variations that could result in impaired protein function. We tested our strategy against the group of already characterized pathogenic missense mutations to assess specificity and sensibility of the method. This approach has then been applied to missense variants reported in human population from the ExAc 0.3 database (~63.000 exomes) to identify candidate missense mutations for functional studies.

Results: Our strategy performed well to correctly classify already known pathogenic mutations. When applied to ExAc 0.3 data, it identified 8 yet uncharacterized missense variants with high probability to affect the SERPINA1 protein function. These variants could represent new rare pathogenic alleles diffused in the human population. Functional consequences of these mutations are being evaluated by in vitro studies.

Conclusions: We have developed a computational strategy useful to prioritize new pathogenic variants in the SERPINA1 gene and identify new potential pathogenic alleles.

P03.39

Disease exome, a powerful diagnostic tool: post-mortem diagnosis of dyskeratosis congenita

J. Pinto-Basto¹, L. S. Almeida¹, F. Melo¹, A. Garrido², C. Barbosa², S. M. Pereira¹, R. Cerqueira¹, P. Tavares¹;

¹CGC Genetics, Porto, Portugal, ²Hospital Center Tondela – Viseu, E.P.E., Viseu, Portugal.

Exome sequencing has become a powerful diagnostic tool to identify the molecular etiology of genetic diseases. We report on a deceased 60yo male with an undiagnosed systemic disease that presented with liver cirrhosis, pulmonary fibrosis, sick sinus syndrome and thrombocytopenia. DNA from post-mortem tissue was obtained and disease exome performed.

Disease exome was performed by capture of target regions using TruSightOne (Illumina) and subsequent NGS of a panel composed by 4813 clinically-relevant genes. Alignment and variant calling was performed using the BWA and GATK, respectively. Variants were filtered and processed with bioinformatic analysis tools to assess its pathogenicity and potential to explain the clinical phenotype. Relevant variants were confirmed by Sanger sequencing. Analysis revealed a novel missense heterozygous variant c.1492G>A (p.Gly498Arg) in TERT gene, affecting a highly conserved residue. Bioinformatic analysis suggests that the variant is very likely pathogenic and is not present in dbSNP, ExAC, 1KGenomes and ESP. Mutations in TERT gene, mostly missense, cause autosomal dominant dyskeratosis congenita (DKC; type2; MIM 613989) and autosomal recessive DKC (MIM 613989). In the context of the clinical phenotype of this patient, this result supports the diagnosis of DKC type2. Segregation studies were not possible as parents and sibs were not available for testing.

We report a post-mortem diagnosis of DKC type2 with a novel variant in the TERT gene, expanding the mutational spectrum of TERT related DKC. Additionally, this result highlights the importance of molecular diagnosis, even post-mortem, as establishing the molecular etiology allows proper genetic counselling to at-risk relatives.

P03.40

Sequence analysis of EPCAM gene in Consanguineous Qatari Families, suffering from tufting enteropathy, identified a founder mutation

Z. Nawaz¹, M. A. Khan², S. Khan², S. Ali¹, H. Abdelrahman², E. abdalbari hamid², F. Al-madhaki³, W. Almasri³, K. Abu Hasima³, K. Hassan³;

¹Genomic Diagnostic Division, Department of Laboratory Medicine and Pathology, Hamad Medical Corporation, Doha, Qatar, ²Genomic Core Facility, Translational Research Institute, Academic Health System, Hamad Medical Corporation, Doha, Qatar, ³Department of Pediatric, Hamad General Hospital, Hamad Medical Corporation, Doha, Qatar.

Background: Tufting enteropathy, also termed as intestinal epithelial dysplasia, is a rare genetic condition with early onset of severe diarrhea. Histologically, it is characterized by villous atrophy, disorganization of the surface epithelium and basement membrane aberrations. The epidemiological data indicates its prevalence as 1 out of 50,000 to 100,000 live births in western population, while it is estimated to be greater in Arab ethnic families due to high rate of consanguinity. Genetic studies have found the association of EPCAM and SPINT2 genes mutation in disease etiology.

Materials and Methods: Sanger DNA sequencing was carried out for the genetic screening of EPCAM gene in affected and corresponding normal family members. The study was approved by ethical committee and sample was obtained after informed written consent.

Results: Two consanguineous Qatari families were enrolled in the present study and sanger sequencing of all coding exons in EPCAM gene was performed. The sequence analysis revealed c.498_499insC mutation in exon 5, which presumably truncates the protein synthesis (p.Gln167Profs*21). This truncation predictably removes the C-terminal domain of EPCAM protein, which is suggestively involved in the attachment of EPCAM protein to intracellular membrane.

Conclusion: The identified mutation, c.498_499insC, seems to have founder effect in Arab population because it has previously been reported in a Qatari, Kuwaiti and Saudi families. The present molecular study has evidenced this mutation as a genetic hotspot and suggests to formulate a molecular diagnostic test in Qatari families, affected with tufting enteropathy, for genetic counseling.

P03.41

Is COMMD1 gene a modifier locus of Wilson disease?

A. Zarina^{1,2}, L. Piekuse¹, M. Kreile^{1,2}, I. Tolmane^{3,4}, V. Sondore³, G. Cernevska⁵, I. Pukite⁵, Z. Krumina⁵;

¹Riga Stradins University Scientific Laboratory of Molecular Genetics, Riga, Latvia, ²Riga Stradins University, Department of Biology and Microbiology, Riga, Latvia, ³Riga East Clinical University Hospital, stationary "Infectology Center of Latvia", Riga, Latvia, ⁴University of Latvia, Faculty of Medicine, Riga, Latvia, ⁵Children Clinical university Hospital, Riga, Latvia.

Introduction. Wilson disease (WD) is an autosomal recessive disorder of copper metabolism, caused by mutations in gene *ATP7B*. Although WD is established as monogenic disorder, heterogeneity in phenotype is observed even among patients possessing the same type of mutations in gene *ATP7B*. One of the candidate genes which might play the role of a modifier locus is *COMMD1* (former *MURR1*).

Materials and methods. 54 patients, clinically diagnosed with WD (Leipzig's Score, 2001) were tested for mutations in *ATP7B* gene: by PCR Bi-PASA and direct sequencing (for other mutations); and for possible changes in gene *COMMD1* by direct sequencing of its three exons.

Results. Wilson disease was genetically confirmed in 42 patients. In total 82.4% of WD patients' alleles were identified: H1069Q (72.22%); M769Hfs*26 (1.85%); Val73GlufsX4 (1.85%) and D1267G, D765N, M645R (0.93% for each); 27.78% of the alleles remained unidentified. Three nucleotide changes were identified in *COMMD1*, of which two represented reported synonymous changes: rs55677935 and rs9096. The third one – two nucleotide deletion in gene's regulatory region (rs569267407) was found only in two patients – siblings, showing different clinical symptoms – one dying from fulminant hepatitis at age of 17, the second – being asymptomatic at age of 19, when first being diagnosed with WD due to family screening. Conclusions.

- 1) There were no variants in gene *COMMD1* found that could be related to different phenotype of WD patients;
- 2) Change found in *COMMD1* regulatory part could be a cause for different protein activity, but the clinical significance remains unclear.

OBSL1 Mutations Represent The Major Gene Defect In A Group Of 3M Syndrome Patients: A Study From Turkey

P. O. Simsek-Kiper¹, E. Z. Taskiran², U. Arslan³, C. Kosukcu², O. Akgun-Dogan¹, G. E. Utine¹, A. Alikasifoglu⁴, N. Kandemir⁴, V. Cormier-Daire⁵, Y. Alanay⁶, M. Alikasifoglu², K. Boduroglu¹;

¹Hacettepe University, Faculty of Medicine, Department of Pediatrics, Division of Pediatric Genetics, Ankara, Turkey, ²Hacettepe University, Faculty of Medicine, Department of Medical Genetics, Ankara, Turkey, ³Hacettepe University, Institute of Public Health, Department of Epidemiology, Ankara, Turkey, ⁴Hacettepe University, Faculty of Medicine, Department of Pediatrics, Division of Pediatric Endocrinology, Ankara, Turkey, ⁵INSERM U781, Université Paris Descartes-Sarbonne Paris Cité, Institut Imagine, Hôpital Necker Enfants Malades Genetics, Paris, France, ⁶Acibadem University, Faculty of Medicine, Department of Pediatrics, Division of Pediatric Genetics, İstanbul, Turkey.

Introduction: 3M syndrome is characterized by severe prenatal and post-natal growth retardation, facial features and normal intelligence. Mutations in *CUL7*, *OBSL1* or *CCDC8* genes have been identified in the etiology so far, *CUL7* mutations being the most common. Materials and Methods: Clinical and molecular features of 18 patients from 14 families were evaluated. DNA sequence analysis of *CUL7*, *OBSL1* and *CCDC8* was performed and genotype-phenotype correlations were investigated. Results: Eight distinct *CUL7* or *OBSL1* homozygous mutations were identified in 11 patients. Of mutation positive patients (n=11), 6 (55%) had *OBSL1* and 5 (45%) had *CUL7* mutations. Of all detected mutations 1 *CUL7* (c.361_362insT) and 3 *OBSL1* (c.1125_1126insT, c.1277_1282+delTCAAGGTCAG, c.1187G>A) mutations were novel. Growth hormone deficiency was detected in 1 patient with *CUL7* and 2 patients with *OBSL1* mutation. Birth weight of patients with *CUL7* mutation was significantly lower than the patients with *OBSL1* mutation (p=0.016). A group of patients with no mutations shared similar clinical and radiological features with mutation positive patients. Conclusions: 3M syndrome is a genetically heterogeneous condition. Although *CUL7* was reported to be the major gene responsible for 3M syndrome so far, *OBSL1* mutations were more common in the present study which might be an indicator of a founder effect in Turkish population. Mutations identified so far do not account for all 3M syndrome patients suggesting the involvement of other genes. Further molecular studies will shed light on the identification of these new genes in the common growth pathway.

P04.002

Altered ABCC9 gene: expanding the clinical phenotype of Cantu Syndrome

H. Fryssira¹, E. Tsoutsou¹, S. Psoni¹, S. Amenta², H. Lüdecke³, J. Czeschick²;

¹Medical Genetics, School of Medicine, National and Kapodistrian University of Athens, "Aghia Sophia" Children's Hospital, Athens, Greece, ²"Mitera" Maternity Hospital, Athens, Athens, Greece, ³Institut für Humangenetik, Universitätsklinikum Essen, Essen, Germany.

Introduction: Cantu Syndrome (OMIM#239850) is a very rare (about fifty cases have been reported so far) autosomal dominant disorder characterized by generalized congenital hypertrichosis, neonatal macrosomia, distinctive coarse faces, cardiomegaly and skeletal abnormalities. The syndrome has been attributed to mutated *ABCC9* and *KCNJ8* genes which encode the SUR2 and Kir6.1 subunits of the ATP-dependent potassium channel (KATP-channel) respectively.

Case Report: We present a four-year-old female patient with developmental delay, dysmorphic features such as narrow forehead with low anterior frontal hairline, micrognathia, low-set dysplastic ears and generalized hypertrichosis since birth. The investigation revealed absent ovaries. FSH and PRL were markedly elevated whilst LH, estradiol, testosterone, DHEA-S and 17-OH progesterone were all normal. Chromosome G-banding technique was also normal. DNA sequencing analysis of the *ABCC9* gene was performed and a heterozygous point mutation c.3460C>T which resulted in the abnormal protein NM-005691.3 (*ABCC9_1001*):p.Arg1154Trp was revealed. This missense, gain-of-function mutation was located in exon 27 of the *ABCC9* gene.

Conclusions: The p.Arg1154Trp point mutation has been reported before in Cantu syndrome patients and is associated to the full phenotype. However, the absence of the ovaries has not been described before. Therefore, this could represent either an expansion of the phenotype or an interaction of *ABCC9* with other genes related to ovarian formation and function.

Since the activating mutations in the *ABCC9* gene are the underlying cause of the Cantu syndrome, a drug that leads to K⁺ channel closure independently to ATP, could serve as a possible treatment.

P04.003

Acrodermatitis enteropathica-like forms of atopic dermatitis revealed by whole-exome sequencing

S. Küry¹, T. Besnard¹, X. Latypova¹, S. Schmitt¹, S. P. Pau², D. Candy³, E. Blouin⁴, S. Bézieau¹;

¹CHU de Nantes, Nantes, France, ²St Richard's Hospital, Chichester, United Kingdom,

³Institute of Child Health, London, United Kingdom, ⁴Laboratoire Labcatal, Montrouge, France.

Background: Acrodermatitis enteropathica (AE; MIM #201100) is a rare and severe autosomal recessive zinc deficiency disorder molecularly diagnosed by the identification of a biallelic anomaly of zinc transporter gene *SLC39A4*. Its pathognomonic symptom is an acral and periorificial dermatitis occurring in early life that responds in a spectacular fashion to zinc therapy. Yet, our experience in the molecular diagnosis of AE showed that more than a half of the cases of suspected AE were not due to a primary zinc dyshomeostasis that would be associated by alterations of *SLC39A4*.

Purpose: Our goal was to determine the genetic cause of genodermatoses very suggestive of an AE, albeit with no *SLC39A4* mutation.

Method: We sequenced the whole-exome of a series of simplex and multiplex families with a AE-like dermatitis.

Results: Beside the identification of a few exceedingly rare syndromes mimicking AE, the most striking result was the presence of dominant mutations in filaggrin and in laminins, some of them were already known to be associated with an increased susceptibility to atopic dermatitis (AD).

Conclusions: Our work highlighted atopic dermatitis as the main clinical diagnosis of AE. This suggests that a sub-group of the common disease represented by AD could be diagnosed by genetic testing. Further studies are needed to determine whether these severe cases of AD are exceptional or if the efficiency of zinc therapy can be extended to the treatment of all AD patients with similar anomalies.

P04.004

Functional modelling of *SLC39A4* zinc transporter mutations effects in Acrodermatitis enteropathica

X. Latypova¹, T. Besnard¹, E. Blouin², P. Hulin³, S. Nedellec³, S. Bézieau¹, S. Küry¹;

¹Service de Génétique Médicale, CHU Nantes, Nantes, France, ²Laboratoire LABCATAL, Montrouge, France, ³Plateau d'imagerie cellulaire MicroPICell, Nantes, France.

Background: Zinc is a key factor of various biological processes. Intestinal absorption is the critical step of zinc homeostasis regulation. *Acrodermatitis enteropathica* is a rare cause of hereditary zinc deficiency. Mutations in *SLC39A4*, coding a transmembrane zinc transporter, mainly expressed in enterocytes, have been described in *Acrodermatitis enteropathica* patients. Since its identification by our group in 2002, clinical molecular testing for *SLC39A4* mutations is available. However, functional consequences of *SLC39A4* mutations are poorly characterized. In these conditions, assessment of pathogenicity of newly identified variants of unknown significance remains challenging.

Methods: We evaluated the effects of missense *SLC39A4* mutations in *HeLa* cells transfected with wild type or mutated, hemagglutinin tagged, *SLC39A4* transcript. To model decrease of transport activity by *SLC39A4*, we performed time-lapse measurements of zinc cytoplasmic levels. Finally, the effects of putative splice-site mutations were tested by minigene assay.

Results: Disruption of *SLC39A4* membrane trafficking has been showed in 8 missense mutations, located in N-terminal extracellular domain of the

transporter. Effect on splicing of c.192 G>C mutation of exon 1 of *SLC39A4* has been confirmed. We propose a strategy to quantify zinc transport to investigate consequences of mutations without effect on *SLC39A4* localization.

Conclusion: Functional assessment of *SLC39A4* mutational spectrum provides key information for interpreting the significance of pathogenicity in the daily practice of a molecular biology laboratory.

P04.005

Broadening the phenotypic spectrum of heterozygous aggrecan mutations in short stature children

O. Nilsson¹, K. E. Heath^{2,3,4}, M. Andrew⁵, L. Sentschordj^{6,7,8}, S. Hallgrimsdottir⁵, A. Brannstrom⁵, M. Crocker⁹, J. Douglas⁹, N. Dunbar¹⁰, D. Flynn¹¹, V. Hwa¹², A. Jorge¹³, S. LaFranchi¹⁴, S. Dauber²¹, International Aggrecan Consortium; ¹Karolinska Institutet, Stockholm, Sweden, ²Institute of Medical & Molecular Genetics (INGEMM), IdiPAZ, Hospital Universitario La Paz, UAM, Madrid, Spain, ³Multidisciplinary Unit of Skeletal dysplasias (UMDE), Hospital Universitario La Paz, Madrid, Spain, ⁴CIBERER, ISCIII, Madrid, Spain, ⁵Cincinnati Children's Hospital Medical Center, Cincinnati, OH, United States, ⁶Institute of Medical & Molecular Genetics, IdiPAZ, Hospital Universitario La Paz, UAM, Madrid, Spain, ⁷Hospital Universitario Infanta Leonor, Madrid, Spain, ⁸Multidisciplinary Unit of Skeletal dysplasias (UMDE), Hospital Universitario La Paz, Madrid, Austria, ⁹Boston Children's Hospital, Boston, MA, United States, ¹⁰Connecticut Children's Hospital, Connecticut, CT, United States, ¹¹St. Luke Regional Medical Center, Boise, ID, United States, ¹²Cincinnati Children's Hospital Medical Center, Cincinnati, OH, United States, ¹³University Sao Paulo, Sao Paulo, Brazil, ¹⁴Oregon Health and Science University, Oregon, OR, United States, ¹⁵Texas Children's Hospital, Texas, TX, United States, ¹⁶Phoenix Children's Hospital, Phoenix, AZ, United States, ¹⁷Children's Hospital of Pittsburgh, Pittsburgh, PA, United States, ¹⁸Hasbro Children's Hospital, Rhode Island, RI, United States, ¹⁹Umeå Universitet, Umeå, Sweden, ²⁰PDEGEN, NICHD, National Institute of Health, Bethesda, MD, United States, ²¹Cincinnati Center for Growth Disorders, Division of Endocrinology, Cincinnati Children's Hospital Medical Center, Cincinnati, ID, United States.

Introduction: Heterozygous aggrecan (*ACAN*) mutations have been reported to cause short stature with bone age (BA) acceleration and premature growth cessation.

In order to characterize the phenotypic spectrum and the response to growth-promoting therapies, a detailed clinical evaluation of 66 individuals from 12 families with *ACAN* mutations, 7 novel truncations, 5 missense, was performed.

Results: Adults have mildly disproportionate short stature (SDS median:-3.3, range:-0.9 to -4.5) with normal/slightly elevated sitting height indices (SDS median:2.1, range:0.4-3.8) and early growth cessation and/or lack of pubertal growth spurt. Growth of upper extremities appears less affected with arm-spans typically greater than height (arm-span-height: median:+5.5cm; range:-4 to +13). Some cases had osteochondritis dissecans and early-onset osteoarthritis requiring knee joint and other large joints replacement surgeries in the 2nd-3rd decade. Two families had degenerative disc disease in the 4th decade.

Prepubertal height is less affected (median SDS:-1.8, range:-1.0 to -4.2). In contrast to most children with short stature, many with *ACAN* mutations show an advanced BA (BA-CA, median:+1.3yr; range:+0 to +3.5) reflecting a reduction in the remaining growth potential. Nine patients have been treated with rhGH and/or GnRH analogs or aromatase inhibitors.

Conclusions: Heterozygous *ACAN* mutations result in a wide phenotypic spectrum ranging from mild and proportionate short stature to a distinct skeletal dysplasia with disproportionate short stature and brachydactyly. Some also cause articular/intervertebral disc cartilage dysfunction leading to early-onset osteoarthritis and degenerative disc disease requiring intervention. Careful monitoring of patients with *ACAN* mutations may help to identify important genotype-phenotype correlations and to understand their pathogenicity.

P04.006

Analysis of PMN function in patients with aggressive periodontitis

R. Werner¹, A. Schossig¹, J. Dudás², J. Zschocke¹, I. Kapferer-Seebacher³;

¹Division of Human Genetics, Medical University, Innsbruck, Austria, ²Department of Otorhinolaryngology, Medical University, Innsbruck, Austria, ³Department of Restorative and Operative Dentistry, Dental School, Medical University, Innsbruck, Austria.

Introduction: Aggressive periodontitis (AgP) is an inflammation disorder with a prevalence of approximately 0.1% in central European population. It is characterized by early age of onset, rapid rate of progression and loss of teeth until age of 35, if untreated. Several studies indicate functional changes in polymorphonuclear leucocytes (PMNs) resulting in altered immune response and destruction of periodontal tissues.

Material and methods: We have investigated phagocytosis and chemotaxis of PMNs extracted from peripheral blood in a 4-generation family with ge-

neralized autosomal dominant inherited AgP (6 affected, 5 non-affected, 5 unrelated controls) as well as in a cohort of unrelated patients with sporadic form of generalized AgP (n = 46) and periodontal healthy 1:2 age- and gender-matched controls.

Results: Phagocytic activity of PMNs in response to non-opsonized E.coli was significantly reduced in familial AgP patients compared to healthy siblings and non-related controls (p = 0.032). A similar reduction of phagocytic activity could not be observed in sporadic AgP in the cohort compared to matched controls. In the family both directed and random migration of PMNs was significantly reduced in AgP patients compared to healthy controls (p = 0.042 and p = 0.028, respectively). This significant reduction in chemotactic activity was not observed in cohort patients compared to matched controls.

Conclusions: The differences in PMN function between familial AgP and the sporadic form suggest distinct pathophysiological pathways, although leading to a similar clinical presentation. To elucidate a possible genetic predisposition testing of known variants related to PMN dysfunction is ongoing.

Role of miRNAs in the etiology of alopecia areata: A genome-wide miRNA association analysis

A. Tafazzoli¹, A. Fostner¹, A. Hofmann¹, S. Redler², L. Petukhova³, F. Basmanav⁴, K. Giehl⁵, S. Eigelshoven⁶, R. Kruse⁶, B. Blaumeiser⁷, M. Böhm⁸, N. Garcia Bartels⁹, G. Lutz¹⁰, H. Wolff¹, U. Blume-Peytavi¹¹, A. Christiano³, M. Nöthen¹, R. Betz¹;

¹Institute of Human Genetics and Department of Genomics, Bonn, Germany, ²Institute of Human Genetics, Bonn, Germany, ³Dermatology and Epidemiology, New York, NY, United States, ⁴Dermatology, Munich, Germany, ⁵Dermatology, Dusseldorf, Germany, ⁶Dermatological Practice, Baderborn, Germany, ⁷Medical Genetics, Antwerp, Belgium, ⁸Dermatology, Munster, Germany, ⁹Clinical Research Center for Hair and Skin Science, Department for Dermatology and Allergy, Berlin, Germany, ¹⁰Hair & Nail, Dermatological Practice, Wesseling, Germany.

Background: Alopecia areata (AA) is a common hair loss disorder characterized by a sudden onset of patchy areas of hair loss, which can occur on the scalp or elsewhere on the body. Immunological and genetic association studies support the hypothesis that AA is autoimmune in nature. Recent evidence points to a significant role of miRNAs in autoimmune diseases; but the role of miRNAs in AA has not been investigated so far.

Methods: We performed a systematic analysis to investigate whether common variants among all known autosomal microRNAs loci contribute to AA development. Gene-based analyses were performed by VEGAS for all miRNAs listed in miRBase and their flanking sequences using the largest GWAS data set of 3,253 patients and 7,543 controls.

Result: As a result, 78 of the 617 investigated microRNAs showed nominally significant p-values. After correction for multiple testing, three microRNAs (miR-1237, miR-30b/d, miR-548h-2) showed significant association with AA. The most promising one was miR-30B. Target gene analyses for 3 disease associated microRNAs revealed 2,072 nominally significant predicted target genes. Gene based p-values were calculated for the predicted target genes revealing 42 of them to be significantly associated with AA after correction for multiple testing, including IL2RA, ERBB3 as genome-wide significant loci from former AA GWA-studies. By luciferase assays, we validated the site-specific regulation of IL2RA, STX17 and TNXB of miR-30B.

Conclusion: Our study is the first to suggest the importance of microRNAs in the pathogenesis of AA which could be of interest for development of therapies in the future.

P04.008

The effects of polymorphisms of death pathway genes and mitochondrial pathway genes in intervertebral disc degeneration

B. Eser¹, O. Eser¹, E. Aslan², H. Dolgun³;

¹Balikesir University, Balikesir, Turkey, ²Afyon Kocatepe University, Afyonkarahisar, Turkey, ³Ministry of Health Diskapi Yildirim Beyazit Education and Research Hospital, Ankara, Turkey.

Introduction: It has been proposed that apoptosis is effective on intervertebral disc degeneration. Especially death receptor pathway and mitochondrial pathway are reported to have a significant role in apoptosis mechanism. This study is the first study in which both polymorphisms and expressions of apoptotic genes in patients with intervertebral disc degeneration (IVDD) are evaluated together. The aim of our study is to determine whether polymorphisms and expressions of apoptotic genes involved in both pathways are related with grades of IVDD or not.

Materials and Methods: Blood and tissue samples of 100 patients diagnosed with lumbar disc degeneration were collected. Patients were divided into 2 groups according to their radiological degeneration grades as grade 2 (mild) and grade 3 and 4 (severe). Polymorphisms in Fas (rs 2234767), Bcl-2 (rs

1801018) and Bax (rs4645878) genes were determined with real-time PCR. Expressions of these genes were analyzed immunohistochemically following Histological Degeneration Scoring.

Results: Whereas no relationship was found among polymorphisms of Fas and Bax genes and their expressions, we have determined a relationship among GG genotype of Bcl-2 and their expressions. Additionally, we have found that ratio of Bax-positive cells is related with IVDD grades. In addition to this, we have found that radiological degeneration grades were compatible with histological degeneration scores.

Conclusions: GG genotype of Bcl-2 gene may influence the level of its expression and may be effective in development of IVDD. Additionally, expression of Bax gene may be related with different grades of IVDD.

P04.009

GLUT10 deficiency leads to oxidative stress and non-canonical $\alpha\beta3$ integrin-mediated TGF β signalling associated with extracellular matrix disarray in arterial tortuosity syndrome skin fibroblasts

N. Chiarelli, M. Ritelli, G. Carini, V. Cinquina, M. Colombi, N. Zoppi;

University of Brescia, Department of Molecular and Translational Medicine, Brescia, Italy.

Arterial tortuosity syndrome (ATS, OMIM #208050) is a rare autosomal recessive connective tissue disorder characterized by tortuosity and elongation of the large and medium-sized arteries and a propensity towards aneurysm formation and vascular dissection. ATS is caused by mutations in SL-C2A10 encoding the facilitative glucose transporter 10 (GLUT10). GLUT10 deficiency leads to the disarray of the extracellular matrix (ECM) and to the activation of the TGF β pathway, but the pathomechanisms of ATS is still an enigma.

To discern the pathomechanisms underlying the ATS aetiology, we performed gene expression profiling and biochemical studies on skin fibroblasts. Transcriptome analyses revealed the dysregulation of several genes involved in TGF β signalling and ECM homeostasis as well as the perturbation of specific pathways that control both the cell energy balance and the oxidative stress response. Biochemical and functional studies showed a marked increase in ROS-induced lipid peroxidation sustained by altered PPAR γ function, which contributes to the redox imbalance and the compensatory antioxidant activity of ALDH1A1. ATS fibroblasts also showed activation of a non-canonical TGF β signalling due to TGFBR1 disorganization, the upregulation of TGFBR2 and connective tissue growth factor, and the activation of the $\alpha\beta3$ integrin transduction pathway, which involves p125FAK, p60Src, and p38 MAPK. Stable GLUT10 expression in patients' fibroblasts normalized redox homeostasis and PPAR γ activity, rescued canonical TGF β signalling, and induced partial ECM re-organization. These data add insights into the dysregulated biological pathways and definition of the pathomechanisms involved in ATS. This work was supported by the Telethon Foundation (grant number GGP13167).

Asphyxiating Thoracic Dysplasia (ATD) and Short Rib-Polydactyly syndrome type III (SRPIII) belong to the SRP group and are characterized by a narrow thorax, short long bones, trident acetabular roof and extraskelatal malformations. SRPIII is uniformly lethal due to pulmonary hypoplasia and other organ system abnormalities. To date, mutations in 11 genes, coding for ciliary proteins, have been reported in ATD/SRPIII. Here, we report the molecular screening of 71 individuals (53 ATD, 18 SRPIII) by targeted NGS of a customized ciliopathy gene panel, called ciliome.

The ciliome allowed us to identify the molecular basis of 70% (50/71) of ATD/SRPIII cases. Mutations in *DYNC2H1* were identified in 34/50 (68%) and were not associated with kidney disease but with liver and retina involvement. Mutations in other genes, namely *IFT140* (6%), *WDR60* (6%), *IFT144* (6%), *WDR34* (4%), *IFT80* (2%), *WDR35* (2%) and *TTC21B* (2%), were associated with multiple organ damage including kidney insufficiency or liver cirrhosis illustrating the overlap with Saldino-Mainzer and Sensenbrenner syndromes. We also identified one heterozygous mutation in *DYNC2H1* and *IFT140* for a living ATD case, supporting a digenism. We finally identified homozygous mutations in a new ciliary gene, *KIF24*, in two ATD sibling fetuses with renal, hepatic and pulmonary involvement. In the 21 families with no identified molecular bases, radiological features were typical and multi organ involvement variable. We conclude that *DYNC2H1* is the major gene responsible for ATD/SRP III. The exclusion of the 11 known genes in 21 families supports the involvement of other causal genes.

P04.011

A novel ATP6V0A2 frameshift mutation causing autosomal recessive cutis laxa with bleeding diathesis and defective wound healing

I. Karacan¹, R. Diz Kucukkaya², A. Tolun³, V. S. Hançer⁴, E. Tahir Turanlı^{1,5};

¹Department of Molecular Biology and Genetics, Istanbul Technical University, Istanbul, Turkey, ²Department of Internal Medicine, Division of Hematology, Faculty of Medicine, Istanbul Bilim University, Istanbul, Turkey, ³Department of Molecular Biology and Genetics, Boğaziçi University, Istanbul, Turkey, ⁴Department of Molecular Biology and Genetics, Faculty of Science, Istanbul Bilim University, Istanbul, Turkey, ⁵Dr. Orhan Ocalgiray Molecular Biology-Biotechnology and Genetics Research Center, Istanbul Technical University, Istanbul, Turkey.

Introduction: Autosomal recessive cutis laxa type-II (ARCL2) syndrome is a rare congenital disorder associated with growth and developmental delay as well as skeletal anomalies. Its prevalence is 1 in 12 million live births. Biallelic mutations in the responsible gene *ATP6V0A2* lead to increased pH in Golgi, resulting in impaired glycosyltransferase activity and organelle trafficking. Here we present a consanguineous family with four unaffected and two affected sibs (a male and a female) with microcephaly, dysmorphic features, cleft lip/palate, vision/hearing impairment, wrinkled skin, tendency to infections, bleeding diathesis and defective wound healing.

Materials and Methods: SNP genotype data were used to detect regions with homozygosity shared only by the patients. Exome sequence data for the index patient were used to search for a rare, homozygous deleterious mutation in the possibly linking regions.

Results: Linkage analysis pointed to a large region at 12q24.21-24.32 with a multipoint LOD score of 2.58 and including 198 genes. Causative mutation search in linkage regions identified homozygous frameshift mutation p.S695RfsX12 (c.2083_2086del) in *ATP6V0A2*. The truncated protein has 705 amino acids instead of the native 856.

Conclusions: We identified a novel disease-causing *ATP6V0A2* mutation responsible for the ARCL2 in the presented family. We did not find a deleterious mutation in another gene that could possibly explain the bleeding diathesis. Furthermore, the male afflicted with ARCL2 and another brother have mental retardation for which we are searching for a causative mutation.

The study was supported by TÜBİTAK (Grant No 114Z829).

P04.012

A homozygous B3GAT3 mutation causes a multisystemic cutis laxa-like syndrome, expanding the phenotype of linkeropathies

B. Guillemin¹, T. Van Damme¹, W. Steyaert¹, D. Syx¹, P. Coucke¹, A. De Paep¹, S. Symoens¹, S. Nampoothiri², F. Malfait¹;

¹Center for Medical Genetics Ghent - Ghent University Hospital, Ghent, Belgium, ²Department of Pediatric Genetics, Amrita Institute of Medical Sciences & Research Center, Elamakkara, Cochin 682041, Kerala, India.

INTRODUCTION: Proteoglycans (PGs) are major components of the extracellular matrix (ECM), and fulfill an essential role as both structural and regulatory biomacromolecules. They are composed of a core protein onto which one or more glycosaminoglycan (GAG) side chains are covalently attached. Specific deficiencies in the enzymes (*XYLT1/2*, *B4GALT7*, *B3GALT6* and *B3GAT3*) involved in the biosynthesis of the tetrasaccharide linker re-

gion between the core protein and its GAGs are known as linkeropathies.

RESULTS: We describe the clinical features of an infant from consanguineous parents from India, in whom we identified the previously reported homozygous p.(Gly223Ser) (c.667G>A) missense mutation in *B3GAT3* using whole-exome sequencing. *B3GAT3* encodes glucuronyltransferase 1, which adds the fourth saccharide to the linker region. The boy, who expired at age 2.5 months, displayed generalized cutis laxa, osteopenia and multiple perinatal fractures, adducted thumbs, bilateral club feet and large joint contractures, severe dysmorphic features, blue sclerae and corneal clouding. Structural modeling of the substitution shows that the mutation substitutes a nonpolar Gly residue by a polar Ser residue in the catalytic pocket of the enzyme. Functional studies to further investigate the pathogenic consequences of the defect are ongoing on a cellular overexpression model of the mutant alleles.

CONCLUSIONS: This is only the fifth reported child with a *B3GAT3* mutation. Two other missense mutations (p.(Arg277Gln) and p.(Pro140Leu)) have been reported. We highlight the extended phenotypic range of *B3GAT3* mutations and provide a comparative overview of the phenotypic features of the linkeropathies associated with mutations in *XYLT1*, *XYLT2*, *B4GALT7*, *B3GALT6* and *B3GAT3*.

P04.013

Whole exome sequencing reveals a new mutation in NOD2 gene in a Mexican family with Blau syndrome

J. Toral-Lopez¹, L. M. Gonzalez-Huerta², S. Cuevas-Covarrubias³;

¹Centro Médico Ecatepec, ISSEMYM, Ecatepec, Mexico, ²Genetica, Hospital General de Mexico, Mexico City, Mexico, ³Genetica, Facultad de Medicina, Hospital General de Mexico, Universidad Nacional Autonoma de Mexico, Mexico City, Mexico.

Blau syndrome (BS; MIM 186580) and early onset sarcoidosis (EOS; MIM 609464) are familial and sporadic systemic granulomatosis diseases respectively; they are caused by heterozygous mutations in the *NOD2/CARD15* gene located on 16q12. The *NOD2* gene plays a role in nuclear NF-kappa-B activation, is associated with innate immune system and in the consequent formation of non-gaseous granulomas. BS is a genetic disorder with dominant autosomal pattern, whereas, EOS is sporadic and appears in young people. Both are clinically characterized by granulomatous arthritis, uveitis/iritis and skin rash. Twenty seven mutations on *NOD2/CARD15* gene have been associated with BS/EOS. In the present study, we analysed the *NOD2* gene from genomic in a Mexican family with BS and 100 normal controls through WES, PCR and genome DNA direct sequencing. We detected a novel mutation in the *NOD2* gene in the affected members of the family that was absent in the non-affected healthy subjects of the family and in 100 normal controls. This allowed discard a polymorphism. This is a first novel mutation observed in Mexican patients that enriches the genomic spectrum observed in BS.

Search for variants in the FLJ42280 genomic region and assessment of their roles in osteoporosis

N. Roca-Ayats¹, M. Gerousi¹, N. Martínez-Gil¹, E. Czwan², R. Urreiziti¹, N. García-Giralte³, L. Mellibovsky², X. Nogués³, A. Díez-Pérez², S. Balcells¹, D. Grinberg¹;

¹Universitat de Barcelona, IBUB, CIBERER, Barcelona, Spain, ²Roche Diagnostics Deutschland GmbH, Mannheim, Germany, ³URFOA, RETICEF, IMIM, Parc de Salut Mar, Barcelona, Spain.

Signals emerging from genome-wide association studies (GWAs) are frequently located in non-coding, poorly studied regions, and are likely to be in linkage disequilibrium with un-genotyped causal variants. GWAs have identified variants associated with bone mineral density (BMD) and osteoporotic fracture, some located in intronic regions of *FLJ42280*, a poorly studied gene of unknown function.

We aimed at exploring the genetic variability and functionality of this *locus*. Firstly, we resequenced the *FLJ42280* genomic region in two extreme BMD groups from the BARCOS cohort of postmenopausal women; we statistically compared the number and frequency of variants between the two groups, and we analyzed their overlap with functional elements from ENCODE. Secondly, we performed *cis*-eQTLs analyses to determine whether the GWAs SNPs, and others in strong linkage disequilibrium with them, correlated with gene expression levels.

We identified 110 variants, 18 of which were novel and 59 were low frequency variants (LFV). The number of LFV was balanced between the two extreme groups and frequency differences of all variants were below the statistical power of the design, although 9 showed trend and are currently being genotyped in the complete BARCOS cohort. One exonic variant was found and 28 variants were located in putative regulatory regions, including an interesting SNP in an active osteoblast enhancer. Functional studies of

the enhancer are currently underway. None of the SNPs showed influence on expression levels of *cis*-genes.

Expanding the genetic spectrum of Caffey disease

S. Symoens¹, G. Mortier², D. Wiczorek^{3,4}, S. Unger⁵, A. Zankl⁶, T. Hospach⁷, P. J. Coucke¹, F. Malfait¹;

¹Center for Medical Genetics Ghent, Ghent University Hospital, Ghent, Belgium,

²Department of Medical Genetics, Faculty of Medicine and Health Sciences, University of Antwerp and Antwerp University Hospital, Antwerp, Belgium, ³Institut für Humangenetik, Universitätsklinikum Essen, Essen, Germany, ⁴Institut für Humangenetik, Universitätsklinikum Düsseldorf, Düsseldorf, Germany, ⁵Medical Genetics Service, CHUV, University of Lausanne, Lausanne, Switzerland, ⁶Academic Department of Medical Genetics, Discipline of Genetic Medicine, The University of Sydney, Sydney Children's Hospital Network, Sydney, Australia, ⁷Pediatric Rheumatology, Klinikum Stuttgart, Olgahospital, Stuttgart, Germany.

Infantile cortical hyperostosis or Caffey disease is an autosomal dominant rare bone disorder, characterized by inflammation associated with cortical and periosteal thickening of affected bones and swelling of the surrounding soft tissues. The disease is diagnosed in young infants and is characterized by spontaneous resolution of the cortical thickening, with episodes of recurrence and reduced penetrance. The underlying genetic cause is a unique recurrent arginine-to-cysteine substitution (p.(Arg1014Cys), c.3040C>T) in the helical domain of the $\alpha 1$ -chain of type I collagen (COL1A1).

We describe six unrelated probands with Caffey disease. Molecular analysis of COL1A1 confirmed heterozygosity for the c.3040C>T (p.(Arg1014Cys)) mutation in three probands. Biochemical collagen studies on one of these probands' dermal fibroblasts showed intracellular $\alpha 1(I)2$ -dimers, which are at least partly secreted into the extracellular matrix. In the remaining three probands a novel c.2752C>T nucleotide change (p.(Arg918Cys)) was identified. This mutation also causes the formation of $\alpha 1(I)2$ -dimers, which were not secreted into the extracellular matrix.

Although both arginine-to-cysteine substitutions are in relative close proximity, they affect different protein regions. While the p.(Arg1014Cys) maps to the gap region between two Major Ligand Binding Regions (MLBR2-3), the p.(Arg918Cys) is located within the cell-interacting domain MLBR2, associated with (severe-to-)lethal Osteogenesis imperfecta.

So far the mechanism driving the temporary hyperostosis and inflammatory reaction in Caffey disease is unknown. Unraveling the genetic spectrum is the first step towards our understanding of its pathophysiology. Future studies will evaluate the effect of intracellular retention of mutant collagens chains and interference with other proteins in the extracellular matrix.

Molecular characterization of three canine models of human rare bone diseases: Caffey, van den Ende-Gupta, and Raine syndromes

M. K. Hytönen^{1,2,3}, M. Arumilli¹, A. K. Lappalainen⁴, M. Owczarek-Lipska⁵, V. Jagannathan⁶, S. Hundi⁷, E. Salmela¹, P. Venta⁸, E. Sarkiala⁴, T. Jokinen⁴, D. Gorgas⁷, J. Kerel^{1,2,8}, P. Nieminen⁹, C. Drögemüller⁵, H. Lohi^{1,2,3};

¹Research Programs Unit, Molecular Neurology, University of Helsinki, Helsinki, Finland,

²The Folkhälsan Institute of Genetics, Helsinki, Finland, ³Department of Veterinary Biosciences, University of Helsinki, Helsinki, Finland, ⁴Department of Equine and Small Animal Medicine, University of Helsinki, Helsinki, Finland, ⁵Institute of Genetics, Vetsuisse Faculty, University of Bern, Bern, Switzerland, ⁶Department of Microbiology and Molecular Genetics, Michigan State University, Michigan, MI, United States, ⁷Division of Clinical Radiology, Department of Clinical Veterinary Medicine, Bern, Switzerland, ⁸Department of Biosciences and Nutrition, Karolinska Institutet, Huddinge, Sweden, ⁹Department of Oral and Maxillofacial Diseases, University of Helsinki, Helsinki, Finland.

Introduction: One to two percent of all children are born with a developmental disorder and for many of them the molecular pathogenesis remains poorly characterized. Parallel developmental disorders in other species could provide complementary models for human rare diseases by uncovering new candidate genes, improving the understanding of the molecular mechanisms and opening possibilities for therapeutic trials. Our study investigated the clinico-pathological features and genetic causes of three developmental syndromes in dogs; craniomandibular osteopathy (CMO), previously undescribed skeletal syndrome, and severe tooth wear due to hypomineralization.

Materials and Methods: We established study cohorts for each disease and characterized their clinical features. Either a genome-wide association study combined with targeted resequencing or whole genome sequencing was utilized to identify the causal variants.

Results: For the studied disorders, we identified pathogenic variants in the

canine *SLC37A2*, *SCARF2* and *FAM20C* genes, respectively. CMO is a clinical equivalent to an infantile cortical hyperostosis (Caffey disease) for which *SLC37A2* is a new candidate gene. *SLC37A2* is a poorly characterized member of a glucose-phosphate transporter family without previous disease associations. Mutations in *SCARF2* and *FAM20C* have been associated with human van den Ende-Gupta and Raine syndromes and our results demonstrate that the canine disorders show remarkable similarity to human syndromes.

Conclusions: Given the growing interest in the molecular characterization and treatment of human rare diseases, our study presents three novel physiologically relevant models for further research and therapy approaches. In addition, identification of mutations in the human orthologues provides molecular identity for the canine conditions.

Identification and validation of novel genetic variants associating with canine hip dysplasia related traits

L. Mikkola¹, S. Holopainen², A. Lappalainen², M. Hytönen^{1,3}, O. Hakosalo⁴, H. Lohi^{1,4,5}, A. Iivanainen¹;

¹Department of Veterinary Biosciences, Faculty of Veterinary Medicine, University of Helsinki, Helsinki, Finland, ²Department of Equine and Small Animal Medicine, Faculty of Veterinary Medicine, University of Helsinki, Helsinki, Finland, ³The Folkhälsan Institute of Genetics, Helsinki, Finland, ⁴Haartman Institute, Helsinki, Finland, ⁵Research Programs Unit, Helsinki, Finland.

Introduction: Canine hip dysplasia (CHD) is a common, complex, and moderately heritable disorder. The genetic background of CHD remains ambiguous despite rigorous studies. It is non-congenital, inflicts pain via secondary osteoarthritis and may lead to euthanasia on humane grounds. We aimed to identify risk loci and gene variant(s) of canine hip dysplasia and to validate our findings with replication studies.

Materials and methods: Our data consisted of German shepherd dogs. Population stratification was considered in our study. Ethylenediaminetetraacetic acid (EDTA) preserved blood samples were genotyped with a high density 173K canine single nucleotide polymorphism (SNP) array. We executed a genome-wide association study (GWAS) in two steps: 1) with a case-control data, and 2) with a larger cohort of dogs with expanded phenotypes. Validation studies were conducted with an independent cohort of dogs, using competitive allele specific PCR (KASP™) based SNP genotyping.

Results: The first GWAS revealed seven suggestive SNPs in one chromosome; the haplotype frequencies demonstrated a significant correlation with the severity of the phenotype in our validation study. The second GWAS detected one genome-wide significant and 29 suggestive SNPs in several additional chromosomes.

Conclusions: We revealed one genome-wide significant and multiple suggestive SNPs, all previously unprecedented, associating with CHD traits. Seven of these SNPs were validated indicating significant correlation with the severity of the phenotype. Additional validation studies are underway for these as well as for the remaining 30 SNPs revealed in the second GWAS. Canine health foundation and the Academy of Finland funded this study.

Cartilage hair hypoplasia: a case with compound heterozygous two novel mutations

B. Akgun¹, S. Candan², E. Isik¹, T. Atik¹, A. Aykut³, A. Durmaz³, F. Ozkinay¹;

¹Ege University Faculty of Medicine, Department of Pediatrics, Subdivision of Pediatric Genetics, Izmir, Turkey, ²Balikesir Ataturk State Hospital, Medical Genetics Department, Balikesir, Turkey, ³Ege University Faculty of Medicine, Department of Medical Genetics, Izmir, Turkey.

Introduction: Cartilage hair hypoplasia (CHH) is an autosomal recessive genetic disorder characterised by short-limb dwarfism, sparse and light-colored hair, Hirschsprung's disease and immune deficiency. It is caused by mutations in the RMRP gene, which encodes the RNA component of the mitochondrial RNA-processing ribonuclease (RNase MRP). Several mutations have been identified in its promoter region or transcribed sequence.

Case report: A 6 month-old girl was born to nonconsanguineous parents at 39th week of gestation by caesarian section. Bilateral rhizomelia on the upper and lower extremities were detected at the prenatal period. She had postnatal growth retardation and chronic constipation. On physical examination, sparse and light colored hair and eyebrows, frontal bossing, anteverted ears, rhizomelic dwarfism and joint laxity were observed. Neuromotor development was normal. Immunological parameters were normal. Short extremities and metaphyseal dysplasia were detected on the bone survey. We detected compound heterozygous two novel mutations [g.4976_4989dupTACTACTCTGTGAA and +22T>C] on the RMRP gene by Sanger sequencing analysis.

Conclusion: In conclusion, in a case who has normal immune phenotype and

prominent skeletal findings compound heterozygous mutations in RMRP gene were reported. Clinical findings of the syndrome depend on the mutation harboring in the gene.

P04.019

Cartilage-hair hypoplasia by a new mutation 151G>C in the RMRP gene

M. Ortiz, A. Lafuente, G. Pi, A. Zuñiga;
Hospital de la Ribera, Alzira (Valencia), Spain.

Cartilage-hair hypoplasia (CHH; MIM#250250) is a form of short-limbed dwarfism due to skeletal dysplasia. CHH is an autosomal recessive disorder characterized by skeletal involvement, short stature, variable features like blond fine sparse hair, and defective cellular immunity affecting T-cell-mediated responses. Patients may have a severe combined immunodeficiency requiring bone marrow transplantation or they may be asymptomatic. CHH is caused by mutations in the RMRP gene (RNA component of mitochondrial RNA-processing endoribonuclease), an untranslated gene with only 267 nucleotides that encode an RNA subunit of an RNase-MRP complex. This is the first nuclear-encoded RNA in which mutations have been found to lead to human diseases. RMRP is characterized by a very high density of SNPs and several pathogenic variants. Subsequently, molecular diagnosis remains problematic.

Proband was a 8 mo male and he is the first child of healthy, non-consanguineous parents. No family history of congenital anomalies was referred. The child was born after 38 weeks of an uneventful pregnancy. Low birth weight, short stature and forearm and hand hypoplasia, with contractures of both wrist and fingers, were the main symptoms after the birth. Karyotype was normal male and CGH array did not detect any CNV. Direct sequencing of RMRP gene detected a known pathological mutation, 195C>T (maternal origin) and a non-previously described mutation 151G>C (paternal origin) in RMRP gene. Phylogenetic analysis indicates that may have a pathological character affecting the secondary structure of the RNase-MRP RNA. Therefore, the patient should carry two pathological mutations that confirm the diagnosis of cartilage-hair hypoplasia.

Congenital contractural arachnodactyly (CCA) is an autosomal dominant connective tissue disorder manifesting joint contractures, arachnodactyly, crumpled ears, and scoliosis as main features. Its rarity and substantial overlap with other conditions including Bethlem myopathy, Marfan syndrome and distal arthrogyposes, make the diagnosis challenging, though important for clinical management. CCA is caused by mutations in FBN2. We performed a comprehensive clinical and molecular assessment in a large cohort of CCA patients to delineate clinical diagnostic criteria and guide molecular analyses for FBN2.

FBN2 analysis using either Sanger Sequencing or PCR-based next-generation sequencing was performed in 122 clinically well-characterized probands. For 10 clinical characteristics, the positive and negative predictive value to find an FBN2 mutation was determined in order to establish a

weighted clinical scoring system on 20 points. Statistics were performed using SPSS 22.0.

Forty-seven probands harbored an FBN2 mutation (mutation uptake rate 39%). All but 2 mutations were located in the neonatal region (exons 22-36) with half of them altering or producing cysteines. Three patients had large intragenic deletions or frameshift mutations. Five FBN2+ patients developed cardiovascular complications. Logistic regression analysis reveals a significantly higher score in FBN2+ versus FBN2- patients (p<0,001). Cut point analysis using a ROC curve revealed that a clinical score of 11+ yields a sensitivity of 84% and a specificity of 60% for the FBN2 result. In addition, in patients presenting with a clinical score of 11+ and at least crumpled ears and arachnodactyly, the probability of finding an FBN2 mutation is 60%. BOF15/MET-V/011; FWO:1881515N

P04.021

Rare variant in the CECR1 gene and susceptibility to autoimmune diseases?

T. Roberta¹, R. Santacroce¹, A. Leccese¹, A. Corrado², M. Margaglione¹;
¹Laboratory of Human Genetics, Foggia, Italy, ²Clinica Reumatologica- Azienda Ospedaliero Universitaria di Foggia, Foggia, Italy.

CECR1 (cat eye syndrome chromosome region, candidate 1) encodes adenosine deaminase 2. Adenosine deaminase (ADA) catalyzes the deamination of adenosine and deoxyadenosine to inosine and deoxyinosine, respectively. ADA, an enzyme essential for the differentiation and proliferation of lymphocytes and the monocyte-macrophage system, has been used for monitoring several diseases in which immunity has been altered.

In previous studies it was observed that compound heterozygous mutations in CECR1 cause a syndrome which includes systemic vasculopathy and inflammation, showing overlap with polyarteritis nodosa and signs of compromised endothelial integrity and endothelial cellular activation. Since this syndrome shared similarities with systemic sclerosis disease (presence of antibodies and connective tissue damage), we performed a mutational analysis of the CECR1 gene on this autoimmune disease to test the hypothesis that gene may be also involved in it.

We identified one CECR1 missense mutation (p.Arg45Trp) in one patient affected by diffuse form of the disease, and it was not observed in the 200 Italian controls analysed in this study. This substitution affects a nucleotide in the dimerization domain, and in silico analysis performed with three prediction algorithms predicts for it a nonneutral role. The other 3 detected variations were synonymous and have already been described in public databases and were identified also in control samples.

The presence of only one mutation in heterozygosity cannot be responsible for the phenotype of the patient and therefore, we did not observe any significant evidence for the implication of this gene in SSc development.

P04.022

The candidate implant materials being Mg-Y-RE's alloys suppressed chondrogenesis

B. Gogebakan, M. Izmirlı, K. Gunduz, L. Atac, N. Bilgic, S. Ozarslan, O. Sahin;
Mustafa Kemal University, Hatay, Turkey.

Osteoarthritis (OA) is the most common form of joint disease and it may commonly develop knees, hips, hands, facet joints and feet. The gold standard for the diagnosis of OA is the histology of synovial cell. The synovial cell consists of from one to four layers of cells including fibroblast cell and several biomarkers for OA and chondrogenesis. For OA, the chondrocyte implantation and osteochondral autograft procedures are used as treatment of methods which are expensive and have side effects. Another method is implants being made of several materials can be used as knee implant. CHI3L1, COMP, MMP1, ADAMTS4, ADAMTS5, HIF1A, NFKB, EPAS1 genes are associated with chondrogenesis and they are well known biomarkers for OA and chondrogenesis. Therefore, we aimed to determine the invitro cytotoxicity and the level of mentioned genes expressions of synthesized Mg-Y-RE12, Mg-Y-RE13 and Mg-Y-RE24 alloys by Micro/Nano-Mechanical Characterization Laboratory of Physic department as implant materials. HEL299 which is the fibroblast cell line as model of synovial fibroblast is used. For this purpose, HEL299 was exposed to various concentrations of Mg-Y-RE12, Mg-Y-RE13 and Mg-Y-RE24 at 24, 48 and 72 hours. Cell viability was evaluated by MTT. The expression levels of genes were evaluated with qRT-PCR. To compare control and exposed HEL299 cell line, Mg-Y-RE12 suppressed COMP, ADAMTS5, HIF1A, NFKB and EPAS1 genes, Mg-Y-RE13 suppressed CHI3L1, ADAMTS5, HIF1A, NFKB, EPAS1 genes and Mg-Y-RE24 suppressed CHI3L1, ADAMTS4, ADAMTS5, MMP1, HIF1A, NFKB, EPAS1 genes. In a conclusion, Mg-Y-RE12, Mg-Y-RE13 and Mg-Y-RE24 cannot suitable for knee implant materials.

P04.023

Cleidocranial Dysplasia - Clinical, radiological and molecular diagnosis of 5 cases

A. R. Soares¹, M. E. Oliveira¹, C. Melo², G. Soares¹, R. Santos¹, A. M. Fortuna¹;
¹Centro Genética Médica Dr. Jacinto Magalhães - CHPorto, Porto, Portugal, ²Serviço
 Pediatria - Centro Hospitalar Médio Ave, Vila Nova Famalicão, Portugal.

Introduction: Cleidocranial dysplasia (CCD, MIM#119600) is an autosomal dominant skeletal dysplasia characterized by hypoplasia/aplasia of the clavicles, delayed closure of the cranial sutures and multiple dental abnormalities. Other features that may be present are macrocephaly, brachycephaly and bossing, short stature and other skeletal abnormalities. The prevalence of CCD is one in 1 million. Mutations in the RUNX2 gene are responsible for 60-70% of the cases (~40% are de novo). The diagnosis is based on clinical and radiological findings and may be confirmed by RUNX2 gene mutation analysis.

Materials and Methods: We report 5 CCD patients (4 families), in which RUNX2 sequence analysis was performed.

Results: All the patients presented with typical clinical features and specific radiological findings. The RUNX2 gene molecular study revealed 2 missense mutations (in 2 families) affecting highly conserved amino acids - p.Arg190Trp and p.Lys218Asn. The later represents a novel base substitution (c.654A>C), located in the DNA-binding Runt domain. Further studies will be performed in the other 2 families.

Conclusions: These cases illustrate the importance of clinical clues for the diagnosis, as well as the intra and interfamilial variability of this disease. The molecular confirmation allowed a more accurate genetic counselling for patients and families, namely by the opportunity to offer prenatal diagnosis. Although CCD has an overall good prognosis, its earlier diagnosis may lead to a better management from a multidisciplinary team thereby providing an improved quality of life for patients.

P04.024

Novel RUNX2 mutation in the runt domain in a Japanese patient with cleidocranial dysplasia

J. Machida¹, H. Goto², A. Shibata², T. Tatematsu², T. Nagao³, K. Shimozato², Y. Tokita⁴;
¹Toyota Memorial Hospital, Toyota, Aichi, Japan, ²Aichi-Gakuin University, Nagoya, Aichi, Japan, ³Okazaki City Hospital, Okazaki, Aichi, Japan, ⁴Institute for Developmental Research, Aichi-Human Service Center, Kasugai, Aichi, Japan.

Introduction: Cleidocranial dysplasia (CCD; MIM 119600) is a rare autosomal-dominant inherited disorder that causes an abnormal skeletal genesis characterized by short stature, absent or delayed closure of cranial sutures, hypoplastic or absent clavicles, and dental anomalies, such as delayed tooth eruption of permanent teeth, hypodontia, and supernumerary teeth. It has been demonstrated that hypomorphic or haploinsufficiency of the runt related transcription factor 2 (RUNX2) gene is causative for CCD. RUNX2 encodes an osteoblast-specific transcription factor, which recognizes specific DNA sequences via the runt domain, and has an important role in the differentiation of osteoblasts and the maturation of chondrocytes.

Materials and Methods:

Mutational analysis was performed with fragments covering the entire coding region of the RUNX2 gene. In addition, biochemical analyses were carried out to investigate the role of detected mutant RUNX2 in the CCD pathologies.

Results and Conclusions:

In this study we described the case of a 9 year old Japanese boy with CCD who carries a novel mutation in the RUNX2 gene (c.473c>a) that resulted in an amino acid substitution (p.A158E) in the runt domain of the gene product. Although A158E RUNX2 showed stable exogenous expression in transfected COS7 cells and a normal nuclear localization pattern, it did not show transcriptional activity in a reporter assay. This indicates that the A158E mutation in RUNX2 is causal for the CCD in our current case.

P04.025

Mutations in COL1A1 and COL1A2 in patients with osteogenesis imperfecta

J. Díaz-Garzón¹, C. Prior¹, C. Gómez¹, L. Pascual¹, R. Núñez¹, R. de Sancho¹, N. Chacón¹, E. Vallespín¹, V. Martínez-González¹, P. Gutiérrez², J. Molano¹, A. Bueno², G. Otafy³, S. Temtam³, M. Aglan³, P. Lapunzina⁴, V. L. Ruiz-Pérez¹;
¹Hospital La Paz, Madrid, Spain, ²Hospital Universitario de Getafe, Madrid, Spain, ³Human Genetics and Genome Research Division, Centre of Excellence of Human Genetics, National Research Centre, Cairo, Egypt, ⁴Instituto Investigaciones Biomédicas, Madrid, Spain.

Introduction: *Osteogenesis imperfecta* (OI) is a connective tissue disorder characterized by skeletal fragility leading to recurrent fractures. It is mainly an autosomal dominant disorder with 85-90% of cases having mutations in

the type I collagen genes *COL1A1* and *COL1A2*.

The objective of this study was to identify mutations in *COL1A1* and *COL1A2* in patients with clinical suspicion of OI.

Material and Methods: The coding regions of *COL1A1* and *COL1A2* were screened in 47 families with OI by next-generation sequencing (NGS). Most families were Spanish, but patients from other countries were included. We confirmed the mutations by conventional Sanger sequencing. Familial analysis were performed when samples were available.

Results: We identified 28 different pathogenic mutations in 31 families (68%). Most common mutations were missense variants affecting glycine residues but splicing and frameshift mutations were also found. There were 12 novel mutations (*COL1A1*=6; *COL1A2*=6) and eight mutations were confirmed to be *de novo*.

Conclusions: NGS is a suitable method to accomplish molecular diagnosis of *osteogenesis imperfecta*. Large deletions/duplications and deep intronic mutations which were not analysed in this study could explain the low rate of mutation detection.

The large majority of pathogenic variants identified were missense mutations affecting glycine residues and thus expected to cause collagen I triple helix disturbance.

P04.026

Mutation in filamin B co-segregating with congenital talipes equinovarus in a chinese family

H. Yang, Z. Zheng, H. Cai, Z. Wang, Q. Fu;
 Shanghai Children's Medical Center, Shanghai Jiao Tong University school of Medicine, Shanghai, China.

Introduction: Congenital talipes equinovarus, also known as clubfoot, is one of the most common musculoskeletal disorders, and its etiopathogenesis is not clearly known. Genetic factors are known as contributors to its pathogenesis. Up to date, a large number of genes were involved in this process, such as PITX1, TBX4 and RBM10. Our aim was to determine the candidate disease-causing mutations in Chinese patients with isolated clubfoot.

Materials and Methods: Genomic DNA was extracted from peripheral blood samples of isolated clubfoot pedigree and 53 sporadic patients. Whole exome sequencing (WES) and Sanger sequencing were performed for identifying disease-causing mutations and validation, respectively.

Results: A putative pathogenic mutation c.4717G>T (p.D1573Y) in filamin B (FLNB) gene was successfully identified by WES and was shown to co-segregate with the family anomaly in a three-generation family with six isolated clubfoot affected individuals. In addition, two novel missense mutations in FLNB [c.1897A>G(p.M633V) and c.2195A>G(p.Y732C)] were further identified from 53 sporadic patients with isolated clubfoot.

Conclusions: Our results indicated that FLNB mutations were associated with isolated clubfoot, and provide a concrete evidence for involvement of FLNB in pathogenesis of isolated clubfoot and expand the clinical spectrum of FLNB mutations.

P04.027

In vitro characterization of the skeletal stem cell niche from calvarial sutures of nonsyndromic craniosynostosis

L. Di Pietro, M. Barba, L. Massimi, P. Frassanito, M. Caldarelli, G. Tamburrini, W. Lattanzi;
 Università Cattolica del Sacro Cuore, ROMA, Italy.

Nonsyndromic craniosynostosis (NSC) is a congenital defect due to the premature fusion of skull sutures. These are mesenchymal gaps that bridge the gaps among flat bones of the skull, and serve as key growth centers coordinating skull-brain concerted development. The suture mesenchyme houses a craniofacial-specific skeletal stem cell niche, recently characterized. Recent evidence suggests that NSC is due to a stem cell abnormality at this site. Our aim is to characterize the stem cell population isolated from open and fused sutures of NSC patients, focusing on the expression of lineage-specific markers.

Calvarial stem cells (CMSC) were isolated from NSC biospecimens and clonally diluted. The expression of bone marrow stem cell markers (THY1, a skeletal stemness-marker; TIE2, tyrosine kinase recognized as haemopoietic/angiogenic marker; ENPEP, glutamyl aminopeptidase involved in osteogenic differentiation of bone marrow stem cells; and ITGAV, an integrin playing a key role in bone marrow niche environment) was analyzed both in suture tissues and matched cell clones, with and without osteogenic induction.

CMSCs clones homogeneously displayed a THY1+/TIE2-/ENPEP- immunophenotype, indicating that explant cultures allow a significant selection of cell populations for both sutures and synostoses. Cells expressed increased levels of THY1 and ITGAV, while decreased levels of ENPEP and TIE2, com-

pared with matched tissue samples. The expression of THY1, ENPEP and TIE2 decreased after the osteogenic induction.

THY1+ represent reasonably the stem cell population inside the calvarial niche, hence a potential target of therapies aimed at reducing the increased osteogenic rate at the site of premature suture fusion.

P04.028

Bardet Biedl Syndrome-gene 9 (BBS9) and primary cilium signaling in the aberrant osteogenic process underlying non-syndromic craniosynostosis

M. Barba, L. Di Pietro, L. Massimi, M. Geloso, F. Michetti, C. Di Rocco, G. Tamburrini, C. Bernardini, W. Lattanzi; *Università Cattolica del Sacro Cuore, ROMA, Italy.*

Nonsyndromic craniosynostosis (NSC) is a congenital malformation due to the premature ossification of calvarial sutures, with an unclear multifactorial etiopathogenesis. The Bardet Biedl Syndrome-associated gene 9 (BBS9), encoding a structural component of the primary cilium, has been associated to the NSC phenotype in a GWAS. The role of BBS9 in the osteogenic commitment and differentiation of somatic stem cells inside skull bone and sutures is unknown.

The aim of this study was to investigate how BBS9 modulation affect ciliogenesis and osteogenesis, in cells isolated from fused (p-CMSC) and unfused (n-CMSC) sutures of NSC patients.

Cells were cultured either in standard growth or in osteoinductive conditions; BBS9 was silenced using siRNA, and its expression analyzed through qPCR. The number of primary cilium-expressing cells, and the activity of the cilium-related Hedgehog pathway were analyzed comparatively in all cells. BBS9 expression was higher in p-CMSC compared with n-CMSC, and underwent a further increase upon osteogenic induction. The number of ciliated cells was lower in p-CMSC compared with n-CMSC. Following BBS9 silencing, the percentage of ciliated cells raised significantly in p-CMSC, equalizing to the percentage observed in n-CMSC. Furthermore, the expression of Hedgehog pathway-related genes (SMO, GLI1, GLI3, IGF1) in p-CMSC was significantly dysregulated, compared with n-CMSC, and reverted to normal upon BBS9 silencing.

Taken together, our data point towards a functional role of BBS9 in the osteogenic commitment of suture-derived cells, highlighting a key role of the primary cilium in the abnormal osteogenic process underlying NSC pathogenesis.

P04.029

Differential expression of candidate genes for skull globularization in nonsyndromic craniosynostosis patients: a common molecular network in skull shape evolution, craniofacial dysmorphism and cognitive disabilities?

W. Lattanzi¹, L. Di Pietro¹, M. Barba¹, C. Boeckx², L. Massimi¹, D. Chieffo¹, G. Tamburrini¹, A. Benitez-Burraco³; ¹Università Cattolica del Sacro Cuore, Rome, Italy, ²ICREA/Universitat de Barcelona, Barcelona, Spain, ³Universidad de Huelva, Huelva, Spain.

Nonsyndromic craniosynostosis (NCS) is a congenital malformation, with unclear etiopathogenesis, due to premature suture fusion, which alters skull-brain landmarks. Cognitive impairment, typically involving the language domain, has been reproducibly found in NCS patients.

In a paleoneurobiology perspective, the skull of anatomically-modern humans (AMHs) has evolved to a more globular shape, compared to Neandertals, while improving cognition and linguistic abilities. Recent studies from our group pointed out that critical genes have been selected in AMHs and should be crucial for skull globularization, while playing a putative role in neurogenesis, neo-cortex and subcortical patterning, neuronal interconnection, and synaptic plasticity.

Hence we aimed to investigate the role of candidate genes for skull globularity in the premature ossification of calvarial sutures occurring in NCS, chosen as a model disease.

To this aim, these selected genes were comparatively analyzed through qPCR in sutures of NCS patients versus control samples from unaffected individuals. Differential expression of DLX5, ROBO1, SLIT2, NCAM1, TGFB2, DCN, RUNX2, and SFRP2 was found. The expression levels of these genes was also significantly modulated in cells induced towards osteogenic differentiation in vitro.

Taken together our data seem to suggest that the molecular signaling acting at the site of premature suture fusion in NCS partially overlaps with the gene regulatory network that shaped the skull and the brain during human evolution and that improved our cognitive abilities. We claim that this overlapping may be informative of the common molecular machinery regulating the skull-brain concerted development and evolution.

Mutations in the E subunit of the vacuolar ATPase complex cause a novel type of autosomal recessive cutis laxa

T. Van Damme¹, A. Kariminejad², M. Mohamed³, B. Guillemin¹, T. Gardeitchik³, W. Steyaert¹, S. Ghaderi-Sohf², E. Morava⁴, D. Syx¹, D. Lefeber³, P. Coucke¹, S. van Kraaij³, D. Dalloyaux³, R. De Rycke⁵, A. De Paepe¹, S. Symoens¹, R. Wevers³, F. Malfait¹, B. Callewaert¹; ¹Center for Medical Genetics Ghent, Ghent University Hospital, Ghent, Belgium, ²Kariminejad-Najmabadi Pathology & Genetics Center, Tehran, Iran, Islamic Republic of, ³Departments of Laboratory medicine, Pediatrics and Genetics, Radboudumc, Nijmegen, Netherlands, ⁴Hayward Genetics Center, New Orleans, LA, United States, ⁵Department of Biomedical Molecular Biology, Inflammation Research Center, Ghent University, Ghent, Belgium.

Introduction: Acidification of vesicular compartments is crucial for the function of intracellular trafficking pathways. Defects in this process due to mutations in genes encoding subunits of the vacuolar-type H⁺-ATPase (V-ATPase) pump cause very different Mendelian disorders. We now identified a homozygous mutation in another subunit of the V-ATPase in a consanguineous Iranian pedigree with a severe cutis laxa phenotype.

Results: Using whole-exome sequencing, we detected a homozygous p.(Leu128Pro) (c.383T>C) missense mutation in *ATP6V1E1*, encoding the E subunit of cytoplasmic V1 part of the V-ATPase complex, in a patient with severe and generalized cutis laxa, arthrogryposis, congenital hip dysplasia, and severe aortic root dilatation and biventricular hypertrophy. Located in the head of this subunit, Leu128 engages a hydrophobic reaction with the opposing B subunit that is predicted to be abolished by the Pro substitution. Proband fibroblasts displayed abnormal swelling and fragmentation of the Golgi apparatus on transmission electron microscopy (TEM) and severely delayed retrograde translocation of Golgi membranes to the endoplasmic reticulum after Brefeldin A treatment, suggesting disturbed vesicular intracellular trafficking. TEM analysis of the proband's dermis showed severe changes in the amount, structure and organization of elastic and collagen fibers, linking this disorder to other types of cutis laxa. Biochemical studies investigating the effect on elastin and collagen are currently ongoing.

Conclusions: This study describes a novel type of cutis laxa caused by mutations in the E subunit of the V-ATPase complex that affects intracellular trafficking and secretion of major extracellular matrix constituents.

P04.031

A New Face of Inherited Recessive Cutis Laxa: ATP6V0A2 gene mutations associated with metabolic defects

G. Ogur¹, F. Malfait², U. Abur³, A. Yilmaz⁴, H. Mutlu Albayrak⁴, E. Altundag⁴, C. Aygün⁵; ¹Ondokuz Mayıs University Medical Faculty, Genetics, Samsun, Turkey, ²Ghent University, Genetics, Ghent, Belgium, ³Ondokuz Mayıs University Medical Faculty, Genetics, Samsun, Turkey, ⁴Ondokuz Mayıs University Medical Faculty, Genetics, Samsun, Turkey, ⁵Ondokuz Mayıs University Medical Faculty, Neonatology, Samsun, Turkey.

Introduction. Cutis laxa (CL) is a rare disorder of elastic fibers and is characterized by lax skin, skeletal and developmental anomalies. Several forms have been described. ARCL2A (OMIM 219200) presents lax skin with persistent wide fontanels, intrauterine growth retardation, hip dislocation, scoliosis, and inguinal hernia. A subgroup of patients with ATP6V0A2 gene mutations have also metabolic problems mostly N- and O-glycan biosynthesis defect.

Here we present two cases of ARCL2A both with homozygous ATP6V0A2 gene mutations, in one of whom, ethylmalonic aciduria was also observed.

Case 1. A 6 year-old male patient from consanguineous parents was referred because of lax skin and a previous sib affected with CL. He showed a large fontanel and lax skin. Mutation analysis revealed homozygous ATP6V0A2 gene mutations, (c.187C>T, p.R63X). No mutations were identified in the FBLN5 gene.

Case 2 was a 17 day-old baby with facial dysmorphism, congenital hip dysplasia, a wide anterior fontanel, lax skin and pectus excavatum. Mutation analysis revealed homozygous nonsense ATP6V0A2 gene mutation, (c.187C>T, p.R63X). During follow up, urine organic acid screening tested because of developmental delay, revealed high levels of ethylmalonic aciduria. A repeated analysis supported the same result.

DISCUSSION: To best of our knowledge no previous association of cutis laxa syndrome with ethylmalonic aciduria has been reported. Increased ethylmalonic acid in urine is observed in a number of inborn errors of metabolism, as well as in people with the SCAD coding region polymorphism. It is of interest that SCAD and ARCL2A are on the same DNA loci, 12q24.31.

Multiple trichoepitheliomas and vulvar cysts: Extending the cutaneous phenotypic spectrum in CYLD mutation carriers

A. Dubois¹, V. Wilson¹, V. Bajaj², Á. Alonso Sánchez¹, A. Husain³, N. Rajan¹;
¹Institute of Genetic Medicine, Newcastle upon Tyne, United Kingdom, ²Department of Dermatology, University Hospital of North Durham, Durham, United Kingdom, ³Department of Pathology, RVI, Newcastle upon Tyne, United Kingdom.

Patients with germline mutations in CYLD are recognised to develop a range of patterns of presentation, including familial cylindromatosis (FC), Brooke-Spiegler Syndrome (BSS) and multiple familial trichoepitheliomas (MFT). Here we present a case of a 29-year-old female patient with multiple facial and genital papules, a pattern not previously associated with CYLD mutation.

The patient began to develop multiple, asymptomatic, skin coloured papules around the nose and upper lip from the age of 16. There was no family history of skin tumours. White, firm papules began to develop within the labia majora from the age of 25, and numbered more than 20. A biopsy of the facial lesions showed trichoepithelioma. The labial lesions demonstrated histological features consistent with epidermoid cysts. Sanger sequencing of the coding exons of CYLD revealed a novel heterozygous base duplication in exon 8, c.966dupG, resulting in a frameshift mutation.

Pubic tumours are a feature recognised in CYLD mutation carriers, and one that challenges the paradigm of ultraviolet radiation induced tumour induction. We undertook local review of records from four further patients carrying a CYLD mutation (c.2460delC) who had undergone excision of genital lesions, and none were found to have epidermoid cysts. A search of the literature did not reveal this pattern of presentation in other patients with CYLD mutations.

MFT may be genetically heterogeneous, with only 44% of patients demonstrating germline mutations in CYLD. Our finding of MFT and labial cysts may represent an infrequent, novel pattern of presentation associated with CYLD mutation.

P04.033

Complete and partial XYLT1 deletion in a patient with neonatal short limb skeletal dysplasia

L. van Koningsbruggen, H. Knoester, R. Bakx, O. Mook, L. Knegt, J. Cobben;
 Academic Medical Centre, Amsterdam, Netherlands.

A boy was born with a neonatal short limb skeletal dysplasia and respiratory problems. Array CGH identified a large deletion on chromosome 16p13, which was also present in his healthy mother. However, detailed analysis of the deleted region pointed at candidate gene XYLT1, a gene reported to be associated with skeletal development. Sequence analysis was performed on the remaining allele and identified a small intragenic deletion, originating from his father. Subsequent RNA studies using NGS technology revealed several out-of-frame transcripts.

XYLT1 mutations have recently been reported as causative in recessive Desbuquois skeletal dysplasia (DBSD), but the skeletal features in our patient do not fit this diagnosis. It is possible that the phenotype of XYLT1 mutations extends to more aspecific types of short limb skeletal dysplasias and not to DBSD alone.

P04.034

Combination of palmoplantar keratoderma and hair shaft anomalies: a warning signal of severe cardiac disorder? A systematic review on desmosomal diseases

L. Polivka, S. Hadj-Rabia, C. Bodemer;
 Hôpital Necker, Paris, France.

Introduction. Inherited desmosomal diseases are characterized by skin and/or cardiac features. The dermatological features might be a clue in the determination of the underlying life-threatening cardiac disease. We propose a clinical algorithm in order to identify the patients at high risk of cardiac involvement and to orientate gene sequencing.

Methods. Systematic review of published articles. The inclusion/exclusion criteria were: 1) at least one identified mutation in the following desmosomal genes: JUP; PKP1, PKP2, DSP, DSG1 to 4, DSC1-3 and CDSN; 2) Description of the dermatological phenotype.

Results. 78 articles fulfilling the criteria were published. They correspond to 458 patients. Palmoplantar keratoderma (PPK), hair shaft anomalies (HSA), and skin fragility were the major features. Isolated PPK or isolated HSA are associated to a desmosomal disease limited to skin. The combination of PPK and HSA was recorded in 161 patients, and this association is at high risk of cardiac disease (129/161 patients, 80.1%). Skin features appeared as the initial clinical manifestations in the majority of cases. However, they had led to cardiac monitoring in only 2.3% of those patients. We delineated three major phenotypes: - the PPK-HSA-non fragile skin subtype (77%), always

associated to cardiac involvement; - the PPK-HSA-skin fragility-normal cardiac function subtype (19.9%) frequently associated Plakophilin1 anomalies; - the PPK-HSA-skin fragility-cardiac involvement subtype (3.1%) always due to DSP mutations. Three mutation hotspots in DSP and JUP account for 90.8% of the patients with cardiac involvement.

Conclusion. The combination of PPK and HSA justify long-term cardiac monitoring.

P04.035

Dyschromatosis universalis hereditaria caused by a recessive mutation in ENPP1 gene

M. Chourabi^{1,2}, J. N. Foo³, D. H. 'mida-Ben Brahim², L. Bousofara⁴, C. Bonnard¹, J. E. Common⁵, B. Sriha⁶, N. Ghariani⁴, A. Aounallah⁴, O. Mama⁷, R. Nouira⁴, B. Lane⁵, J. Liu^{3,7}, A. Saad², M. Denguézi⁸, B. Reversade⁹;
¹Laboratory of Human Genetics and Embryology, Institute of Medical Biology, A*STAR, Singapore, Singapore, ²Laboratory of Human Cytogenetic, Molecular Genetics and Reproductive Biology, Farhat Hached University Hospital, Sousse, Tunisia, ³Human Genetics, Genome Institute of Singapore, A*STAR, Singapore, Singapore, ⁴Department of Dermatology and Venereology, Farhat Hached University Hospital, Sousse, Tunisia, ⁵Laboratory of Epithelial Biology, Institute of Medical Biology, A*STAR, Singapore, Singapore, ⁶Department of Pathological Anatomy and Cytology, Farhat Hached University Hospital, Sousse, Tunisia, ⁷Saw Swee Hock School of Public Health, National University Health Systems, National University of Singapore, Singapore, Singapore.

Dyschromatosis Universalis Hereditaria (DUH) is a rare genodermatosis characterized by asymptomatic hyper- and hypo-pigmented macules over the body. These irregular lesions appear in infancy or early childhood. DUH is subtyped into different forms. The genetic etiology of autosomal recessive DUH remains unknown.

In this study we investigated 8 patients belonging to 3 related Tunisian families with autosomal recessive DUH presents with punctate palmoplantar keratosis (PPK). To find the causative gene, we performed homozygosity mapping followed by trio whole-exome sequencing.

In the mapped candidate locus on chromosome 6q, a unique single nucleotide variant in the *ENPP1* gene was identified. Sanger sequencing confirmed the segregation of this variant (c.358T>C; p.Cys120Arg) with the disease in the 3 families. *ENPP1* encodes the ectonucleotide pyrophosphatase/phosphodiesterase 1, a cell surface enzyme that catalyses the hydrolysis of ATP to AMP and generates extracellular inorganic pyrophosphate. *ENPP1* has been shown to play a role in skin pigmentation as the underlying cause for dominant Cole disease. Whereas Cole Disease mutations are heterozygous and affect conserved cysteine residues in the SMB2 domain of ENPP1, this novel Cys120 missense mutation is located in the SMB1 domain and must be in the homozygous state to cause DUH.

We suggest that these two genodermatoses represent a clinical spectrum of dyschromatosis, where this newly identified DUH stands for a recessive, more severe and extended form of Cole Disease.

P04.036

Dystrophic Epidermolysis Bullosa in two sisters

S. Garcia¹, A. M. Poyatos², A. Rubio¹, M. Martinez², S. Padrinac³, T. De Haro¹;
¹Hospital San Cecilio, Granada, Spain, ²AGS Sur- Hospital de Santa Ana, Motril, Spain, ³Hospital Virgen de las Nieves, Granada, Spain.

Severe generalized recessive dystrophic epidermolysis bullosa (RDEB-sev gen) is the most severe subtype of dystrophic epidermolysis bullosa. It is a severe skin disorder beginning at birth characterized by extremely fragile skin: blisters and skin erosions occur with minimal trauma and this result in mutilating scarring and contractures of the hands, feet, and joints. Affected individuals have an increased risk of developing aggressive squamous cell carcinoma.

The reported prevalence varies between populations, from 1/1,250,000 inhabitants in Scotland to 1/2,381,000 inhabitants in the United States. In Spain the estimated prevalence is 0.8/100,000.

The disease is caused by null mutations within the type VII collagen gene (COL7A1) that usually lead to a lack of functional collagen VII, the main constituent of anchoring fibrils that anchor the basement membrane to the dermis.

We present the case of two sisters of 28 and 32 years, they have clinical diagnosis of the disease and family history of parental consanguinity. The older sister has a healthy baby born by caesarean section. Gene sequencing of COL7A1 gene shows the homozygous mutation c.469insA (c.497dupA). The RDEB-sev gen comprises two types based on inheritance pattern: Dominant DEB and Recessive DEB (more several). Molecular characterization of pathogenic variants is the only accurate method to determine mode of inheritance and recurrence risk; phenotype severity and EM/IF findings alone are not sufficient. The offspring of an individual with RDEB are obligate heterozygotes (carriers) for a pathogenic variant in COL7A1.

P04.037

Zebrafish modeling of the $\beta 4\text{GalT7}$ -deficient type of Ehlers-Danlos syndrome

S. Delbaere, T. Van Damme, A. Willaert, S. Symoens, P. Coucke, F. Malfait;
Center for Medical Genetics Ghent, Ghent University Hospital, Ghent, Belgium.

Introduction: Proteoglycans are found on the surface of animal cells and in the extracellular matrix. They consist of glycosaminoglycan (GAG) side chains attached to a core protein through a linker region. Biallelic mutations in *B4GALT7*, the gene encoding galactosyltransferase I ($\beta 4\text{GalT7}$) which is an essential enzyme for the biosynthesis of the tetrasaccharide linker region, are the cause of the rare progeroid variant of the Ehlers-Danlos syndrome (EDS). This disorder, which lacks a relevant *in vivo* animal model, is mainly characterized by short stature, hypotonia, a progeroid facial appearance and skeletal abnormalities.

Methods: We developed and characterized a knockdown (KD) zebrafish model for the progeroid type of EDS by using morpholino injections targeted against *b4galt7*.

Results: Morphant embryos showed morphological abnormalities such as a small, round head, withdrawn jaw, more front-facing eyes and mild developmental delay compared to wild-type and negative control embryos. The total amount of sulfated GAGs was severely reduced in morphant embryos and whole-mount immunohistochemistry showed that heparan and chondroitin sulfate proteoglycans were severely diminished in the heads of *b4galt7* KD embryos. In addition, alcian blue staining demonstrated that cartilage structure in the head of morphant embryos are absent or strongly misshapen and immunohistochemical staining revealed a disturbed filamentous actin pattern in their head and tail.

Conclusion: A *b4galt7* KD zebrafish model has been developed which seems to be specific as it mimics partly the human phenotype of patients suffering from progeroid EDS. Currently, a *b4galt7* knockout zebrafish model is being created using the CRISPR/Cas technology.

P04.038

Homozygous missense COL5A2 mutation associated with Ehlers-Danlos Syndrome

B. B. Geckinli¹, K. Delil¹, M. A. Soylemez¹, A. Turkyilmaz¹, H. Simsek¹, Z. Gormez², H. Demirci², B. Yuceturk², A. I. Guney¹, A. Arman¹;

¹Medical Genetics Department, Marmara University Medical School, Istanbul, Turkey, ²Advanced Genomics and Bioinformatics Research Center, The Scientific and Technological Research Council of Turkey (TUBITAK), Kocaeli, Turkey.

Classic Ehlers-Danlos syndrome is a rare autosomal dominant connective tissue disorder, characterized by skin hyperextensibility, articular hypermobility, and tissue fragility. It is caused by collagen alpha-1(V) gene (*COL5A1*) or the collagen alpha-2(V) gene (*COL5A2*) mutations, causing deficiency of type V collagen.

We report a 16 year-old girl who was born with uncomplicated pregnancy at term to unrelated parents. She was referred to our clinic because of dysmorphic features, hand deformities, operated congenital hip dislocation, thrombocytopenia, splenomegaly, and previously followed-up ventricular septal defect. On physical examination, her weight was 70 kg (90-97P), height 161 cm (25-50P) and occipitofrontal circumference 52 cm (<3P). She had mild intellectual impairment. Her clinical features were short and webbed neck, a low posterior hairline, myopia, high palate, small and deformed hands, abnormal palmar creases, pes planus, hallux valgus and striae rubra on lumbar skin. X-ray showed, loss of cervical lordosis and mild scoliosis. Homozygosity mapping with whole exome sequencing identified a homozygous missense mutation c.3794A>G (p.Asp1265Gly) in *COL5A2* exon 51, affecting C-terminal propeptide domain. Her parents were heterozygous carriers for the same substitution. Previously, this homozygous mutation has not been reported in Ehlers-Danlos syndrome.

P04.039

Adding to the knowledge of the phenotype of musculocontractural Ehlers-Danlos syndrome caused by mutations in the DSE gene

S. Markholt¹, U. B. Jensen¹, C. K. Lautrup²;

¹Aarhus University Hospital, Aarhus N, Denmark, ²Aalborg University Hospital, Aalborg, Denmark.

Introduction: The diagnosis musculocontractural Ehlers-Danlos syndrome (mEDS) has recently been discovered. Most of the patients have been diagnosed with mEDS type I and mutations in the *CHST14* gene. Only 3 patients have been published with mEDS type II caused by mutations in the *DSE* gene and the phenotype is less well-described. We present detailed phenotype of an 18 years old male patient with mEDS type II.

Clinical findings: The patient was the second child of consanguineous parents of Turkish descent. In infancy he presented with hypertelorism, large anterior fontanel, flattened occiput, low hair line and wide neck, bilateral adducted thumbs and arachnodactyly. He had umbilical hernia, diastasis recti, constipation, bilateral hydronephrosis, as well as cryptorchidism. He had delayed psychomotor development. MRI of cerebrum showed a cortical heterotopia of 5-12 mm, interpreted as neuronal migration defect. He had myopia, strabismus and mild unilateral perceptible hearing loss. He was diagnosed with scoliosis, joint hypermobility, repeated shoulder luxations, and had surgery for pes cavus. The skin was hyperextensible with delayed wound healing, easy bruising and development of large hematomas.

Results: No mutations were found in the *CHST14* gene. Sequencing of the *DSE* gene revealed homozygosity for a stop mutation c.960T>A (p.Tyr320*). **Conclusion:** This is the first time cryptorchidism, hydronephrosis, joint dislocations, myopia and hearing impairment are described as part of mEDS type II. The phenotype of mEDS type I and type II seem very similar, although the impression is that the phenotype in mEDS type II is moderately milder.

P04.040

A girl with FKBP14-related Ehlers-Danlos syndrome and secondary mitochondrial dysfunction in muscle biopsy - a case report

J. Pilch¹, C. Fauth², M. Kajor³, E. Karczmarewicz⁴, M. Witsch-Baumgartner⁵, D. Piekutowska-Abramczuk⁵, E. Jamroz¹;

¹Department of Paediatrics and Developmental Age Neurology, Medical University of Silesia, Katowice, Poland, ²Division of Human Genetics, Innsbruck Medical University, Innsbruck, Austria, ³Department of Histopathology, Medical University of Silesia, Katowice, Poland, ⁴Department of Biochemistry, Radioimmunology, and Experimental Medicine, The Children's Memorial Health Institute, Warsaw, Poland, ⁵Department of Medical Genetics, The Children's Memorial Health Institute, Warsaw, Poland.

FKBP14-related Ehlers-Danlos syndrome (EDS) is a recently identified inherited connective tissue disorder characterized by severe muscular hypotonia at birth, progressive kyphoscoliosis, joint hypermobility, hyperelastic skin, myopathy, hearing loss and vascular complications. Due to severe muscle involvement patients frequently undergo muscle biopsy which sometimes may yield unusual findings.

We present an 8-year-old girl with FKBP14-related EDS and COX negative fibers in muscle biopsy. She was born prematurely with microcephaly, hip dysplasia, valgus deformity of feet, severe muscular hypotonia and muscle atrophy. During the first months of life excessive sweating and hyperlactacidemia was noted. Motor milestones were delayed. Acyl carnitine profile in serum and transferrin electrophoresis were normal. EMG showed a myopathic pattern which prompted us to muscle biopsy. Histopathology and EM showed no structural abnormalities. However, COX staining was negative and activity of respiratory chain complexes II+III was reduced. Thus, a mitochondrial disorder was suspected and selected mitochondrial genes (*SURF1*, *SCO2* and *MTATP6*) were screened but no mutation was found. During infancy motor function improved, but joint hypermobility was noted and she developed hearing impairment, easy bruising, chest deformity and scoliosis starting at the age of 7 years. Based on these findings FKBP14-deficient EDS was suspected and confirmed by sequence analysis which revealed the recurrent homozygous c.362dupC mutation in *FKBP14* gene.

In conclusion, muscle biopsies in FKBP14-related EDS may sometimes yield unusual findings such as mitochondrial dysfunction which probably is a secondary finding. However, the exact pathophysiology of FKBP14-related EDS and its impact on muscle function still remain to be elucidated.

P04.041

Significance and correlation of ultrastructural and molecular genetic approaches in the diagnostics for Ehlers-Danlos syndrome (EDS) patients with the classic and vascular type including the potential of next-generation sequencing (NGS)

K. Mayer¹, I. Hausser², R. Brumm¹, S. Doelken¹, H. Klein¹;

¹Center for Human Genetics and Laboratory Diagnostics (AHC), Martinsried, Germany, ²Institute of Pathology Heidelberg (IPH), Heidelberg, Germany.

EDS represents a clinically and genetically heterogeneous group of rare connective tissue disorders (CTDs) with challenges in establishing a precise testing strategy to define an accurate diagnosis. Six main EDS subtypes can be assigned clinically and substantiated by investigations like ultrastructural analysis of a skin biopsy and genetic analysis of collagen or collagen modifying genes.

Matching of pseudonymized data sets consisting of morphological investigations from 1511 patients achieved between 1984 and 2015 and genetic analyses of 1187 patient samples performed between 2002 and 2015 resulted in an intersection of 157 cases. 45 specimen were morphologically

compatible with the classic type, 45 with the vascular type, 16 with the hypermobile type, 26 with a CTD without specification, 25 showed no pathological morphology.

With respect to the morphological classification, in 10/45 cases with the classic and 19/45 cases with the vascular assignment the diagnosis was confirmed by a mutation identified with Sanger sequencing in COL5A1/2 or COL3A1, respectively. To uncover the genetic basis in mutation negative patients with a clear morphological assignment to the classic (35) or vascular (26) group, we performed NGS applying a panel of 41 genes known to be mutated in different EDS subtypes or related CTDs like cutis laxa, Loeys Dietz syndrome, Marfan syndrome and TAAD. In addition, whole-exome sequencing was undertaken to identify mutations not previously associated with EDS. In preliminary results of 19 reanalyzed patient samples gene panel analysis determined a molecular diagnosis in one case with classic morphology and in three cases with vascular morphology.

P04.042

Contribution of NGS in the Ehlers-Danlos syndromes diagnosis and characterization

A. Legrand^{1,2,3}, V. Boccio¹, A. Talbi¹, X. Jeunemaitre^{1,2,3}, J. M. Albuissou^{1,4,5},
¹APHP, Hôpital Européen Georges Pompidou, Paris, France, ²INSERM U970 Paris Cardiovascular Research Centre, Paris, Austria, ³Centre de Référence des Maladies Vasculaires Rares, Paris, Austria, ⁴INSERM U970 Paris Cardiovascular Research Centre, Paris, France.

Introduction: Ehlers-Danlos syndrome (EDS) is a phenotypically and molecularly heterogeneous group of inherited connective tissue disorders that share joint hypermobility, skin extensibility, abnormal scarring and tissue fragility. Vascular EDS (vEDS), the most severe EDS characterized by arterial fragility, is caused by COL3A1 mutations. Analysis of COL3A1, the gene for vEDS is performed in the Genetics Department, Georges Pompidou European Hospital, Paris. Other EDS types can be responsible for arterial fragility with minor clinical criteria, but with a better vascular prognosis and a different clinical follow-up.

Materials and Methods: we developed a NGS gene panel for types 1 to 7, but also rarest recessive types of EDS, corresponding to 16 genes (COL1A1, COL1A2, COL3A1, COL5A1, COL5A2, COL6A1, TNXB, PLOD1, FKBP14, FBLN5, ELN, ADAMTS2, CHST14, DSE, B4GALT7, and B3GALT6). Regions of interest were targeted with a custom Haloplex enrichment kit, followed by sequencing on Miseq. The data analysis was carried out using 3 different bioinformatics pipelines. To date 42 patients with positive Villefranche criteria were analysed.

Results: Causal mutations were identified in 9 patients (21%) in TNXB, COL5A1, COL1A1 and COL3A1. Numerous variants of unknown significance remain to be explored and large rearrangements to be confirmed. The identification of one patient with a COL3A1 mutation and hypermobility phenotype highlights the phenotypic overlap in EDS types.

Conclusion: This panel provides a powerful tool for the molecular diagnosis in EDS and will help for the characterization and best knowledge of the different EDS types, but also the genetic counseling and the management of patients.

P04.043

Chronic leg ulcer associated with premature dental loss in two brothers in Ehlers-Danlos syndrome type VIII

J. Kárteszi¹, A. L. Kovács², R. Gyula², A. Lócsai-Fekete¹, K. Hadzsiiev¹, B. Melegh¹;
¹Department of Medical Genetics, University of Pécs, Pécs, Hungary, ²Department of Dermatology, University of Pécs, Pécs, Hungary.

Introduction: We report two young male patients with the clinical diagnosis of Ehlers-Danlos syndrome type VIII (MIM130080), which entity is a very rare autosomal dominant disorder characterized by periodontal disease at young age and necrobiosis lipidica diabetiformis like skin alterations. Additional features like marfanoid habitus, joint hypermobility, osteoarthritis and vascular manifestations were described in literature. The striking symptom of chronic leg ulcer was also noted in one or two cases. Neither the pathomechanism nor the underlying gene has been determined so far.

Case Report: We performed detailed clinical phenotype analysis of our patients, who are brothers, taking into account that less than hundred patients were published until now and plenty of questions are unanswered yet. Both of our patients were attending at dermatological examination because of chronic leg ulcer to be formed on the basis of brownish plaques over the tibia. Obvious causes in the background like diabetes, arterial and venous circulation problems were excluded. Karyotype was normal. Anamnesis unraveled almost complete loss of teeth caused by periodontitis in both of them. **Discussion:** Our poster contains beside the presentation of anamnestic data,

physical examination and basic laboratory studies the results of the histological, endocrinological, radiological and immunological work up.

Conclusion: We confirm that chronic leg ulcer can be an important sign leading to the diagnosis of Ehlers-Danlos syndrome type VIII as it was proposed in a previous publication by Ronceray et al. (Case Reports in Dermatological Medicine, 2013).

P04.044

Molecular analysis of 26 Ellis van Creveld syndrome (EVC) families using targeted NGS, MLPA and array CGH technologies reveals high frequency of a recurrent maternal deletion of EVC.

Ellis-van Creveld (EVC) syndrome is characterized by short ribs, shortened tubular bones, trident aspect of the acetabular roof, post-axial polydactyly, congenital cardiac defects, dysplastic nails and teeth and labio-gingival adhesions. EVC is caused by mutations in EVC or EVC2. More recently, mutations in DYNC2LI1 or WDR35 have been reported in a few cases.

Here, we report the molecular screening of 26 EVC family (31 cases, 17 fetuses and 14 postnatal cases) by targeted NGS (called ciliome), associated with MLPA and array CGH technology.

By Ciliome analysis, we identified variants in 20/26 families (10 nonsense, 5 splice site, 1 missense, 5 deletions) in EVC (10), EVC2 (9), EVC/EVC2 (2) and DYNC2LI1 (1). In 18 cases, the absence of any variant (6/18) and the identification of i) an heterozygous variant only (5/18), ii) an "homozygous" variant confirmed only at the heterozygous state in the father (3/18), iii) deletions identified by ciliome (4/18) prompted us to perform MLPA and CGH at EVC/EVC2 loci. We identified in 6 families the same deletion of 48Kb encompassing exon 3 to 11 of EVC always inherited from the mother. Finally, in 4/26 families only one heterozygous variant was detected and in 6/26 families, neither variant nor deletion were detected in EVC/EVC2, supporting the involvement of another disease gene. Exome sequencing is in progress. By combining ciliome analysis, MLPA and array CGH, we conclude that EVC and EVC2 account for 73 % of EVC families. Our study emphasizes the high frequency of an EVC deletion of maternal origin.

P04.045

Epidemiology approach in skeletal dysplasia in France: 8-year experience by the centres of reference for rare skeletal dysplasia

C. Messiaen¹, G. Baujat², A. Ruel¹, M. Cohen Solal³, V. Forin⁴, C. Roux⁵, R. Chapurlat⁶, C. Michot⁷, R. Choquet¹, V. Cormier-Daire⁸;

¹Banque Nationale de données Maladies Rares, Hôpital Universitaire Necker-Enfants Malades, APHP, PARIS, France, ²Centre de Référence Maladies Osseuses Constitutionnelles (Reference Centre for Genetic Bone Diseases), Hôpital Universitaire Necker-Enfants Malades et Institut Imagine (AP-HP), PARIS, France, ³Centre de Référence Maladies Osseuses Constitutionnelles (Reference Centre for Genetic Bone Diseases), Hôpital Lariboisière (AP-HP), PARIS, France, ⁴Centre de Référence Maladies Osseuses Constitutionnelles (Reference Centre for Genetic Bone Diseases), Hôpital Trousseau (AP-HP), PARIS, France, ⁵Centre de Référence Maladies Osseuses Constitutionnelles (Reference Centre for Genetic Bone Diseases), Hôpital Cochin (AP-HP), PARIS, France, ⁶Centre de Référence Dysplasies Fibreuses des Os (Reference Centre for Osteofibrous dysplasia), Hôpital Edouard Herriot (HCL), LYON, France.

OBJECTIVES: Skeletal dysplasias (SD) are responsible for variable types of short statures, deformations and pain, leading to severe disabilities. Since

2007, all patients seen for expertise in the french Centre of Reference (CR) for skeletal dysplasia, are systematically recorded in CEMARA, database dedicated to rare diseases.

The study objective is to characterize the epidemiological data about SD in France, to better assess care services needs.

METHODS: The CEMARA system records for each patient a common data set, sharing its ontology according to the Nosology and Classification of Constitutional Skeletal Dysplasias.

CEMARA cases were reviewed for the period 2007-20015. A « case » was defined according to the status of the diagnosis assertion: confirmed, likely, unlikely. The regional prevalences were standardized.

RESULTS: On the 31/12/2015, 7.874 patients with SD were identified in CEMARA. The mean of annual new cases was 887. Two third were of pediatric age. The three main diagnoses were Osteogenesis Imperfecta (1120), achondroplasia (272) and fibrous dysplasia (242). 42% of the diagnosis were confirmed. The age at onset was 14% in antenatal, 28% at birth, and 43% at a later stage. The median transport time to the CR was 33 minutes (30 km). The prevalence of patients with SD at the 31/12/2015 was 18.20 per million (IC 95% [11.59 - 27.46]) in Paris region.

CONCLUSION: This is the first global study about SD at an almost national level. This descriptive study allows approaching the epidemiology on specific rare diseases in France.

P04.046

Application of gene panel targeted massively parallel sequencing in genetic diagnosis of patients with Epidermolysis bullosa

M. Hýblová^{1,2}, J. Radvánszky^{3,2}, P. Silló⁴, L. Striešková¹, T. Szemes^{1,2};

¹Faculty of Natural Sciences, Comenius University, Bratislava, Slovakia, ²Geneton Ltd., Bratislava, Slovakia, ³Institute of Clinical and Translational Research, Biomedical Research Centre, Slovak Academy of Sciences, Bratislava, Slovakia, ⁴Faculty of Medicine, Semmelweis University, Budapest, Hungary.

Introduction: Epidermolysis bullosa dystrophica is severe often life and health threatening disease affecting sublamina densa of epiderma-derma junction of the skin. This disorder is caused exclusively by mutations in COL7A1 gene resulting in recessive or dominant condition. While nonsense, frameshift and splicing mutation are characteristic for recessive condition, missense mutations particularly glycine substitution can contribute to either dominant or recessive condition. Currently, more than 300 disease causing variants in COL7A1 are known.

Materials and methods: Mutational analysis was carried out in 11 Hungarian patients with phenotype either autosomal recessive and dominant epidermolysis bullosa dystrophica (DEB) using targeted next generation sequencing followed by variant analysis. We analysed all exons and their flanking regions of COL7A1 gene. Genomic DNA was extracted from peripheral blood leukocytes. DNA library was prepared using transposon based protocol and analysed by massively parallel sequencing on Illumina MiSeq platform. Resulting reads were mapped to human genome hg19 and data were further evaluated using GeneTalk and HGMD database.

Results: MPS analysis of 552 genes in patients with assumed recessive type of EB revealed pathogenic homozygotic mutation (c.425A>G, K142R) in 2 patients, which is prevalent in central Europe. In addition, previously unknown compound heterozygote frameshift, nonsense and missense mutations were found. In dominant EB patients we identified 4 novel missense glycine substitutions and 1 glycine missense mutation previously annotated as pathogenic.

Conclusion: Using gene panel approach and massively parallel sequencing we were able to effectively identify novel mutations in epidermolysis bullosa patients.

P04.047

Farber disease: a growing clinical cohort indicates that acid ceramidase deficiency has a broader clinical spectrum and higher incidence than previously anticipated

A. Solyom¹, C. Simonaro², X. He², E. Schuchman²;

¹Plexcera Therapeutics LLC, New York, NY, United States, ²Icahn School of Medicine at Mt. Sinai, New York, NY, United States.

Farber disease (Farber lipogranulomatosis) represents a broad clinical spectrum presenting from infancy through late childhood, with joint disease (arthritis and/or contractures), subcutaneous nodules and hoarseness associated with the pro-inflammatory and pro-apoptotic characteristics of the lipid ceramide. Farber is caused by mutations in the *ASAH1* gene, which lead to acid ceramidase deficiency, accumulation of ceramide, and a distinct variety of disease phenotypes, culminating in two recognized diseases: Farber disease and Spinal Muscular Atrophy with Progressive Myoclonic Epilepsy

(SMA-PME). The prevalence of both diseases is currently unknown and awareness of them is limited due to their rarity; both are likely underdiagnosed. We have begun collecting data including genotypes, clinical, biochemical and immunologic phenotypes, on a growing cohort of over 30 living Farber patients from around the world. Our findings so far reinforce the validity of the characteristic symptoms of Farber disease (arthritis, nodules, dysphonia). However, it also reveals that there are patients who present with only one or two of these symptoms, and that the spectrum of disease includes remarkably attenuated forms with relatively little associated disability. These insights provide an indication for screening of certain pediatric and young adult polyarticular arthritis patients for acid ceramidase deficiency, and such programs are being initiated. Acid ceramidase enzyme therapy is currently under development, and Plexcera Therapeutics is working with physicians and patients to develop a natural history study framework to better understand disease progression and factors influencing the different phenotypes, as well as what benefits can be derived from currently available anti-inflammatory treatments.

P04.048

Prevalence of fibrodysplasia ossificans progressiva (FOP) in France

R. Choquet¹, C. Messiaen¹, S. Boue², V. Cormier-Daire¹, V. Jeanbat³, K. Le Quan Sang³, A. Rue¹, C. Michot², D. Lapidus⁴, P. Landais⁵, G. Baujat²;

¹Hôpital Universitaire Necker-Enfants Malades, Paris, France, ²Cemka-Eval, Bourg la Reine, France, ³Centre de Référence Maladies Osseuses Constitutionnelles, Paris, France, ⁴LapidusData Inc, Oklahoma City, OK, United States, ⁵Université de Montpellier, Montpellier, France.

Introduction: FOP is rare, severely disabling genetic disorder characterised by heterotopic ossification of muscle and soft tissues. The objective of this study was to estimate the prevalence of FOP in France using data from two national health data collection systems: registry data from CEMARA and medical/administrative data from PMSI.

Materials and Methods: Records in CEMARA and PMSI (for the period 2006-2012) were reviewed for evidence of FOP. Patients who either died before or were born after 01/01/2012 (prevalence date) were excluded.

Results: CEMARA 85 patients with FOP were identified in CEMARA. At the prevalence date, 63 had an FOP diagnosis, 10 had experienced symptoms but had not yet received an FOP diagnosis, and the remaining 12 did not have an available diagnosis date. The prevalence was therefore 1.3 cases per million. The mean age was 29, and the age distribution was as follows: 44%<20, 48% 20-60, and 8%>60.

PMSI

242 patients with the ICD-10 code for FOP were identified in PMSI. The mean age was 42, and the age distribution was as follows: 18%<20, 60% 20-60, and 22%>60. The prevalence of patients with the FOP code was 3.7 cases per million; however, it is unknown whether these patients have a corresponding clinical diagnosis.

Conclusion: This study shows a minimum prevalence of 1.3 cases per million, higher than previous studies demonstrating 0.36/M (Spain) and 0.61/M (UK). A forthcoming study linking the two data sets will help to refine the accuracy of this estimate.

P04.049

Identification by whole exome sequencing of two novel heterozygous mutations in SH3PXD2B gene in a first case of Moroccan patient with frank-ter haar syndrome.

A. Zrhidri¹, I. C. Jaouad^{1,2}, J. Lyahyai¹, L. Raymond³, G. Egea³, M. Taoudi³, S. El Moutassim⁴, A. Sefiani^{1,2};

¹Centre de Génomique Humaine, Faculté de Médecine et de Pharmacie, Mohammed V University in Rabat, Rabat, Morocco, ²Département de Génétique Médicale, Institut National d'Hygiène, Rabat, Morocco, ³Département de Génétique Moléculaire, Laboratoire Biomnis, Lyon, France, ⁴Département de Génétique Moléculaire, Laboratoire Biomnis, Rabat, Morocco.

Introduction: Frank-Ter Haar syndrome (FTHS), also known as Melnick-Needles like syndrome, is an autosomal-recessive disorder characterized by skeletal, cardio-vascular, and eye abnormalities, such as increased intraocular pressure, prominent eyes, and hypertelorism. The most common underlying genetic defect in Frank-Ter Haar syndrome appears to be a mutation in the SH3PXD2B gene on chromosome 5q35.1. Until now, only six mutations in SH3PXD2B gene has been identified. A genetic heterogeneity of FTHS was suggested in previous studies.

Material and Methods: FTHS was suspected clinically in a girl of 2 years old, born from non-consanguineous Moroccan healthy parents. The patient had been referred to a medical genetics outpatient clinic for dysmorphic facial features. Whole exome sequencing was performed in the patient and their parents, in addition to Sanger sequencing that was carried out to confirm

the results obtained by whole exome sequencing.

Results: We report the first description of a Moroccan FTHS patient with two novel compound mutations c.806G>A; p.Trp269Ter (maternal allele) and c.892delC; p.Asp299ThrfsTer44 (paternal allele) in the SH3PXD2B gene. Sanger sequencing confirmed this mutation in the affected girl and demonstrated that their parents carry this mutation in heterozygous state. **Conclusion:** Our results confirm the clinical diagnosis of FTHS in this reported family and contribute to expand the mutational spectrum of this rare disease. Our study shows also, that exome sequencing is a powerful and a cost-effective tool for the diagnosis of a supposed genetically heterogeneous disorder such FTHS.

P04.050

A PheWAS approach in studying genital prolapse

M. B. Khadzhieva^{1,2}, D. S. Kolobkov¹, S. V. Kamoeva³, L. E. Salnikova^{1,2};

¹N.I. Vavilov Institute of General Genetics, Russian Academy of Sciences, Moscow, Russian Federation, ²Federal Research Center of Pediatric Hematology, Oncology and Immunology named after Dmitry Rogachev, Moscow, Russian Federation, ³Pirogov Russian National Research Medical University, Moscow, Russian Federation.

Genital prolapse (GP) is the dropping of the pelvic organs caused by weakness or damage to the normal support of the pelvic floor. We used the PheWAS (Phenome-wide association studies) Catalog for the search of SNPs associated with GP (P-value<0.05). 159 SNPs were found for the GP PheWAS group which consisted of 718 women. These SNPs were assigned to 175 genes with GSA-SNP web server. The enrichment analysis of the PheWAS Catalog gene set associated with GP was performed with KOBAS2.0 resource in comparison with the NHGRI Catalog gene-phenotype associations. We set the minimum number of genes per category to five, and Benjamini-Hochberg FDR corrected P-value<0.10. GP associations corresponded to those found for bone mineral density (BMD) (spine). The most pronounced effect in the series of six genes (*WLS*, *SP7*, *MEPE-HSP90AB3P*, *C6ORF10*, *CCDC170* and *SPTBN1*) related to BMD was observed for the *SP7* gene. The *SP7* rs10876432-A allele has been associated with BMD decrease in the NHGRI GWAS Catalog and with genital prolapse (P=0.006243, OR=1.195) in the PheWAS Catalog. *SP7* controls mesenchymal-stem-cell differentiation; it is a bone specific transcription factor required for osteoblast differentiation and bone formation. Relationship between lower BMD and POP is well-known, with a purported pathophysiological mechanism based on the global collagen dysfunction for both disorders. Since supporting and binding tissues of all sorts are differentiated from common precursors, the role of the genes related to skeletal progenitor differentiation in POP development is plausible.

This work was supported by the Russian Foundation for Basic Research, Project 15-04-02378.

Characterization of germline genotypes in MC1R, ATM and MITF genes in Spanish Giant Congenital Melanocytic nevi patients

J. A. Puig-Butillé^{1,2}, G. Tell^{3,2}, V. Martins da Silva³, K. Jagirdar⁴, M. Potrony⁵, D. L. Duffy⁵, H. P. Soyer^{6,4}, S. Puig^{3,2}, R. Sturm⁴, A. Vicente⁷, M. A. Gonzalez-Ensenyat⁷, J. Malvehy^{3,2};

¹Biochemistry and Molecular Genetics Department, Melanoma Unit, Hospital Clinic & IDIBAPS (Institut d'Investigacions Biomèdiques August Pi i Sunyer), Barcelona, Spain, ²CIBERER, Instituto de Salud Carlos III (ISCIII), Barcelona, Spain, ³Dermatology Department, Melanoma Unit, Hospital Clinic & IDIBAPS (Institut d'Investigacions Biomèdiques August Pi i Sunyer), Barcelona, Spain, ⁴Dermatology Research Centre, School of Medicine, The University of Queensland, Translational Research Institute, Brisbane, Australia, ⁵QIMR-Berghofer Medical Research Institute, Brisbane, Australia, ⁶Department of Dermatology, Princess Alexandra Hospital, Brisbane, Australia, ⁷Clinic of Dermatology, Hospital Universitari Sant Joan de Déu, Barcelona, Spain.

Introduction: Giant congenital melanocytic nevi (GCMN) are rare melanocytic benign tumors associated with neurocutaneous melanosis and risk of melanoma and other malignancies. The genetic cause is likely to be the acquisition of postzygotic alterations. There are evidences of predisposition for GCMN development. We hypothesized that germline variants in melanoma susceptibility genes (MC1R, ATM and MITF) have a role on this predisposition.

Materials and Methods: Analysis of MC1R gene was performed in 21 patients by Sanger sequencing. Evaluation of ATM and p.E318-MITF variant was performed in 76.2% (16/21) of them by CoreExome genotype platform (Illumina). ATM variants were evaluated by ExAC Browser European frequency (EB-E freq) and functional effect (Polyphen and Shift information).

Results:

MC1R variants were detected in 57.1% GCMN patients. Statistically significant differences between patients and control population (N=296) in terms of number of alleles or type (Red hair vs non-Red hair alleles) were

not detected. However, we observed a higher prevalence of patients harboring >1 MC1R variant (19%) compare to control population (9.8%). Moreover, 18.7% (3/16) GCMN patients carry rare ATM variants: p.L1420F (EB-E freq= 0.019; benign/tolerated), p.V410A (EB-E freq= 0.003; benign/deleterious) and p.S333F (EB-E freq= 0.001; possibly damaging/deleterious). In contrast, p.E318K-MITF variant was not detected in the set of patients.

Conclusions: The study suggests that GCMN patients have a higher incidence of MC1R variants and rare ATM variants. Study of a large number of patients is necessary to confirm such findings.

Fundings was provided by FEDASEM, FEDER, Isabel Gemio Research Foundation and Leo Messi Foundation.

P04.052

Cellular and molecular defects in Hermansky-Pudlak syndrome with a novel mutation in HPS5

J. Stephen¹, Y. Tadafumi¹, N. Tolman², K. J. O'Brien¹, B. P. Brooks³, L. Hury³, D. Adams^{2,4}, D. Chen⁵, W. A. Gahl^{1,2,4}, M. V. Malicdan^{2,4}, B. R. Gochuico¹;

¹Medical Genetics Branch, National Human Genome Research Institute, National Institutes of Health, Bethesda, MD, United States, ²NIH Undiagnosed Diseases Program, Common Fund, Office of the Director, National Institutes of Health, Bethesda, MD, United States, ³Ophthalmic Genetics & Visual Function Branch, National Eye Institute, National Institutes of Health, Bethesda, MD, United States, ⁴Office of the Clinical Director, National Human Genome Research Institute, National Institutes of Health, Bethesda, MD, United States, ⁵Division of Hematopathology, Mayo Clinic, Rochester, MN, United States.

Hermansky Pudlak Syndrome (HPS) is a heterogeneous group of genetic disorders that typically manifests with oculocutaneous albinism and bleeding diathesis. HPS is associated with defects in Biogenesis of Lysosome-related Organelle Complexes (BLOCs), a unique group of proteins that function together in the formation and/or trafficking of endo-lysosomal compartments. BLOC-2, for example, consists of three proteins HPS3, HPS5 and HPS6. Here we present a patient with defective BLOC-2 due to a novel mutation in HPS5. Under NHGRI clinical protocol 95-HG-0193, we performed extensive phenotyping in a patient with mild oculocutaneous albinism, easy bruising, absent platelet dense bodies, and no pulmonary fibrosis. Targeted panel sequencing identified a novel homozygous intronic mutation (NM_181507.1:c.285-10A>G) in HPS5 that predicted to activate a cryptic acceptor splice site. RT-PCR analysis showed an insertion of nine nucleotides in the transcript level that predicted to lead to in-frame insertion of three amino acids (p.Ser95_Gln96insSerCysSer) in protein level. Gene expression analysis revealed 60-70% reduction of two shorter transcripts of HPS5 and significantly reduced amounts of HPS5 protein and its interacting partners (HPS3&HPS6). Western blot and immunofluorescence microscopy showed accumulation of early endosomes (EEA1) and altered expression and distribution of late (Rab7) and recycling (Rab11) endosomes and lysosomes (CD63) in patient cells compared to control, affirming pathogenicity of the mutation. Our study broadens the genetic and phenotypic data of HPS subtype 5 and confirms the distinctive role of BLOC-2 in endosome maturation.

P04.053

Pleiotropic effects of noncoding variants near EFEMP1, WT1, ADAMTS6, and EBF2 on the risk of abdominal hernias support an etiological role for collagen and elastin homeostasis in hernia susceptibility

E. Jorgenson¹, N. Makki², K. K. Thai¹, D. C. Chen³, W. L. Eckalbar², A. Avins¹, N. Ahituv²;

¹Kaiser Permanente Division of Research, Oakland, CA, United States, ²University of California, San Francisco, San Francisco, CA, United States, ³UCLA Lichtenstein Amid Hernia Clinic, Los Angeles, CA, United States.

Abdominal hernias are some of the most frequently diagnosed conditions in clinical practice, with more than twenty million hernia repair surgeries performed annually around the world. While family studies suggest that genetic factors play an important role in hernia susceptibility, studies assessing specific genetic risk factors have been limited. Because the risks associated with hernias, specifically, bowel incarceration with a substantial risk of mortality, must be balanced against the risks associated with their treatment, which include chronic pain (6%) and hernia recurrence (10%), there is a clear need for a better understanding of hernia etiology and improved treatment options. We conducted the first large-scale genetic study of hernia risk, identifying noncoding variants at four novel genetic loci underlying the risk of inguinal hernia—the most common type of hernia. We showed that four genes in these loci (EFEMP1, WT1, EBF2, and ADAMTS6) are expressed in mouse connective tissue. We investigated whether risk SNPs in these loci were associated with other abdominal hernia subtypes, specifically, umbilical, femoral, and ventral hernias. We observed significant associations between the EFEMP1 and WT1 loci and each of these subtypes, including a genome-wide significant association between EFEMP1 and ventral hernia

($p = 7.9 \times 10^{-10}$). Pathway analysis suggested that WT1 and EFEMP1 might influence connective tissue maintenance/homeostasis through their action on extracellular matrix enzymes, including matrix metalloproteinases that degrade collagen and elastin fibers. This indicates that these loci affect the risk of hernias across anatomical sites and suggests their mechanism of action may underlie hernia susceptibility more generally.

Introduction: Hypophosphatasia (HPP) is a rare skeletal dysplasia caused by a deficiency in the tissue non-specific alkaline phosphatase enzyme, which is encoded by ALPL. Clinical features ranges from extremely severe phenotype up to moderate adult forms. Modes of Inheritance could be either autosomal dominant or recessive.

Material and Methods: Patients were classified according their first clinical evidence as: i) Intra-uterine and perinatal: Perinatal HPP. ii) After birth and before 6 months of age: Infantile. iii) Between 6 months to 18 years: Childhood and iv) after 18 years old: adult. Sequencing of ALPL has been performed in 49 index patients and eleven familiars. In silico analysis for those mutations without evidence of HPP has been performed.

Results: 37 different mutations have been found in all the 49 patients with HPP. Additionally familial study was positive in the 11 families. Interestingly, we found in 13 patients 11 new mutations that have not been previously related to HPP yet. In silico analysis these 11 mutations have shown a clear pathogenic effect. Cosegregation analysis also supported this idea. Clinical features of these new variants included: 4-adult, 2-childhood, 4-infantile and 3-perinatal HPP.

Conclusions: Although ALPL has been widely studied in Hypophosphatasia, our studies highlighted the possibility to find new undescribed mutations that expands the genotype responsible for HPP and adds clinical information correlated to these new variants that is very useful for molecular diagnosis and also to follow-up patients with HPP because a new enzyme-replacement therapy for HPP has been developed.

P04.055

High diagnostic yield using next generation sequencing in patients with congenital ichthyosis

T. Skodje, J. C. Sitek, K. B. Rypdal, M. A. Kulseth, S. S. Amundsen, E. Nafstad, H. Johnsen, V. Boger, M. Kirkevold, B. Skinningsrud, Y. Sheng, Y. Strahm, L. Retterstål; Oslo University Hospital, Oslo, Norway.

Background: Congenital ichthyosis encompasses a heterogenous group of skin cornification disorders. It is characterized by scaling and hyperkeratosis of the skin. Ichthyosis may be isolated or syndromic. The severity of the disease varies significantly with a clinical spectrum ranging from dry skin to life-threatening conditions. Genes involved in keratinocyte differentiation and skin barrier function are known to cause ichthyosis. A molecular dia-

gnosis establishing the genetic cause may have important clinical implications for prognosis, follow-up, and accurate genetic counseling.

Next Generation Sequencing (NGS) may be a favorable method to reach a molecular diagnosis, due to the complex features of the different ichthyoses, the lack of definite genotype-phenotype profiles, and the high number of genes involved.

Method: Between 2013 and 2015 26 patients clinically diagnosed with congenital ichthyosis were analyzed with NGS. All patients were investigated with a panel of 40 genes using Whole Exome Sequencing with Agilent Sure-Select capture kit on Illumina HiSeq 2500, followed by bioinformatic analysis and filtering.

Results: Pathogenic genetic variants providing a molecular diagnosis were identified in 17 patients (65%).

Conclusion: Performing NGS with a panel of 40 well-established genes seems an efficient method in clinical practice for reaching a molecular diagnosis in patients with congenital ichthyosis.

P04.056

A novel homozygous IFT122 p.I460N (c.1379T>A) mutation in Sensenbrenner syndrome: a rare disorder within two cousins.

I. Akalin¹, N. Elcioglu², Z. Gormez³, C. Candan⁴, S. Yilmaz¹, B. Yuceturk⁵, H. Demirci³, P. Turhan⁴, B. Yukse⁵, M. S. Sagiroglu⁵, S. Ceylaner⁶;

¹Istanbul Medeniyet University, Faculty of Medicine, Department of Medical Genetics, Istanbul, Turkey, ²Marmara University, Faculty of Medicine, Department of Pediatric Genetics, Istanbul, Turkey, ³TUBITAK, Advanced Genome & Bioinformatics Research Center (IGBAM), Kocaeli, Turkey, ⁴Istanbul Medeniyet University, Goztepe Training and Research Hospital, Department of Pediatric Nephrology, Istanbul, Turkey, ⁵TUBITAK, Marmara Research Center, Kocaeli, Turkey, ⁶Intergen Genetic Diagnosis Center, Ankara, Turkey.

Introduction: Cranioectodermal dysplasia (CED) also known as Sensenbrenner syndrome is a rare autosomal recessive heterogeneous ciliopathy primarily characterized by skeletal and ectodermal abnormalities accompanied with progressive renal failure. Genetic heterogeneity has been described with at least 4 associated genes: *IFT122* (606045), *WDR35*(613602), *IFT43*(614068) and *WDR19*(608151) on chromosomes 3q21, 2p24.1, 14q24.3 and 4p14, respectively.

Materials and Methods: We present two cousins with similar phenotype from both consanguineous parents. Whole exome sequencing and analysis was performed by core facility of IGBAM (TUBITAK) using Illumina HiSeq 2000/2500 and HomSI (TUBITAK, Turkey) homozygosity mapping analyses program.

Results: The boys (at 9 and 5 y.o. when referred) presented similar dysmorphic facial appearance (high prominent forehead, frontal bossing, telecanthus, hypertelorism, epicanthal folds, broad nasal bridge, anteverted nares, full cheeks, micrognathia and low-set prominent ears). Skeletal findings were short stature, limb shortening, short ribs, narrow chest, brachydactyly. Ectodermal findings were abnormally shaped teeth, dental fusion, hypo/microdonty, sparse hair, clinodactyly, abnormal nails and skin and joint laxity. Elder patient had progressive renal failure and transplantation is programmed. Both had normal karyotypes: 46,XY.

Using WES, we found novel homozygous missense p.I460N (c.1379T>A) mutation in *IFT122* gene that cosegregated with the disease (transcript ID: ENST00000296266 and p.I200N for transcript id: ENST00000440957). Results were Sanger confirmed.

Conclusions: *IFT122* is essential in cilia development and mutations were prone to Sensenbrenner Syndrome. We report a novel conserved deleterious (Polyphen2, SIFT) homozygous p.I460N (c.1379T>A) mutation unique to these consanguineous families, up to the literature.

Granted by TUBITAK (#:100132) and Ministry of Development (#:2011K120020), Turkey.

P04.057

Co-segregation of both dominant and recessive mode of inheritance in a novel family with IGF1R mutation

M. Willems¹, F. Brioude², C. Amouroux³, C. Jeandel³, L. Hebrard⁴, M. Boubal⁵, O. Prodhomme⁶, M. Al Khoury⁷, D. Genevieve¹, I. Netchine²;

¹Département de Génétique Médicale, Hôpital Arnaud de Villeneuve, Montpellier, France, ²Laboratoire de Biologie moléculaire et d'explorations fonctionnelles endocriniennes, hôpital Armand Trousseau, Paris, France, ³Département d'Endocrinologie Pédiatrique, Hôpital Arnaud de Villeneuve, Montpellier, France, ⁴MPEA, Pedopsychiatrie, Hôpital Saint ELOI, Montpellier, France, ⁵Département de Pédiatrie, Hôpital Arnaud de Villeneuve, Montpellier, France, ⁶Département de Radiologie Pédiatrique, Hôpital Arnaud de Villeneuve, Montpellier, France, ⁷Département de Gastro-enterologie pédiatrique Hôpital Arnaud de Villeneuve, Montpellier, France.

Background: Loss of function mutations in the IGF1 receptor (IGF1R) gene lead to prenatal and postnatal growth retardation associated with insulin

resistance. To date, both dominant and recessive transmissions were reported but without phenotypic expression in heterozygous carriers in families with recessive mode of inheritance.

Methods: We investigated a consanguineous family consisting in two parents and their four children, including the proband, referred for primordial dwarfism. She had prenatal and postnatal short stature and microcephaly below -4SD for height and OFC, moderate developmental delay, feeding difficulties, minor facial features, and normal X-rays. Two children had normal psychomotor development and height at average range. The fourth child had learning difficulties and height at -2SD. Their mother and father's heights were at -2,5 SD. Based on unusual high IGF1 levels in the proband, we performed IGF1R molecular analysis in this family.

Results: An Homozygous missense mutation c.384T>C;p.Phe112Leu was identified in the proband. Both parents and the child having height at -2SD and learning difficulties were heterozygous, whereas both siblings having average height didn't harbour the mutation.

Discussion: To our knowledge, this is the first family described with phenotypic expression in both heterozygous and homozygous carriers of IGF1R mutation. It seems that each pathogenic allele confers a -2SD height and OFC drop associated with learning difficulties, leading to mild phenotype in heterozygous carriers and severe phenotype evoking primordial dwarfism in homozygote carrier. Since this diagnosis requires special care, it is necessary to identify these patients referred for primordial dwarfism by performing IGF1 dosage.

P04.058

Mosaic mutation of KITLG in a non-progressive, congenital, linear naevoid hyperpigmentation

A. Sorlin¹, A. Maruani², Y. Duffourd^{1,3}, P. Kuentz^{1,3,4}, M. Chevarin¹, J. St-Onge¹, T. Jouan¹, C. Thauvin-Robinet^{1,3,5}, L. Faivre^{1,3,5}, J. Rivière^{1,3,4}, P. Vabres^{1,5,6},

¹EA4271 GAD, Université Bourgogne-Franche Comté, Dijon, France, ²Service de Dermatologie, CHU de Tours, Université François Rabelais, Tours, France, ³FHU TRANSLAD, CHU de Dijon et Université Bourgogne-Franche Comté, Dijon, France, ⁴Biologie moléculaire, Plateau Technique de Biologie, CHU Dijon, Dijon, France, ⁵Centre de référence Anomalies du Développement et Syndromes Malformatifs, CHU Dijon, Dijon, France, ⁶Service de Dermatologie, CHU de Dijon, Dijon, France.

Linear and whorled naevoid hypermelanosis (LWNH) consists of hyperpigmented macular swirls and streaks following Blaschko's lines. This condition has often been considered as a nonspecific manifestation of mosaicism. It has sometimes been mistaken with the pigmentary stage of incontinentia pigmenti. In a few patients, various X chromosome rearrangements have been reported, but the molecular basis of LWNH has remained unknown.

We performed deep exome sequencing on skin DNA from a 6 year-old patient with congenital non-progressive linear naevoid hyperpigmentation following Blaschko's lines on his trunk and limbs, without other cutaneous or neurosensory symptoms. We identified a postzygotic heterozygous KITLG c.329A>G (p.Asp110Gly) mutation, confirmed by targeted deep sequencing in skin fibroblasts (28% of reads) and blood (18%).

KITLG (c-KIT Ligand) regulates skin pigmentation through control of melanocyte migration, proliferation and survival, and melanin synthesis. Germline KITLG mutations have been reported in patients with Familial Progressive Hyper- and Hypopigmentation (FPHH), who exhibit early-onset hyperpigmented macules, increasing in size and number until adulthood, hypopigmented macules and larger café-au-lait macules, and recently in patients with isolated hearing loss or Waardenburg syndrome type 2A (congenital hearing loss, pigmentary abnormalities of the hair, skin, and eyes). The p.Asp110Gly mutation is the first reported mosaic mutation of KITLG, in a patient with normal hearing, extending the spectrum of clinical manifestations associated with mutations in KITLG. This is also the first report of a genetic basis for LWNH, which can now - at least in this patient - be considered as a mosaic presentation of a Mendelian disorder, FPHH.

A novel truncating LACC1 mutation in patients with rheumatoid factor-negative polyarticular juvenile idiopathic arthritis

R. Rabionet^{1,2}, A. Remesal³, A. Mensa-Vilaró⁴, S. Murias³, R. Alcobendas³, E. Gonzalez-Roca⁴, O. Drechsel¹, E. Ruiz-Ortiz⁴, A. Puig¹, D. Comas⁵, S. Ossowski¹, J. Jagüé⁴, R. Merino³, X. Estivill¹, J. I. Arostegui¹,

¹Center for Genomic Regulation, Barcelona, Spain, ²Dept. of Genetics, University of Barcelona, Barcelona, Spain, ³Dept. of Pediatric Rheumatology, Hospital la Paz, Madrid, Spain, ⁴Dept. of Immunology-CDB, Hospital Clínic-IDIBAPS, Barcelona, Spain, ⁵8Departament de Ciències Experimentals i de la Salut, Institute of Evolutionary Biology. CSIC-Universitat Pompeu Fabra, Barcelona, Spain.

We observed three siblings from a Moroccan consanguineous family with an early-onset chronic and symmetric arthritis diagnosed as rheumatoid fac-

tor-negative polyarticular juvenile idiopathic arthritis (JIA). Genome-wide SNP genotyping and whole-exome sequencing (WES) were performed in affected and unaffected siblings to identify the causative gene defect.

Four homozygosity regions in chromosomes 3, 6 (n: 2) and 13 were identified as exclusively shared by affected siblings. WES identified three potential candidate variants in these regions: two amino acid substitutions, Pro86Ser in TATDN2 and Asp169Val in FARS2, and a frameshift deletion in the LACC1 gene. Genotyping of 352 healthy Moroccan individuals and bioinformatic analyses supported the frameshift c.128_129delGT variant in the LACC1 gene, leading to a truncated protein (p.Cys43Tyrfs*6), as the most probable causative gene defect in this family. Additional analyses of the LACC1 gene in a group of 23 Spanish sporadic patients with systemic-onset JIA revealed no additional pathogenic mutations.

Our findings show a homozygous truncating LACC1 mutation as the genetic defect underlying a severe inflammatory joint disease that segregated in a family with a recessive mode of inheritance. These evidences expand the clinical phenotype associated with LACC1 mutations to other forms of JIA than the previously described systemic-onset JIA.

P04.060

Loeys-Dietz syndrome 2 might be caused by a new mutation in TGFBR2 gene

A. Khmyrova, O. Agranovich, E. Mikiashvili, S. Vissarionov, V. Larionova;
The Turner's Scientific and Research Orthopedic Institute for Children, Saint-Petersburg, Russian Federation.

The Loeys-Dietz syndrome (LDS) is autosomal dominant disease caused by mutations in TGFBR1, TGFBR2, TGFB2, TGFB3, and SMAD3 genes, characterized by systemic involvement of arterial tortuosity and aneurysms, hypertelorism, bifid uvula or/and cleft palate.

We report on 3.5-year-old male patient with clinical features of LDS. He was born with congenital clubfoot fingers deformations and compensated hydrocephalus. He presented with craniosynostosis, dolichoplagiocephaly, microretrognathia high palate; hypertelorism, blue sclerae, hyperopia; patent foramen ovale of the heart; Increased elasticity of the skin, velvety texture; clinodactyly and camptodactyly of 2nd-5th fingers, flexion contracture with ulnar deviation of 3rd-5th fingers, arachnodactyly; talipes equinovarus, recurvated knee joints; scoliosis, pectus carinatum, straightening of physiological curves of the spine, spina bifida posterior displastica S1-S2; hypermobility, dolichostenomelia, hydrocephalus. Aiming to confirm the diagnosis, we have sequenced genes known to be associated with contractual arachnodactyly, Marfan syndrome, and other congenital diseases with similar clinical features. New mutation was found in exon 6 of TGFBR2 gene (chr3: 30715721G>C) causing an amino acid substitution Arg485Pro (NM_001024847.2). This mutation has not been described in control samples of "1000 genomes", ESP6500, and ExAC. Pathogenicity prediction algorithms defined this mutation as most likely pathogenic (SIFT: 0.000, Polyphen2_HDIV: 1.000, Polyphen2_HVAR: 1.000, MutationTaster: 1.000, PROVEAN: -6.820, LRT: D). Conclusions: Based on clinical features and genetic testing results we proposed that the mutation detected might be pathogenic one causing the Loeys-Dietz syndrome type 2. The proband's relatives did not demonstrate any clinical features, thus this mutation occurred de novo.

P04.061

Novel mutations in LRP6 highlight the role of WNT signaling in tooth agenesis

Devriendt², N. Roeveldt¹, S. N. Jhangiani⁶, L. E. L. M. Vissers¹, J. R. Lupski⁶, J. de Ligt⁷, J. W. Von den Hoff⁸, R. Pfundt¹, H. G. Brunner¹, H. Zhou¹, J. Dixon⁴, E. Mangold⁹, H. van Bokhoven¹, M. Dixon⁴, T. Kleefstra¹, A. Hoischen¹, C. E. L. Carels¹;

¹Radboud University Medical Center, Nijmegen, Netherlands, ²University Hospitals KU Leuven, Leuven, Belgium, ³University of Bonn, Bonn, Germany, ⁴University of Manchester, Manchester, United Kingdom, ⁵University Hospitals KU Leuven, Leuven, Netherlands, ⁶Baylor College of Medicine, Houston, TX, United States, ⁷KNAW and University Medical Center Utrecht, Utrecht, Netherlands.

Introduction: We aimed to identify a novel genetic cause of tooth agenesis (TA) and/or orofacial clefting (OFC), both common and burdensome congenital defects, by combining whole exome sequencing (WES) and targeted re-sequencing in a large cohort of TA and OFC patients.

Materials and methods: WES was performed in two unrelated patients, one

with severe TA and OFC and another with severe TA only. After identifying deleterious mutations in a gene encoding the low density lipoprotein receptor-related protein 6 (*LRP6*) with WES, all its exons were re-sequenced with molecular inversion probes, in 67 patients with TA, 1,072 patients with OFC and in 706 controls.

Results: We identified a frameshift (c.4594delG, p.Cys1532fs) and a canonical splice site mutation (c.3398-2A>C, p.?) in *LRP6* respectively in the patient with TA and OFC, and in the patient with severe TA only. The targeted re-sequencing showed significant enrichment of unique *LRP6* variants in TA patients, but not in nonsyndromic OFC. From the 5 variants in patients with TA, 2 affect the canonical splice site and 3 were missense variants; all variants segregated with the dominant phenotype and in 1 case the missense mutation occurred *de novo*. Additional features in patients with unique *LRP6* variants were short stature (4/7), other dental anomalies (5/7) and clinodactyly (3/7).

LRP6 acts as a co-receptor in the WNT/ β -catenin signaling pathway. Our findings further expand the spectrum of *LRP6* phenotypes and highlight the role of WNT signaling in dental and orofacial development.

Conclusion: Mutations in *LRP6* cause (severe) tooth agenesis.

P04.062

Whole exome sequencing study identifies HSPG2 and MAML1 as novel candidate genes for vertebral bone marrow signal changes (Modic changes)

M. Kraatari^{1,2,3}, S. Skarp^{1,2,4}, J. Karppinen⁵, M. Männikkö^{1,2,4,4},

¹Center for Life Course Health Research, Faculty of Medicine, University of Oulu, Oulu, Finland, ²Center for Cell – Matrix Research, Faculty of Biochemistry and Molecular Medicine, University of Oulu, Oulu, Finland, ³Medical Research Center Oulu, Oulu University Hospital and University of Oulu, Oulu, Finland, ⁴Biocenter Oulu, University of Oulu, Oulu, Finland, ⁵Finnish Institute of Occupational Health, Health and Work Ability, and the Disability Prevention Center, Oulu, Finland.

Introduction: Low back pain (LBP) is a common debilitating condition. It was ranked as top cause for global years lived with disability in all developed countries. Lumbar disc degeneration (LDD) is one of the contributing factors behind low back pain (LBP). Vertebral bone marrow signal changes also known as Modic changes (MC) are a specific phenotype of LDD. MC have heritability of MC is estimated around 30% and strong association with LBP. Materials and Methods: Two Finnish families were studied using whole exome sequencing and traditional genotyping to identify variants co-segregating with MC. We focused on rare (MAF < 0.01) and private variants with harmful in silico predictions and variants located in regulatory regions.

Results: In Family I an insertion and deletion mutation in the heparan sulfate proteoglycan 2 (*HSPG2*) gene, resulting in a premature stop codon, co-segregated with MC. The *HSPG2* encodes structural protein in mammalian cartilage and basement membranes called perlecan. Mutations in *HSPG2* cause rare autosomal recessive disorders with osteochondrodysplasia. Mutations in *HSPG2* have also been associated with idiopathic scoliosis. In the Family II a single nucleotide polymorphism in the *MAML1* gene was identified in all affected family members. *Maml1* knock out mice suffer from impaired chondrocyte maturation. Additionally *MAML1* affects the activity of *RUNX2* transcription factor. *RUNX2* affects the osteoblast differentiation, bone formation and chondrocyte maturation and is highly expressed in the degenerated discs.

Conclusions: We identified two promising candidate genes for MC, *HSPG2* and *MAML1*. Our findings are novel in lumbar spine degenerative phenotypes.

P04.063

TUFT1 - A novel susceptibility gene for metatarsophalangeal arthritis

E. Sliz¹, M. Taipale¹, M. Welling¹, J. Ignatius¹, L. Ruddock¹, R. Nissi², M. Männikkö¹;

¹University of Oulu, Oulu, Finland, ²Oulu University Hospital, Oulu, Finland.

Background: Osteoarthritis (OA) is a common musculoskeletal disease characterized by degeneration of the protective cartilage layer of articulating joints. The first metatarsophalangeal (MTP I) joint is commonly affected by OA, but MTP I OA is poorly studied when compared to hip or knee OA. Nissi et al. reported a Finnish family with 13 out of 52 family members affected by early-onset MTP I OA. The aim of the present study was to identify the genetic defect(s) causing this disorder using exome sequencing.

Methods: Three patients and two healthy non-family members were exome sequenced. Rare variants with harmful prediction that were shared by the patients, but not found from the healthy controls, were validated by Sanger sequencing in four affected and five unaffected family members. The functional role of the identified variant was studied in vitro.

Results: A variant rs41310883 on *TUFT1* introducing Thr175Met substi-

tution was found to co-segregate with the disease. The variant was shown to decrease *TUFT1* expression at both mRNA and protein levels in HEK293 cells. Thr175Met overexpression in ATDC5 cells resulted in increased calcium content and reduced proteoglycans in ECM when compared with overexpression of wild type *TUFT1* and cells with empty vector. Furthermore, ATDC5 cells overexpressing wild type and mutant *TUFT1* displayed reduced expression of marker genes of chondrogenic differentiation and disrupted formation of cartilage nodules during differentiation.

Conclusions: We identified a novel susceptibility gene for MTP I OA. Further studies are needed to fully characterize the role of *TUFT1* in the pathophysiology of OA.

P04.064

Neuromuscular disease as sole symptom in a patient with COMP-related multiple epiphyseal dysplasia: a case report

J. M. Jensen¹, H. Okkels², M. B. Petersen¹, C. K. Lauthrup¹;

¹Department of Clinical Genetics, Aalborg University Hospital, Aalborg, Denmark,

²Section of Molecular Diagnostics, Clinical Biochemistry, Aalborg University Hospital, Aalborg, Denmark.

Multiple epiphyseal dysplasia (MED) is a clinically and genetically heterogeneous group of skeletal dysplasias. MED is characterized by pain particularly in hips and knee joints. Early-onset joint pain usually progress to osteoarthritic degeneration, necessitating total joint arthroplasty. A short stature, waddling gait, and enhanced fatigability are often seen. Mild childhood neuromuscular disorders have previously been reported as a presentation of MED caused by mutations in *COMP*.

Here, we present a striking case of a 68-year-old woman initially diagnosed with myopathy from the age of 50. Throughout life, she exhibited difficulties in more heavy physical activity due to fatigue, but otherwise she had no joint-related symptoms.

The pedigree revealed multiple members diagnosed with early onset arthritis or Legg-Calvé Perthes disease, as well as several members diagnosed with childhood or adult onset of myopathy. Within the family, numerous analyses had been conducted without final molecular diagnosis.

According to the pedigree, an autosomal dominant inheritance was strongly suspected. Molecular analysis of five *MED*-related genes identified a c.2152C>T mutation in the *COMP* gene consistent with the diagnosis of autosomal dominant *MED*.

To our knowledge, this is the first case of *COMP*-related *MED* with myopathy in adulthood without other *MED* characteristic joint symptoms. As patients with *MED* may be wrongly diagnosed with neuromuscular disorders, it is important to be aware of neuromuscular symptoms as a sole symptom in *MED* in all age groups.

P04.065

Myhre syndrome with a full spectrum of cardiovascular and gastrointestinal complications

A. M. Spinelli¹, A. Morgan², E. Rubinato¹, M. C. Pellegrin³, A. Delise³, V. Guastalla³, A. Benetton², I. Bruno², F. Faletra²;

¹University of Trieste and University of Padova, Trieste, Italy, ²Institute for Maternal and Child Health - IRCCS Burlo Garofolo, Trieste, Italy, ³University of Trieste, Trieste, Italy.

Introduction. Myhre syndrome/LAPS is a rare cause of syndromic limitation of the range of joint motion, generally presenting with variable degrees of intellectual disability and short stature. Fifty-six molecularly proven cases have been reported in the medical literature to date.

Clinical report. The patient was born SGA at term as the only child of healthy Italian parents. Paternal and maternal ages at conception were 39 and 31 years respectively. We evaluated the girl at 14 years. Cardinal history findings were delayed motor milestones with normal speech development and a full-scale IQ of 74; mild autistic traits; stiffness gradually involving small and large joints and resulting in pronounced functional impairment of the shoulder girdle and tibiotarsal joints in her early teens; GH deficiency; thelarche variant; bilateral chronic otitis media with effusion leading to tympanosclerosis; marked retinal vessel tortuosity; astigmatism; laryngospasm during procedural sedation. Congenital heart disease (CHD) requiring surgery (tetralogy of Fallot and peripheral pulmonary stenosis) was identified at 2 weeks of age. Her long-standing hepatomegaly, already present at 6 months, and mild protein losing enteropathy might be pathogenetically related to perturbed extracellular matrix homeostasis, as both of them were not significantly modified either by cardiac therapies or, more recently, by constrictive pericarditis. On physical examination stocky build, short palpebral fissures and skin thickening were noted. Direct sequencing of *SMAD4* identified the recurrent *de novo* mutation p.Ile500Val (NM_005359.5:c.1498A>G).

Conclusions. We report a new case of Myhre syndrome whose gastrointestinal features and unusually severe CHD broaden the clinical spectrum of the disease.

P04.066

Myhre to Marfan Syndrome: Two opposite ends of the TGFβ/BMP driven connective tissue disorder spectrum with new evidence for an abnormal fibrotic process in Myhre syndrome

L. J. Starr¹, D. Perry², L. Y. Sakai³, D. Keene³, J. W. Delaney², J. M. Hammel⁴, A. Lin⁴, J. R. Stone⁴, M. E. Lindsay⁴, A. Haskins Olney⁴, J. N. Sanmann¹, A. T. Yetman⁵;

¹University of Nebraska Medical Center, Omaha, NE, United States, ²Children's Hospital and Medical Center, Omaha, NE, United States, ³Shriners' Hospital, Portland, OR, United States, ⁴Mass General Hospital, Boston, MA, United States, ⁵Children's Hospital Medical Center, Omaha, NE, United States.

Patients with either Myhre or Marfan syndrome may have devastating complications of the cardiovascular, pulmonary, and skeletal systems, but with nearly opposite characteristics. Herein we provide thorough phenotypic information on Myhre patients, including the first detailed report of advanced pathologic findings in the heart, lung, and other tissues in the less-understood Myhre syndrome. We provide evidence that an abnormal fibrotic process is occurring in these patients and provide pathologic evidence of the life-threatening abnormal wound healing that leads to restrictive disease. Marfan syndrome, caused by pathogenic mutations in *FBNI*, involves dysregulation of TGFβ/SMAD pathways and is characterized by long bone overgrowth, joint laxity, cystic lung disease and aortic dilation. Myhre syndrome, caused by mutations in one of two codons in *SMAD4*, is a condition in which patients have short long bones, compact body habitus with tightening of the joints, hearing loss and thickening of tissues. As we describe, this thickening includes cardiac and lung tissue, which can cause restrictive disease. Although undoubtedly underdiagnosed in the past, greater awareness of this condition and the availability of clinical whole exome sequencing have resulted in a rapid increase in the number of reported patients with Myhre syndrome.

We provide the first reported images and descriptions of Myhre tissue, demonstrating an abnormal healing process, which involves proliferative fibrosis and adhesions. We propose screening protocols for patients with Myhre syndrome and recommend restricting instrumentation and elective procedures for these patients to prevent significant morbidity and mortality.

Targeted next-generation sequencing provides novel insights into the genetic basis of amelogenesis imperfecta

M. Prasad¹, H. Dollfus^{1,2}, A. Bloch-Zupan^{3,4};

¹Laboratoire de Génétique Médicale, INSERM U1112, Fédération de Médecine Translationnelle de Strasbourg (FMTS), Institut de Génétique Médicale d'Alsace, Université de Strasbourg, Strasbourg, France, ²Centre de Référence pour les Affections Rares en Génétique Ophtalmologique, Service de Génétique Médicale, HUS, Strasbourg, France, ³Université de Strasbourg, Faculté de Chirurgie Dentaire; Hôpitaux Universitaires de Strasbourg (HUS), Pôle de Médecine et Chirurgie Bucco-dentaires, Centre de Référence des Manifestations Odontologiques des Maladies Rares, Strasbourg, France, ⁴Institut de Génétique et de Biologie Moléculaire and Cellulaire, Centre Européen de Recherche en Biologie et en Médecine, Université de Strasbourg, CNRS UMR7104, INSERM U964, Illkirch, France.

Amelogenesis imperfecta (AI) is a clinically and genetically heterogeneous group of diseases characterised by enamel defects. To date, mutations in >20 genes have been implicated in either isolated or syndromic AI. We used a next-generation sequencing (NGS) panel targeting 585 known or candidate genes in dental disorders to screen a cohort of 61 patients with isolated and syndromic forms of AI. We were able to identify the molecular defect underlying the patients' phenotypes in 15 cases (~25%), suggesting that several additional genes mutated in AI remain to be discovered. Interestingly, mutations in COL17A1 were the most frequent cause of isolated AI in our cohort, accounting for 8% of patients with isolated AI. Furthermore, NGS-based screening of multiple AI genes allowed us to identify a rare case of digenic inheritance in AI, with unlinked heterozygous mutations in COL17A1 and LAMA3 modifying the severity of the phenotype. Finally, sequencing in a seven-year-old patient presenting with isolated AI revealed the presence of a homozygous missense mutation in CNNM4, mutations in which result in Jalili syndrome, a diagnosis that was subsequently confirmed by ophthalmological investigation. Therefore, we demonstrate that a large proportion of the genetic heterogeneity of AI remains unsolved and that non-Mendelian inheritance patterns exist in AI. We also demonstrate that the dental clinic may be a gateway for the diagnosis and management of rare genetic disorders. This EU-funded project (ERDF) A27 „Oro-dental manifestations of rare diseases“ is supported by the RMT-TMO Offensive Sciences initiative, INTERREG IV and INTERREG V RARENET programs. www.genosmile.eu.

Nine novel mutations in NF1 gene in patients with Neurofibromatosis type 1

C. Martinez-Bouzas^{1,2}, M. A. Lopez-Ariztegui^{1,2}, I. Llano-Rivas^{1,2}, M. Garcia-Barcina³, R. Saez⁴, H. Maortua^{1,2}, B. Gener^{1,2};

¹Department of Genetics, OSI Euzkerraldea-Enkarterri-Cruces, BioCruces Health Research Institute, Cruces, Vizcaya, Spain, ²GCV-CIBER de Enfermedades Raras (CIBERER-ISCIH), Madrid, Spain, ³Genetics Unit. OSI Bilbao-Basurto, Bilbao, Vizcaya, Spain, ⁴Genetics Unit. OSI Donostialdea, San Sebastian. Guipuzkoa, Spain.

Neurofibromatosis type 1 (NF1) is a clinically heterogeneous genetic disorder characterized by café-au-lait spots, iris Lisch nodules, axillary and inguinal freckling, and multiple neurofibromas. It is caused by dominant loss of function mutations in the suppressor gene *NF1* that encodes for neurofibromin that functions as a negative regulator of RAS activity signalling.

In the present study we report clinical and molecular findings of 14 patients (6 unrelated and 7 from 3 families). We screened DNA and RNA isolated from peripheral blood leucocytes from patients that fulfil clinical criteria for NF1. In addition, single and multi-exon deletions/duplications screening was performed by MLPA (Kits P81, P82 and P122). The entire *NF1* gene coding region was PCR amplified from total cDNA in several overlapping fragments, and sequenced afterwards.

We identified 9 novel mutations 6 of those were *de novo*: c.1218_1224delTCACTAT; c.1569delA; c.6752delG; c.3975-?_8457+?del, r.1722_1748del27 and c.7044G>A (p.Gly23478Stop). The c.6987del24 causes a frameshift mutation which co-segregates with the clinical phenotype in family one. The missense mutations c.3965A>G (p.Asp1322Gly) and c.4972A>G (p.Ile1658Val) is considered likely pathogenic *in silico* analysis and in 2 families co-segregate with the clinical phenotype in the proband and in at least one affected relative.

Besides, clinical follow-up is being performed in patient less than 4 years old with the *de novo* missense variation c.2188A>T (p.Asn730Tyr) despite it is considered likely benign *in silico* analysis who shows already five café-au-lait spots.

This study expands the database for NF1 mutations in patients with neurofibromatosis type 1.

P04.069

The non-coding RNA, PRINS regulates IL-6 production of human keratinocytes

J. Danis¹, A. Göblös¹, Z. Bata-Csörgő^{1,2}, L. Kemény^{1,2}, M. Szélf²;

¹University of Szeged, Dept of Dermatology and Allergology, Szeged, Hungary, ²MTA-SZTE Dermatological Research Group, University of Szeged, Szeged, Hungary, ³University of Szeged, Dept of Medical Genetics, Szeged, Hungary.

The previously identified non-coding RNA, PRINS, is differentially expressed in psoriatic uninvolved and healthy epidermis. Our *in vitro* experiments in keratinocytes showed that PRINS expression is altered after exposure to various stressors i. e. UVB, translation inhibition and microbial agents. A recently described potential stress signal in psoriatic involved skin may be the extracellular DNA, a potent activator of several inflammatory pathways, but its involvement in PRINS signaling was not studied before.

The aim of our study was to investigate which pathways are induced in keratinocytes by extracellular DNA, and whether PRINS is able to affect the induced inflammatory reactions, thereby its high expression in psoriatic uninvolved epidermis may contribute to disease pathogenesis.

The synthetic DNA analogue poly(dA:dT) induced PRINS expression and the production of psoriasis associated cytokines IL-6, IL-8, IL-12, IL-23 and TNF-α. Cytokine production was mediated through NFκB-, STAT3- and MAPK- pathways in keratinocytes. To study the role of PRINS in the poly(dA:dT) induced cytokine production we silenced or forced its expression by vector based methods. Robust overexpression of PRINS reduced poly(dA:dT) induced IL-6 and IL-8 production on mRNA as well as protein level, but did not affect the production of the other investigated cytokines. *In silico* analysis revealed an approximately 100 nucleotide long complementary region between PRINS and IL-6, suggesting the direct interaction between the two RNA molecules. According to our result we propose that PRINS might act as a regulator of IL-6 production through the interaction with IL-6 mRNA, leading to the degradation of it.

P04.070

Loss-of-Function mutations in the WNT co-receptor LRP6 cause autosomal-dominant oligodontia

M. P. G. Massink¹, M. A. Créton¹, F. Spanevello¹, W. M. Fennis¹, M. S. Cune², S. M. Savelberg³, I. J. Nijman¹, M. M. M. Maurice¹, M. van den Boogaard¹, G. van Haften¹;
¹University Medical Center Utrecht, Utrecht, Netherlands, ²University Medical Center Groningen, Groningen, Netherlands.

Introduction: Tooth agenesis is one of the most common developmental anomalies in man. Oligodontia, a severe form of tooth agenesis, occurs both as an isolated anomaly and as a syndromal feature.

Materials and Methods: We performed exome sequencing on 20 unrelated individuals with apparent non-syndromic oligodontia and failed to detect mutations in genes previously associated with oligodontia.

Results: In three of the probands, we detected heterozygous variants in LRP6, and sequencing of additional oligodontia-affected individuals yielded one additional mutation in LRP6. Three mutations (c.1144_1145dupAG [p.Ala383Glyfs(*8)], c.1779dupT [p.Glu594(*)], and c.2224_2225dupTT [p.Leu742Phefs(*7)]) are predicted to truncate the protein, whereas the fourth (c.56C>T [p.Ala19Val]) is a missense variant of a conserved residue located at the cleavage site of the protein's signal peptide. All four affected individuals harboring a LRP6 mutation had a family history of tooth agenesis. LRP6 encodes a transmembrane cell-surface protein that functions as a co-receptor with members from the Frizzled protein family in the canonical Wnt/ β -catenin signaling cascade. In this same pathway, WNT10A was recently identified as a major contributor in the etiology of non-syndromic oligodontia. We show that the LRP6 missense variant (c.56C>T) results in altered glycosylation and improper subcellular localization of the protein, resulting in abrogated activation of the Wnt pathway.

Conclusions: Our results identify LRP6 variants as contributing to the etiology of non-syndromic autosomal-dominant oligodontia and suggest that this gene is a candidate for screening in DNA diagnostics. This work was supported the Netherlands Organization for Scientific Research NWO (VICI grant to M.M.M.).

A novel de novo Mutation in Frizzled2 gene in a patient with an autosomal dominant Omodysplasia

S. Türkmen^{1,2}, M. Spielmann^{2,3}, N. Günes⁴, R. Flöttmann², S. Mundlos^{2,3}, B. Tüysüz²;
¹Labor Berlin Charité Vivantes, Berlin, Germany, ²Charité Institute of medical Genetics, Berlin, Germany, ³Max Planck Institute for Molecular Genetics, Berlin, Germany, ⁴Department of Pediatric Genetics, Cerrahpaşa Medical School, Istanbul University, Istanbul, Turkey.

Omodysplasia-2 (OMOD2; OMIM #164745) is a rare autosomal dominant skeletal dysplasia characterized by shortened humeri, shortened first metacarpal, and craniofacial dysmorphism including depressed nasal bridge, broad base of the nose, and long philtrum. Recently a de novo heterozygous nonsense mutation (p.Trp548*) in the Frizzled2 (FZD2) gene was shown to cause autosomal dominant omodysplasia syndrome. Here we present the clinical and molecular genetic data of a Turkish patient with OMOD2 in whom the whole exome sequencing revealed a novel second mutation in the FZD2 gene. This is the published second mutation in the literature. This data support the findings of Haal et al and point that the heterozygous FZD2 is the cause of OMOD2.

P04.072

Polymorphisms in the Osteoprotegerin gene are associated with bone mineral density and fracture risk in Maltese postmenopausal women

M. M. Formosa, A. Xuereb-Anastasi;
 Department of Applied Biomedical Science, Faculty of Health Sciences, University of Malta, Msida, Malta.

Introduction: Osteoprotegerin (OPG) is a decoy receptor for the Receptor activator of nuclear factor kappa-B ligand (RANKL), which blocks the interaction between RANKL and RANK thereby inhibiting osteoclastogenesis and bone resorption. Four polymorphisms within the OPG gene, and one polymorphism located 43kb upstream of OPG were analysed in relation to bone mineral density (BMD) and low-trauma fractures in Maltese postmenopausal women.

Methods: A case-control collection of 1045 women was used. Cases were women who suffered a fracture, whereas controls had no fracture history. Genotyping was performed by polymerase chain reaction followed by restriction fragment length polymorphism or real-time PCR.

Results: Homozygosity for the A163G minor allele G was associated with lower spine BMD (adjusted OR: 2.6 [95% confidence interval 1.0-7.0]) relative to research subjects with a normal BMD. Women carrying two copies of

the minor allele for the T950C, G1181C and rs2062377 variants had an increased fracture risk which was independent of BMD (adjusted OR: 2.7 [1.2-6.5], 2.7 [1.2-6.6], 2.4 [1.1-7.0] respectively). The same variants increased wrist and humerus fracture risk. No association with BMD or fractures was seen for the T245G variant. Haplotype-based analysis revealed that the haplotype block containing all major alleles was protective for fractures (OR: 0.7 [0.5-0.8]), whereas that containing the minor allele for the T950C and G1181C variants increased fracture risk by 3-fold, highlighting the possibility that the effect of the rs2062377 could be through linkage with these polymorphism.

Conclusion: OPG gene polymorphisms predispose to reduced BMD or increased fracture susceptibility in Maltese postmenopausal women.

Changes in telomere position effect contribute to primary osteoarthritis

L. Kuszel¹, T. Trzeciak², B. Begier-Krasinska³, J. Eastwood⁴, M. Richter², J. Zhang⁵, V. Dasa⁶, M. Czarny-Ratajczak^{1,4};

¹Department of Medical Genetics, Poznan University of Medical Sciences, Poznan, Poland, ²Department of Orthopedics and Traumatology, Poznan University of Medical Sciences, Poznan, Poland, ³Department of Hypertensiology, Angiology and Internal Diseases, Poznan University of Medical Sciences, Poznan, Poland, ⁴Tulane Center for Aging, Department of Medicine, Tulane School of Medicine, New Orleans, LA, United States, ⁵Thermo Fisher Scientific, Waltham, MA, United States, ⁶Department of Orthopedic Surgery, Louisiana State University Health Sciences Center, New Orleans, LA, United States.

Introduction: Osteoarthritis is one of the most debilitating diseases involving degeneration of the articular cartilage of joints and causing disabilities, especially in the elderly population. Genetic and epigenetic factors contribute to development of primary osteoarthritis. In this study we analyzed the consequences of telomere shortening on cartilage transcriptome in patients with osteoarthritis. The silencing effect of telomeres on genes located nearby is known as telomere position effect and the aim of our study was to determine if telomere shortening causes changes in expression of these genes. **Materials and Methods:** We analyzed patients with knee osteoarthritis and utilized unaffected and affected cartilage, collected from the same joint of each patient during total joint replacement surgery. We measured relative telomere length in chondrocytes obtained from 50 patients with qPCR. Additionally, analysis of 20 cartilage transcriptomes was completed via RNA-Seq on Ion Proton in 10 patients with osteoarthritis. RNA-Seq data were analyzed with STAR, Bowtie2, HTSeq and R.

Results: Analysis of relative telomere length in 50 patients with osteoarthritis revealed severe shortening of telomeres in affected cartilage compared to unaffected cartilage. Analysis of cartilage transcriptomes showed significant enrichment in differentially expressed genes from the telomere-proximal regions of all chromosomes in the cartilage with telomere shortening.

Conclusions: Our results show that telomere shortening affects telomere position effect and contributes to osteoarthritis pathology through changes in the cartilage transcriptome of telomere-proximal genes.

Acknowledgments: This research was funded by a grant from the National Science Centre 2011/03/B/NZ2/06409 and NIH (NIGMS) grant P20GM103629:552729.

What may be hidden behind a clinical diagnosis of OI

S. Ivanov¹, R. Vazharova^{1,2}, L. Balabanski¹, S. Andonova³, M. Malinov¹, A. Savov³, D. Toncheva^{1,4};

¹GARH Malinov, Genomic Laboratory, Sofia, Bulgaria, ²Sofia University St. Kliment Ohridski, Sofia, Bulgaria, ³UHOG Maichin dom, National genetic laboratory, Medical University Sofia, Sofia, Bulgaria, ⁴Department of Medical Genetics, Medical University Sofia, Sofia, Bulgaria.

Introduction: Establishing proper diagnosis is critical for therapeutic treatment and reproductive planning of patients and families affected by rare monogenic disorders. NGS gives opportunity to shorten the way to reliable diagnosis and to enable correct genetic counseling. Here we report a rare case of male with severe X-linked hypophosphatemic rickets who was believed to be affected with Osteogenesis imperfecta (OI) for 32 years. The patient sought confirmation of the clinical diagnosis by DNA testing during the first pregnancy of his wife.

Materials and methods: Analysis of patient's genomic DNA was performed using TruSight One gene panel on the Illumina MiSeq system and confirmed by Sanger sequencing.

Results: Patient's diagnosis was believed to be Osteogenesis imperfecta type 1 based mainly on observation of 11 long bones fractures during childhood, asymmetric legs shortening and short adult height. No fractures have been observed after puberty. During one hospitalization for surgical treatment increased level of serum parathyroid hormone was registered but no further

tests have been performed. NGS testing revealed no mutations in all known genes implicated in OI, but a rare probably pathogenic missense variant in PHEX gene (p.Pro401Leu). Further laboratory tests of blood and urine confirmed diagnosis of X-linked hypophosphatemic rickets.

Conclusion: Phenotypic variability is well-known feature of many genetic disorders, may cause misdiagnosis and even mistreatment of patients. NGS technology gives opportunity to resolve at early stage such complex cases and correct patient's medical management.

Absence of the ER cation channel *TMEM38B*/TRIC-B disrupts intracellular calcium homeostasis and dysregulates collagen synthesis in recessive osteogenesis imperfecta

J. C. Marini¹, W. A. Cabral¹, M. Ishikawa^{2,3}, E. N. Makareeva⁴, B. M. Sargent¹, M. Weis⁵, A. M. Barnes¹, E. A. Webb^{6,7}, N. J. Shaw⁷, L. Ala-Kokko⁸, F. L. Lachawan^{9,10}, W. Högl^{6,7}, S. Leikin¹, D. R. Eyre², Y. Yamada²;

¹Section on Heritable Disorders of Bone and Extracellular Matrix, NICHD, NIH, Bethesda, MD, United States, ²Molecular Biology Section, NIDCR, NIH, Bethesda, MD, United States, ³Present Address: Department of Restorative Dentistry, Division of Operative Dentistry, Tohoku University, Graduate School of Dentistry, Sendai, Japan, ⁴Section on Physical Biochemistry, NICHD, NIH, Bethesda, MD, United States, ⁵Department of Orthopaedics and Sports Medicine, University of Washington, Seattle, WA, United States, ⁶School of Clinical and Experimental Medicine, Institute of Biomedical Research, University of Birmingham, Birmingham, United Kingdom, ⁷Department of Endocrinology and Diabetes, Birmingham Children's Hospital, Birmingham, United Kingdom, ⁸Connective Tissue Gene Tests, Allentown, PA, United States, ⁹Department of Medical Genetics, Children's National Medical Center, Washington, DC, United States, ¹⁰Present Address: Molecular Genetics Pathology Section, Department of Molecular Pathology, Robert Tomsich Pathology and Laboratory Medicine Institute, Cleveland Clinic, Cleveland, OH, United States.

Introduction: Type XIV osteogenesis imperfecta (OI) is a novel form of moderately severe OI caused by null mutations in *TMEM38B*. *TMEM38B* encodes the ER membrane monovalent cation channel, TRIC-B, proposed to counterbalance IP₃R-mediated Ca²⁺ release from intracellular stores. However, the molecular mechanisms by which *TMEM38B* mutations cause OI are unknown.

Methods: We identified 3 probands with recessive mutations in *TMEM38B* and investigated calcium signaling and collagen synthesis in proband fibroblasts and osteoblasts.

Results: TRIC-B protein is undetectable in proband fibroblasts and osteoblasts, although *TMEM38B* transcripts are present at 19-86% of control levels. TRIC-B deficiency causes impaired release of ER luminal Ca²⁺, associated with deficient store-operated calcium entry, despite normal stability of SERCA and IP₃R, the channels for ER Ca²⁺ uptake and release, respectively. Disturbed Ca²⁺ flux is consistent with ER stress and increased BiP. In the absence of TRIC-B, synthesis of type I collagen is dysregulated at multiple steps. Collagen helical lysine hydroxylation is reduced despite increased LH1, and telopeptide hydroxylation is increased despite decreased Ca²⁺-dependent FKBP65. Although PDI levels are maintained, procollagen chain assembly is delayed in proband cells. The resulting misfolded collagen is substantially retained in TRIC-B null cells, consistent with a 50-70% reduction in secreted collagen. Lower-stability forms of collagen that elude proteosomal degradation are not incorporated into extracellular matrix, resulting in matrix insufficiency.

Conclusions: These data support a role for TRIC-B in intracellular Ca²⁺ homeostasis, and demonstrate that absence of *TMEM38B* causes OI by dysregulation of multiple Ca²⁺-regulated collagen-specific chaperones and modifying enzymes in the ER.

P04.077

Familial case of osteogenesis imperfecta with three variants of clinical interest.

J. López¹, S. Franco², S. Carmona¹, C. Torres¹, J. Lezana¹, I. Diez¹, M. Ruíz¹, C. Benito², C. Sánchez¹, J. López-Siles¹;

¹M.G.C. Genetaq, Málaga, Spain, ²Fetal-Maternal Hospital, Málaga, Spain.

Introduction. We show a consanguineous family case with diagnosis of osteogenesis imperfecta (OI). The two siblings exhibited multiple bones fractures and *valgus* foot, compatible with OI type I. No relatives had clinical features of the disease.

Materials and methods. The sibling with the most severe clinical findings was selected for the sequencing of all genes (14) associated with OI so far. Targeted genes were captured and amplified using TruSight One library and sequenced by NextSeq (Illumina).

Results. Three variants of clinical interest were detected in heterozygous state in the proband:

Gene	Variant	Accession number (HGMD / NCBI)	Classification
<i>COL1A1</i>	c.1249C>T (p.Pro417Ser) ^(*)	-	Variant Of Unknown clinical Significance (VOUS)
	c.3564_3572dupCCCTGGTC	CI013220	Pathogenic
<i>COL1A2</i>	c.3313G>A (p.Gly1105Ser)	CM123314/rs139851311	Likely pathogenic

^(*)Without literature information.

The familial analysis of these variants was:

- Proband's brother: the same genotype as the proband.
- Proband's father: the same genotype as the proband.
- Proband's mother: c.1249C>T and c.3313G>A. Heterozygous state.
- Paternal aunt 1: c.3313G>A. Heterozygous state.
- Paternal aunt 2: no mutations.

Conclusions. According to the evidences for the segregation and clinical findings, the mutation c.3564_3572dupCCCTGGTC in *COL1A1* gene could be the molecular cause of the pathology, and it could be in somatic mosaicism in the proband's father. The previously considered deleterious variant c.1249C>T, according to HGMD database, and the VOUS c.3313G>A seem not to be the molecular cause of the clinical findings in this family.

P04.078

Prenatal diagnosis of the Otopalatodigital Spectrum Disorders: a case report

M. Mijovic¹, G. Cuturilo^{1,2}, A. Miletic¹, J. Ruml¹, N. Borlja¹;

¹University Children's Hospital, Department of Medical Genetics, Belgrade, Serbia,

²Faculty of Medicine, University of Belgrade, Belgrade, Serbia.

Introduction: The otopalatodigital (OPD) spectrum disorders are characterized primarily by skeletal dysplasia, inherited in an X-linked manner. In recent years, the interest in the fetal phenotypes in OPD spectrum disorders has been increased. The couple has been admitted to our genetic outpatient clinic during the second pathological pregnancy. The first pregnancy was completed by giving birth to a male newborn, who died after a few days, due to poor postnatal adaptation and respiratory complications. The newborn had skeletal dysplasia with broad thumbs and cleft soft palate. The Rubinstein-Taybi syndrome had previously been diagnosed in other institution. In the second pregnancy, with male fetus, the following anomalies have been discovered by ultrasound: low-set ears, microretrognathia, widely spaced eyes, small trunk and anomalies of the thumbs, fingers and carpal bones. Mother has telecanthus, and her healthy daughter has mild hypertelorism and mandibular hypoplasia.

Materials and Methods: Genomic DNA was extracted from fetal blood sample. We performed next generation sequencing and analysis of genes related to clinical presentation observed in patient, primarily *FLNA* gene.

Results: We identified the hemizygous variant c.620C>T (NM_001110556.1) in *FLNA* gene, which causes a substitution of aminoacid proline with aminoacid leucine in position 207. The variant has previously been reported as pathogenic in cases OPD1 (OMIM:300017.0009, ClinVar).

Conclusion: Some typical radiological and craniofacial findings in OPD spectrum disorders allow prenatal diagnosis. Molecular diagnosis is useful for refining the clinical diagnosis according to the type and location of *FLNA* mutation and for completing genetic information of the family.

P04.079

Frequent genetic disorder associated with premature loss of teeth

I. S. M. Sayed¹, T. Elbadry¹, M. I. Mostafa¹, M. R. Abouzaid¹, N. F. Hassib¹, H. A. Elsadek¹, N. M. Ahmed¹, M. A. Ibrahim¹, M. I. Mehrez¹;

¹Orodontal Genetics department, National Research Centre, Dokki, Egypt.

Introduction: Premature loss of teeth is one of the features of some genetic disorder. The aim of this retrospective study is to determine the most frequent genetic disorders associated with premature loss of teeth.

Materials and Methods: The patients were selected from data record of the outpatients clinic of the Orodental Genetics department, National Research Centre, Giza, Egypt over a period of three years.

Results: The most frequent genetic disorders associated with premature loss of teeth were Papillon Lefevre syndrome and Congenital insensitivity to pain with anhidrosis. One of the characteristic features of Papillon-Lefevre Syndrome is early-onset aggressive periodontitis that affects both the primary and permanent dentitions and leads to early loss of teeth. Congenital insensitivity to pain with anhidrosis is a disorder characterized by lack of sensation to painful stimuli and self mutilating behavior which results in

autoextraction and premature loss of teeth.

Conclusions: Papillon-Lefevre Syndrome followed by Congenital insensitivity to pain with anhidrosis were the most frequent genetic disorders associated with premature loss of teeth and we report that both diseases may share similar clinical pictures and they should be included in the differential diagnosis of premature loss of teeth.

P04.080

A novel homozygous nonsense mutation in the calpastatin (CAST) gene associated with peeling skin phenotype in a Turkish child

S. G. Temel^{1,2}, H. Sarıcaoğlu³, B. Turkgenç^{4,5}, U. Kiran³, B. Erguner⁶, B. Yuceturk⁶, M. Sagiroğlu⁶, H. Demirci⁶, M. Yalciner⁷;

¹University of Near East, Faculty of Medicine, Department of Histology & Embryology, Lefkosa, Cyprus, ²University of Uludag, Faculty of Medicine, Department of Histology & Embryology, Bursa, Turkey, ³University of Uludag, Faculty of Medicine, Department of Dermatology, Bursa, Turkey, ⁴Marmara University, Faculty of Medicine, Department of Medical Biology and Genetics, Istanbul, Turkey, ⁵University of Acibadem, Acibadem Genetic Diagnostic Center, Istanbul, Turkey, ⁶Advanced Genomics and Bioinformatics Research Group (IGBAM) TÜBİTAK BİLGEM UEKAE, Gebze/Kocaeli, Turkey, ⁷University of Acibadem, Faculty of Arts and Sciences, Department of Molecular Biology and Genetics, Istanbul, Turkey.

Peeling skin syndrome (PSS) is characterized by continuous shedding of the stratum corneum of the epidermis with onset from birth or infancy and lasting throughout life. Skin peeling can be accompanied by erythema, vesicular lesions, or other ectodermal features including fragile hair and nail abnormalities. PSS can be divided into acral and generalized PSS. We report a 5.5 year old boy who initially presented with skin fragility. He was the first-born of IVF twins from a consanguineous marriage at 33+5 week gestational age with hypotonia at birth. Clinical findings included fragile skin, woolly hair, sparse eyelashes and brows, palmoplantar punctate keratoderma, follicular hyperkeratosis, knuckle pads and cheilitis. Moreover mild cerebral atrophy and mild muscle involvement were observed on his MRI and NCV/EMG, respectively. His aunt also had similar clinical features but in milder form with in addition nail dystrophy. Exome sequencing revealed a homozygous c.544G>T (p.Glu182*) nonsense mutation in the CAST gene. The segregation of this rare variant in the family was confirmed by Sanger sequencing. This novel stop-gain E182X variant produces a truncated protein lacking inhibitory domains II-IV. CAST is an endogenous specific inhibitor of calpain, a calcium-dependent cysteine protease. Recently, autosomal recessive loss of function mutations in CAST were described in PLACK syndrome characterized by generalized peeling skin, leukonychia, acral punctate keratoses, cheilitis, and knuckle pads. As far as we know our case is the fifth case of PLACK syndrome without leukonychia but with some additional previously unreported associated features including mild cerebral atrophy and muscle involvement.

P04.081

Epidermolysis bullosa simplex versus peeling skin syndrome

N. Nagy^{1,2,3}, K. Farkas², A. Sulák¹, K. Tripolszki¹, L. Kemény^{2,3}, M. Széll^{1,2};

¹University of Szeged, Dept of Medical Genetics, Szeged, Hungary, ²MTA-SZTE Dermatological Research Group, Szeged, HUNGARY, Szeged, Hungary, ³Department of Dermatology and Allergology, University of Szeged, Szeged, Hungary.

Introduction: Localised epidermolysis bullosa simplex (EBS, OMIM 131800) is a rare monogenic skin disease featured by development of blisters on the hands and feet. Acral peeling skin syndrome (APSS, OMIM 609796) is a monogenic condition characterized by superficial painless peeling of the skin predominantly on the dorsal aspects of hands and feet. In this study, we investigated a Hungarian patient, whose clinical symptoms suggested the localised form of EBS.

Materials and methods: After informed consent was given, genetic investigations have been performed in order to identify the causative genetic abnormality responsible for the development of the skin symptoms.

Results: Mutation screening with direct sequencing of the coding regions and the flanking introns of the keratin 5 and keratin 14 genes detected only wild type sequences. Since the clinical symptoms of localised EBS and APSS may overlap with each other, mutation screening of the transglutaminase 5 (TGM5) gene has also been performed. Two missense mutations have been detected in heterozygous form: one is a novel mutation (p.Trp143Arg) and one is a recurrent mutation (p.Gly113Cys) of the TGM5 gene.

Conclusions: Taken together, we report that patient with clinically suspected EBS carried TGM5 mutations and in fact suffered from APSS. Our study give further insight into the understanding of the underlying genetic background of those patients whose have been diagnosed with localised EBS, but the disease-causing mutation could not be identified with the screening of the classical EBS genes.

P04.082

Clinical study of 459 polydactyly cases in China, 2010 to 2014

Y. Xiang, J. Bian, Z. Wang, Y. Xu, Q. Fu;

Shanghai Children's Medical Center, Shanghai, China.

Background: Polydactyly is one of the most common hereditary limb malformations, involving additional digits on the hands and/or feet, which is a very attractive model to appreciate clinical and genetic heterogeneity. A high level of heterogeneity in polydactyly has been identified in different regions. However, such data of the medical literature for Asian populations is relatively less.

Methods: This study was intended to shed light on the phenotypic manifestations of polydactyly in the recruited Chinese population and to characterize the medical literature on this condition. A total of 459 well-characterized polydactyly cases from Shanghai Children's Medical Center were recruited. Their phenotypes, inheritance patterns, and clinical heterogeneity were obtained from clinical medical records.

Results: It was found that 4.8% of cases were familial and 95.2% were sporadic. The proportions of preaxial and postaxial polydactyly types were 74.7% and 25.3%, respectively. In preaxial polydactyly, type I formed the overwhelming majority (95.9%). Among the postaxial polydactyly cases, type A was most prevalent at 69.8% and type B was witnessed in 30.2% of cases. Familial and sporadic polydactyly patients mainly had unilateral presentations. A total of 583 limbs with additional digits were recorded in the 459 subjects. Upper limb involvement was more common than lower, and right hand involvement was more common than left for preaxial polydactyly, and lower limb involvement was more common than upper in postaxial polydactyly.

Conclusions: This cohort adds useful clinical/epidemiological information to the polydactyly literature in the Chinese population and highlights its marked clinical heterogeneity.

P04.083

GAPO syndrome versus Cleidocranial dysplasia regarding management of pseudoanodontia

N. F. Hassib¹, M. I. Mostafa¹, M. A. AbdelRahmen¹, H. A. ElSadek¹, M. I. Mehrez¹, M. A. AbdelKader²;

¹National Research Centre, Giza, Egypt, ²National Research centre, Giza, Egypt.

Introduction: Pseudoanodontia is considering one of the most challenging problems encountering the dental field. GAPO syndrome and Cleidocranial dysplasia anomaly are characterized by the presence of impacted teeth known as pseudoanodontia. The aim of the study is to present a case of GAPO syndrome and another case of Cleidocranial dysostosis and their suggestive dental managements done. Materials and Methods: The two cases were collected from the out patients clinic of the Oro-dental genetics department, National Research Centre, Giza, Egypt. Results: Despite, the pseudoanodontia are one of the main feature in both diseases, the ankylosed teeth present in the patient of GAPO syndrome required to be treated using removable appliance, while, an orthodontic traction intervention to pull impacted teeth and put them in their correct position in the dental arches was the suggested dental treatment with the patient having Cleidocranial dysplasia. Conclusions: Pseudoanodontia in both GAPO syndrome and Cleidocranial dysplasia required a separate and different dental management regarding teeth ankylosis, teeth position and occlusion evaluation.

P04.084

Rare modifier variants alter the severity of cardiovascular disease in Pseudoxanthoma Elasticum

E. Y. De Vilder^{1,2}, L. Martin³, G. Lefthériotis⁴, P. Coucke¹, A. De Paepe¹, F. Van Nieuwerburgh⁵, O. M. Vanakker¹;

¹Center for Medical Genetics Ghent, Ghent University Hospital, Ghent, Belgium, ²PhD Fellow of the Research Foundation - Flanders, Ghent, Belgium, ³Department of Dermatology, Angers University Hospital, Angers, France, ⁴Department of Vascular Physiology and Sports Medicine, Angers University, Angers, France, ⁵Department of Pharmaceutics, Laboratory of Pharmaceutical Biotechnology, Ghent University, Ghent, Belgium.

Introduction: Pseudoxanthoma elasticum (PXE), an autosomal recessive ectopic mineralization disorder caused by *ABCC6* and *ENPP1* mutations, is characterized by skin, ocular and cardiovascular symptoms. Due to striking phenotypic variability, modifier genes are intensively researched to improve counseling. We evaluated the collective influence of multiple rare variants on cardiovascular disease severity in PXE.

Material and Methods: Mixed effects of rare missense/nonsense variants were assessed by Whole Exome Sequencing in 12 PXE patients with an extreme cardiovascular phenotype (based on clinical presentation and vascular calcium scoring). Statistical analysis (SKAT-O and C-alpha testing) was

performed to identify new modifier genes significantly associated with the severe cardiovascular cohort and enrichment analysis was used to evaluate pathway and gene ontology features for these modifiers (Reactome Pathway Database).

Results: Respectively 16 (SKAT-O) and 57 (C-alpha) genes were significantly associated to the severe cohort. Top significant genes could be stratified in 3 groups - calcium homeostasis (*OTOP2*, *HCRAR3*), association with vascular disease (*TOR2A*, *NLRP1*) and induction of apoptosis (*AHNAK2*, *BRWD1*) - while enriched pathways involved FGFR1 signaling (*FLG*) and gamma-carboxylation (*GCCX*, *VKORC1*), both associated with mineralization.

Conclusion: This study explored for the first time the cumulative effect of rare variants on the severity of cardiovascular disease in PXE, leading to a panel of candidate modifier genes. Hypothesis-free analysis revealed the most significant genes and enriched pathways to be already involved in vascular disease or mineralization, both hallmarks of PXE. This panel will aid in risk stratification and genetic counseling of PXE patients (FWO14/ASP/084).

P04.085

Functional investigation of a genetic locus associated with psoriasis

H. F. Ray-Jones, K. Duffus, A. McGovern, S. Eyre, R. B. Warren; University of Manchester, Manchester, United Kingdom.

Introduction: Psoriasis is a complex, chronic autoimmune condition with a genetic component. Recent genome-wide association studies have identified several psoriasis-associated loci in intergenic regions whose function is not well understood. Here, bioinformatic and molecular biology techniques were used to identify potentially disease-causing variants and their target genes in an intergenic risk locus at 9q31.

Materials and methods: The 9q31 locus was characterised using several available datasets in order to (1) identify all SNPs in tight linkage disequilibrium with the lead SNP, rs10979182, and (2) search for regulatory features within the SNP set. Chromatin immunoprecipitation (ChIP) and chromosome conformation capture (3C) were used to confirm the presence of regulatory SNPs and identify gene targets, respectively, in a keratinocyte cell line (HaCaT).

Results: 90 SNPs were highly correlated with rs10979182 ($r^2 > 0.8$) and intersected three regions clearly displaying marks of enhancers, H3K4me1 and H3K27ac, in several cell types according to ENCODE. ChIP confirmed that three SNPs in these regions also bind to these histone marks in HaCaT cells. Preliminary 3C experiments suggested the presence of long-range DNA interactions between intergenic regions and the candidate gene *KLF4*, but further tests are required to confirm if the psoriasis-associated SNPs are involved in these interactions.

Conclusions: This work has identified SNPs in the 9q31 locus that have a potential regulatory function in psoriasis. Further 3C analyses, alongside other functional techniques, must be conducted to identify which genes are likely to be affected by these SNPs.

Funding source: PhD studentship from The Sir Jules Thorn Charitable Trust.

Mutations in *IL36RN*, *CARD14* and *AP1S3* have been implicated in different pustular psoriatic manifestations, especially in generalized pustular psoriasis (GPP). We recruited 51 GPP patients, 3 patients with acute generalized exanthematous pustulosis (AGEP) and 4 patients with acrodermatitis continua Hallopeau (ACH), and screened them for qualitative and quantitative changes in *IL36RN*, *CARD14* and *AP1S3* as well as for point mutations in further 4 genes coding for other members of the IL-36-pathway.

Within the GPP cohort, we identified 13 homozygous/ compound-hetero-

zygous carriers of mutations (25.5%) and 3 carriers of a single mutation (5.9%) in *IL36RN*. Carriers of two mutations had a significantly lower age of onset than non-carriers ($p < 0.01$). Concomitant skin/ mucous manifestations as well as a continuous course of disease were less often observed in carriers of two *IL36RN* mutations than in non-carriers, while there was no difference in frequency of psoriatic arthritis. Two of the four ACH patients carried one *IL36RN*-mutation. We identified 4 GPP patients that carried heterozygous missense variants in *CARD14* predicted/ previously shown to lead to a change in NF- κ B levels. Allele-frequency of two *AP1S3* mutations was similar in pustular psoriasis (2.6%) and in normal individuals (2.3%). We did not observe any evidence for quantitative changes or point mutations in genes coding for other members of the IL-36-pathway in any of the 58 patients.

Our analyses point to further genetic overlap between pustular psoriatic manifestations and indicate a specific phenotype in *IL36RN*-caused generalized pustular psoriasis.

The molecular basis of a cluster of Pycnodysostosis in a region of the Brazilian Northeast and the analysis of the spreading of the CTSK mutations from a highly inbreeding region

T. F. Araujo¹, E. M. Ribeiro², A. P. Arruda³, C. A. Moreno¹, D. P. Cavalcanti¹;

¹State University of Campinas, Campinas, Brazil, ²Hospital Infantil Albert Sabin, Fortaleza, Brazil, ³Faculdade de Medicina de Juazeiro do Norte, Campinas, Brazil.

Pycnodysostosis is a rare AR disease classified among the sclerosing skeletal dysplasia. Despite its estimated low prevalence (1 per million), in the last years we found 27 affected individuals (22 families) in the Ceará State (CE) at the Brazilian Northeast, giving a local prevalence of 3 per million (population of CE: 8,904,459 inhabitants). This cluster prompted us to genotype the affected individuals, under the work hypothesis of a possible founder effect. This investigation also included 15 families from other Brazilian regions. We have studied 39 individuals (33 families), of which 18 were from Ceará. The sequencing of the CTSK by the Sanger method identified six different mutations, being five previously described, and a novel one - W29Mfs*10. This mutation appears to be concentrated in the northwest of the Ceará. The molecular analysis associated with the investigation of the origin of the parental families allowed us to the following conclusions. 1 - The high frequency of Pycnodysostosis in the CE is a consequence of the high inbreeding, rather than a founder effect. 2 - The analysis of the origin of the families showed that the most of the found mutations in the other Brazilian regions came from Northeast by a process of intern migration of the population. 3 - The haplotype study reinforced the hypothesis of founder effect related to the novel mutation. 4 - The high frequency of homozygous mutations among the patients from CE (close to 80%) suggests that the real inbreeding is higher than the referred consanguinity (33%).

Analysis in Chilean population of the contribution to the rheumatoid arthritis susceptibility of the marker SNPs previously described by GWAS in European and Asian populations

P. Castro-Santos, B. Assor-Cordones, G. Essmann-Antonio, M. Yáñez-Martínez, R. Díaz-Peña;

Universidad Autónoma de Chile, Talca, Chile.

Introduction: Rheumatoid arthritis (RA) is an autoimmune inflammatory rheumatic disease that affects many tissues and organs, mainly synovial joints. Like many other autoimmune diseases, RA exhibits a multifactorial etiology in which genetic and environmental factors have been established. The aim of this study was the analysis of previously described associations in GWAS developed in Caucasian and Asian populations in a Chilean population.

Materials and Methods: We carried out a high-density genotyping study in candidate genes, evaluating their association with RA in Chilean population accomplishing the ACR 1987 criteria (313 cases/487 controls). In total, we have genotyped 128 SNPs using the OpenArrayTM TaqMan platform (Applied Biosystems Inc.). Additionally, we have identified the HLA-DRB1 alleles using the commercial typing kit for Luminex HLA-DR SSO (Tepnel Lifecodes). Statistical analyses were made using the software PLINK and Haploview. For HLA-DRB1 alleles association with RA susceptibility testing we used the statistical software IBM SPSS Statistics 21.

Results: We have evaluated SNPs from previous GWAS (SNPs selection from the literature), including also haplotype-tag (ht)-SNPs located inside the regions of some candidate genes (PTPN22, CTLA4, TNFAIP3, CCR6, STAT4

and PADI4). In general, significance values of the associations described in GWAS are moderate, suggesting the existence of genetic particularities in Chilean, and probably other Latin-American populations.
Conclusions: Our results support the existence of some genetics factor for RA risk shared with Caucasian and Asian population but also the presence of some differential genetic characteristics of the RA Chilean population.

A 34-year-old girl with PEX7-related rhizomelic chondrodysplasia punctata

L. Gigante^{1,2}, **E. Pisaneschi**³, **F. C. Sangiuolo**⁴, **A. Novelli**⁵, **T. Levade**⁵, **F. Brancati**^{6,7};
¹Division of Cardiology, Azienda Ospedaliero-Universitaria di Parma, Parma, Italy,
²Humanitas Clinical and Research Center, Milano, Italy, ³Laboratory of Medical Genetics, Bambino Gesù Pediatric Hospital, IRCCS, Rome, Italy, ⁴Genetics Section, Department of Biomedicine and Prevention, University of Rome "Tor Vergata", Rome, Italy,
⁵Laboratoire de Biochimie Métabolique, Institut Fédératif de Biologie, and INSERM UMR1037, CRCT, Toulouse, France, ⁶DSMOB Department Gabriele D'Annunzio University of Chieti-Pescara, Chieti, Italy, ⁷Medical Genetics Unit Policlinico Tor Vergata University Hospital of Rome, Rome, Italy.

Rhizomelic Chondrodysplasia Punctata type 1 (RCDP1) is a peroxisome biogenesis disorder caused by mutations in PEX7 gene encoding a peroxisomal matrix proteins receptor with type 2 peroxisome targeting signal (PTS2). Punctate calcifications in epiphyseal cartilages and coronal clefts of vertebral bodies, cataract, intellectual disability and growth retardation characterized RCDP1. Most patients die before 10 years for respiratory distress or cardiac malformations. Less than 20% survive 12 years, and single patients beyond 20 years are reported.

We describe a 34 year-old girl, second child of healthy parents from a small Italian village. Pre and post-natal growth restriction, congenital bilateral cataract, seizures, absence of pituitary gland with GH deficiency and mitral insufficiency with atrial regurgitation were recorded. At clinical examination she presented with severe intellectual disability, shortening of long bones with prominent proximal involvement, spasticity, keratosis pilaris and scaling skin. RCDP1 was suspected but skeletal X-rays of childhood were not available.

Peroxisomal function evaluation revealed reduced red blood cell plasmalogens, increased plasmatic phytanic acid concentration, and normal levels of very long-chain fatty acids. PEX7 molecular testing demonstrated a homozygous c.653C>T (p.Ala218Val) mutation, a recurrent mutation previously associated to milder RCDP1.

We report clinical, biochemical and molecular features of one of the oldest ever-reported patients with RCDP1, the first with congenital pituitary hypoplasia and GH deficiency. Interestingly, mutations in PEX7 can also cause an atypical phenotype with longer survival and milder neurologic involvement, normal or near-normal growth, and absence of rhizomelia. More studies are needed to clarify the mechanisms underlying clinical variability.

P04.090

What is the etiology of acanthosis nigricans in SADDAN syndrome?

I. T. Perva¹, **M. Puiu**², **R. A. Popp**³, **A. Chirita-Emandi**²;
¹University of Medicine & Pharmacy Victor Babes, Timisoara, Romania, ²University of Medicine & Pharmacy Victor Babes, Genetics Department, Center of Genomic Medicine, Timisoara, Romania, ³Medical Genetics, Molecular Science Department, Iuliu Hatieganu University of Medicine and Pharmacy, Cluj-Napoca, Romania.

Background: SADDAN syndrome is a rare severe form of achondroplasia associating developmental delay and acanthosis nigricans.

Aim: To present a case report and perform a literature search to understand the aetiology of the severe AN, within the syndrome. **Method:** The child had history and clinical assessment, laboratorz work-up (for the aetiology of AN), genetic testing and imaging to evaluate foramen magnum and cranium. **Results:** A 7 year old boy, known with achondroplasia phenotype from birth, presents with specific dysmorphic features of achondroplasia, severe obesity (BMI=33.9 kg/m², >3SD WHO reference), scoliosis in the thoracic and lumbar spine, cervical, axillary and arm folds achantosis niachantosis and linguistic delay, with difficulties adjusting to normal school curriculum. He had normal values of glucose, insulin (HOMA index 0.93), Hb1C and IGF-I. Hypothalamic-pituitary axis assessment was normal. Other lab work were unremarkable. CT of the neck and cranium revealed slightly reduced foramen magnum and mild hydrocephalus (Evans index=32). The PCR-RFLP test showed a heterozygotic G1138A mutation in FGFR3 gene. The clinical, paraclinical workup, genotype and imagistics, suggested the diagnoses of SADDAN syndrome and severe obesity. Diet and lifestyle changes were recommended. The genetic cause for this severe form of achondroplasia is not known.

Conclusions: A cause for the severe AN was not established in this case. Further assessment should investigate malignant causes for acanthosis nigricans and a specific genotype correlated with this phenotype. This research was done in the Center of Genomic Medicine from the University of Medicine and Pharmacy Victor Babes, POSCE Project ID1854, cod SMIS48749.

P04.091

WES approach for an early diagnosis of Dyggve-Melchior-Clausen syndrome in a pair of siblings with skeletal defects, severe intellectual disability and cerebral abnormalities

M. Dentici, **M. Niceta**, **F. Pantaleoni**, **M. Tartaglia**, **B. Dallapiccola**;
 Bambino Gesù Pediatric Hospital, IRCCS, Rome, Italy., Rome, Italy.

Dyggve-Melchior-Clausen syndrome (DMCs) is a rare skeletal dysplasia belonging to the group of the Spondyloepimetaphyseal dysplasia (DSME), characterized by progressive short-trunk dwarfism, short barrel chest, microcephaly and mild/moderate intellectual disability (ID). Skeletal radiographic features include flattening of vertebral bodies, barrel chest and anteroaxial instability. Mutations have been identified in the DYM gene with an autosomal recessive inheritance.

We report two male dizygotic twins first evaluated at 4 years of age with severe short stature (-4.6SD and -6.9SD, respectively), microcephaly (-5SD), severe ID. In both siblings radiologic findings enclosed generalized platyspondyly with minimal notches and anterior pointing of the vertebral bodies, rhizomelic limb shortening. Both siblings have cerebral abnormalities (hypoplastic corpus callosum, lateral ventricular dilatation and one sibling presents cerebellar vermian hypoplasia with secondary dilatation of the IV ventricle). Differential diagnosis was discussed among DSME group arguing that cerebral malformations are not typically reported in the DSME. Moreover, the typical barrel chest of DMCs was not clinically evident at our first evaluation.

We performed WES (Illumina platform HiSeq 2000), on the siblings samples using an in-house implemented pipeline. The analysis identified in both patients a homozygous known mutation in the DYM gene (c.1877delA; p.Lys626AsnfsX720), for which predictive studies suggested loss of function of the relative protein. The variant was confirmed with Sanger sequencing. This study prompted to an early diagnosis of DMCs allowing an earlier access to a long term care, crucial for the progressive orthopaedic complications that, at the time of the diagnosis, were not fully conclamate in our patients.

From phenotype to genotype and back again: effective whole exome sequencing in patients with skeletal dysplasia

P. Louro^{1,2}, **A. Belezá**³, **S. Lillis**³, **M. Jansson**³, **J. Ahn**⁴, **K. Ryan**³, **A. Calder**⁵, **C. Hall**⁶, **A. Offiah**⁶, **M. Simpson**⁷, **S. Yau**³, **S. Mohammed**³, **M. Irving**^{1,7};
¹Department of Clinical Genetics, Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom, ²Medical Genetics Unit, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal, ³Genetics Laboratories, Viapath, London, United Kingdom, ⁴Genetics Laboratories, Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom, ⁵Radiology Department, Great Ormond Street Hospital for Children NHS Foundation Trust, London, United Kingdom, ⁶Academic Unit of Child Health, Sheffield Children's NHS Foundation Trust, Sheffield, United Kingdom, ⁷Division of Genetics and Molecular Medicine, King's College London School of Medicine, London, United Kingdom.

Background: Skeletal dysplasia (SD) is a genetically heterogeneous group of rare diseases. The clinical diagnosis of a specific SD condition may be accomplished by a clinician with expertise with the aid a skeletal survey. However, it is frequently challenging to make a diagnosis without accompanying molecular testing. Thus, our purpose is to highlight the clinical utility of whole exome sequencing (WES) as a diagnostic tool for SD.

Methods: Eighteen suspected SD patients were selected, including cases of osteogenesis imperfecta type 1, osteopetrosis, spondylocostal dysostosis and spondyloenchondromatosis. WES was performed using Agilent Sure-SelectXT Human All Exon V5 followed by sequencing on an Illumina HiSeq 2500. Raw sequence data was aligned using Novoalign, and variants called with Samtools. Qiagen Ingenuity Variant Analysis was used to aid assessment of variant pathogenicity after applying a virtual panel of 220 SD genes in combination with multidisciplinary clinical interpretation.

Results: Pathogenic variants were detected in six cases, while in four cases variants were identified that require additional work to clarify their pathogenicity. Of the remaining eight cases with no detected pathogenic variants in the selected SD genes, clinical reassessment suggests that three are unlikely to have SD.

Conclusions: WES analysis provided a definitive diagnosis in at least one third (6/18) of our selected SD patients. These results demonstrate WES

analysis using targeted gene analysis is an effective diagnostic tool for SD. However, it also emphasizes the importance of a thorough clinical evaluation and close analytical liaison with clinical scientists to provide an optimal and efficient service.

P04.093

Sweet's syndrome in a patient with compound heterozygous mutations in the Mediterranean fever gene (MEFV)

M. Michelson Kerman, Chana Vinkler, Dorit Lev;
Wolfson Medical Center, Holon, Israel.

Sweet's syndrome (SS) is a rare disorder that often occurs in association with other systemic diseases.

The disorder is characterized by development of nonpruritic, painful erythematous plaques with pseudovesicles, pustules and rare bullae. SS consists of a triad of erythematous plaques infiltrated by neutrophils in association with fever and leukocytosis. The pathological features of SS involve the dermis.

The treatment of choice are systemic corticosteroids.

We present an unusual course of SS in a man who carries compound heterozygous mutations in the MEFV gene.

A 38 year old man from Sephardic Jewish ancestry, had suddenly developed fever, malaise, arthralgia and painful erythematous plaques with pustules and bullae on the upper extremities. Diagnostic evaluation included leukocytosis, elevated erythrocyte sedimentation and C-reactive protein rate.

The symptoms exacerbated despite treatment with systemic corticosteroids. Mutational analysis of the MEFV gene revealed compound heterozygous M694V and V726A mutations. Clinical improvement appeared after administration of colchicine.

Familial Mediterranean fever (FMF) is an autosomal recessive disease characterized by recurrent attacks of fever with serosal inflammation. The FMF gene (MEFV) encodes the protein pyrin that plays an important role in modulating the innate immune response.

MEFV mutations have been identified primarily in patients from Mediterranean populations

Sweet's syndrome has been described in a patient with classical FMF as a possible new cutaneous feature and has never been described as a presenting sign of FMF.

We suggest that SS skin lesions might be an only cutaneous presentation of FMF.

P04.094

Identification of intragenic deletions of TCF12 by whole genome sequencing

J. A. C. Goos¹, A. L. Fenwick², S. M. A. Swagemakers¹, S. R. F. Twigg², A. J. M. Hoogeboom¹, M. F. van Dooren¹, F. J. Magielsen¹, I. M. J. Mathijssen¹, A. O. M. Wilkie^{2,3}, P. J. van der Spek¹, A. M. W. van den Ouweland¹;

¹Erasmus MC, University Medical Center, Rotterdam, Netherlands, ²MRC Weatherall Institute of Molecular Medicine, University of Oxford, John Radcliffe Hospital, Oxford, United Kingdom, ³Craniofacial Unit, Oxford University Hospitals NHS Trust, John Radcliffe Hospital, Oxford, United Kingdom.

Introduction: Coronal synostosis can be caused by heterozygous loss-of-function mutations of TCF12. Until now, however, large intragenic deletions in this gene have not been described as a cause of TCF12-related craniosynostosis. Here, we describe three large intragenic deletions in TCF12 identified by whole genome sequencing (WGS).

Materials and methods: Within the framework of a broader study on craniosynostosis, WGS of nineteen index-cases with coronal synostosis and their family members (forty-six samples in total) was carried out by Complete Genomics, a BGI Company (Mountain View, CA, USA). The WGS data were analyzed using an autosomal dominant disease model. Deletion-specific PCR and dideoxy-sequence analysis were performed to confirm the WGS results. **Results:** Using WGS, three large intragenic deletions of 84,949, 8,580 and 5,363 base pairs were identified in TCF12, deleting exons 7-18, 19, and 20, respectively. The first two deletions overlap the exons in which most pathogenic point mutations have been described. All index patients had coronal suture synostosis and all deletions were inherited. However, not all parents with the deletions showed clinical signs. Similar non-penetrance has previously been described in TCF12-related craniosynostosis caused by point mutations.

Conclusions: Three large intragenic deletions were identified in TCF12 using WGS, indicating the importance of screening for larger rearrangements in patients suspected for TCF12-related craniosynostosis.

P04.095

TGFB1 variant and MLH1 mutation in a patient with aortic aneurysm and colon cancer

S. Azzarello-Burri, P. Joset, A. Baumer, T. Herget, A. Rauch;
Institute of Medical Genetics, 8952 Schlieren, Switzerland.

Aortic aneurysms and dissections are a typical complication of connective tissue disorders such as Marfan and Loeys-Dietz syndrome, which are caused by increased TGFB signaling. Since the latter was also found in cancer, the question of increased cancer risk in patients carrying germline mutations of TGFB signaling members raised when we recently observed a patient who next to an aortic aneurysm and skeletal signs of Marfan syndrome had colon cancer at the age of 60 years. We therefore performed exome sequencing with selective analysis of known connective tissue genes and found a potentially disease causing TGFB1 variant c.553C>T/= (p.Arg185Trp/=). Mutations in the TGFB1 gene are known to cause Camurati-Engelmann disease, which is characterized by hyperostosis of the long bones and the skull, proximal muscle weakness, severe limb pain, a wide-based waddling gait, and joint contractures. Since there is one patient with Camurati-Engelmann disease and aortic dissection in his teenage years described in the literature, we assumed that the connective tissue phenotype of our patient was caused by this variant. We considered that his colon cancer might also be related to the TGFB1 variant, but for safety reason extended the exome analysis to known colon cancer genes, which indeed showed in addition a known MLH1 splice site mutation c.2103+1G>T/=. Our observation therefore indicates that despite the link between TGFB signaling and cancer development, increased cancer risk in patients with germline mutations has not been described so far and may actually be attributable to an independent second disorder.

P04.097

TRPS1 gene defects in patients with trichorhinophalangeal syndrome

R. Solc¹, K. Hirschfeldova², M. Klugerova¹, J. Vcelak³, A. Baxova², M. Kuklik^{3,4}, J. Vseticka⁵; ¹Charles University in Prague, Faculty of Science, Department of Anthropology and Human Genetics, Prague, Czech Republic, ²Charles University in Prague, 1st Faculty of Medicine, Institute of Biology and Medical Genetics, Prague, Czech Republic, ³Institute of Endocrinology, Department of Molecular Endocrinology, Prague, Czech Republic, ⁴Genetic clinic Olsanska, Prague, Czech Republic, ⁵Genetika Ostrava s.r.o., Ostrava, Czech Republic.

Introduction: The aim of the study was to determine genetic defects in the group of patients with a trichorhinophalangeal syndrome (TRPS) phenotype derived from the Czech population.

Materials and Methods: Each of 9 probands (8 with TRPS I and 1 with TRPS II) was analyzed by use of the 228-B1 MLPA kit (MRC Holland), which covers the relevant 8q24 chromosomal region in order to detect TRPS1 gene and EXT1 gene rearrangements. Additionally, mutational analysis of the coding part of the TRPS1 gene was conducted.

Results: In the proband with TRPS II, a large deletion was detected (about 10 Mb), which includes genes TRPS1 and EXT1. In 6 of 8 probands with TRPS I we found some mutations which consider to be the causal ones. It was one large TRPS1 intragenic deletion (exons 2 – 5); two small structural mutations (a deletion in the exon 5, an indel mutation in the exon 4); two nonsense substitutions (in the exon 4 and in the exon 5); and one missense substitution (in the exon 6). Both the two small structural aberrations and the two nonsense substitutions have not been described yet. Moreover we discovered several probably polymorphic substitutions in TRPS1 gene 3'UTR sequences.

The study was supported by the Charles University in Prague, project GAUK202615.

P04.098

Sclerotic bone lesions in Tuberous Sclerosis Complex

S. Boronat^{1,2}, I. Barber¹, E. A. Thiele²;

¹Hospital Vall d'Hebron, Barcelona, Spain, ²Massachusetts General Hospital, Boston, MA, United States.

Background: Tuberous sclerosis complex (TSC) is due to mutations in TSC1 or TSC2 genes resulting in hyperactivation of the mTOR pathway. Many tissues can be affected, including brain, skin, eye, heart, bone, kidney or lung. Sclerotic bone lesions have been reported in TSC but there is scarce information about them in the literature.

Methods: Abdominal MR scans of 70 children with TSC who had TSC1/TSC2 mutational studies were reviewed for sclerotic bone lesions, and a longitudinal study was performed in 50 patients who had two or more MR scans. Chest CT scans of 92 adult TSC patients (70 with mutational TSC studies) were reviewed for sclerotic bone lesions.

Results: 173 sclerotic bone lesions were detected in 51 of 70 children (73%)

and affected mainly the vertebrae pedicles. The youngest patient with these lesions was 18 months old. New lesions appeared in 50% of the patients during a follow-up period of 1 to 6 years and growth of previous lesions was documented in 37% patients. Patients with sclerotic bone lesions were more frequently females (75% vs 37%) and they had more renal involvement than patients without bone lesions (84% vs 47%). Sclerotic bone lesions were found in chest CT studies of 82 adult patients (89%). Patients without bone lesions had no mutation identified in 86%.

Conclusion: Sclerotic bone lesions are very frequently found in MR and CT studies of TSC patients. They are usually present within the first years of life, and new lesions appear with age.

P04.099

A case of Weaver Syndrome caused by a novel frameshift EZH2 mutation

H. Simsek, B. B. Geckinli, K. Deilil, M. A. Soylemez, A. Turkyilmaz, E. Arslan Ates, M. Avsar, P. Ata, A. I. Guney, A. Arman;

Medical Genetics Department, Marmara University Medical School, Istanbul, Turkey.

Weaver Syndrome is a rare overgrowth syndrome characterized by prenatal/postnatal overgrowth, accelerated osseous maturation, characteristic craniofacial appearance and developmental delay. Weaver syndrome is an autosomal dominant disorder caused by heterozygous mutation in the EZH2 gene which encodes histone methyltransferase.

Our patient is a 4 year-old girl who was referred to our clinic due to speech and neurodevelopmental delay. She was born at 32nd weeks of gestation by cesarian section because of mothers' preeclampsia. Her birth weight was 3000 gr (>97P), height was 52 cm (>97P), occipitofrontal circumference was 34 cm (>97P). On physical examination, she weighed 24 kg (>97P), lengthed 117 cm (>97P), and occipitofrontal circumference was 54,5 cm (>97P). Clinical examination showed macrocephaly, a broad forehead, round face, long philtrum, hypertelorism, depressed nasal bridge, large ears, large hands and feet, tibial bowing, enlarged wrists and knees, hallux valgus, umbilical hernia and pigmented nevi on trunk. Her radiographic findings were advanced carpal bone maturation of 6 years and enlarged metaphysis of long bones. DNA sequence analysis of EZH2 gene showed a de novo novel heterozygous p.D730* (c.2187_2188insT) frameshift mutation in exon 19. This truncating mutation is identified at the SET domain. Identification of EZH2 gene mutations is important to clarify genotype-phenotype correlations in Weaver syndrome.

P04.100

Whole Exome Sequencing reveals a mutation in an osteogenesis imperfecta patient

M. A. Ergun¹, G. Bilgili², U. Hamurcu³, A. Ertan⁴;

¹Gazi University Faculty of Medicine, Department of Medical Genetics, Ankara, Turkey, ²Gazi University Faculty of Medicine, Department of Physiology, Ankara, Turkey, ³Hamurcu Clinic, Ankara, Turkey, ⁴Hacettepe University, Faculty of Dentistry Department of Prosthetic Dentistry, Ankara, Turkey.

Introduction: Osteogenesis imperfecta (OI) is an autosomal dominant disorder characterized mainly by bone fragility and blue sclerae. OI is caused by mutations in type I collagen genes; COL1A1 and COL1A2. Dentinogenesis imperfecta is a common disorder for osteogenesis imperfecta patients. More than half of the OI patients have also dentinogenesis imperfecta. Whole Exome sequencing (WES), involves exome capture, which limits sequencing to the protein coding regions of the genome, composed of about 20,000 genes, 180,000 exons, and constituting approximately 1% of the whole genome. A major indication for use is molecular diagnosis of patients with suspected genetic disorders or of patients with known genetic disorders with substantial genetic heterogeneity involving substantial gene complexity.

Materials and Methods: In this study, we performed WES for a patient pre-diagnosed as Osteogenesis Imperfecta. He had also dentinogenesis imperfecta.

Results: The WES results confirmed with Sanger sequencing revealed as a misense mutation at codon 560 of COL1A1 gene: c.1678 G>A (G560S). The mutation was on exon 25 and according to the dbSNP database this mutation corresponded to rs67507747.

Conclusions: It is very important to perform WES after an algorithm. This algorithm has to include, a suspect of a mendelian disorder, multiple genetic conditions in the differential diagnosis, and even if it is available the conventional diagnosis is prohibitively expensive. Finally, Sanger sequencing in order to confirm the results is also advised.

P04.101

Role of missense variants in Wnt pathway genes in BMD determination

N. Martínez-Gil¹, N. Roca-Ayats¹, R. Urreiziti¹, H. Franco-Valls¹, N. Garcia-Giralte², L. Mellibovsky², X. Nogués², A. Díez-Pérez², D. Grinberg¹, S. Balcells¹;

¹Universitat de Barcelona, IBUB, CIBERER, Barcelona, Spain, ²URFOA, RETICEF, IMIM, Parc de Salut Mar, Barcelona, Spain.

Osteoporosis is a common disease characterized by decreased bone mineral density (BMD) and an increased fracture risk. It is determined by environmental and additive genetic susceptibility factors. In a meta-analysis by Estrada *et al.* (2012), 56 loci were found associated with BMD, 14 of which were also associated with osteoporotic fracture. Notably, the list was enriched for genes of the Wnt pathway.

To better understand the role of Wnt pathway genes in determining osteoporosis, we aimed at exploring the allelic architecture of *SOST*, *WNT16* and *DKK1* with an emphasis in their coding regions. We resequenced all the exons and intronic flanking regions in two extreme BMD groups from the BARCOS cohort of Spanish postmenopausal women. Selected variants were then genotyped in the full cohort and tested for association to BMD.

Initially, 17, 3 and 13 single nucleotide variants were identified in *WNT16*, *SOST* and *DKK1*, respectively. Seven SNPs showing biased frequencies in the two extreme groups and 6 rare variants located in putative regulatory elements were genotyped. Significant results were obtained for an intronic SNP (rs142005327) in *WNT16* and for all the missense variants in *WNT16* (rs2908004, p.G72R/p.G82R; rs2707466, p.T2531/p.T2631) and *SOST* (rs17882143, p.V10I). The associated SNPs are in linkage disequilibrium with the respective GWAS hits. A rare variant (rs570754792, *SOST*) was found in 3 women whose BMD was below the mean of the BARCOS cohort. Our results, suggest that missense variants in *SOST* and *WNT16* are most likely to influence BMD.

P04.102

Novel mutations in the keratin-74 (KRT74) gene underlie autosomal dominant woolly hair/hypotrichosis in Pakistani families

N. W. Naveed¹, W. Ahmad²;

¹Institut für Humangenetik, Uniklinik, Ulm, Germany, ²Department of Biochemistry, QAU, Islamabad, Pakistan.

Autosomal dominant woolly hair (ADWH) is an inherited condition of tightly curled and twisted scalp hair. Recently, a mutation in human keratin-74 (KRT74) gene has been shown to cause this form of hereditary hair disorder. In the present study, we have described two families (A and B) having multiple individuals affected with autosomal dominant form of hair loss disorders. In family A, 10 individuals showed ADWH phenotype while in the family B, 14 individuals showed hypotrichosis of the scalp. Genotyping using polymorphic microsatellite markers showed linkage of both the families to type II keratin gene cluster on the chromosome 12q12-14.1. Mutation analysis of the KRT74 gene identified two novel mutations in the affected individuals of the families. The sequence analysis revealed a splice acceptor site mutation (c.IVS8-1G>A) in family A and a missense variant (c.1444G>A, p.Asp482Asn) in family B. Mutations identified in the present study extend the body of evidence implicating the KRT74 gene in the pathogenesis of autosomal dominant hair loss disorders.

P05.01

Genetic variants in familial abdominal aortic aneurysms identified by whole genome and exome sequencing.

A. Ijpm, D. Heijnsman, M. Oomen, H. Brüggewirth, I. van den Boogert, D. Majoor-Krakauer;

Erasmus MC, Rotterdam, Netherlands.

Introduction: Abdominal aortic aneurysm (AAA) is a frequent disorder with a prevalence of approximately 5% in the elderly population. In 20% of the patients AAA is familial. No genetic causes for AAA have been identified so far. The goal of this study is to identify genes that play a role in the formation of abdominal aneurysms. Methods: The study includes approximately 950 AAA patients. So far we sequenced the DNA of 341 patients with a family history of abdominal aortic aneurysm. Whole genome sequencing (WGS)

was performed in 3 families (15 individuals) and whole exome sequencing (WES) was performed in 50 families (107 individuals) and 219 single AAA patients with familial disease. Prioritization of resulting variants was performed according to the following gene sets: 1. Genes in diagnostics panel as applied in the Erasmus MC in thoracic or syndromic aneurysms (n=25) 2. A broad selection of genes involved in vascular function or disease (n=4209) 3. All genes in the genome Results: We present the detailed workflow of the analysis of the genomics data, including the results so far. In 105 out of 267 families a variant in one of the set 1 genes was found. Further analysis of the set 2 and 3 genes so far led to the identification of several candidate genes that show variants in more than one AAA family and that have not been linked to AAA before.

P05.02

Associations between selenoprotein gene variants and selenoprotein levels and aortic diseases: abdominal aortic aneurysm and aortoiliac occlusive disease

E. Strauss^{1,2}, J. Tomczak¹, L. Wawrzynska¹, R. Staniszewski¹, G. Oszkiniś¹; ¹Department of General and Vascular Surgery, Poznan University of Medical Sciences, Poznan, Poland, ²Institute of Human Genetics, Polish Academy of Sciences, Poznan, Poland.

Introduction. In this study the role of common genetic variants in selenoprotein genes (SEPP1 rs3877899, rs7579, SELS rs34713741 TXNRD1 rs35009941, TXNRD2 rs9605031, GPX4 rs713041) and SOD2 gene (rs4880) in the development of abdominal aortic aneurysm (AAA) and aortoiliac occlusive disease (AIOD), as well as their associations with cardiac diseases and function in patients were evaluated.

Materials and methods. A series of 516 AAA patients, 352 AIOD patients, and 510 controls were analyzed. Patients were characterized in terms of coronary and non-coronary atherosclerosis and its complications. Genotyping was performed using the TaqMan-based assays. Selenoprotein P (SeP) and thioredoxin (Trx) levels in plasma were assessed by ELISA.

Results. Higher plasma SeP levels were associated with more favorable cardio-metabolic profile in our patients (BMI values, HDLC, TG levels). In AIOD, as compared to AAA, the increased frequency of the GPX4 rs713041TT homozygotes was observed: OR=1.66, P=.023 (OR=1.62, P=.046 for AAA without concomitant peripheral atherosclerosis). In patients with systolic heart failure, lower frequency of carriers of the SEPP1 rs3877899G-rs7579G haplotype, and increased levels of studied selenoproteins were found. Higher plasma selenoprotein levels were also associated with presence of small AAA.

Conclusions. This study identified variant alleles of the selenoprotein genes as potential genetic markers that indicate predisposition to occlusive and aneurysmal types of arterial disease and to systolic heart failure. Expression of selenoproteins seems to be induced during AAA and heart failure development, to protect against oxidative stress. Supported by the NSC in Poland under NN403250440 grant, and PUMS under 502-01-02214335-05962 and 502-14-02214335-10268 grants.

P05.03

Association between C reactive protein and abdominal aortic aneurysm: Mendelian randomization analysis

J. Juan¹, X. Qin¹, Y. Wei², K. Sun¹, S. Zuo³, W. Guo³, Y. Hu¹; ¹Peking University, Beijing, China, ²Beijing Center for Diseases Prevention and Control, Beijing, China, ³Chinese PLA general hospital & medical school PLA, Beijing, China.

Introduction: Several studies have suggested C-reaction protein (CRP) is associated with the development of abdominal aortic aneurysm (AAA), but it is unclear whether this association is causal. To avoid confounding or reverse causality, we used Mendelian randomization analysis to study the causal role of CRP and diameter of abdominal aorta.

Materials and Methods: 465 Chinese participants were included in the analysis. CRP gene rs1205 was used as an instrumental variable of plasma high-sensitivity CRP level. We assessed the association of hs-CRP levels with diameter of abdominal aorta and other risk factors or confounders in the conventional models, and also assessed the associations of the gene with the diameter of abdominal aorta, hs-CRP and other factors. We used two-stage least squares for the Mendelian randomization analyses to assess the relationship between the expected hs-CRP level estimated from the gene and the diameter of AAA.

Results: In the conventional analysis, hs-CRP was associated with AAA ($P < 0.001$, 95% CI 0.03-0.12). rs1205 in CRP gene was associated with hs-CRP levels ($P < 0.0001$), but unrelated to other factors, including age, gender, smoking, drinking and history of hypertension. The results of Mendelian randomization analysis showed a null association of hs-CRP with AAA

($P = 0.71$, 95% CI -0.30-0.20). The first-stage F-statistics was 12.87, indicating sufficient strength to ensure the validity.

Conclusions: Mendelian randomization analysis indicates that hs-CRP level may not be causally associated with AAA in this population. This suggests that the results of conventional analysis may be affected by confounding or reverse causality.

P05.05

Is there any association between insulin resistance and apelin gene expression in non-diabetic subjects?

M. Zarkesh¹, E. Yuzbashian², G. Asghari², M. Hedayati¹, P. Mirmiran², A. Khalaj³; ¹Cellular and Molecular Endocrine Research Center, Research Institute for endocrine sciences Shaheed Beheshti University of Me, Tehran, Iran, Islamic Republic of, ²Nutrition and Endocrine Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran, Islamic Republic of, ³Obesity Treatment Center, Department of Surgery, Shahed University, Tehran, Iran, Tehran, Iran, Islamic Republic of.

Background and aim: Adipose tissue-derived hormones like apelin play a functional role in the glucose tolerance through its effects on insulin secretion and insulin sensitivity which is also a risk factor for type 2 diabetes. In the current study, we aimed to investigate the association of apelin mRNA expression in omental and subcutaneous adipose tissues with fasting glucose, insulin, and insulin resistance among non-diabetic subjects.

Material & methods: Under a cross-sectional analytical design a total of 62 non-diabetic subjects, aged ≥ 18 years, were eligible for the study. Omental and subcutaneous adipose tissues were obtained during open abdominal surgery. The mRNA expression of apelin in omental and subcutaneous adipose tissues were assessed by Real-Time PCR. Serum levels of apelin, triglycerides, total cholesterol, glucose, and insulin were measured and homeostatic model assessment of insulin resistance index (HOMA-IR), β -cell function (HOMA-B), and the quantitative insulin sensitivity check index (QUICKI) were calculated.

Results: Apelin mRNA expression in omental adipose tissue was positively correlated with insulin levels ($r = 0.281$, $P = 0.034$) and HOMA-IR ($r = 0.270$, $P = 0.043$) and negatively correlated with QUICKI ($r = -0.270$, $P = 0.043$). In addition, apelin gene expression in subcutaneous adipose tissue was negatively correlated with triglycerides levels ($r = -0.404$, $P = 0.041$).

Conclusion: In conclusion, our data indicate that up-regulation of apelin in omental adipose tissue is associated with glucose hemostasis and insulin resistance.

Clinical application of a multigene panel associated with many inherited cardiac conditions: challenges of defining risks, clinical outcomes and off-target findings

D. du Sart¹, B. Chong¹, S. Pantaleo¹, I. Macciocca¹, P. James²; ¹Victorian Clinical Genetics Services, Murdoch Childrens Research Institute, Melbourne, Australia, ²Clinical Genetics, Royal Melbourne Hospital, Melbourne, Australia.

Introduction: Genetic testing for inherited cardiac conditions impacts on clinical management options for families. These conditions have complex genetic pathology, often heterogeneous disorders with overlapping clinical symptoms that are not always penetrant. Classifying variants as pathogenic, as influencing clinical severity or just normal variation is complex.

Materials and Methods: Multigene panels are cost- and time-effective analyses to identify familial pathogenic variants. Patients with inherited arrhythmia, cardiomyopathy, aortopathy and sudden death conditions are screened with a 101-cardiac-gene NGS panel. Gene variants are analysed according to patient phenotype, but the analysis flags variants classified as pathogenic in all genes.

Results: More than 1000 probands were tested, followed by segregation analyses for clinically actionable variants (see table). Pathogenic variants in "off-target" genes (1.6%) lead to many challenges for both laboratory and clinical teams. Biological interpretation of variants suggest a strong association with clinical disease, but lack of information on clinical outcomes make pathogenic classification uncertain. Counselling challenges included conveying unexpected information about different cardiac genes. Clinical assessment revealed no evidence of clinical association with the "off-target" genotype.

Conclusion: Pathogenic variants in "off-target" genes identify significant gaps in our gene-specific phenotype knowledge base. Documentation of these cases will improve knowledge about the spectrum of disease associated with genes and will impact on future management in families with asso-

ciated phenotypes. Does this justify the complexities raised by “off-target” gene variants?

	Arrhythmia	Cardiomyopathy	Aortopathy	Sudden Death / Extended Panel
Pathogenic / Likely pathogenic variant	45%	51%	26 %	33%
Variant of unknown significance	24%	38%	34%	57%
No clinically actionable variant	31%	11%	40%	10%
“Off-target” gene pathogenic variants in 1000 probands	10 probands: 7 stop/frame shift 3 splice [+1]	2 probands -pathogenic in LQT	4 probands 3 stop 1 splice [-1]

Desmosomal genetic variants in young competitive athletes: Pathogenic mutations or innocent bystanders?

M. Cason¹, M. Schiavon², A. Zorzi³, R. Celeghin¹, E. Lazzarini¹, E. Carturan¹, B. Bauce¹, I. Rigato¹, C. Basso¹, D. Corrado¹, G. Thiene¹, K. Pilichou¹;

¹Dept. of Cardiac, Thoracic and Vascular Sciences, University of Padua, Padova, Italy, ²Sports Medicine & Phys. Activities Unit, ULSS 16, Padova, Italy.

Introduction. Arrhythmogenic Cardiomyopathy (AC) is an inherited myocardial disease characterized by fibro-fatty replacement of myocardium and increased risk of sudden death (SD), which may be the first disease manifestation in young and athletes. About half of AC patients harbor genetic variants in genes encoding for desmosomal proteins.

Purpose. To assess the frequency of rare desmosomal variants in a cohort of apparently healthy athletes in order to evaluate their pathogenic role.

Methods. 188 unrelated young athletes (mean age 20 yrs, male/female ratio 3:1), eligible at the pre-participation clinical evaluation, underwent conventional genetic screening for major disease causative genes: Desmoglein2-DSG2, Desmoplakin-DSP, Plakophilin2-PKP2, Desmocollin2-DSC2, Plakoglobin-JUP. Variants selection was based on the absence or low frequency (minor allele frequency <0.0002) of the genetic variants in the general population, aminoacid conservation across species, in silico pathogenic evaluation. **Results.** Genetic screening identified putative pathogenic rare genetic variants in 8 (4.26%) athletes: 3 in DSG2, 2 in DSP and PKP2 respectively and 1 in DSC2. Only one of these variants was also reported in a patient with definite AC criteria. All 8 genotype positive athletes had no family history for AC or SD and showed no clinical signs of the disease at the second-level cardiological evaluation.

Conclusion. Our study demonstrated the presence of rare genetic desmosomal variants in healthy athletes, questioning their contribution in AC phenotype. The presence of desmosomal variants in the healthy population highlights the importance of clinical evaluation and cascade genetic screening in the families of mutation carriers to determine genetic variants pathogenicity.

P05.08

Contribution of non desmosomal variants in AC pathogenesis.

R. Celeghin, E. Lazzarini, I. Rigato, M. Cason, E. Carturan, D. Corrado, G. Thiene, B. Bauce, C. Basso, K. Pilichou;

University of Padua, Padova, Italy.

Introduction. Arrhythmogenic Cardiomyopathy (AC) is an inherited myocardial disease characterized by fibro-fatty replacement of myocardium, mainly linked to mutations in desmosomal genes. Next Generation Sequencing (NGS) enables the analysis of many genes at the same time in a single run.

Purpose. We developed a targeted NGS panel for the parallel analysis of 150 genes associated with different cardiomyopathies in the diagnostic setting. **Materials and methods.** 62 AC patients were analyzed using NGS technology on a Miseq platform (Illumina) using a custom panel of 150 genes associated with cardiomyopathies. The selection of the detected variants was based on the frequency, the conservation rate of the aminoacid, the potential pathogenicity and the functional effect on the protein.

Results. We identified 92 potentially pathogenic variants in desmosomal genes in 27 patients (43%), 7 of them carried 11 additional non-desmosomal variants, while 26 probands (44%) carried exclusively rare variants in sarcomeric (MYO6, MYH7, MYBPC3, MYH13, TNNT2, TNNT1) and ion-channel genes (KCNQ3, CACNA1C, SCN11G, TRPM4, SCN5A, SCN10A, KCNA5,

KCNE3, CACNA1B, KCNQ1, KCNK3).

Conclusions. The presence of rare likely pathogenic variants in non-desmosomal genes in AC probands may exert independent or synergistic effect on pathogenesis of AC. Deeper investigation is necessary to determine the role of these variants on the onset of the clinical phenotype. Cascade genetic screening remains imperative to clarify their role in AC families and to identify relatives at risk.

P05.09

Mutation screening of a panel of genes involved in inherited cardiomyopathies by using targeted next generation sequencing

M. Calore^{1,2}, I. E. A. Li Mura³, A. Telatin², I. Zara³, A. Lorenzon², M. De Bortoli², G. Poloni², B. Bauce⁴, B. Simionati², A. Rampazzo²;

¹Department of Cardiology, School for Cardiovascular Diseases, Faculty of Health, Medicine and Life Sciences, Maastricht University, Maastricht, Netherlands, ²Department of Biology, University of Padua, Padua, Italy, ³BMR Genomics, Padua, Italy, ⁴Department of Cardiac, Thoracic, and Vascular Sciences, University of Padua, Padua, Italy.

Inherited cardiomyopathies are caused by mutations in different genes, which makes genetic screening particularly challenging. Targeted-next-generation sequencing (NGS) enables mutation detection in large cohorts of patients affected with genetically heterogeneous diseases.

Purpose: developing and validating a targeted-NGS system for the genetic diagnosis of inherited cardiomyopathies.

Methods: Mutation screening was performed in 19 probands affected with arrhythmogenic cardiomyopathy (ACM), 2 with hypertrophic cardiomyopathy, and 1 with dilated cardiomyopathy, using a NGS gene-panel comprising the exons and adjacent boundaries of 56 genes involved in the main inherited cardiomyopathies. Target capture was performed by HaloPlex kit (Agilent) and samples were sequenced on a MiSeq sequencer (Illumina) at BMR-Genomics (Padua). Variants were called using GATK Unified Genotyper, GATK Haplotype Caller, FreeBayes and VarScan2 and annotated with Annovar and SNP-Shot (BMR-Genomics), the latter used also for variant prioritization.

Results: We identified 38 variants validated by Sanger sequencing (SS) and 2 expected false positives (unbalanced variants) and we confirmed 25 out of 27 variants previously detected by SS. Coverage >20X was obtained for 91.95% of 1.416.998 analyzed nucleotides and 90.93% of ACM genes. Among ACM patients, 11 carried mutations in ACM genes and 3 genotype-negative carried variants in genes associated to other cardiomyopathies.

Conclusions: Our approach represents a valuable tool for mutation screening in patients affected with inherited cardiomyopathies. Optimization of target capture will further improve the ability of mutation detection.

Grants: Strategic Program of the University of Padua, Ricerca Sanitaria Finalizzata (Veneto Region), University of Padua research project (PRAT) CPDA133979, POR CRO parte FESR 2007-2013-Asse1-Azione1.1.3

P05.10

Diagnostic utility of the extended next generation sequencing gene panel in a cohort of 31 Czech patients with arrhythmogenic right ventricular dysplasia/cardiomyopathy (ARVD/C): a pilot study

L. Piherová¹, J. Paderova², A. Krebsova³, P. Kubus⁴, M. Kubanek³, J. Kautzner³, J. Janousek⁴, S. Knoch¹, M. Macek Sr.², M. Macek Jr.²;

¹Institute of Inherited Metabolic Disorders, 1st Faculty of Medicine and VFN, Prague, Czech Republic, ²Department of Biology and Medical Genetics, 2nd Faculty of Medicine and FN Motol, Prague, Czech Republic, ³Department of Cardiology, Institute of Clinical and Experimental Medicine, Prague, Czech Republic, ⁴Children's Heart Centre, 2nd Faculty of Medicine, Charles University, Prague, Czech Republic.

Introduction: ARVD/C is a rare hereditary cardiovascular disorder associated with a higher risk of sudden cardiac death.

Patients and Methods: Altogether, 31 cases with clinical diagnosis of ARVD/C underwent genetic counseling followed by TruSight One panel sequencing (Illumina, USA). Detected variants, classified according to ACMG. net, were confirmed by Sanger DNA sequencing and familial segregation analysis, where possible.

Results: Positive family history was present only in 3 cases (10%) with severe ARVD/C. Likely pathogenic variants were revealed in 22/31 (71%) of patients in known ARVD/C-associated genes, mainly PKP2 in 10/31 of all cases (32%). In addition, variants in DSP, DSG, DSC were identified in 2/31 (6% each). Likely pathogenic variants in DES, TMEM43, TGFB3, ANK3, LDB3, JPH2 and SCN5A occurred once (3% each). One compound heterozygote for DSP/JPH2 mutations was revealed. In 9/31 patients (29%) the molecular etiology was not elucidated by our approach. Only 4/9 patients did not have a detectable DNA variant, in 5/9 patients variants in genes associated with other type of hereditary cardiovascular disease were observed (e.g. KCNE3/

TRPM4, SCN10A/TRDN, TRPM2, SOS1, FBN1).

Conclusion: We carried out a pilot study of ARVD/C variant distribution by an extended next generation sequencing panel in a representative cohort of Czech patients with a predominantly severe ARVD/C. Majority of likely pathogenic variants were found in PKP2 and the significance of DNA variants in other "non-ARVD/C-related" genes should be further assessed in order to provide clinical guidance and risk assessment in extended families.

Association study of polymorphic variants in leading candidate-genes from genome-wide association study in Bulgarian coronary artery disease patients and healthy population controls

R. Tzveova¹, G. Naydenova², T. Yaneva-Sirakova³, G. Dimitrov³, S. Vandeva⁴, D. Pendicheva⁵, P. Atanasov⁶, I. Popov⁷, C. Naydenov⁷, R. Turnovska-Kadreva³, G. Nachev⁸, V. Mitev¹, R. Kaneva¹;

¹Molecular Medicine Center, Department of Medical Chemistry and Biochemistry, Medical University, Sofia, Bulgaria, ²Second Department of Cardiology, UMHAT „Dr. Georgi Stranski“, Pleven, Bulgaria, ³Department of Internal Medicine, UMHAT „Alexandrovskia“, Cardiology clinic, Medical University, Sofia, Bulgaria, ⁴Clinical Center of Endocrinology and Gerontology, Medical University, Sofia, Bulgaria, ⁵Department of Experimental and Clinical Pharmacology, Medical University, Pleven, Bulgaria, ⁶National Sport Academy, Sofia, Bulgaria, ⁷Department of Medical Chemistry and Biochemistry, Medical University, Sofia, Bulgaria, ⁸University National Specialized Hospital for Active Treatment Hospital „Sv. Ekaterina“, Medical University, Sofia, Bulgaria.

The polymorphic variants in or near NRP3, ATP2B1 and CDH13 genes have been found to be associated with blood pressure measurements in some European populations. Hypertension is a major cause for coronary atherosclerosis, therefore the aim of this study was to investigate the possible association of three markers, rs1173771 (NRP3-C5orf23), rs2681472 (ATP2B1), and rs11646213 (CDH13), with the risk of coronary artery disease (CAD) and myocardial infarction (MI) in Bulgarians.

The study included both 324 CAD patients (199 with MI and 125 without MI) and 496 population controls. The studied variants were genotyped by using TaqMan genotyping assays. Genotype and allele frequencies were calculated and associations with disease were estimated using χ^2 .

The polymorphic variant rs1173771 did not show association with coronary atherosclerosis in the studied group (Aallele OR1.03; CI0.78-1.37; p=0.58). The Gallele of rs2681472 showed a link to higher risk of both CAD without MI (OR1.40; CI1.09-1.82; p=0.01) and with MI (OR1.48; CI0.10-1.99; p=0.009). In the subgroup analysis, this dependence was recorded only in men with CAD without MI (OR1.60; CI1.14-2.24; p=0.01). Furthermore, the same allele was associated with an increased risk of MI in men (OR1.87; CI1.29-2.72; p=0.001). Finally, allele A of rs11646213 showed an association with lower risk of MI (OR0.56; CI 0.38-0.85; p=0.005).

In this study we found for the first time association between investigated polymorphisms and CAD with/without MI in Bulgarians. Further studies in larger cohorts are needed to confirm the obtained results.

Barth syndrome phenotypically manifested in a heterozygous female carrier

T. Todorov¹, D. Avdjieva-Tzavella², H. Kathom², I. Yordanova¹, M. Ivanova³, R. Tincheva², A. Todorova^{4,1};

¹Genetic Medico-Diagnostic Laboratory Genica, Sofia, Bulgaria, ²University Pediatric Hospital, Medical University Sofia, Sofia, Bulgaria, ³National Genetic Laboratory, University Hospital „Majcin Dom“, Sofia, Bulgaria, ⁴Medical University Sofia, Sofia, Bulgaria.

Barth syndrome (BTHS) is an X-linked recessive disease typically characterized by dilated cardiomyopathy, predominantly proximal skeletal myopathy, prepubertal short stature and neutropenia. From biochemical point of view the disease is associated with excess of 3-methylglutaconic acid, hypoglycemia, lactic acidosis, hyperammonemia. The disease is caused by mutations in the tafazzin gene (TAZ) which lead to cardiolipin deficiency and mitochondrial dysfunction. Male patients have variable clinical findings, while female carriers are usually asymptomatic.

The TAZ gene was screened for mutations by Sanger sequencing (using Big-Dye terminator v3.1 Cycle Sequencing Kit) in male and female siblings both with left ventricular noncompaction and hypotonia. Additionally, the brother presented an intermittent

neutropenia and increased urinary levels of 3-methylglutaconic and 3-methylglutaric

acid. The molecular genetic testing of the TAZ gene revealed a novel mutation c.253insC, p.(Arg85Profs*54) in exon 3 of the TAZ gene. Both siblings carry the same mutation. The mutation was inherited from asymptomatic mother.

To the best of our knowledge this is the first case of Barth syndrome phenotypically manifested in a heterozygous female carrier with normal karyotype. A possible explanation could be non-random X inactivation predominantly involving the non-affected X chromosome.

Exome-wide association study fails to identify genetic variation contributing to the development of bicuspid aortic valve

M. Gago-Díaz^{1,2}, C. Newton-Cheh^{3,4}, S. Body^{4,5}, Á. Carracedo^{2,6}, G. Teixidó-Turà⁷, D. García-Dorado⁷, A. Evangelista⁷, B. María^{1,2};

¹Xenética de enfermidades cardiovasculares e oftalmológicas, Instituto de Investigación Sanitaria de Santiago de Compostela, Complejo Hospitalario Universitario de Santiago de Compostela, Santiago de Compostela, Spain, ²Grupo de Medicina Xenómica, Instituto de Investigación Sanitaria de Santiago de Compostela-Universidade de Santiago de Compostela-Fundación Pública Galega de Medicina Xenómica, Santiago de Compostela, Spain, ³Cardiovascular Research Center and Center for Human Genetic Research, Massachusetts General Hospital and Harvard Medical School, Boston, MA, United States, ⁴The Broad Institute of Massachusetts Institute of Technology and Harvard University, Cambridge, MA, United States, ⁵Anesthesia and Pain Management, Brigham and Women's Hospital, Boston, MA, United States, ⁶Center of Excellence in Genomic Medicine Research (CEGMR), King Abdulaziz University, Jeddah, Saudi Arabia, ⁷Servei de Cardiologia, Hospital Universitari Vall d'Hebron, Barcelona, Spain.

Introduction: Bicuspid aortic valve is the most common cardiovascular congenital malformation affecting humans with a prevalence of 0,5- 2% in general population. Although it can be diagnosed as an incidental finding, many patients develop life-threatening complications that have awoken interest in understanding a molecular basis that remains unknown. Based on 90% heritability and high incidence of familial clustering, our objective was to identify any genetic factor that could predict patients at risk of developing symptomatology.

Materials and Methods: Assuming a complex mode of inheritance, we conducted a transversal exome-wide association study in a discovery cohort of 570 cases and 484 Spanish controls that we genotyped with the Axiom Exome Array (Affymetrix) and imputed association results based on the Phase 3 1000 Genomes Project reference panel. We performed association analysis for the total sample and 6 different subgroups classified based on thoracic aortic measurements and valve morphology. The replication series comprised 512 cases and 1,483 European controls that we genotyped with MassArray System (Sequenom). Finally, we performed meta-analysis using METAL.

Results: We prioritized 13 markers identified during the discovery study for replication along with 5 FBN1 markers previously described as associated, but were not able to replicate any result.

Discussion and Conclusions: These negative results support bicuspid aortic valve complexity (that should not longer be considered a unique entity), the need to establish worldwide collaborations to increase sample size and power and the association of FBN1 with thoracic aortic dilation and not the valvular malformation itself. Funding: PI13/00933 and RD12/0042/0037, ISCIII-FEDER.

P05.15

Genetic characterization of a BAV population of Italian origin. Results from GISSI OUTLIERS VAR study.

S. Pileggi¹, S. Barlera¹, B. Merlanti², B. De Chiara², L. Martinelli³, A. Maseri⁴, M. G. Franzosi⁵;

¹Department of Cardiovascular Research, IRCCS Istituto di Ricerche Farmacologiche "Mario Negri", Milan, Italy, ²Department of Cardiology and Cardiovascular Surgery, Niguarda Ca' Granda Hospital, Milan, Italy, ³Cardiothoracic Surgery, ICLAS-Istituto Clinico Ligure Alta Specialità, Rapallo, Italy, ⁴Heart Care Foundation, Florence, Italy.

Introduction: Bicuspid aortic valve (BAV) formation is genetically determined, with reduced penetrance and variable expressivity. NOTCH1 gene is a well-proved candidate gene and its mutations have been found both in familial and sporadic cases of BAV.

Materials and Methods: 66 BAV patients from the GISSI VAR study have been genotyped for the NOTCH1 gene.

Results: We identified 64 variants, both in heterozygous and in homozygous state. Fifty-two are common polymorphisms present in almost all patients. Eleven variants are new and never reported in literature: two are non-synonymous substitution, Gly540Asp in exon 10 and Glu851Gln in exon 16;

one is in the 3'UTR region and 7 in introns, one corresponds in a T allele insertion in intron 27. We selected four statistically relevant and seven new variants identified in six BAV patients and correlated them with clinical and demographic variables as well as imaging and histological parameters. Our preliminary data show that 4 were BAV patients with isolated stenosis in over 60 year-old patients. We suppose that these variants correlate with a late necessity to undergo to surgery that is driven by the presence of stenosis and not by aortic valve regurgitation or ascending aortic aneurysm. Conclusions: We completed the genotyping of 66 BAV patients and found 11 new variants in the NOTCH1 gene never reported in literature. These data confirm that the identification of new clinically relevant biomarkers for BAV requires a deeper genetic understanding of the NOTCH1 gene variants, that could be targeted by future diagnostic and therapeutic strategies.

P05.16

Copy number variation in clinical tests for inherited cardiomyopathies and arrhythmias

J. Tahiliani, N. Johnson, S. Aguilar, A. Daly, E. Decker, B. Herrera, D. Beltran, L. Murillo, R. Harte, J. Garcia, S. Lincoln, E. Haverfield, S. Aradhya, Invitae, San Francisco, CA, United States.

Introduction: The clinical significance of exon-level copy number variation (CNV) in inherited cardiovascular conditions has not been widely studied to date. Sequence changes make up the vast majority of reported pathogenic variants in genes associated with inherited cardiomyopathies and arrhythmias.

Methods: We considered a sequential series of 287 patients submitted for an arrhythmia panel, 370 for a cardiomyopathy panel, and 36 for both. Germline DNA from blood was tested, and the gene panels were selected by ordering physicians based on each patient's clinical indication. Sequence and CNV analysis was performed by validated Next Generation sequencing (NGS) methods, and identified CNVs were confirmed by microarray analysis. Results: Six single- or multi-exon deletions were identified in patient samples: two deletions in MYBPC3 in two unrelated patients presenting with hypertrophic cardiomyopathy; two RYR2 deletions in two unrelated patients presenting with arrhythmia; a PKP2 deletion in a patient presenting with arrhythmogenic cardiomyopathy; and a CTNNA3 deletion in a patient presenting with cardiomyopathy. Except CTNNA3, all deletions were classified as pathogenic, and no other pathogenic variants were identified in these individuals.

Conclusions: Historically, CNV analysis for these genes was either not widely available clinically or was available as a reflex test. In this case series, CNVs accounted for about 4% of the positive findings, suggesting that CNV analysis may be an important component of genetic testing for inherited cardiomyopathies and arrhythmias in the future.

P05.17

Genetic screening in idiopathic cardiomyopathy: should we broaden our perspective?

E. Vanhoutte¹, M. Hazebroek², L. Montfort¹, M. Witjens¹, M. Hoos², A. Helderma-van den Enden¹, F. van Tienen¹, G. Claes¹, A. Wijngaard¹, S. Heymans², I. Krapels¹, ¹Department of Clinical Genetics, Maastricht University Medical Center, Maastricht, Netherlands, ²Department of Cardiology, Maastricht University Medical Center, Maastricht, Netherlands.

Introduction: The ESC guidelines recommend genetic testing merely in patients with dilated cardiomyopathy (DCM). However, a significant subgroup presents with left ventricular (LV) dysfunction without dilatation. Our aim is to compare the yield of NGS gene testing and prognosis in LV dysfunction patients versus DCM patients.

Materials and Methods: 262 DCM and 127 LV dysfunction patients underwent complete cardiologic evaluation and NGS gene testing of 46 cardiomyopathy genes. Genetic or familial predisposition was defined as familial inheritance pattern and/or a (likely) pathogenic mutation. Long-term outcome used a combined endpoint of life-threatening arrhythmia, heart transplantation, and death.

Results: A genetic or familial predisposition was equally distributed between DCM and LV dysfunction patients (100 (38%) vs 57 (45%); P=0.21). A (likely) pathogenic mutation was more frequently found in patients with positive familial inheritance, irrespective of a DCM or LV dysfunction phenotype (20 (25%) vs 17 (9%); P=0.001 and 12 (27%) vs 11 (13%) P=0.049, respectively). After a median follow-up of 56 months, long-term outcome did not differ between DCM and LV dysfunction. However, in both DCM and LV dysfunction patients outcome was worse in the presence of a genetic/familial predisposition.

Conclusion: The diagnostic yield of NGS gene testing is comparable between

DCM and LV dysfunction without dilatation. Prognosis is worse in both DCM and LV dysfunction patients with a genetic or familial predisposition. Therefore, genetic screening should also be performed in patients with LV dysfunction.

Genetic testing in dilated cardiomyopathies: increasing the diagnostic yield by next generation sequencing techniques

A. T. J. M. Helderma-vd Enden¹, M. Riemersma¹, E. K. Vanhoutte¹, L. van Montfort¹, M. I. Witjens¹, M. B. Hoos¹, M. R. Hazebroek², F. H. J. van Tienen¹, G. F. R. Claes¹, S. R. B. Heymans², I. P. C. Krapels¹, A. van den Wijngaard¹;

¹Department of Clinical Genetics, Maastricht University Medical Center, Maastricht, Netherlands, ²Department of Cardiology, Maastricht University Medical Center, Maastricht, Netherlands.

Purpose: Dilated cardiomyopathy (DCM) is characterized by ventricular chamber enlargement and systolic dysfunction. Nowadays 30-50 genes are associated with DCM and a genetic cause of this heterogeneous disorder is found in 30-40% of all patients. The aim of this study was to increase the diagnostic yield of genetic testing by using next-generation sequencing (NGS) techniques.

Methods: In 406 idiopathic DCM patients Sanger sequencing was performed for several genes. A subgroup of 172 patients received one or both of the following gene panel tests: CardioChip (34 genes) and next-generation whole exome sequencing using a targeted filter (45 genes). In the gene panel subgroup, *TTN* was tested in 93 patients. Genetic variants were defined as variants of unknown clinical significance (VUS), likely pathogenic (LP) and pathogenic (P) variants.

Results: Sanger sequencing of several genes detected a genetic variant in 16.5%. Genetic variants were found in 46% by gene panel testing. In the gene panel subgroup of 172 patients, a variant in *MYH7*, *PLN* and *LMNA* was detected in 4.1%. A variant in other genes was found in 40.7%. The highest detection rates of likely pathogenic variants or pathogenic variants were found in *TTN* (13%), *RBM20* (3.2%) and *MYH7* (2.5%). **Conclusions:** Our data illustrate that gene panel testing in DCM patients increases the diagnostic yield, with the highest diagnostic yield in *TTN*. We suggest that genetic analysis in idiopathic DCM patients starts with NGS gene panel testing without prior single gene testing.

P05.19

Detection of known and novel cardiovascular diseases gene variants by next generation sequencing in terms of improved treatment and prognosis

S. Josifovska^{1,2,3}, R. Vazharova^{1,4}, L. Balabanski¹, S. Ivanov¹, R. Staneva², S. Hadjidekova², M. Malinov¹, S. Panov³, D. Toncheva²;

¹SBALGAR "Malinov", Sofia, Bulgaria, ²Department of Medical Genetics, Medical University of Sofia, Sofia, Bulgaria, ³Faculty of Natural Sciences and Mathematics, "Ss. Cyril and Methodius" University, Skopje, Macedonia, ⁴The Former Yugoslav Republic of, ⁴Medical Faculty, Sofia University "St. Kliment Ohridski", Sofia, Bulgaria.

Introduction: According to the WHO, cardiovascular diseases (CVD) are the main cause of death worldwide. CVD involve a large group of heterogeneous disorders that cannot always be precisely diagnosed, so therapy and outcome heavily depend on proper genetic profiling. The aim of this study was to determine genetic variants in patients with CVD.

Materials and Methods: DNAs from 11 patients with CVD were analyzed using NGS targeted resequencing of 176 genes included in TruSight Cardio gene panel (Illumina). Variant detection was upon reference human genome (GRCh37).

Results: Detected gene variants are as follows: heterozygous *ACTA2*:p.Arg258Cys, in a patient with aortic dissection; heterozygous *KCNJ2*:p.Arg218Trp in a patient with LQTS; double heterozygosity for *CACNA1C*:p.Arg514Gly and *SCN5A*:p.Arg800His in a patient with severe hypertrophic obstructive cardiomyopathy and arrhythmia; double heterozygosity for *ELN*:c.890-1G>A and *SCN5A*: p.Gly9Val in a patient with SVAS, pulmonary valve stenosis and arrhythmia. An interesting finding is the co-occurrence of dominant pathogenic variants in different genes, as in the case of two of the patients, which may explain the complexity and severity of the observed phenotypes.

In conclusion, detection of common and new variants in the patients with CVD has confirmed or shifted diagnosis, further establishing genetic association studies involving NGS as analysis of choice for clinical diagnosis and research with large implication on treatment and prognosis of patients and their families.

Molecular autopsy: a potential tool to identify pathogenic CNVs in congenital heart defects

F. A. R. Madia¹, C. Milani¹, A. T. Dias¹, E. A. Zanardo¹, J. G. Damasceno¹, M. Rocha², A. M. Nascimento¹, T. V. M. M. Costa¹, G. M. Novo-Filho¹, M. M. Montenegro¹, A. F. Amorim¹, Y. G. Oliveira¹, C. H. Chung¹, J. R. M. Ceroni¹, R. Schultz¹, F. T. Gonçalves¹, C. Fridman¹, C. A. KIM¹, L. D. Kulikowski^{1,2};
¹Faculdade de Medicina da USP, SAO PAULO, Brazil, ²Faculdade de Medicina do ABC, Santo André, Brazil.

Introduction: Congenital heart defects (CHD) is the most prevalent group of congenital malformations affecting approximately 8-1,000 live births and is a significant cause of childhood morbidity and mortality. Recently, the increased frequency of pathogenic copy number variants (CNVs) in congenital heart disease was demonstrated by several different studies.

Materials and Methods: We investigate the contribution of CNVs in the pathogenesis of CHD using molecular methods in 29 cases of stillbirth and new-born from Serviço de Verificação de óbitos, HC-FMUSP. DNA samples from skin and heart tissues were evaluated using AmpF ℓ STR ® MiniFiler ™ PCR Amplification Kit (Life Technologies ™ , California, USA) and Multiplex Ligation-dependent Probe Amplification (MLPA) with different kits (MCR-Holland, Amsterdam, the Netherlands).

Results: The results showing several different CNVs such as ZNF74, NCAM2, NFATC1 and AR genes associate with cardiac phenotype. In 9 of 28 stillbirth and new-born (32%) with CHD and additional structural abnormalities, we identified cases of Edwards Syndrome, Patau Syndrome, Down Syndrome and one case of Phelan-McDermid Syndrome with duplication of ZNF74. Also we identified one case of Turner Syndrome and one case of Turner Syndrome with Y chromosome mosaicism. Only one isolated CHD case did not showed pathogenic CNVs.

Conclusion: Molecular autopsy showed efficiency for identifying pathogenic CNVs associated with CHD and also allowed the adequate genetic counseling.

Grants: FAPESP: 09/53105-9 and FINEP-CT INFRA 0160/12 SP8.

The novel coronary artery disease risk gene KIAA1462 regulates endothelial cell function

P. D. Jones¹, R. Rajmohan¹, T. R. Webb¹, N. J. Samani^{1,2};
¹University of Leicester, Leicester, United Kingdom, ²NIHR Leicester Cardiovascular Biomedical Research Unit, Leicester, United Kingdom.

Genome wide association studies have identified 56 chromosomal loci that are associated with coronary artery disease (CAD). However, for most of these loci both the gene responsible and the mechanism by which they affect CAD risk is unclear. The CAD-associated locus at 10p11.21 contains 9 CAD-associated SNPs, located within the gene *KIAA1462*, which encodes a poorly characterised cell junction protein. As the role of *KIAA1462* is poorly understood, we set out to assess its functional role in endothelial cells, using siRNA gene knock-down. Compared with a control siRNA, an siRNA directed at *KIAA1462* resulted in a consistent 80 % reduction in *KIAA1462* expression. *KIAA1462* knock down resulted in slower cell proliferation, with approximately 15% fewer cells after 48 hours of proliferation compared to control siRNA transfected cells (t-test after 48 hours, p=0.001). An *in vitro* wound healing assay showed approximately 30% slower migration in knock-down cells (p=0.004). We also found increased apoptosis in *KIAA1462* knock-down cells, with a 15% increase in apoptosis as measured by Caspase 3/7 activity (p=0.030). In addition, we used a matrigel tube-formation assay as an *in vitro* assay for angiogenic capability of the cells. This showed approximately a 32% reduction in total tube length formed in *KIAA1462* knock-down cells compared to controls (p=0.002). These data suggest that *KIAA1462* is involved in the regulation of endothelial cell function and angiogenesis and this may explain its involvement in CAD.

P05.23

Genotype based pathway analysis of genetic loci associated with coronary artery disease

S. E. Hamby^{1,2}, T. Webb^{1,2}, N. J. Samani^{1,2};
¹University of Leicester Cardiovascular Research Center, Leicester, United Kingdom, ²NIHR Leicester Cardiovascular Biomedical Research Unit, Leicester, United Kingdom.

Introduction: Genome wide association studies have identified 56 genetic loci associated with increased risk of coronary artery disease (CAD). Many contain genes not previously linked to disease and potentially involve hitherto unrecognised biological processes. Investigating differential expression of pathways between risk/non-risk genotypes may allow identification of novel molecular mechanisms.

Materials and methods: We analysed gene expression data from 849 Monocyte, and 684 Macrophage samples collected from 459 individuals with CAD/MI and 458 controls as part of the Cardiogenics transcriptomic study (Rotival M, et al. *PLoS Genet.* 2011;12:e1002367). We utilised the QuSAGE R package (Yaari G et al. *Nucleic Acids Res.* 2013;41(18):e170) to explore differential expression of pathways between risk/non-risk genotypes for CAD loci. QuSAGE is a pathway analysis tool, modelling overall pathway fold change between sample groups utilising probability density functions.

Results: For seven CAD loci, we identified genotype related differential expression in specific pathways at FDR q value <0.1, with functions encompassing cytokine signalling, inflammation, calcium homeostasis and muscle contraction (Table). For the 9p21 locus we observed distinct pathways in monocytes/macrophages suggesting cell type specific effects.

Pathways differentially expressed at specific CAD loci in monocytes/macrophages

Locus Name	Cell type	Reactome Pathway Name	Log Fold Change	FDR

17q21.32	Monocyte	VEGF Ligand Receptor Interactions	-0.056	0.095

Conclusions: Using QuSAGE we have identified several pathways related to CAD associated variants. This methodology provides a useful tool to examine the biological mechanisms of complex disease genetics.

P05.24

Expression of COX7A1 as a potential marker of congenital heart defects

A. Dobosz¹, M. Bik-Multanowski¹;
 Jagiellonian University Medical College, Krakow, Poland.

* Congenital heart defects occur in approximately 50% of children with Down syndrome and in 1% of general population. The most common defects include ventricular septal defect (VSD), common atrioventricular channel (CAVC) and atrial septal defect (ASD). These defects are usually detected by means of fetal sonographic examination performed during pregnancy. We aimed at defining a molecular blood marker, which could allow for early detection of such defects in case of prenatal testing, performed due to suspected congenital malformation.

* **Methods:** * We conducted a whole genome expression analysis in 21 children with Down syndrome, with or without congenital heart defect. We used microarray technology to compare the whole genome expression in blood mononuclears between both subgroups. Next we used GeneSpring software for data analysis. Moderated t-test was applied with the Westfall-Young correction for multiple comparisons to detect significant differences between compared groups.

* **Results:** * We found upregulation of the *COX7A1* gene in patients born with heart defect (Fold Change 2.83). The *COX7A1* protein is one of the nuclear-coded polypeptide chains of cytochrome c oxidase, the terminal oxidase in mitochondrial electron transport in the muscle cell, and can play a role in heart muscle pathology. Our results show potential value of assessment of *COX7A1* expression in blood as a screening test for prenatal detection of congenital heart defects.

The study was sponsored by the Polish National Science Centre (DEC-2011/03/B/NZ5/01328).

The characterisation of a novel nonsense mutation in RYR2 using human induced pluripotent stem cells

C. Bailey¹, A. Tijssen², L. Maizels², I. Huber², G. Arbel², A. Gepstein², N. Moreton³, B. Brown⁴, L. Venetucci¹, W. G. Newman^{1,3}, L. Gepstein²;

¹University of Manchester, Manchester, United Kingdom, ²Technion - Israel Institute of Technology, Haifa, Israel, ³Manchester Centre for Genomic Medicine, Manchester, United Kingdom, ⁴University Hospital of South Manchester, Manchester, United Kingdom.

Introduction: Heterozygous missense mutations in RYR2 are associated with catecholaminergic polymorphic ventricular tachycardia. We identified a novel nonsense mutation p.(Arg4790*) in RYR2 in a young woman following resuscitation from a cardiac arrest. We generated human induced pluripotent stem cells (hiPSCs) to characterise this mutation.

Methods: We generated hiPSCs from the affected individual and differentiated these cells into cardiomyocytes (hiPSC-CMs). We performed confocal calcium imaging on the hiPSC-CMs and undertook analysis to determine the molecular mechanism by which the mutation results in a phenotype.

Results: Baseline calcium imaging showed significantly more patient hiPSC-CMs displayed calcium transient abnormalities compared to control hiPSC-CMs (66.7% vs 28%). 52.6% of patient hiPSC-CMs which displayed normal transients at baseline developed transient abnormalities in response to isoproterenol whilst only 19% of control hiPSC-CMs developed abnormalities. More patient hiPSC-CMs displayed spontaneous calcium transients at lower external calcium concentrations suggesting a lower threshold for store overload-induced calcium release (SOICR). The application of carvedilol corrected baseline calcium transient abnormalities in 80% of patient hiPSC-CMs. Allele-specific qPCR showed expression of both RYR2 alleles, suggesting that the p.(Arg4790*) mutation does not result in haploinsufficiency.

Conclusions: The patient hiPSC-CMs display an abnormal calcium handling phenotype with increased abnormalities at baseline and after application of isoproterenol, and a reduced threshold for SOICR. The abnormal calcium handling phenotype was rescued by carvedilol indicating a potential therapeutic approach to prevent arrhythmias.

This research was funded by a BIRAX Regenerative Medicine Fellowship and facilitated by Manchester Biomedical Research Centre and the NIHR Greater Manchester: Clinical Research Network.

The RYR2 p.R420W mutation causes premature sudden cardiac death

O. Abdel-Razek¹, A. Collier², S. Predham², F. Curtis², A. Bullen², J. Houston², T. Benteau², S. Stuckless³, T. Young², S. Connors⁴, K. Hodgkinson^{2,3};

¹Memorial University, Department of Internal Medicine, St. John's, NL, Canada,

²Memorial University, Discipline of Genetics, St. John's, NL, Canada, ³Memorial University, Unit of Clinical Epidemiology, St. John's, NL, Canada, ⁴Memorial University, Department of Internal Medicine, Division of Cardiology, St. John's, NL, Canada.

Background: Catecholaminergic Polymorphic Ventricular Tachycardia (CPVT) is an arrhythmia syndrome causing sudden cardiac death (SCD). A putative founder mutation in RYR2 (p.R420W) located in the cytosolic portion of the protein crucial for calcium channel regulation has been ascertained in Newfoundland. Juvenile deaths were ascribed to this mutation in a previous publication without DNA confirmation.

Research Question: Does the RYR2 p.R420W mutation affect survival in a well ascertained autosomal dominant, multiplex (5 generation) three pedigree population?

Study population: All persons born at an a-priori 50% risk from three pedigrees segregating the RYR2 p.R420W were ascertained (n=79). Individuals were included if the disease status of ≥ 50% of their sibship was known (n=66). We excluded 6 juvenile (< 9yrs) deaths (n=60). Affected individuals included mutation positive and/or obligate carriers (OC) and/or SCD under 50 years. Unaffected status was defined as mutation negative. The remainder were unknown (UK).

Methods: Genetic and clinical data from all available medical records were collected from family members. Of 60 individuals, 27 (45%) were affected (16 mutation positive, 6 OC and 5 SCD) and 26 (43%) were unaffected. The unaffected and UK groups were combined. Time to death was compared using Kaplan-Meier time to event analysis and multivariate Cox regression.

Results: Affected status was significantly associated with mortality: RR = 4 (95% CI: 1.1-14.5) and affected males died earlier than females RR=7 (95% CI 1.5-34.5).

Conclusions: The RYR2 p.R420W mutation significantly affects mortality, particularly for males. Six juvenile deaths (with unknown mutation status) have occurred in these families.

Ospedale Niguarda Cà Granda, IV Divisione di Cardiologia, Milano, Italy.

Background. Catecholaminergic polymorphic ventricular tachycardia (CPVT; MIM 619138) is a rare inheritable disorder due to mutations in RYR2, CASQ, CALM1 and TRDN genes. It can be both autosomal dominant (RYR2 and CALM1) or recessive (CASQ2 and TRDN). It is clinically characterised by adrenergically induced polymorphic ventricular tachycardia (VT) in absence of structural heart diseases. Presentation includes syncope or sudden cardiac death (SCD) in young patients. Exercise testing is the gold standard for the clinical diagnosis and genetic testing may unravel additional asymptomatic carriers within the family.

Methods. We present a consecutive series of 25 young athletes (aged less than 18) with clinical suspicion of CPVT after undergoing pre-participation testing for competitive sports. Clinical assessment included: physical examination, surface ECG, echocardiogram and exercise testing (Bruce protocol). After genetic counselling, molecular testing was started by means of Next Generation Sequencing (NGS) on an Ion PGM platform with a targeted-resequencing panel of 148 cardiac genes.

Results and Conclusion. After testing, we found 8 (32%) mutation-carriers of the RYR2 gene, 4 (16%) mutations-carriers of the CASQ2 gene and 2 (8%) mutation-carriers of the CALM1 gene. Cascade testing revealed additionally RYR2 (n=13), CASQ2 (n=7) and CALM1 (n=3) mutations carriers with (47%) and without (53%) clinical signs. The study proved that proper clinical for sport activity in the young athletes is of utmost importance in identifying potentially individuals at risk of life-threatening arrhythmias. However psychosocial evaluations must included in order to overcome the life-style modifications subsequent to the genetic testing for the probands and their relatives.

P05.28

Next-generation sequencing to identify genetic causes of dilated cardiomyopathies

J. Bernasovska¹, I. Boronova¹, I. Bernasovsky¹, J. Kmec²;

¹University of Presov, Presov, Slovakia, ²Cardiocentre, Hospital of J.A. Reiman, Presov, Slovakia.

Dilated cardiomyopathy (DCM) is most common form of heart muscle disease and a leading cause of congestive heart failure. The genetics of cardiomyopathies represents one of the most active areas for the research in molecular genetics. The aim of our study was genetic testing of 29 patients with diagnosed DCM using next generation sequencing technology. All probands underwent clinical examination and genetic analysis. The control group included thirty healthy asymptomatic subjects without cardiovascular disease or a family history of DCM. Genomic DNA was extracted from whole peripheral blood using the standard extraction kit. Exome libraries were sequenced on a SOLiD 5500xl flowchip in paired end mode (75plus 25bp). Molecular-genetic analyses included also 50 different genes implicated in causing DCM. We didn't find any causal mutation in these genes in patients with dilated cardiomyopathy. On the other hand, we found missense mutations in other genes: SCN5A, SLC9A5, SLC26A9, SLC8A3 and MEGF8. In six patients with dilated cardiomyopathy was detected a disease causing mutation rs1805124, T/C in SCN5A gene. This mutation is disease specific for hypertrophic cardiomyopathy, however, the findings in the dilated cardiomyopathy has not yet been described. We recognised a novel missense mutation in SLC9A5 (NHE-5) gene, termed c.C826T:p.R276C (NM_004594.2) and mapped to the chromosomal, region16:67,289,748 in three patients. Early diagnosis and correct assessment of the patient's risk profile plays a key role in determining the start of treatment. This study is the result of implementation of the projects APVV-0644-12 and ITMS 26220120241.

P05.29

Recurrent early-onset dilated cardiomyopathy and left ventricular noncompaction in a family with germline mosaicism for a MYH7 mutation

L. Fernández¹, P. Muñoz-Cabello¹, K. Ibáñez¹, V. Fdez-Montaño¹, F. Nieto¹, E. Mansilla¹, F. Santos-Simarro¹, J. Silla-Castro¹, C. Labranderó², M. Ortega², J. Nevado¹, S. García-Miñaur¹, Á. del Pozo¹, P. Lapunzina¹, E. Vallespin¹;
¹INGEMM-IDIPAZ-HULP, Madrid, Spain, ²Cardiology Department-IDIPAZ-HULP, Madrid, Spain.

Introduction: Dilated cardiomyopathy and left ventricular noncompaction are overlapping, genetically heterogeneous disorders with an average low diagnostic yield. Multigene testing may raise detection rate, while a larger increase in variants of uncertain significance hinders genetic counseling. We report a case of recurrent neonatal dilated cardiomyopathy with left ventricular noncompaction in two consecutive pregnancies from a healthy consanguineous couple that suggested autosomal recessive inheritance.

Materials and Methods: The index patient was studied with a custom-designed CardioMass v2.1 NGS panel including 268 genes associated with cardiomyopathies and cardiac rhythm disorders. Capture was based on Roche NimbleGen technology and sequencing was performed on a MiSeq Illumina platform. Family studies confirmed NGS variants by direct sequencing.

Results: An apparently de novo mutation in MYH7 in the two siblings disclosed germline mosaicism in the family. Furthermore, both children, as well as their healthy parents, were carriers of a rare heterozygous variant in HCN4 which was previously described in association with bradycardia-tachycardia syndrome and left ventricular noncompaction.

Conclusions: These results highlight the usefulness of a NGS approach for genetically heterogeneous disorders. This case further shows the challenge of interpretation and the importance of familial segregation studies in the diagnosis of patients with multiple potentially pathogenic variants.

Identification of shear stress responsive enhancer elements in endothelial cells

O. Bondareva^{1,2}, R. Tsaryk², A. Siekmann², H. Schnittler¹;

¹Institute of Anatomy and Vascular Biology, Münster, Germany, ²Max Plank Institute for Molecular Biomedicine, Münster, Germany.

Shear stress is a frictional force that significantly modulates endothelium structure and function due to change in metabolism, gene expression and posttranslational modifications. Unidirectional arterial shear stress levels are atheroprotective, supported by negative regulation of apoptotic signaling in vivo and in vitro. By contrast disturbed oscillatory flow acts as a pathological stimulus contributing to atherosclerosis and vasculopathies. Many studies demonstrated shear stress induced changes in gene expression, however the underlying transcriptional regulatory mechanisms remain unknown. In this study we aimed to identify shear stress responsive enhancer elements. Human umbilical vein endothelial cells were exposed to different shear stress profiles using the cone-and-plate based BioTechFlow System®. After application of 18 dyn/cm² unidirectional or ±3 dyn/cm² of oscillatory shear stress (0.5 and 6 hours stimulation) we performed chromatin immunoprecipitation of H3K27ac mark for active enhancers. Bioinformatical analysis of the sequenced immunoprecipitated DNA fragments revealed thousands of unique specific shear stress induced peaks corresponding to activated enhancers which were frequently found in proximity of genes regulated by shear stress. Further investigation of the peaks identified binding sites of several transcription factors implicated in shear stress responses and adaptation processes, e.g. SMADs for unidirectional and HIC1 for oscillatory flow. In conclusion, we demonstrate a genome-wide analysis of shear stress responsive regulatory elements that control the expression of genes important for shear stress-induced physiological and pathological endothelial phenotypes. The data provide a deeper insight into the diseases such as atherosclerosis and might open novel targets for therapy. Funded by CiM Flexible Funds, Münster, Germany.

Familial Hypercholesterolaemia cascade genetic screening: A blind trial to evaluate the Randox FH Multiplex Arrays

D. A. Bailie¹, P. J. Hart¹, M. J. Latten², R. J. L. Martin¹, T. L. Watson², H. A. Murray², J. V. Lamont², S. P. Fitzgerald², M. A. Crockard², C. A. Graham^{1,2};

¹Northern Ireland Regional Genetics Centre, Belfast Health and Social Care Trust, Belfast, United Kingdom, ²Randox Laboratories Ltd, 55 Diamond Road, Belfast, United Kingdom.

Introduction: Familial Hypercholesterolaemia (FH) is a common genetic disorder characterised by elevated low density lipoprotein cholesterol and early symptoms of coronary heart disease. Estimates suggest <10% of FH patients are diagnosed in most countries. Cascade genetic testing, as recommended by the National Institute for Health and Clinical Excellence (2008) and the European Atherosclerosis Society (2013), may successfully identify new cases. This study aims to determine the effectiveness of the Randox FH Multiplex Arrays for this purpose. This FH array is designed to detect 40 FH causing genetic alterations, accounting for 71% of mutations in Great Britain and Ireland.

Materials and methods: Close relatives (N=199) of mutation-positive index cases (previous confirmation by DNA sequencing) were selected for genetic testing. Screening was conducted as a blind study to remove bias. Mutational analysis was performed using the FH Multiplex Arrays I & II and the Evidence Investigator analyser (Randox Laboratories Ltd, Crumlin, UK).

Results: A true positive rate of 97.8% (89/91 patients) and a true negative rate of 100% (108/108 patients) demonstrates the sensitivity and specificity of the test in detecting 37 of 40 targeted family mutations present on the arrays, suggesting a concordance rate of 99% for the Randox FH Multiplex Arrays for cascade genetic screening.

Conclusion: The FH arrays successfully identify the most prevalent mutations in the Great Britain and Ireland cascade screening population. This will enable a cost effective method for targeted identification of people affected by FH, permit enhanced FH monitoring/management thus reducing FH associated morbidity and mortality.

P05.32

Rare variants in PCSK9 protect against familial hypercholesterolaemia in a patient with a pathogenic LDLR mutation

S. Rodríguez-Novoa¹, C. Rodríguez¹, K. Heath¹, A. del Pozo¹, M. Tress², E. Vallespin¹, P. Lapunzina¹, P. Martínez²;

¹INGEMM-Hospital La Paz, Madrid, Spain, ²CNIO, Madrid, Spain, ³Medicina Interna-Hospital La Paz, Madrid, Spain.

Introduction: Familial Hypercholesterolaemia (FH) is characterized by elevated low density lipoproteins (LDL-c) leading to premature cardiovascular disease. FH is caused by lost-of-function variants in LDLR, APOB and gain-of-function variants in PCSK9. Lost-of-function PCSK9 variants lead to decreases in LDL-c. Herein, we describe a family with a LDLR pathogenic mutation and two rare PCSK9 variants and their phenotype consequence.

Patients and Methods: LDLR, APOB, PCSK9 and LDLRAP1 were analysed in a FH family, by NGS and MLPA.

Results: A heterozygous known pathogenic LDLR mutation, c.2479G>A was observed in the proband and two offspring (Table). Interestingly, son 3 had normal-LDLc levels despite having the LDLR mutation. Two variants in PCSK9: [c.137G>T; c.2023delG]+[c.137G>T] was also detected. PCSK9:c.137G>T is a previously described lost-of-function variant associated with decreases in LDL-c. PCSK9:c.2023delG;p.Val675Leufs*130 is a rare variant in the C-terminal, identified in a single individual in ExCA. In silico analyses predict the absence of two conserved Cysteines, critical for the correctly folding of the protein, therefore leading to a lost-of-function.

Table. Phenotype and genotype at LDLR and PCSK9 found in the family.

	LDL levels	LDLR genotype	PCSK9 Genotype	
		c.2479G>A; p.Val827Ile	c.137G>T; p.Arg46Leu	c.2023delG; p.Val675Leufs*130
Proband	High-LDLc	Yes, htz	Yes, htz	
Daughter 1	High-LDLc	Yes, htz	Yes, htz	
Daughter 2	Normal-LDLc	No	Yes, htz	Yes, htz
Son 3	Normal-LDLc	Yes, htz	Yes, hmtz	Yes, htz

Discussion: The presence of lost-of-function variants in PCSK9 could ameliorate the effect of LDLR variants associated with FH. The counteracting effects of different genes should be explored in FH patients in order to improve genetic counselling.

P05.33

Next generation sequencing of familial hypercholesterolaemia-related genes in a Mediterranean European cohort

P. F. Dingli, R. Attard, K. Cassar, R. Farrugia, S. Bezzina Wettinger; Department of Applied Biomedical Science, Faculty of Health Sciences, University of Malta, Msida, Malta.

Introduction: The aim of this study was to identify the polymorphisms responsible for familial hypercholesterolaemia in the Maltese population.

Methods: Dutch Lipid Clinic Network scores were calculated for each research subject in the Maltese Acute Myocardial Infarction Study which included 423 first myocardial infarction cases, 210 relatives of cases and 465 controls. Three cases had probable Familial Hypercholesterolemia (FH) and 67 cases had possible FH. All probable FH subjects and three samples from the list of possible FH were selected, the latter, based on LDL level. Libraries for FH were prepared using the SureSelect target enrichment protocol (Agilent Technologies) and sequenced on an Illumina HiSeq 4000. Next-GENE® software was used to read data and obtain a list of variants.

Results: A summary of the SNPs found in LDLR, LDLRAP, APOB and PCSK9 is provided in table 1.

Mutation Function	APOB	LDLR	LDLRAP1	PCSK9
In-Frame	1			2
Missense	31	1	5	13
Noncoding	60	84	88	136
Synonymous	6	29	5	12
Total	98	114	98	163

Table 1. SNPs in chosen samples

Non-synonymous single nucleotide polymorphisms and polymorphisms in the adjacent introns were researched in known databases and in the literature. 4 candidate SNPs were short-listed – two in ApoB (P2739L, T98I) and two in PCSK9 L22_L23insL, V474I)

Conclusion

No strong mutation in known FH genes was observed indicating a polygenic cause for elevated LDL in these subjects.

Parental somatic mosaicism in FBN1 and TGFBR1 genes in aortic pathology syndromes

P. Fernández Alvarez¹, M. Borregan Prats¹, L. Martinez Ribot¹, M. del Campo Casanelles¹, F. López Grondona¹, M. Masas Castro¹, A. Outeriral Adán¹, G. Teixidó i Turá², A. Evangelista Masip², A. Cueto González², T. Vendrell Bayona¹, E. García-Arumi^{1,3}, E. Tizzano Ferrari^{1,3};

¹Department of Clinical and Molecular Genetics and Rare Disease Unit, Hospital Universitari Vall d'Hebron, Barcelona, Spain, ²Department of Cardiology, Marfan Unit, Hospital Vall d'Hebron, Barcelona, Spain, ³Biomedical Network Research Centre on Rare Diseases (CIBERER), Instituto de Salud Carlos III, Madrid, Spain.

Molecular studies in patients with aortic pathology syndromes such as Marfan and Loeys-Dietz syndromes include NGS of FBN1, TGFBR1 and TGFBR2 as well as their parents to determine the origin of the mutation. Recent reports have shown that somatic mosaicism in parents of individuals with autosomic monogenic genetic diseases is more common than previously thought. Thus, an important proportion of de novo mutations could be the consequence of low-level mosaicism in one of the parents.

We analyzed 44 parents of patients considered as de novo mutations in FBN1 (n=42) and TGFBR1 (n=2) in order to detect somatic mosaicism. PCR amplicons for the exons of interest in each case were obtained followed by NexteraXT technology to generate libraries and deep sequencing using Mi-seq sequencer. The obtained data were analyzed using a somatic alignment to detect low-frequency mosaicisms.

In 3 index cases we found low-frequency mosaicism in one of their parents (in DNA blood sample and buccal cell swab and urine when available).

Gene	Mutation	origin	%blood DNA	% buccal swab DNA	% urine DNA
FBN1	c.1664G>A (p.Cys555Tyr)	paternal	19.13%	17.69%	In process
FBN1	c.425G>A (p.Gly142Glu)	maternal	13.02%	In process	In process
TGFBR1	c.683_685del (p.Glu228del)	paternal	4.52%	8.48%	4.36%

According to our results almost 10% of the de novo FBN1 mutations could

be the result of parental mosaicism. Thus, it is likely a more common occurrence than the expected in genes related with aortic pathology. Detection of these cases improves genetic counseling and allow the parents a cardiac follow up given that the somatic mutation may be expressed in the aortic tissue.

Introduction: Fibromuscular dysplasia (FMD) is a nonatherosclerotic vascular disease leading to stenosis, dissection and aneurysm affecting mainly the renal and cerebrovascular arteries. FMD is often an underdiagnosed cause of hypertension and stroke, has higher prevalence in females (~80%) but its pathophysiology is unclear.

Methods and Results: We analyzed ~26K common variants (MAF>0.05) generated by exome-chip arrays in 249 FMD patients and 689 controls. We replicated 13 modestly associated loci (P<10⁻⁴) in 402 cases and 2,537 controls and confirmed an association between FMD and a variant in the phosphatase and actin regulator 1 gene (PHACTR1). Three additional case-control cohorts including 512 cases and 669 controls replicated this result (overall OR=1.39; P=7.4x10⁻¹⁰; 1,154 cases and 3,895 controls). The top variant, rs9349379, is intronic to PHACTR1, a risk locus for coronary artery disease, migraine, and cervical artery dissection. The analyses of geometrical parameters of carotids from 2,500 healthy volunteers indicate higher intima-media thickness (P=1.97x10⁻⁴) and wall to lumen ratio (P=0.002) in rs9349379-A carriers, suggesting indices of carotid hypertrophy previously described in carotids of FMD patients. Immunohistochemistry detected PHACTR1 in endothelium and smooth muscle cells of FMD and normal human carotids. The expression of PHACTR1 by genotypes in primary human fibroblasts showed higher expression in rs9349379-A carriers (N=86, P=0.003). Phactr1 knockdown in zebrafish resulted in dilated vessels indicating impaired vascular development.

Conclusions. We report the first susceptibility locus for FMD and provide evidence for a complex genetic pattern of inheritance and indices of shared pathophysiology between FMD and other cardiovascular and neurovascular diseases.

Abnormal folate metabolism is associated with metabolic syndrome components in spontaneous hypertensive rats (SHR)

V. Kozich¹, M. Pravenec², J. Krijt¹, J. Sokolová¹, V. Zidek², V. Landa², P. Mlejnek², J. Šilhavý², M. Šimánková², V. Škop³, J. Trnovská³, L. Kazdová³, T. W. Kurtz⁴;

¹Institute of Inherited Metabolic Disorders, Charles University, First Faculty of Medicine, Prague, Czech Republic, ²Department of Model Diseases, Institute of Physiology, Czech Academy of Sciences, Prague, Czech Republic, ³Center of Experimental Medicine, Department of Metabolism and Diabetes, Institute for Clinical and Experimental Medicine, Prague, Czech Republic, ⁴Department of Laboratory Medicine, University of California, San Francisco, CA, United States.

Background: Metabolic syndrome (MS) is a multifactorial common risk factor for cardiovascular disease. A number of studies indicated that abnormal metabolism of sulfur amino acids and folates is associated with MS components.

Methods and results: We analyzed the role folate deficiency in pathogene-

sis of the metabolic syndrome in the spontaneously hypertensive rat (SHR) model. The SHRs fed a folate-deficient diet showed significantly reduced serum folate (104 ± 5 vs. 11 ± 1 nmol/L) and urinary folate excretion (4.3 ± 0.6 vs. 1.2 ± 0.1 nmol/16 h), ectopic fat accumulation, impaired glucose tolerance and increased systolic blood pressure. Next, by using BXH/HXB recombinant inbred strains derived from the spontaneously hypertensive rat (SHR) and Brown Norway progenitors we detected a deletion variant in the folate receptor 1 (Folr1) promoter resulting in decreased expression of Folr1 mRNA in the kidney. Analysis of the SHR.BN-chr.1 congenic strain confirmed that the Folr1 promoter variant in SHR cosegregates with reduced renal expression of the mRNA and renal folate reabsorption, decreased serum folate levels, ectopic fat accumulation, reduced muscle insulin sensitivity, and increased blood pressure. Transgenic rescue experiments performed by expressing a Folr1 transgene in the SHR ameliorated most of the metabolic disturbances.

Conclusions: These data support hypothesis that genetic and nutritional folate deficiency is associated with development of the metabolic syndrome in SHR model and constitutes a previously neglected mechanism that may contribute to increased risk for cardiovascular disease.

P05.37

Molecular screening of GATA4 in a Moroccan population suffering from non-syndromic tetralogy of Fallot (TOF)

I. El Bouchikhi^{1,2}, K. Belhassan¹, F. Moufid^{1,2}, M. Iraqui Houssaini², L. Bougenouch¹, I. Samri³, K. Ouldini³, S. Atmani³;

¹Medical Genetics and Oncogenetics Laboratory, Hassan II University Hospital, Fez, Morocco, ²Laboratory of Microbial Biotechnology, Faculty of Sciences and Techniques, University of Sidi Mohammed Ben Abdellah, Fez, Morocco, ³Medico-Chirurgical Unit of Cardio-pediatrics, Department of Pediatrics, Hassan II University Hospital, Fez, Morocco.

Introduction: Tetralogy of Fallot is one of the most common congenital heart disease (CHD) with an incidence of 7% of CHDs. This disorder consists of four anomalies: ventricular septal defect; over-riding aorta; right ventricular outflow obstruction and right ventricular hypertrophy. Several transcription factors were identified to be involved in non-syndromic Tetralogy of Fallot, notably *NKX2-5* and *GATA4*. The latter is a zinc-finger protein that regulates the down-stream target genes, through binding to the specific motif (T/A)GATA(A/G), in order to control cell proliferation in the developing heart. The aim of this study was to screen the *GATA4* mutations in series of Moroccan patients with Tetralogy of Fallot.

Materials and Methods: thirty-one patients were recruited in cardio-pediatric department of HASSAN II university hospital-Fez. After obtaining consents, we have collected blood samples, and extracted genomic DNA specimens. Then, we carried out PCR and direct sequencing of the *GATA4* coding regions for each patient. The obtained sequences were analysed by Bioinformatic alignment tool.

Results: we detected two missense mutations and five synonymous mutations. These mutations were clustered on exons two and five. In addition to eight polymorphisms spread over the intronic regions, in particular, introns one and four. Considering the non-synonymous mutations alone, *GATA4* mutation rate in our cohort reaches 6.5%.

Conclusions: given the important role of *GATA4* in regulating the heart development process, the identified mutation seems most likely to be responsible of the observed phenotype in the mutation carriers. Finally, to confirm these results a larger Moroccan TOF cohort will be pertinent.

Universidade da Coruña (UDC), A Coruña, Spain, ²Servicio de Cardiología. Instituto de Investigación Biomédica de A Coruña (INIBIC), Complejo Hospitalario Universitario de A Coruña (CHUAC), Sergas, A Coruña, Spain, ³Department of Anatomic Pathology, Heart and Vascular Institute, Cleveland Clinic, Cleveland, OH, United States.

Introduction: Heart transplant (HT) is a life-saving treatment for patients with end-stage heart failure. A low incidence but significant problem in HT is the antibody-mediated rejection (AMR). In AMR, there is complement activation which contributes to graft damage.

Purpose: The aim of this study is to analyze if genetic variants in genes related to complements pathway could be associated with the development of AMR.

Methods: Genetic variants in 42 genes related to complement pathway have been analyzed by next generation sequencing (Trusight one sequencing panel-Illumina) in 48 HT patients, 24 with and 24 without AMR. Statistical was performed with SNPstats.

Results: 287 Single nucleotide polymorphisms (SNPs) in 42 genes were analyzed in both groups (AMR vs control). Three SNPs (rs1143674, rs7562325 and rs1143676) in ITGA4, which codifies for integrin alpha-4 protein, showed significant association with AMR. Haplotype-association analysis, comprising these 3 SNPs, showed that there is a significant association between AGT haplotype and AMR (OR (95%)=9.33 (2.14-40.58) p=0.0047). Other three SNPs (rs1899450_MBL2, rs1048118_CFP, and rs3774268_MASP1) also showed significant association with AMR (p<0.05).

Conclusions: AGT haplotype in ITGA4 gene and rs1899450_MBL2, rs1048118_CFP, and rs3774268_MASP1 could be associated with development of AMR in HT patients. However, more research must be done to determine the possibly role of these variants in the development of AMR.

Rare synonymous variants in LDLR gene are associated with Familial Hypercholesterolaemia

C. Rodríguez Antolín¹, C. Rodríguez Jiménez¹, L. Reinares², F. Arrieta³, E. Vallespín¹, P. Lapunzina¹, S. Rodríguez Nóvoa¹;

¹INGEMM, Madrid, Spain, ²Hospital Universitario Clínico San Carlos, Madrid, Spain, ³Hospital Universitario Ramón y Cajal, Madrid, Spain.

INTRODUCTION: Familial hypercholesterolaemia (FH) is an autosomal dominant disease caused by mutations in LDLR, APOB, PCSK9, characterized by high levels of LDL-c increasing the risk of cardiovascular disease. About 35-40% of FH-individuals lack of mutations. Herein we analyse the synonymous variants found in individuals without genetic confirmation of the disease.

PATIENTS AND METHODS: Individuals with possible/confirmed clinical diagnosis of FH were remitted to our service for genetic testing. LDLR, APOB, PCSK9 and LDLRPA1 was analysed by Next Generation Sequence (NGS). MLPA was performed to detect large insertion/deletions in LDLR. Synonymous variants with frequency <0.01 were selected for in silico analyses.

RESULTS: Rare synonymous variants were found in 12 out of 100 patients. The synonymous LDLR:c.2388C>T;p.Ile759Ile, with allele frequency of 0.00001 in ExCA, is located at the -2 position of the splice donor site within exon-16. In silico analyses using Human Splicing Finder identified a new site in enhancer motifs (ESE) and other splicing motifs predicting an impact in protein expression. Ex-SKIP revealed the mutated allele has a higher chance of exon skipping than wild type. ESEfinder predicts the lost of two junction sites to SRF1 in the mutated allele with respect to wild type. These data suggest this variant might affect critical regulatory sequences which could change the primary structure protein.

CONCLUSIONS: Rare synonymous variants should be analysed in patients without genetic confirmation of FH especially those with any predicted impact on protein regulation. Further studies should be performed in order to elucidated the mechanism proposed for pathogenicity of LDLR:c.2388C>T;p.Ile759Ile.

A genome-wide association study for hypertriglyceridemia in ethnic Saudi Arabs

M. M. Alrasheed¹, S. M. Waki², R. Ram³, N. P. Muiya², G. Moraham⁴, B. F. Meyer², N. Dzimiri²;

¹College of Pharmacy, King Saud University, Riyadh, Saudi Arabia, ²King Faisal Spec. Hospital and Research Centre, Riyadh, Saudi Arabia, ³Western Australian Institute for Medical Research, University of Western Australia, Australia, Perth, Australia, ⁴Western Australian Institute for Medical Research, University of Western Australia, Perth, Australia.

Introduction: Hypertriglyceridemia (hTG) is a primary cause for coronary artery disease (CAD), with a strong genetic component. However the genetic basis for hTG is not fully understood yet

Materials and Method: In the present study, we performed a common variant association study (CVAS) using the Affymetrix High Density Axiom platform on the disease in the ethnic Saudi Arab population (927 cases versus 3159).

Results: The lead variant was the rs1558861 [1.99(1.73-2.30); p=7.37x10⁻²²], residing on chromosome (chr) 11 at the apolipoprotein A-1 (APOA1) locus. The rs780094 [1.34(1.21-1.49); p=8.57x10⁻⁸] on chr 2 at the

glucokinase regulatory protein (GCKR) locus was similarly significantly associated, while the rs10911205 [1.29(1.16-1.44); $p=3.52 \times 10^{-6}$] on chr 1 at the laminin subunit gamma-1 (LAMC1) locus showed suggestive association with disease. Furthermore, the rs17145738 [0.68(0.60-0.77); $p=6.69 \times 10^{-9}$] on chr7 at the carbohydrate-responsive element-binding protein-encoding (MLXIPL) gene locus displayed significant protective characteristics, while another variant rs6982502 [0.76(0.68-0.84); $p=5.31 \times 10^{-7}$] on chr8 showed similar but weaker properties. These findings were replicated in 317 cases versus 1415 controls from the same ethnic Arab population. Conclusion: Our data reveal several variants across the human genome that are associated with hTG in ethnic Arabs.

P05.41

Impact of renin-angiotensin-aldosterone polymorphisms and mitochondrial haplogroups in phenotypic expression of hypertrophic cardiomyopathy in genotyped patients

I. Perez¹, M. Sabater¹, E. García-Molina¹, C. Muñoz², M. Navarro², M. Olmo², D. López², J. Gimeno²;

¹Hospital Clínico Universitario Virgen de la Arrixaca. Inherited cardiomyopathies unit, Murcia, Spain, ²University Hospital Virgen de la Arrixaca, Department of Cardiology, Murcia, Spain.

Introduction: Hypertrophic Cardiomyopathy (HCM) is a cardiovascular condition, with a variable penetrance and expression. The renin-angiotensin-aldosterone system (RAAS) and mitochondrial DNA (mtDNA) inherited variants have been associated with left ventricular hypertrophy and play a role in phenotype of HCM.

Purpose: To study the role of RAAS polymorphisms and mitochondrial haplogroups on the HCM clinical expression in a population of patients with HCM and genetic diagnosis.

Methods: Study population comprised 156 patients with HCM carrying a causative mutation in the sarcomeric MYBPC3 and MYH7 gene. All individuals underwent cardiac examination. We genotyped six RAAS polymorphisms and six mitochondrial single nucleotide polymorphisms (SNP's) which define the most common European haplogroups.

Results: On multivariable analysis, CMA polymorphism (-1903A) carriers showed a phenotype characterised by systolic impairment and left ventricular dilatation. The DD-ACE was associated with a lower survival free from AF and stroke. Polymorphism T174M, was related to a higher hypertrophy. The mitochondrial haplotype V was associated with a reduced survival free from AF and limiting dyspnoea. Haplotype U was associated to dyspnoea. Carriers of haplotype J had more often systolic impairment. Haplotype HV was associated with non sustained ventricular tachycardia and sudden death risk score.

Conclusions: Our data suggest that the genetic variation at some RAAS SNP's could contribute to the different expression in HCM. Moreover, mtDNA haplotypes may have the potential of becoming biomarkers in cardiomyopathy.

SNP's	Variable	p
(-1903A)	Systolic impairment	<0.001
(-1903A)	Left ventricular dilatation	0.02
DD-ECA	Survival free from AF	0.017
DD-ECA	Stroke	0.032
AGT (T174M)	IMLVWT	0.022
Mitochondrial Haplogroup	Variable	p
V	Survival free from AF	0.029
V	NYHA III-IV	0.002
U	NYHA III-IV	0.05
J	Systolic impairment	0.012
HV	NSVT	0.031
HV	Risk Score	0.015

P05.42

Mutation analysis of Hypertrophic Cardiomyopathy genes using Next-Generation Sequencing

A. M. Coutinho, J. Tavares, M. Carmo-Fonseca;

GenoMed, Instituto de Medicina Molecular, Faculdade de Medicina, Universidade de Lisboa, Lisbon, Portugal.

Introduction: Hypertrophic Cardiomyopathy (HCM) is a common autosomal dominant genetic disease associated with sudden death and progressive heart failure. Genetic testing is routinely offered to these patients as a means to improve prognosis through appropriate lifestyle and medical interventions. However, because mutations in at least 30 genes have been linked to HCM, conventional diagnosis by Sanger sequencing is laborious and time consuming. Advances in high throughput sequencing technologies have the potential to solve this problem, but they also raise new challenges. The aim of this study was to develop a Next-Generation Sequencing (NGS) approach to screen for mutations in patients with this disorder.

Methods: The study population comprised 60 unrelated consecutively eva-

luated patients diagnosed with HCM. A capture library was designed and target regions were sequenced on an Illumina platform. The study was designed to screen the coding DNA sequence of either 20, 46 or 57 genes implicated in HCM and other inherited cardiomyopathies: *ABCC9, ACTC1, ACTN2, BAG3, CASQ2, CAV3, CHRM2, CRYAB, CSR3, DES, DMD, DOLK, DSC2, DSCG2, DSP, DTNA, EMD, FHL2, GATAD1, GLA, ILK, JPH2, JUP, LAMA4, LAMP2, LDB3, LMNA, MYBPC3, MYH6, MYH7, MYL2, MYL3, MYLK2, MYOZ2, MYPN, NEXN, PDLIM3, PKP2, PLN, PRKAG2, PTPN11, RAF1, RBM20, RYR2, SCN5A, SGCD, TAZ, TCAP, TMEM43, TNNC1, TNNI3, TNNT2, TPM1, TRDN, TTN, TTR* and *VCL*.

Results: Pathogenic mutations were detected in 17 patients (28.3%).

Conclusions: We developed an NGS procedure for screening mutations in 57 genes associated with HCM. The advantage of expanding the number of genes screened for mutations will be discussed.

P05.43

Clinical application of a whole genome sequencing (WGS) approach to Inherited Cardiac Disorders

P. A. James¹, T. Thompson¹, D. Du Sart², R. Leach³, D. Floeke³, R. Tearle³, D. Zentner¹, A. Trainer¹, J. Vohra¹, I. Winship¹;

¹Royal Melbourne Hospital, Melbourne, Australia, ²Victorian Clinical Genetic Service, Melbourne, Australia, ³Complete Genomics, Mountain View, CA, United States.

Background: Identifying the underlying mutation in families affected by inherited cardiac disorders allows optimal screening and risk management but in practice this remains unachievable in many families reflecting the complexity of these disorders. We examined the potential of whole genome sequencing (WGS) compared to current standard practice in the setting of a multidisciplinary cardiac-genetics clinic (CGC).

Methods: Living index cases assessed in the CGC (n=100) were consented for WGS alongside usual care. The genome was sequenced and annotated (Complete Genomics). Variants were filtered against public databases and data from healthy elderly controls. Clinical interpretation was applied to high quality calls for SNPs, InDels, structural variants and CNVs. To manage the scope of unintended findings analysis and validation was limited to genes associated with a cardiac phenotype (HPO database).

Results: Analysis of 75 genomes has been completed (36 Cardiomyopathy, 31 Familial Arrhythmias, 5 Aortopathy) revealing an average of 125 protein-altering variants per genome in genes with a reported cardiac phenotype. For 21 individuals (28%) a potentially causative mutation was detected in standard care. This increased to 42 individuals (56%) following WGS ($p<0.001$). In 12% of cases more than one likely pathogenic change was detected, while 46 (61%) carry clinically suspicious variants that are currently unclassifiable. The broad genetic data allowed the additional identification of undiagnosed syndromic disorders and novel candidate genes where multiple truncating mutations were observed in highly constrained genes.

Conclusion: While highly complex, whole genome sequencing achieved a significant improvement in genetic diagnosis over standard investigation and gene testing.

P05.44

Correlation with platelet parameters and genetic markers of thrombophilia panel (factor II g.20210G>A, factor V Leiden, MTHFR (C677T, A1298C), PAI-1, β -fibrinogen, factor XIIIa (V34L), glycoprotein IIIa (L33P)) in ischemic strokes

S. Tasdemir¹, H. B. Erdem¹, I. Sahin¹, L. Ozel², G. Ozdemir², R. Erozu³, A. Tatar¹;

¹Ataturk University Department of Medical Genetics, Erzurum, Turkey, ²Ataturk University Department of Neurology, Erzurum, Turkey, ³Duzce University Department of Medical Genetics, Duzce, Turkey.

Introduction: Ischemic stroke, an important type of arterial thrombosis, is associated with increased mortality risk, severe disability and life quality impairment. In this study we analyzed mean platelet volume (MPV), platelet count (PLT) values and genetic thrombophilia markers of patients who have ischemic stroke history and searched the relationship with genetic predisposition of ischemic stroke and platelet parameters.

Materials and Methods: A retrospective, clinical trial was performed by reviewing the ischemic stroke history (except cryptogenic events) of 599 patients, and 100 controls. The results of the genetic thrombophilia panel were used to classify the study group and control group into low and high risk for thrombophilia groups. The high-risk group included patients homozygous/heterozygous for factor II g.20210G>A or factor V Leiden mutations with/without any other polymorphism. The low-risk group included patients heterozygous or homozygous for MTHFR (C677T, A1298C), PAI-1, β -fibrinogen, factor XIIIa (V34L) and glycoprotein IIIa (L33P) polymorphisms or negative in terms of both mutations and polymorphisms.

Results: High risk group mutations were significant; but low risk group polymorphisms were not significant for ischemic stroke. There was significant difference between MPV and PLT values of ischemic stroke and control group.

Conclusion: Factor II g.20210G>A and factor V Leiden mutations are important risk factors for ischemic stroke. Thrombophilia mutations and polymorphisms do not have a significant effect on MPV and PLT values in ischemic stroke patients.

Summary of descriptive statistics for the groups.								
		n	Mean PLT±SD	p	Mean MPV±SD	p	Mutation score	p
Patients	High risk group	139	267±68	0.014a 0.392b 0.048c	8.4±1	0.000a 0.365b 0.000c		0.275d
	Low risk group	460	268±65		8.4±1		3.3	
Control		100	251±57		7.8±0.8		3.2

New mutation c.IVS2+45T>G in LMNA gene causing aberrant splicing and leading to cardiac conduction defect and variable myopathy

Y. Rogozhina¹, S. Mironovich¹, A. Shestak¹, T. Adyan², A. Bakulina³, A. Polyakov², E. Zaklyazminskaya^{1,4};

¹Petrovsky Russian Research Center of Surgery, Moscow, Russian Federation, ²Research Centre of Medical Genetics, Moscow, Russian Federation, ³Novosibirsk State University, Novosibirsk, Russian Federation, ⁴Pirogov Russian National Research Medical University, Moscow, Russian Federation.

Introduction: Most of mutations in LMNA gene are unique and were found in 1-2 unrelated families. Interpretation of new genetic findings especially beyond the coding area and canonical splice sites can be difficult and requires advanced investigation.

Materials and Methods: The clinical and molecular-genetic study was performed for the patient with cardiac conduction defect and variable myopathy. Genetic study included: DNA-testing in LMNA gene by Sanger sequence. The prevalence of new genetic variant was tested in cohort of EDMD patients (99 DNA samples) by MLPA, and in control group (100 healthy volunteers) by RFLP method. Potential influence of c.IVS2+45T>G was performed by open bioinformatics tools. Bidirectional Sanger sequencing followed non-quantitative RT-PCR of target fragment of LMNA cDNA was performed. In silico modeling was performed with CCBulder server and Modeller software. Results: Diagnosis EDMD was established in proband based on clinical investigation. Genetic testing revealed new intronic variant c.IVS2+45T>G in LMNA gene in proband and affected daughter but not in two healthy sons. Activation of cryptic splice site was predicted by open bioinformatics sources. Insertion of 45 bp was confirmed in proband's cDNA. The possible functional effects of aberrant protein were predicted.

Conclusion: New variant c.IVS2+45T>G in LMNA gene is pathogenic and causative for EDMD in this family. Deep intronic variants in the LMNA gene can be responsible for some genotype-negative EDMD cases.

The burden of complex arrhythmic genotypes in a consecutive series of Sardinian population of patients with primary arrhythmic disorders.

N. Marziliano¹, P. Berne¹, G. Viola¹, V. Carboni¹, D. Fiscella², A. Fiscella², P. A. Merlini⁴, F. Notarangelo⁵, N. Gaibazzi⁵, D. Ardissino⁵, G. Piras¹, M. Monne¹, R. Asproni¹, G. Casu¹;

¹Presidio Ospedaliero "San Francesco", ASL3 Nuoro, Laboratorio Specialistico di Oncoematologia, Nuoro, Italy, ²Azienda Ospedaliera di Rilievo Nazionale e di Alta Specializzazione "Garibaldi, S. Luigi-S. Curro, Ascoli-Tomaselli". Presidio Ospedaliero Garibaldi-Nesima-Catania. UO di Cardiologia, Catania, Italy, ³Fondazione Floresta Longo, Catania, Italy, ⁴Azienda Ospedaliera Ospedale Niguarda Cà Granda, IV Divisione di Cardiologia, Nuoro, Italy, ⁵Azienda Ospedaliera Universitaria di Parma, Parma, Italy.

Brugada syndrome (BrS), Long QT syndrome (LQTS), Short QT syndrome (SQTS) and catecholaminergic polymorphic ventricular tachycardia (CPVT), are primary inherited cardiac arrhythmic disorders that can lead to sudden death. Prevalence might change according to the ethnicity and affecting mainly male patients in their third to fourth decade of life. They are inherited as autosomal dominant traits; but recent studies identified complex thought rare genotypes.

We aimed to investigate the prevalence of mutations in the disease-genes underlying such inherited disorders in 400 patients of Sardinian ancestry.

We analysed -by means of NGS - 148 arrhythmogenic genes in a consecutive series of 400 Sardinian patients enrolled at the San Francesco Hospital from years 2014 to 2015. In addition, to identify genes significantly enriched in the Sardinian series, we performed a mutation burden test by using as control dataset of continental Italians.

We confirmed the genetic heterogeneity of the BrS, LQTS and CPVT but in addition we identified: a) a burden of complex genotypes (compound/double heterozygous and triple mutation carriers) with a higher prevalence in Sardinians compared with continental Italians (7.8% vs 3.2%) and b) new potential CPVT/LQTS candidates (such as CACNA1B, CASQ2) thus confirming the idea of a possible genetic overlap between the different disorders. As expected, the use of NGS in the Sardinian population to assess the contribution of genetics to such malignant cardiac traits, can further elucidate causal mechanisms and in addition these results identify a burden of complex genotypes that, in panels derived from more cosmopolitan populations, are missing.

Identification of genomic region associated with Lipoprotein Cholesterol: Genome-wide association studies (GWAS) in Tehran Cardio-metabolic Genetic Study (TCGS)

M. S. Fallah^{1,2}, M. Daneshpour¹, B. Sedaghatkhatay¹, K. Guity¹, F. Aziz²;

¹Cellular and Molecular Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran, Islamic Republic of, ²Kawsar Human Genetics Research Center, Tehran, Iran, Islamic Republic of, ³Endocrine Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran, Islamic Republic of.

Introduction: Genome-wide association studies (GWAS) have become an important strategy for genetic examination of human complex diseases. LDL cholesterol (LDL-C) plays a proven effect as risk factor in the cardiovascular disease and needs further investigation to provide a better understanding of the pathogenesis. Here we report results of a GWAS in an Iranian population participating in Tehran cardio-metabolic genetic study (TCGS).

Material and Methods: GWAS data was used; including 699,950 quality-checked SNPs (HumanOmniExpress-24-v1-0 bead at deCODE genetics) from 8174 participants with measures of blood LDL-C concentrations (with normal distribution and excluding outlier data ($\pm 4SD$)). Efficient Bayesian mixed-model analysis with the help of Bolt-LMM v2.1 was used for association analysis in total population, male and female separately.

Results: At the genome-wide level ($p < 10^{-7}$), 27 SNPs that was associated with LDL-C concentration in total population mostly in both sexes. Associated signals were concentrated in 19p13.2, 1p13.3, 2p24.1 and 5q13.3 genomic region.

Conclusion: In this study we discovered four loci with protein coding genes (LDLR, CELSR2, APOB and HMGR) which confirm the previous reports in other ethnicities. This study is the first GWAS in Iran and results could provide better understanding of the underlying biological mechanism of LDL-C regulation and consequent using in therapeutic targets and clinical care for cardiovascular disease.

A genome-wide association study for low HDL-cholesterol levels in ethnic Saudi Arabs

N. P. Muiya¹, S. M. Wakil¹, R. Ram², E. Andres¹, N. Mazhar¹, S. Hagos¹, G. Morahan², B. F. Meyer¹, N. Dzimir¹;

¹King Faisal Spec. Hospital and Research Centre, Riyadh, Saudi Arabia, ²Western Australian Institute for Medical Research, University of Western Australia, Australia, Perth, Australia.

Introduction: The genetic basis for changes in high density lipoprotein-cholesterol (HDL) levels is not fully elucidated yet. We performed a GWAS for this disorder in ethnic Arabs.

Methods: We employed the Affymetrix high density Axiom Genome-Wide ASI Array (Asian population) that provides high genetic coverage containing a total of 598,000 SNPs to genotype a total of 5495 individuals in the discovery and validation experiments.

Results: Two variants, the rs1800775 [1.31(1.22-1.42); $p = 3.41E-12$] on the CETP gene and rs359027 [1.26(1.16-1.36); $p = 2.55E-08$] on the LMCD1 gene were significantly associated with harbouring of low HDL-cholesterol. Furthermore, the rs3104435 [1.26(1.15-1.38); $p = 1.19E-06$] at the MATN1 locus, rs9835344 [1.16(1.08-1.26); $p = 8.75E-06$] in the CNTN6, rs1559997 [1.3(1.14-1.47); $p = 9.48E-06$] in the SDS and rs1670273 [1.2(1.1-1.31); $p = 4.81E-06$] at the DMN/SYNM gene locus exhibited suggestive association with the disease. Seven other variants including the rs1147169, rs10248618, rs476155, rs7024300, rs10836699, rs11603691 and rs750134 exhibited borderline protective properties. The validation and joint meta-analysis

experiment resulted in the rs1800775, rs3104435 and rs359027 retaining their predisposing properties, as well as the rs10836699 and rs11603691 showing protective properties.

Conclusions: Our data demonstrate association of several variants across the genome with changes in low HDL-cholesterol levels in ethnic Arabs.

P05.49

Genetic Testing for Marfan And Loeys-Dietz Syndrome - Utility of the Ghent Nosology as a clinical selection tool

J. Dean;

University of Aberdeen, Aberdeen, United Kingdom.

Marfan and Loeys-Dietz syndromes are aortopathies with additional connective tissue features. Marfan is associated with mutation in FBN1 and Loeys-Dietz syndrome with mutation in TGFBR1 and TGFBR2. The clinical diagnosis of Marfan syndrome is made using the International (Ghent) Nosology, originally described in 1996, and updated in 2010. Aortic dilatation or ectopia lentis are key features - other findings are aggregated to create the systemic score. A score of 7 or more contributes to a diagnosis of Marfan. The nosology does not help directly to diagnose Loeys-Dietz syndrome. 77% of probands attending the Aberdeen Marfan Clinic who fulfil the Ghent 2010 nosology for a diagnosis of Marfan syndrome, and 74% who fulfil Ghent 1996 have an FBN1 mutation. In probands who do not fulfil the nosology, 16% of those with aortic dilatation and any systemic score below 7 have TGFBR1 or TGFBR2 mutations, but none in this group have FBN1 mutation. In those with no ocular features, and no aortic findings, around 20% of those with a systemic score of 5 have FBN1 mutations, but few cases with scores below this have mutations. This case series suggests it is worth considering Marfan syndrome and testing for FBN1 in probands with a systemic score of 5 or greater under Ghent 2010 but no cardiac or ocular findings, and that probands with aortic dilatation but a systemic score of less than 7 are more likely to have Loeys-Dietz than Marfan.

Orsola-Malpighi, University of Bologna, Bologna, Italy, ⁸Cardio-Thoracic Radiology Unit, Policlinico S. Orsola-Malpighi, University of Bologna, Bologna, Italy.

Marfan syndrome (MFS) is a highly variable, autosomal dominant condition, mainly characterized by ocular, cardiovascular and musculo-skeletal manifestations. Aortic root dilatation and mitral valve prolapse are the most common cardiovascular signs and source of major clinical concern because they can lead to severe complications. Arrhythmias such as atrial flutter and ventricular dysrhythmias have been described in MFS, but currently available knowledge is limited.

We report on a 13-year old female who presented with several unexplained episodes of ventricular dysrhythmia/fibrillation; recurrent myocarditis and cardiomyopathy were excluded and an ICD was positioned. Previously, she underwent corrective surgery for inguinal hernia and flat feet. Pre-operative ECGs resulted normal. Additional clinical investigations revealed abnormal ECGs, severe aortic root dilatation, mitral valve prolapse, mild pectus carinatum and scoliosis, arachnodactyly and mild craniofacial MFS signs, while ectopia lentis and myopia were excluded.

Molecular genetic analysis of FBN1 (HRM and MLPA), TGFBR1/2, SMAD3 and TGFBR2 for suspected MFS or Loeys-Dietz syndrome resulted negative. Therefore, whole exome sequencing (WES) was performed which led to the identification of a de novo heterozygous nonsense mutation in FBN1 (NM_000138 c.7800C>G p.Tyr2600X), previously described in a subject with Marfan syndrome (UMD-FBN1 mutations database ID 207), and absent in genetic databases of general population cohorts (1000 genomes, ExAC databases).

To our knowledge, this is the first description of ventricular fibrillation as presenting symptom in a pediatric MFS patient. This case confirms that potentially life-threatening arrhythmias should be considered in MFS. Large multi-centre studies are needed to gain information on this issue.

MicroRNA-625-5p as a novel candidate modulator of AMPK pathway in statin-treated individuals without coronary artery disease

N. Coban¹, D. Pirim², A. Erkan³, F. Guclu-Geyik⁴, B. Ekici³, N. Erginel-Unaltuna⁴;

¹Institute for Experimental Medical Research, Department of Genetics, Istanbul University, Istanbul, Turkey, ²Department of Molecular Biology and Genetics, Mus Alparslan University, Mus, Turkey, ³Department of Cardiology, Medical Faculty, Ufuk University, Ankara, Turkey, ⁴Institute for Experimental Medical Research, Department of Genetics, Istanbul, Turkey.

Aim: AMP-activated protein kinase (AMPK) is a signal molecule that phosphorylates and inactivates 3-hydroxy-3-methylglutaryl coenzyme A reductase, the key enzyme controlling cholesterol biosynthesis. We aimed to test whether AMPK signaling pathway is effective in human macrophages which play crucial role in atherosclerosis. In addition, to identify novel modulators of AMPK pathway while exploring the effect of statins on plasma microRNA (miRNA) profile of individuals without coronary artery disease (CAD). Method: We measured the expressions of selected genes involved in AMPK pathway in THP-1 macrophages treated with simvastatin to assess dependence of their expression on cholesterol level. The Agilent's miRNA Microarray analyses were performed to compare plasma miRNA profile of individuals ($\leq 30\%$ stenosis) treated with and without statin. MiRDB target prediction tool was utilized to identify miRNA target genes involved in AMPK pathway for differently expressed miRNAs. Expressions of target genes were analyzed by using real-time PCR. Results: Significantly decreased expression of 5 miRNAs (miR-625-5p, miR-550a-3-5p, miR-550b-2-5p, miR-550a-5p, miR-let-7d-5p) were observed in individuals receiving statins compared to non-statin group (fold change > 1.5 , $p < 0.05$). In addition, simvastatin increased the expression of AMPK $\alpha 1$, AMPK $\alpha 2$, AMPK $\beta 1$, AMPK $\beta 2$ and SREBF2 in THP-1 macrophages. Using miRDB target prediction tool, we identified AMPK $\alpha 1$ is a strong candidate (target score = 95) for miR-625-5p. Conclusion: Our results suggests that statin may downregulate the expression of miR-625-5p and induce AMPK $\alpha 1$ expression which in turn may activates cholesterol synthesis pathway. Apoptosis-associated miR-625 may be used as a novel biomarker for effectiveness of statins therapy in patients with atherosclerosis.

From Facebook to gene: how social media helped to find a gene for a cardiac disease

W. S. Kerstjens-Frederikse¹, B. Frentz¹, H. G. Yntema², T. Rinne², I. van der Burgt², P. A. van der Zwaag¹, K. Löhner¹, B. Flapper³, C. M. A. van Ravenswaaij-Arts¹;

¹Department of Genetics, University of Groningen, University Medical Center, Groningen, Netherlands, ²Department of Human Genetics, Radboud University Medical Center, Nijmegen, Netherlands, ³Department of Pediatrics, University of Groningen, University Medical Center, Groningen, Netherlands.

A patient support group, communicating with each other through Facebook, requested us to develop research on chromosome 6 anomalies. With the help of this patient support group, we recruited 253 patients with deletions or duplications of chromosome 6. We received detailed clinical information (including array reports) of 101 of these patients.

Genotype-phenotype comparison revealed a recurrent phenotype in seven patients with an overlapping 6q25.1 deletion. *TAB2* was the most likely candidate gene in this region. Their phenotype (mitral valve defect and/or dilating cardiomyopathy (DCM), short stature, hyperlaxity and facial features, resembling Noonan syndrome) was so specific, that it could be matched to two unsolved familial cases without chromosome anomalies, known to our department. Exome sequencing and targeted sequencing of *TAB2* was performed and mutations segregating with the phenotype were detected in both families. We concluded that mutations of *TAB2* and deletions of chromosome 6q25.1 including *TAB2* are associated with cardiac disease and a Noonan syndrome-like phenotype. We show that a Facebook based patient support group was able to participate in research, leading to the recognition of a disease gene and the associated phenotype.

Funding

The Chromosome 6 Research Project is funded by an e-health grant from ZonMw, the Netherlands Organization for Health Research and Development and by crowd funding by the parents of the Chromosome 6 Facebook group.

Zebrafish model for MYBPC3 variants demonstrates pathogenicity

M. Sabater Molina¹, M. Anhelin², M. Cayuela², I. Pérez Sánchez¹, E. García-Molina¹, M. Olmo Conesa¹, M. Oliva Sandova², J. Gimeno Blanes¹;

¹Inherited Cardiac Disease Unit, University Hospital Virgen de la Arrixaca, Murcia, Spain, ²University Hospital Virgen de la Arrixaca, Murcia, Spain, ³Cardiology Department, University Hospital Virgen de la Arrixaca, Murcia, Spain.

Introduction: The majority of founder MYBPC3 mutations that cause hypertrophic cardiomyopathy (HCM) are truncation mutations, nevertheless few functional studies exist regarding the different factors that modify HCM phenotypes. To elucidate the underlying mechanisms in the phenotypic differences of HCM caused by MYBPC3 truncated mutation using a zebrafish model.

Material and Methods: We performed the functional study of two new founder mutations in MYBPC3 which cause HCM and origin truncated proteins of different lengths: variant A (p.Pro108Alafs*9,-91%) and variant B (p.R891Afs*160, -17%). We injected MYBPC3 variants A or B mRNA in zebrafish embryos at one cell stage to analyze the cardiac size and function.

Results: We created a viable zebrafish model of HCM with expression of the human variants A and B. Pathogenicity was suggested by changes in cardiac chambers. Ventricular size was increased when MYBPC3 variant A mRNA was injected. Similar results were found with variant B vs control; nevertheless the differences were not significant between variant A and B. These preliminary results could indicate that two variants have a dominant effect over phenotype expression of HCM, in contrast with others authors who suggest haploinsufficiency mechanisms due to a markedly lower protein expression of small truncated transcripts. More studies are needed to complete the characterization of this animal model and to explore future therapies.

	Control	Variant A	Variant B	p
End Systolic Ventricular Area (mm ²)	7.43x10 ⁻³ (1.14 x10 ⁻³)	8.45 x10 ⁻³ (7.27 x10 ⁻⁴)	8.75 x10 ⁻³ (1.55 x10 ⁻³)	0.057
End Diastolic Ventricular Area (mm ²)	1.03 x10 ⁻² (1.66 x10 ⁻³)	1.27 x10 ⁻² (1.27 x10 ⁻³)	1.27 x10 ⁻² (1.43 x10 ⁻³)	0.002

Interactions of coagulation Factor II G20210A and Factor V Leiden with cardiovascular risk factors increase risk of myocardial infarction.

J. A. Camilleri^{*}, F. Borg Carrott^{*}, R. Attard, P. Dingli, C. Doggen, K. Cassar, R. Farrugia, S. Bezzina Wettinger; University of Malta, Msida, Malta.

Introduction: The effect of Coagulation Factor II G20210A (FIIIG20210A) and Factor V Leiden (FVL) combined with cardiovascular risk factors on the risk of myocardial infarction (MI) was studied in a Maltese population.

Methods: Samples from the Maltese Acute Myocardial Infarction (MAMI) study including 423 cases with first MI and 465 controls were tested for the FVL and FIIIG20210A mutations using PCR-RFLP with MnlI and HindIII respectively. Interactions with lifestyle and metabolic risk factors were tested using data from questionnaires and medical history. Odds ratios (OR) and 95% confidence intervals (95%CI) were calculated to estimate the risk of MI overall and in subgroups.

Results: The estimated risk of MI is 1.6 (95%CI 0.64-3.9) for FVL and 1.5 (95%CI 0.76-2.96) for FIIIG20210A. An association between FVL and MI was observed in smokers [OR 5.3 (95%CI 1.3-21.5)] but not in non-smokers [OR 0.95 (95%CI 0.24-3.84)]. FIIIG20210A was associated with a risk of MI amongst research subjects with at least one metabolic risk factor (diabetes, hypertension or hypercholesterolaemia), [(OR 3.5 (95%CI 1.5-8.4)]. In individuals having at least one triggering factor (metabolic and/or smoking), a 4.4-fold (95%CI 1.3-14.8) and 3.6-fold risk (95%CI 1.5-8.6) were observed with FVL and FIIIG20210A respectively.

Conclusion: FIIIG20210A and FVL increase risk of MI in the presence of certain cardiovascular risk factors with which they interact synergistically. This may be the basis of contradictory results in the literature. These findings highlight the importance of prevention and treatment of these risk factors.

Genetic evaluation of next-generation sequencing results in dilated cardiomyopathies

I. Boronova¹, J. Bernasovska¹, J. Kmec², I. Bernasovsky³, V. Szabadosova¹, P. Ferenc¹, E. Petrejčikova¹;

¹Department of Biology, Faculty of Humanities and Natural Sciences, University of Presov, Presov, Slovakia, ²Cardiocentre, Faculty Hospital of J.A.Rayman, Presov, Slovakia, ³Institute of Roma Studies, University of Presov, Presov, Slovakia.

Dilated cardiomyopathy (DCM) is a genetically heterogeneous disease, known to be one of the leading causes of heart failure and sudden cardiac death. Due to the large number of causative genes and high rate of private mutations, mutational screening requires the use of extremely sensitive and specific detection methods. Recent technical advances by introduction of next generation sequencing (NGS) technologies provide new possibilities of dilated cardiomyopathies detection. The aim of our study was evaluation of genetic profile of next-generation sequencing results in Slovak patients with dilated cardiomyopathy. In the cohort of 19 unrelated patients with clinical diagnosis of dilated cardiomyopathy (n=19; 12 male, 7 female, age range 29-71 years) H558R mutations (exon 12) in SCN5A gene in heterozygous and homozygous form were detected. Altogether, 105 376 sequence variants were identified, 94% were single nucleotide sequence variants, 6% of sequence variants represented insertions and deletions. Among the 103 non-synonymous variants three sequence variants (rs34580776, rs41277370, rs942077) were predicted to be „damaging“ associated with cardiomyopathy (SIFT score 0-0.5). NGS analyses revealed also the presence of novel mutation of CANX gene. The results of our study reflect necessity of evaluation of genomic variants in the genes involved in cardiomyopathies as a part of NGS genetic testing. NGS analyses identifies novel DNA sequence variants for which pathogenicity is unresolved.

Key words: next generation sequencing, mutations, dilated cardiomyopathy
This study is the result of implementation of project APVV-0644-12.

P05.58

The necessity of original NGS data reanalysis in the diagnosis of inherited cardiac diseases with hindsight of 2 years.

J. Kadlecová¹, A. Veverková², D. N. Grochová¹, M. Hiemerová¹, M. Matyášová¹, L. Grochová^{1,3,4}, L. Skutková⁴, P. Vlašín^{1,3};

¹Cytogenetic laboratory Brno, s.r.o., Brno, Czech Republic, ²Masaryk University Brno, Faculty of Science, Brno, Czech Republic, ³Center of prenatal diagnosis, Brno, Czech Republic, ⁴International Clinical Research Center, St. Anne's University Hospital Brno, Brno, Czech Republic.

Next generation sequencing, also called massively parallel sequencing (MPS), currently is the fastest growing method in the field of molecular genetics. This new technology enables diagnostics of genetically heterogeneous diseases with a significant phenotypic and genetic overlap. On the basis of precise molecular genetic diagnosis it is possible to clarify the diagnosis in patients with cardiac disease and especially to identify pre-symptomatic individuals in the family for purposes of monitoring or treatment. Here we present our diagnostic NGS workflow for the analysis of 46 genes involved in pathogenesis of the inherited cardiomyopathy using TrueSight Enrichment technology (Illumina) and for the 51 genes described in association with arrhythmia disorders using PED Mast Plus technology (Multiplicom) followed by sequencing on the MiSeq (Illumina). This study comprised group of 130 unrelated patients with DCM, ARVC, ventricular fibrillation and arrhythmias.

In this study we reanalysed variants detected in our group of patients with a hindsight of 2 years. Based on different databases (dbSNP, ClinVar etc.) as well as co-segregation analysis in pedigrees we revealed that several variant originally classified as pathogenic or potentially pathogenic were false-positive and are newly classified as variants with unknown clinical significance or benign. We will demonstrate this discrepancy on several selected cases and family pedigrees.

Our findings point to the need of periodical reassessment of described variants because their interpretation is constantly changing. Moreover, tight cooperation, clinical and NGS data sharing between investigators focused on the same diagnostic is extremely important to clarify and interpret detected variants.

A genome-wide association study in ethnic Arabs reveals novel susceptibility loci for obesity

N. Dzimiri¹, S. M. Wakil¹, R. Ram², N. P. Muiya¹, O. Alboudari¹, E. Andres¹, N. Mazhar¹, S. Hagos¹, B. F. Meyer¹, G. Morahan², M. Alshahid¹;
¹King Faisal Spec. Hospital and Research Centre, Riyadh, Saudi Arabia, ²University of Western Australia, Perth, Australia.

Introduction: Obesity (OBS) constitutes a major predisposing factor for many cardiovascular diseases. Genome-wide association approach continues to reveal association of gene polymorphism with OBS in different populations. Such studies have not been reported for ethnic Arabs.

Materials: In this study, we performed a genome-wide association study using the Affymetrix High Density Axiom platform GWAS for OBS incidence in 5,016 Saudis of Arab ancestry (3013 controls, 2003 cases).

Results: In the discovery set, we identified four susceptibility SNPs for OBS: the rs564702 (OR=1.31; P=1.85x10⁻⁸) residing on the KCNMB2 gene, rs16891982 (OR=1.56; P=4.31x10⁻⁸) on the SLC45A2 gene, rs2523946 (OR=1.30; P=2.72x10⁻⁸) on the MICD and rs7180536 (OR=1.29; P=4.82x10⁻⁸) on the SQRDL gene that demonstrated genome-wide significance levels. Furthermore, two variants, the rs7551194 (OR=1.36; p=7.22x10⁻⁷) on POU3F1 and rs2171693 (OR=1.39; P=1.08x10⁻⁷) on the PBX1 gene both located on chr1, were also strongly linked to obesity. Besides, three other variants, rs10810271 (OR=1.38; p=6.02 x 10⁻⁶) on the FREM1, rs7135639 (OR=1.25; p=5.19x10⁻⁶) on the MED13L and rs7890737 (OR=1.30; p=6.92x10⁻⁶) on the GPM6B as well as two protective variants, the rs17118166 (OR=0.71; P=3.80x10⁻⁶) on SGCD and rs35488337 (OR=0.74; p=3.88x10⁻⁶) on ETS1 gene showed borderline association with disease. These variants retained their associations in the replication set, and several haplotypes were similarly implicated in the disease. We also replicated 3 SNPs on chromosome 9 that have been associated with OBS in different populations.

Conclusion: These findings provide new insights into genetic pathways contributing to the susceptibility for OBS in ethnic Arabs.

P05.60

Therapy dependent role of an Oct1 polymorphism in cardiovascular death in patients with type 2 diabetes

N. Schweighofer¹, B. Genser^{2,3}, W. März⁴, M. E. Kleber⁵, O. Trummer¹, T. R. Pieber^{1,6}, B. Obermayer-Pietsch^{1,6};

¹Department of Internal Medicine, Division of Endocrinology and Metabolism, Medical University, Graz, Austria, ²BG Statistical Consulting, Vienna, Austria, ³Institute of Public Health, Social and Preventive Medicine, Medical Faculty of Mannheim, University of Heidelberg, Mannheim, Germany, ⁴Synlab Center of Laboratory Diagnostics, Heidelberg, Germany, ⁵Department of Molecular Evolution and Genomics, University of Heidelberg, Heidelberg, Germany, ⁶CBmed, Center for Biomarker Research in Medicine, Graz, Austria.

AIM: Type 2 diabetes individuals have high risk for microvascular complications and cardiovascular incidents are increased two- to three-fold compared to non-diabetics. Various substrates of organic cation transporter 1 are associated with cardiovascular biomarkers. We investigated, whether the Oct1 polymorphism rs2297374 is associated with cardiovascular biomarkers and with the risk of cardiovascular death and if the associations found are influenced by antidiabetic therapy.

METHODS: The data from the LURIC study, a prospective cohort study of Caucasian individuals scheduled for coronary angiography, were used. We identified 1208 type 2 diabetics, whereof 72 use metformin and 1135 are not on metformin therapy. Cardiovascular mortality was assessed in non-diabetics, type 2 diabetics and metformin and non-metformin users with different Oct1 rs2297374 genotypes using Cox proportional hazard models and associations with cardiovascular biomarkers were investigated.

RESULTS: Cardiovascular mortality risk was for each minor allele copy HR 0.83 95% CI 0.70, 0.98 in patients with T2DM and HR 0.82 CI 0.69-0.97 in non-metformin users. In these 2 patients groups the variants of rs2297374 were significantly associated with HDL and total cholesterol levels. No differences in cardiovascular mortality and no associations with the investigated biomarkers were seen in non-diabetics and type 2 diabetics on metformin therapy.

CONCLUSION: The minor C allele of rs2297374 in the Oct1 gene is associated with decreased cardiovascular mortality in non-metformin users eventually due to its influence on HDL and total cholesterol levels. This work was funded by the Austrian Government in the COMET K1 Center Programme of Styria and Vienna.

Genome-wide multi-phenotype and eQTL analyses provide novel insights into omega fatty acid metabolism

M. Kaakinen¹, A. Claringbould^{1,2}, F. Hagenbeek^{1,3,4}, R. Mägi⁵, P. Soininen⁶, M. Järvelin^{1,7}, BIOS Consortium, A. P. Morris⁸, I. Prokopenko¹;

¹Imperial College London, London, United Kingdom, ²University Medical Centre Groningen, Groningen, Netherlands, ³VU University Amsterdam, Amsterdam, Netherlands, ⁴EMGO+ Institute for Health and Care Research, Amsterdam, Netherlands, ⁵Estonian Genome Center, University of Tartu, Tartu, Estonia, ⁶University of Eastern Finland, Kuopio, Finland, ⁷University of Oulu, Oulu, Finland, ⁸University of Liverpool, Liverpool, United Kingdom.

Introduction: There is evidence for favourable effects of diets rich in omega-3 fatty acids (FAs) on cardiovascular disease. However, little is known on the genetic contribution to FA levels, since most studies have focused on serum lipid concentrations typically used in clinical practice.

Materials and Methods: We undertook common and rare variant genome-wide multi-phenotype analyses (MPA) of FA levels using nuclear magnetic resonance-based measures of FAs and 1000 Genomes imputed data from the Northern Finland Birth Cohorts 1966 (N=4949) and 1986 (N=3055). To avoid multicollinearity issues, we selected four FAs for MPA: omega-3, -6, -7/9 and other polyunsaturated FAs. Expression quantitative locus (eQTL) analysis was performed on the Dutch BIOS consortium RNA-seq data (N=2116).

Results: The common variant meta-analysis detected 10 signals associated with FAs (P<5x10⁻⁸), including a novel FA locus at *MACROD1* (rs1006207). Variation in the other identified loci *PCSK9*, *GCKR*, *FADS1*, *ZNF259*, *LIPC*, *PDXDC1*, *PBX4*, *APOE* and *ADAMTS3* has previously been associated with triglycerides and cholesterol levels, but not specifically with FAs. *FADS1* was also identified in the rare variant MPA. The eQTL analysis indicated eight out of 10 MPA-identified signals with significant cis-eQTL effects on gene expression levels. The novel *MACROD1* variant was a cis-eQTL for *PRDX5* expression, suggesting a role in protection against oxidative stress.

Conclusions: With a combination of refined lipid measures, MPA and eQTL analysis we have identified genetic loci and differentially expressed genes involved in FA metabolism, providing novel clues for the complex relationship between lipids and cardiovascular disease.

The effects of diabetes mellitus and/or genetic polymorphisms on the formation of the peripheral arterial diseases

Z. Yalim¹, S. Tutgun Onrat², O. Akci¹, G. Ozkececi¹, M. Aldemir³, A. Avsar⁴, I. Dogan⁴, E. Onrat¹;

¹Afyon Kocatepe University, Faculty of Medicine, Department of Cardiology, Afyonkarahisar, Turkey, ²Afyon Kocatepe University, Faculty of Medicine, Department of Medical Genetics, Afyonkarahisar, Turkey, ³Afyon Kocatepe University, Faculty of Medicine, Department of Cardiovascular Surgery, Afyonkarahisar, Turkey, ⁴Afyon Kocatepe University, Faculty of Medicine, Department of Biostatistics, Afyonkarahisar, Turkey.

Introduction: Peripheral arterial disease (PAD) is a condition that is caused by narrowing of limb arteries due to atherosclerosis. Femoral, popliteal and tibial arteries are more affected in patients with diabetes mellitus (DM). In this study, we investigated the effects of diabetes mellitus and genetic background, solely and together in the pathogenesis of PAD.

Materials and Methods: In our study we planned to evaluate the effects of Factor V LEIDEN, Factor V H1299R, Prothrombin G20210A, Factor XIII V34L, B-Fibrinogen -455 G>A, PAI-1 4G/5G, HPA1, MTHFR C677T, MTHFR A1298C, ACE I/D, APO B R3500Q, and APO E polymorphisms using a ViennaLab CVD StripAssay. Patients were placed into four groups: 50 patients with DM and PAD, 50 patients with PAD and without DM, 30 patients with DM and without PAD and 30 controls.

Results: In the formation of PAD regardless of the presence of diabetes, MTHFR A1298C and PAI 4G/5G homozygous mutation seems to be determinant (p<0.05 for both). In the presence of DM, PAI 4G/5G homozygous mutation determined the formation of PAD (p<0.05). In regression analysis, PAI-1 4G/5G gene homozygous mutation was 17,1 times more risky, (p<0,008) 95% CI(2,113-138,660), MTHFR A1298C homozygous mutation was 316,6 times more risky (p<0.001)95%CI(10,763-9315,342) the possibility of diabetes mellitus with peripheral artery diseases.

Conclusions: It seems to be that, in the presence of DM, PAI 4G/5G homozygous mutation is powerful predictor to determine the formation of PAD. In the regardless of DM, MTHFR A1298C and PAI 4G/5G homozygous mutation are also predictor in the formation of PAD.

P05.63

New insights in Pseudohypoaldosteronism type II

G. J. Voortman, A. J. M. Verkerk, E. J. G. Sijbrands, J. Versmissen, A. H. van den Meiracker, E. C. H. Friesema;
Erasmus University Medical Center, Rotterdam, Netherlands.

Pseudohypoaldosteronism type II (PHAII), also known as Gordon's syndrome or familial hyperkalemic hypertension (OMIM 145260), is a rare monogenic disorder mainly characterized by arterial hypertension and hyperkalemia. So far, 4 genes have been identified to be mutated in PHAII patients, either WNK1, WNK4, KLHL3 or CUL3. All patients can be effectively treated by thiazide diuretics, compatible with over-activity of the thiazide-sensitive Na⁺-Cl⁻ cotransporter in the kidney.

A 60 years old female patient had been diagnosed with hyperkalemia e.c.i. > 10 years. Metabolic acidosis and hypertension were not present. Plasma potassium level was 6.3 mmol/L (normal range 3.5-5.1 mmol/L) as well as a mild hyperchloremia with low plasma levels of aldosterone and low-normal plasma levels of renin.

Sanger sequencing revealed a novel heterozygote G>A mutation in exon 11 of KLHL3, leading to an amino acid change (V434M). This mutation was adjacent to already known disease-causing mutations. Prediction models indicate that this V434M has a deleterious effect on KLHL3 function. No additional mutations were found in WNK1, WNK4, and CUL3. The patient was treated with hydrochlorothiazide, which resulted in normalization of potassium plasma levels as well as in lowering of her normal blood pressure.

Genetic analysis of her two daughters, revealing the same hyperkalemia (6.3 and 5.9 mmol/L, respectively) without hypertension, showed that both carry the same heterozygote mutation in KLHL3. They were also treated with hydrochlorothiazide.

The genetic analysis of KLHL3 in this family revealed that the diagnosis of PHAII is not always the obligatory combination of hyperkalemia plus hypertension.

Whole genome sequencing and deep phenotyping identifies rare protein-coding and non-coding variants in a large cohort of unrelated idiopathic and heritable pulmonary arterial hypertension cases

S. Gräf, M. Bleda¹, C. Hadinnapola¹, M. Haimel¹, H. J. Bogaard², G. Coghlan³, P. A. Corris⁴, S. Gibbs⁵, D. G. Kiely⁶, A. Lawrie⁷, R. D. Machado⁸, A. J. Peacock⁹, J. Pepke-Zaba¹⁰, M. Toshner¹⁰, R. C. Trembath¹¹, A. Vonk Noordegraaf¹², J. Wharton¹², M. R. Wilkins¹², S. J. Wort¹³, N. W. Morrell¹, on behalf of the NIHR BioResource Rare Diseases (BRIDGE) PAH Consortium, and the UK National PAH Cohort Study Consortium;

¹University of Cambridge, Cambridge, United Kingdom, ²VU University Medical Centre Amsterdam, Amsterdam, Netherlands, ³Royal Free Hospital, London, United Kingdom, ⁴Freeman Hospital, Newcastle, United Kingdom, ⁵Hammersmith Hospital, London, United Kingdom, ⁶Royal Hallamshire Hospital, Sheffield, United Kingdom, ⁷University of Sheffield, Sheffield, United Kingdom, ⁸University of Lincoln, Lincoln, United Kingdom, ⁹Golden Jubilee National Hospital, Glasgow, United Kingdom, ¹⁰Papworth Hospital, Papworth, United Kingdom, ¹¹King's College, London, United Kingdom, ¹²Imperial College, London, United Kingdom, ¹³Royal Brompton Hospital, London, United Kingdom.

Introduction: Despite the identification of rare causal variation in several genes, most notably BMPR2, a large proportion of cases of heritable (~20%) and idiopathic pulmonary arterial hypertension (PAH) (~80%) still remain unexplained at the molecular level.

Methods: As part of the UK 10,000 Genomes BRIDGE project the whole genomes of 1,250 unrelated individuals diagnosed with idiopathic and heritable PAH are being sequenced and extensively phenotyped. Stringent filtering based on MAF < 1/10,000 in both BRIDGE and ExAC and deleteriousness and conservation scores are used to prioritise pathogenic variants, coupled with phenotypic information.

Results: To date, 5844 whole genomes of rare disease patients have been sequenced including 625 PAH cases. 107 PAH subjects (17%) possess clearly or likely pathogenic mutations in one of the known PAH genes. The majority of loss-of-function and likely pathogenic missense mutations have been identified in BMPR2 (73 PAH cases [12%]). A further 14 subjects had (micro-)deletions of 5kb to 3.8Mb affecting either the entire BMPR2 locus or one or more exons within the gene. Additional variants in the promoter and other non-coding regions of BMPR2 are undergoing functional investigation. We also identified individuals with homozygous (n=6) and potential compound heterozygous (n=6) mutations in EIF2AK4 (2%).

Conclusions: Of the known PAH genes, BMPR2 mutations are the most common. It is likely that non-coding variation around known PAH genes, in particular BMPR2, will explain further PAH cases. The genetics underlying PAH appear complex and a large sample size is necessary to test for novel rare sequence variation association.

P05.65

Novel SMAD2 mutations in two families with LDS-like syndromic presentations of aortic aneurysm

E. Cannars¹, M. Kempers², J. Richer³, L. Beauchesne⁴, A. Verstraeten¹, N. Peeters¹, B. Loey¹, L. Van Laer¹;

¹Center of Medical Genetics, Faculty of Medicine and Health Sciences, University of Antwerp and Antwerp University Hospital, Antwerp, Belgium, ²Department of Human Genetics, Radboud University Nijmegen Medical Center, Nijmegen, Netherlands, ³Department of Medical Genetics, Children's Hospital of Eastern Ontario, Ottawa, ON, Canada, ⁴Division of Cardiology, University of Ottawa Heart Institute, Ottawa, ON, Canada.

Aortic aneurysms/dissections are common manifestations in hereditary connective tissue disorders, including Marfan syndrome (MFS) and Loeys-Dietz syndrome (LDS). Exploration of underlying pathomechanisms has revealed prominent dysregulation of the transforming growth factor (TGF)- β signaling pathway. Most recently, mutations in SMAD2, encoding a key transcriptional regulator of TGF- β signaling, have been shown to cause aortic aneurysmal disease. Here, we expand the phenotypic spectrum associated with SMAD2 mutations in two families presenting with syndromic aortopathy.

The application of a custom targeted resequencing panel, including SMAD2, led to the identification of two novel missense mutations, both affecting highly conserved amino acids in the functionally important DNA binding MH2 domain of SMAD2.

The first mutation (p.Asn318Lys) was found in a 63-years old female proband presenting with an LDS phenotype: facial features (high arched palate, broad uvula, downslanting palpebral fissures), skeletal abnormalities (arachnodactyly, pectus excavatum and scoliosis surgeries at ages 11 and 36 years), aortic root replacement (age 53 years). Segregation analysis revealed the presence of the SMAD2 mutation in the daughter who presents with marfanoid features. The second mutation carrier (p.Ser397Tyr) was diagnosed with LDS. Cardiovascular symptoms include aortic root dilatation and marked tortuosity of the neck vessels, no major skeletal abnormalities were noted. We confirmed presence of the mutation in a daughter with hypertelorism and arterial tortuosity and mother with hypertelorism and normal echocardiography.

In conclusion, SMAD2 mutations are causal in patients with LDS and MFS features. This gene should be included in the expanding list of candidate genes causing these conditions.

Search for somatic mitochondrial DNA mutations in carotid atherosclerotic plaques by massive parallel sequencing

M. V. Golubenko^{1,2,3}, N. P. Babushkina¹, M. S. Nazarenko^{1,3}, A. V. Markov^{1,3}, S. V. Buikin¹, A. A. Sleptsov^{1,3}, O. L. Barbarash², V. P. Puzrev^{1,3};

¹Institute for Medical Genetics, Tomsk, Russian Federation, ²Institute for complex issues of cardiovascular diseases, Kemerovo, Russian Federation, ³Tomsk State University, Tomsk, Russian Federation.

Introduction: Atherosclerosis is accompanied by increased oxidative stress. MtDNA is exposed to oxidative damage, since it is located near the ROS production sites. To describe possible somatic mtDNA mutations arising during atherogenesis, we have compared heteroplasmic mtDNA variations in the carotid plaques and blood using massive parallel sequencing.

Materials and methods: Ten paired samples of DNA extracted from the ablated carotid plaques and from the blood of the patients, were analyzed. MtDNA was amplified in two overlapped PCR-products, sequenced and analyzed on the MiSeq platform, using 1% threshold for variant calling. Single nucleotide indels were not considered if detected in more than two individuals. **Results:** The mean base coverage across the mitochondrial genome was about 8000. All individuals had heteroplasmic positions at the minimum 1% level (average 3.2 positions per plaque sample and 3.1 positions per blood sample). Altogether, 50 heteroplasmic positions were revealed, 12 of them were common for the blood and plaque samples, and only 1 position was found to be heteroplasmic in two individuals. The heteroplasmic positions were concentrated in the control region (30%), and in protein-coding genes (54%). Transition to transversion ratio was elevated (9:1), as well as nonsynonymous mutations (73% of all protein-coding heteroplasmies, including 2 frameshifts), comparing to population polymorphisms.

Conclusions: There is considerable heteroplasmic mtDNA variation in atherosclerosis, with no significant differences between blood and carotid plaques. The somatic mtDNA variation characteristics differ from those of inherited polymorphisms.

The study is supported by Russian Science Foundation, grant no. 14-15-00305.

The involvement of ER-retention and quality control in the cellular mechanisms underlying hereditary hemorrhagic telangiectasia and familial pulmonary arterial hypertension caused by mutations in TGF- β growth factor receptors

B. R. Ali¹, P. Kizhakkedath, A. John, L. Al-Gazali;

United Arab Emirates University, Al-Ain, United Arab Emirates.

Introduction: The transforming growth factor- β (TGF- β) superfamily signaling plays critical roles in the regulation of cellular growth, differentiation and development. Mutations in the plasma membrane components of the TGF- β signaling pathways including mutations in BMPR2, ENDOGLIN and ALK1 genes have been shown to cause pulmonary arterial hypertension and hereditary hemorrhagic telangiectasia types 1 (HHT1) and 2 (HHT2), respectively. However, the underlying cellular mechanisms of the majority of the reported mutations are unknown.

Materials and Methods: The C-terminally tagged cDNAs of BMPR2, ENDOGLIN and ALK1 in mammalian expression vectors were used as templates to generate the required missense disease-causing mutations by QuikChange site-directed mutagenesis. The constructs were transfected into HeLa and HEK293 cells and the expressed proteins were analyzed biochemically and by confocal microscopy.

Results: Ten of the examined eighteen missense mutants in BMPR2 have shown aberrant subcellular trafficking with the extracellular domain mutants predominantly retained within the lumen of the ER. Similarly, the majority of the analyzed missense mutants in ALK1 and ENDOGLIN exhibited aberrant trafficking and intracellular retention by the ER quality control machinery. In addition, we found that the plasma membrane trafficking of these mutants was amenable to correction by chemical chaperones.

Conclusions: ER retention of TGF- β mutant proteins is a major cellular mechanism underlying pulmonary arterial hypertension and hereditary hemorrhagic telangiectasia. Manipulation of this ER retention is a potential target for therapeutic intervention in these diseases.

Targeted Next-Generation Sequencing Helps to Unravel the Genetic Heterogeneity of Hypertrophic Cardiomyopathy

M. Cecconi¹, M. I. Parodi¹, F. Formisano², P. Spirito², C. Autore³, M. B. Musumeci³, S. Favale⁴, C. Forleo⁴, C. Rapezzi⁵, E. Biagini⁵, S. Davi⁶, E. Canepa¹, L. Pennese¹, M. Castagnetta¹, D. Degiorgio^{1,6}, D. A. Coviello¹;

¹Laboratory of Human Genetics, E.O. Ospedali Galliera, Genoa, Italy, ²Cardiology Unit, E.O. Ospedali Galliera, Genoa, Italy, ³Cardiology Unit, St. Andrea Hospital, Sapienza University, Rome, Italy, ⁴Cardiology Unit, Department of Emergency and Organ Transplantation, University of Bari, Bari, Italy, ⁵Cardiology Unit, Policlinico S. Orsola-Malpighi, University of Bologna, Bologna, Italy, ⁶Department of Experimental Medicine, University of Genoa, Genoa, Italy.

Hypertrophic cardiomyopathy (HCM) is caused mostly by mutations in MYH7 and MYBPC3 genes; less frequently mutations in other genes have been reported. The aim of this study is to evaluate a target-Next Generation Sequencing (NGS) panel, which includes sarcomeric genes not only encoding thick/intermediate and thin myofilament (TTm) proteins, but also other sarcomeric genes and some causative genes of HCM-phenocopy. A Ion AmpliSeq™ Custom Panel for the enrichment of 19 genes, 9 of which not encoding TTm proteins, was established. By using Ion Personal Genome Machine, we studied: (i) a training set (n. 73 DNA-samples) already genotyped to optimize the NGS strategy; (ii) a discovery set (n. 19 DNA-samples). In the training set we identified 71 out of 72 expected mutations and 15 additional mutations, 10 of which in genes not encoding TTm proteins; of them, 4 are identified in MYOM1 gene. In the discovery set we identified 20 mutations: the diagnostic yield was increased of about 20% and, among the mutations not belonging to genes encoding TTm proteins, we identified mutant alleles of MYOZ2 (one), MYOM1 (two) and LAMP2 (one) genes. Our combined targeted NGS-Sanger sequencing-based strategy allowed: a) the molecular diagnosis of HCM with greater efficiency than using the conventional (Sanger) sequencing alone; b) the identification of less frequently mutant alleles associated to HCM like MYOM1 and MYOZ2 genes (Siegert et al., 2011; Osio et al., 2007). Mutant alleles identification in genes not encoding sarcomeric TTm proteins may better contribute to explain the genetic heterogeneity of HCM.

Study of the contribution of copy number variation to the pathogenesis of bicuspid aortic valve associated aortopathy

I. Luyckx¹, E. Reyniers¹, E. Dekeyser¹, K. Vanderstraeten¹, G. Vandeweyer¹, F. Wünnemann², C. Preuss², P. Eriksson³, S. A. Mohamed⁴, G. Andelfinger², A. Verstraeten¹, L. Van Laer⁴, B. L. Loey^{1,5}, MIBAVA Leducq consortium;

¹Center for Medical Genetics, Edegem, Belgium, ²Cardiovascular Genetics, Department of Pediatrics, Centre Hospitalier Universitaire Saint-Justine Research Centre, Université de Montréal, Montreal, QC, Canada, ³Karolinska Institutet and Karolinska University Hospital, Stockholm, Sweden, ⁴Department of Cardiac and Thoracic Vascular Surgery, University Clinic of Schleswig-Holstein, Luebeck, Germany, ⁵Department of Human Genetics, Radboud University Nijmegen Medical Center, Nijmegen, Netherlands.

Affecting 1–2% of the population, bicuspid aortic valve (BAV) is the most common congenital heart malformation. Although it is usually asymptomatic, 10–20% of individuals with BAV develop life-threatening thoracic aortic aneurysms (TAA). Several studies have indicated that up to 10% of left-sided heart defects are caused by deleterious copy number variations (CNVs). Hence, we hypothesize that CNVs may also contribute to the pathogenesis of BAV/TAA.

CNV analysis was performed in 100 unrelated BAV/TAA patients using the CytoSNP12.2 array, followed by data analysis with the CNV-WebStore tool. CNVs affecting protein-coding genes with a potential role in the cardiovascular system and with a low frequency in healthy individuals (MAF<0.5%) were manually prioritised for validation with MLPA/qPCR/MAQ.

Each BAV/TAA patient carried approximately 14 CNVs, which is comparable to what is observed in healthy individuals. After filtering based on gene content, 15 candidates remained, of which six could be validated. These CNVs did not encompass any known BAV/TAA genes and segregation analysis did not support fully-penetrant pathogenicity. According to DECIPHER, CNVs overlapping with candidate CNVs were also identified in controls or in highly dissimilar diseases without cardiovascular involvement, further demonstrating the unlikelihood that these CNVs directly cause BAV/TAA.

Our results show that this BAV/TAA cohort is not enriched for deleterious CNVs causing BAV/TAA. This finding is in contrast to prior studies of other left-sided heart defects, which identified CNVs as a major causative factor. However, we cannot exclude the possibility that certain CNVs contribute as modifiers, creating a sensitised background for BAV/TAA.

A common variant association study for type 2 diabetes mellitus in ethnic Saudi Arabs

D. Bakheet¹, N. P. Muiya¹, S. M. Wakil¹, R. Ram², B. F. Meyer¹, G. Morahan², N. Dzimir¹;
¹King Faisal Spec. Hospital and Research Centre, Riyadh, Saudi Arabia, ²Western Australian Institute for Medical Research, University of Western Australia, Australia, Perth, Australia.

Introduction: Type 2 diabetes mellitus (T2D) is a debilitating disease that contributes to the manifestation of complex disease, such as coronary heart disease, with a strong genetic component. However the genetic basis for the disease is not fully understood yet.

Materials and Method: In the present study, we performed a genome-wide association study using the Affymetrix High Density Axiom platform for the disease in the ethnic Saudi Arab population (cases versus).

Results: In all, in the discovery study, we identified nine variants that displayed significant ($P \leq 10^{-7}$) or suggestive ($P \leq 10^{-6}$) association with the disease. The lead variant was the rs4506565 [1.29(1.19-1.40); $p = 8.78E-10$] on chr10 in the TCF7L2 gene. Another variant rs16976967 [1.22(1.12-1.33); $p = 4.17E-06$] on chr15 in the MNS1 gene showed suggestive association with disease. On the other hand seven other variants showed weak protective properties against the disease. These included the rs10789192 [0.83(0.76-0.9); $p = 4.52E-06$] on chr1 in the PDE4B gene, rs681828 [0.82(0.76-0.88); $p = 5.44E-07$] on chr1 in the KCNK1 gene, rs13411975 [0.84(0.77-0.92); $p = 8.76E-06$] on chr2 in the SNTG2 gene, rs9824601 [0.82(0.76-0.88); $p = 1.39E-07$] on chr3 in the MRPL3 gene, rs4352831 [0.88(0.82-0.95); $p = 6.48E-06$] on chr8 in the ADCY8 gene, rs150524 [0.82(0.76-0.89); $p = 1.47E-06$] on chr17 in the CCL1 gene and the intergenic rs9948423 [0.7(0.6-0.81); $p = 2.15E-06$] on chr18. Interestingly, we were able to validate the associations of these variant with disease in a separate cohort.

Conclusions: The study revealed several variants throughout the genome that conferred risk for type 2 diabetes mellitus. Our validation experiment suggests a strong genetic link to the disease in ethnic Arabs.

P05.74

Next generation sequencing to unravel the genetic architecture of KNG1 and F11 loci

L. Martín-Fernández¹, G. Gavidia¹, I. Corrales², H. Brunel¹, L. Ramírez², J. C. Souto³, F. VidaF, J. M. Soria⁴;

¹Unit of Genomics of Complex Diseases, Biomedical Research Institute Sant Pau (IIB-Sant Pau), Barcelona, Spain, ²Unit of Molecular Diagnosis and Therapy, Blood and Tissue Bank, Barcelona, Spain, ³Unit of Hemostasis and Thrombosis, Department of Hematology, Barcelona, Spain.

Introduction: Factor XI (FXI) level is an intermediate phenotype of venous thromboembolism -- a complex disease with a high heritability (~60%). The Genome Wide Association Study (GWAS) performed in the GAIT-1 (Genetic Analysis of Idiopathic Thrombophilia) Project revealed significant associations between the FXI levels and SNPs in *KNG1* and *F11* genes. Our aim was to identify the genetic variability of *KNG1* and *F11* that could explain such association.

Materials and Methods: The *KNG1* and *F11* were completely sequenced (exons, introns and promoters) in 110 unrelated individuals from the GAIT-2 Project using Next generation sequencing (NGS) Illumina MiSeq Platform. Association analyses were performed with FXI levels using the PLINK and SKAT package. Also we identified by data filtering and *in silico* predictions the putative causal mutations.

Results: A total of 762 genetic variants were detected. Several significant nominal associations were identified between common variants and clustered low frequency variants in *KNG1* and *F11* with FXI levels. Among these associations, the missense rs710446 was significant after the permutation test. In addition, two putative causal mutations were related with high and low FXI levels.

Conclusions: Using NGS we investigated the genetic architecture of the *F11* and *KNG1* loci. This information contributes to the identification of the "missing heritability" of this key intermediate phenotype. Concretely, we identified putative rare mutations, common variants and clustered low frequency variants associated with FXI levels that may contribute to the risk of venous thromboembolism.

Whole-exome sequencing as diagnostic tool in a quartet family with Abetalipoproteinemia

A. Sanchis-Juan¹, D. Perez-Gil¹, C. Martínez-Costa², V. Martínez-Barquero³, V. Gonzalez-Albert¹, P. Marin-García¹, F.J. Chaves^{1,3}, A. García-García^{1,3};

¹Genotyping and Genetic Diagnosis Unit, INCLIVA, Valencia, Spain, ²Pediatric Service, Clinical Hospital of Valencia, Valencia, Spain, ³CIBER de Diabetes y Enfermedades Metabólicas Asociadas (CIBERDEM), Valencia, Spain.

Abetalipoproteinemia (ABL) is a rare lipid metabolism disease, where mutations in causative known genes can only explain a low percentage of cases. This disease is characterized by very low plasma concentrations of triglycerides and total cholesterol (under 30mg/dl), and undetectable levels of LDL and ApoB. Later in life, ABL is associated with atypical development of retinitis pigmentosa, coagulopathy, column neuropathy and myopathy.

We used whole-exome sequencing (WES) to study a family with two affected children and their asymptomatic parents. Mutations in causative known genes for ABL (MTTP) and for diseases with similar phenotype such as Familial Hypobetalipoproteinemia (APOB, PCSK9 and ANGPTL3) have been previously discarded by Sanger sequencing.

By examining homozygous and compound heterozygous inherited variants, we found that both children carried mutations in TMC6 and SEC23A genes. Although TMC6 does not show a consistent relationship with lipid metabolism, recent studies have demonstrated that SEC23A, an essential component of coat protein complex II (COPII)-coated vesicles, could be involved in the apoB100-lipoproteins exit from the endoplasmic reticulum to de Golgi apparatus.

Besides, SEC23A has been associated with Cranioleptosutural dysplasia (CLSD), disorder characterized by late-closing fontanels among other features. Since both children showed unexplained late-closing fontanels, our study strongly indicate that SEC23A could be a new ABL causative gene not previously described. Functional assays are currently being developed for both genes to confirm these results.

Loss of function of the mitochondrial repressor RIP140 halts axonal degeneration in the peroxisomal disease X-linked adrenoleukodystrophy

P. Ranea-Robles^{1,2}, M. Ruiz^{1,2}, J. Galino^{1,2}, A. Schlüter^{1,2}, I. Ferrer³, A. Pujol^{1,2,4}, S. Fourcade^{1,2};

¹IDIBELL, Hospitalet de Llobregat-Barcelona, Spain, ²CIBERER U759, Centro de Investigación en Red sobre Enfermedades Raras, Barcelona, Spain, ³Institute of Neuropathology, Pathologic Anatomy Service, Bellvitge Biomedical Research Institute, IDIBELL, Hospitalet de Llobregat-Barcelona, Spain, ⁴Institució Catalana de Recerca i Estudis Avançats (ICREA), Barcelona, Spain.

X-linked adrenoleukodystrophy (X-ALD) is a rare disease, with fatal prognosis and no satisfactory treatment, characterized by brain inflammatory demyelination and/or axonal degeneration of corticospinal tracts in the spinal cord. It is caused by loss-of-function of the peroxisomal transporter ABCD1. As a result, very long-chain fatty acids (VLCFA) such as C26:0 accumulate in tissues and plasma. The murine model of X-ALD (*Abcd1*) exhibits a late-onset axonal degeneration in spinal cords. We have previously reported that excess of C26:0 produced oxidative stress of mitochondrial origin, which compromises energy metabolism and suppresses the mitochondrial biogenesis pathway driven by the SIRT1/PGC-1 α /PPAR γ network, very early in the physiopathogenetic cascade.

In this study, we have identified RIP140, a novel transcriptional regulator of energy metabolism that antagonizes PGC-1 activation of mitochondria biogenesis, as being overexpressed in the X-ALD mouse spinal cords. We show that RIP140 is directly regulated by C26:0 *via* an oxidative stress-dependent mechanism. Further, a double knockout mouse X-ALD/RIP140 shows normalized mitochondrial respiration and bioenergetic failure, as well as axonal degeneration and associated locomotor disabilities. Altogether, these results highlight RIP140 as a novel therapeutic target for X-ALD, and suggest that its pharmacological inhibition may be a valuable strategy to treat this and other axonopathies in which energetic homeostasis and mitochondria biogenesis may be impaired.

This work was supported by grants from the Spanish Institute for Health Carlos III and "Fondo Europeo de Desarrollo Regional (FEDER)" (FIS PI14/00410). P.R.R. is a fellow of Spanish Institute for Health Carlos III (PFIS program: FI12/00457).

A BCAT2 mutation causes a novel inborn error of metabolism due to mitochondrial branched-chain amino acid aminotransferase deficiency and results in developmental delay and autism

I. Knerer¹, J. Urquhart¹, J. Hughes¹, Y. Rogers¹, S. Jones², S. Lynch¹, E. P. Treacy¹, P. Mayne¹, S. Banka^{3,2}, S. Olpin⁴;

¹Temple Street Children's University Hospital, Dublin, Ireland, ²St Mary's Hospital, Manchester, United Kingdom, ³University of Manchester, Manchester, United Kingdom, ⁴Sheffield Children's Hospital, Sheffield, United Kingdom.

Introduction: Plasma amino acid profile in an adolescent boy with history of early onset developmental delay and autism revealed profoundly elevated levels of branched-chain amino acids (BCAA) - leucine, valine and isoleucine, without an increase in their corresponding branched-chain 2-ketoacids. Notably, alloisoleucine was not detected and Maple Syrup Urine Disease was ruled out. The biochemical phenotype suggested a defect in the first step of BCAA catabolism.

Results: Targeted Sanger sequencing of BCAT2 gene that encodes mitochondrial BCAA aminotransferase revealed a novel homozygous inframe deletion (NM_0011190; c136_147del; p.His46_Pro49del). Studies conducted on patient's fibroblasts demonstrated a marked reduction in valine oxidation and somewhat impaired leucine oxidation supporting a deficiency of the BCAT enzyme. Protein structural analysis and additional functional studies are ongoing to elucidate the mechanism linking the mutation and enzyme activity.

Conclusion: Till date, there is only one reported case of BCAT2 deficiency in the literature that resulted from two compound missense heterozygous BCAT2 mutations in a 25-year-old man with normal development and six-year history of headaches with mild memory impairment (Wang et al 2015). Our findings lead to discovery of a novel inborn error of catabolism of BCAAs caused by an inframe BCAT2 deletion resulting in developmental delay and autism.

Unexpected findings from Next Generation Sequencing (NGS) panel suggesting mitochondrial disorder in two patients.

K. Simenson¹, S. Pajusalu^{1,2}, T. Kahre^{1,3}, R. Zordania¹, R. Rein³, K. Õunap^{1,2};
¹Department of Genetics, United Laboratories, Tartu University Hospital, Tartu, Estonia,
²Department of Biomedicine, Institute of Biomedicine and Translational Medicine, University of Tartu, Tartu, Estonia, ³Department of Pediatrics, Institute of Clinical Medicine, University of Tartu, Tartu, Estonia.

Mitochondrial diseases are clinically heterogeneous group of disorders affecting energy production. Due to clinical and genetic complexity it is difficult to recognize them in clinical practice. We present two cases which were clarified by targeted NGS panel.

Case 1: 14-year-old male who was born by Caesarian section due to fetal overgrowth. He has intellectual disability (ID), verbal dyspraxia, mildly decreased muscle tone, bilateral moderate sensorineural hearing loss and seizures. MRI and EEG were normal. We found compound heterozygous mutations in BCS1L gene (c.232A>G, p.Ser78Gly and c.245C>T, p.Ser82Leu; NM_001257342.1). Mutations in BCS1L gene are associated with mitochondrial respiratory chain complex III deficiency which leads to reduced activity of electron-transport chain and increased production of reactive oxygen species.

Case 2: 15-year-old female, who was born with microcephaly (occipito-frontal circumference 31cm, -3SD). She has dysmorphic features, severe ID, microcephaly, epilepsy and mitral valve prolapse. In infancy lactate and alanine were mildly elevated. CT showed enlargement of lateral ventricle and brain atrophy. Muscle electronmicroscopical investigation was normal. We found a novel de novo heterozygous frameshift mutation in PDHA1 gene (c.1014_1017dup, p.Arg340Leufs*13, NM_001173454.1). Mutations in PDHA1 gene are associated with pyruvate dehydrogenase complex deficiency. This causes malfunction of citric acid cycle and deprives the body of energy.

We asked for ID and epilepsy associated genes for case 1, microcephaly and ID associated genes for case 2 from NGS panel. These cases illustrate that NGS is a powerful tool which enables diagnosing patients with non-classical phenotypes and thus sometimes provides a new perspective to clinicians.

Admixture Analysis between allelic effect and HDL-C concentration related to metabolic syndrome (MetS) in Tehran cardio-metabolic genetic study (TCGS)

B. Sedaghatkhatay¹, M. Fallah¹, K. Guity¹, S. Masjoodi¹, F. Azizi², M. Daneshpour¹;
¹Cellular and molecular endocrine research center, Research Institute for endocrine sciences Shahid Beheshti University of Medical Sciences, Tehran, Iran, Islamic Republic of, ²Endocrine Research Center, Research Institute for endocrine sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran, Islamic Republic of.

Background: HLD-C variation is one of the main phenotypes in most non-communicable disorders like metabolic syndrome. Genetics and environmental factors have undeniable effects on level of HDL-C; among them can be noted to body mass index (BMI) and FTO gene. The current study wants to examine interaction between BMI and FTO and CETP SNPs and their effects on HDL-C level changes in metabolic syndrome.

Material and methods: 1142 subjects were selected from TCGS (%49 male). 382 well defined MetS used as a case and the others used as control. Nine selected polymorphisms from FTO and CETP genes were genotyped by Tetra ARMS-PCR. After adjustment for covariate like age, sex and smoking, the association and interactions between studied alleles and HDL-C and metabolic syndrome in different BMI groups, was tested using plink software and PASW Statistics 18.

Results: Among all nine SNPs, in presence of BMI, lower serum HDL-C had the strongest association with 3 SNPs: rs3764261 (OR: 0.6281, CI95%; 0.6243-0.632, P=2.31*10⁻⁶), rs1800775 (OR: 1.517, CI95%; 1.508-1.526, P=7.15*10⁻⁶) and rs1864163 (OR: 1.062, CI95%; 1.018-1.108, P=5.08*10⁻³). Also other SNPs with other parameters of lipid profile showed significance association.

Conclusion: In summary, there are some significance relationships between HDL-C level and studied polymorphisms in the presence of BMI in metabolic syndrome subjects. It seems that the effects of FTO variations on HDL-C level are affected by BMI, and BMI play a important role.

P06.07

Mutational spectrum of non-PMM2 Congenital Disorders of Glycosylation in the Spanish population

C. Medrano¹, A. Vega¹, M. Girós², M. Serrano³, M. Ecañ¹, M. Ugarte¹, B. Pérez¹, C. Pérez-Cerdá¹;

¹Centro de Diagnóstico de Enfermedades Moleculares. CBM. Universidad Autónoma de Madrid. CIBERER. IDIPAZ., Madrid, Spain, ²Servicio BGM, Sección ECM, Hospital Clínico Barcelona, CIBERER, Barcelona, Spain, ³Dep. Neuropediatría, Hospital San Joan de Déu, CIBERER, Barcelona, Spain.

Congenital disorders of glycosylation (CDG) are a heterogeneous group of disorders that entails defects on proteins of the glycosylation pathways. The majority of them are involved in the N-glycosylation pathway of proteins (N-CDGs), being PMM2-CDG the most frequent disease. Nevertheless, recent studies have revealed that some glycosylation disorders occur with greater frequency than current estimates. The aim of our work was to establish the mutational spectrum of CDG patients in the Spanish population, focusing on non-PMM2-CDG. 83 suspected-CDG patients were selected based on their clinical ground and/or abnormal serum transferrin isoforms. Sanger sequencing and/or enzymatic analysis identified 45 PMM2-CDG patients (54%). The genetic analysis of the remaining 38 suspected non-PMM2-CDG was addressed by Sanger sequencing or targeted exome sequencing of 43 CDG-genes or whole-exome sequencing or TruSight™ One sequencing panel (Illumina). 23 non-PMM2-CDG patients were genetically diagnosed (60.5%), finding pathogenic mutations on 15 different CDG-genes (ALG1, ALG6, ATP6V0A2, B4GALT1, CCDC115, COG7, DOLK, DPAGT1, DPM1, GFPT1, MPI, PGM1, RFT1, SRD5A3, SSR4). All of them are involved in the synthesis of the oligosaccharide linked to dolichol or its transfer onto the protein except ATP6V0A2, B4GALT1, CCDC115 and COG7 which are involved in the processing of the glycan or Golgi homeostasis. Overall, 28 different mutations were identified, 14 of them are novel mutations. In conclusion: next-generation sequencing has improved the diagnosis of these heterogeneous pathologies but reverse phenotyping of the CDG patients will lead an accurate molecular diagnosis because without phenotype information, genome analysis would be of limited medical value. Development and delivery of an integrated biochemical and genetic testing service for cerebral creatine deficiency syndromes

R. E. Mitchell¹, I. R. Berry¹, R. Barski², N. Camm¹, K. Prescott¹, C. M. Watson¹,

¹Deciphering Developmental Disorders Study², R. Charlton¹;
¹Yorkshire Regional Genetics Service, St James's University Hospital, Leeds, United Kingdom, ²Special Laboratory Medicine, St James's University Hospital, Leeds, United Kingdom, ³Wellcome Trust Sanger Institute, Cambridge, United Kingdom.

Cerebral creatine deficiency syndromes (CCDS) are inborn errors of metabolism involving defects in endogenous synthesis and transport of creatine resulting from pathogenic mutations in the genes *GAMT*, *GATM* and *SLC6A8*. CCDS have a broad differential diagnosis; clinical features include intellectual disability, speech delay and seizures. Although rare, CCDS are thought to be under-diagnosed with defects in the creatine transporter, *SLC6A8*, estimated to account for 2% of X-linked intellectual disability and 1% of males with intellectual disability of unknown aetiology. Here, a targeted CCDS sequencing panel was validated for diagnostic use in the Leeds Genetics Laboratory, delivered as an integrated service involving first-line biochemical testing. This service has thus far detected a pathogenic *SLC6A8* mutation in one child with global developmental delay and a homozygous pathogenic *GAMT* mutation in two children with severe speech and language delay, with further familial testing where appropriate. Additionally, Whole Exome Sequencing data were obtained from 1133 trios in the Deciphering Developmental Disorders Study, of which 42% of probands were males with at least one relevant clinical feature and 5% had an X-linked variant reported by the DDD Study. No pathogenic variants in *SLC6A8* were identified in this cohort, consistent with the predicted rarity of CCDS. Nonetheless, this is the first CCDS genetic diagnostic testing offered in a United Kingdom accredited laboratory, uniquely integrated alongside a biochemistry service. It remains likely that CCDS is significantly under-diagnosed and it is therefore anticipated that the service validated here will contribute to an increased diagnostic rate in the UK.

Persistence of positive renal and cardiac effects of migalastat in patients with Fabry disease (FD)-amenable mutations following 30 months of treatment in ATTRACT (Study 012)

D. G. Bichet¹, D. P. Germain², R. Giugliani³, D. Hughes⁴, R. Schiffmann⁵, W. R. Wilcox⁶, J. P. Castelli⁷, E. S. Cantor⁸, J. Kirk⁹, N. Skuban⁷, J. A. Barth⁷, M. Bechter⁶;

¹Hôpital du Sacré Coeur, University of Montreal, Montréal, QC, Canada, ²Hôpital Raymond Poincaré (APHP), University of Versailles-St. Quentin en Yvelines (UVSQ), Garches, France, ³Medical Genetics Service, Hospital de Clinicas de Porto Alegre, UFRGS, Porto Alegre, Brazil, ⁴University College London, London, United Kingdom, ⁵Baylor Research Institute, Dallas, TX, United States, ⁶Emory University, Atlanta, GA, United States, ⁷Amicus Therapeutics, Cranbury, NJ, United States, ⁸Amicus Therapeutics UK Limited, Buckinghamshire, United Kingdom.

Introduction: FD, an X-linked lysosomal α -galactosidase A deficiency disorder, leads to substrate accumulation and clinical sequelae. Migalastat, an oral pharmacological chaperone, stabilizes amenable mutant forms of α -galactosidase A in FD patients, increasing lysosomal activity. ATTRACT is an 18-month, open-label study, comprising a randomized comparison study of ERT-experienced patients switching to 150 mg QOD migalastat HCl (n=36) or remaining on ERT (n=21) and a 12-month open-label extension (OLE) with migalastat.

Materials and Methods: In the migalastat group, 31 patients with amenable mutations completed the 18-month period and entered 12-month OLE; 49 with amenable mutations received ≥ 1 migalastat dose during the combined 30 months.

Results: In patients receiving migalastat for 30 months, the mean (95% CI) annualized rate of change (mL/min/1.73m²) from baseline (cbl) in eGFR/CKD-Epi and mGFR/iohexol were -1.7 (-2.7, -0.8) and -2.7 (-4.8, -0.6); rates were comparable to those reported in patients receiving ERT for 18 months. In patients receiving migalastat for 30 months, the mean (95% CI) cbl in LVMi (g/m²) were -3.8 (-8.9, 1.3) for all patients and -10.0 (-16.6, -3.3) for those with LVH. For ERT-treated patients, previously reported 18-month changes in LVMi were -2.0 (-11.0, 7.0) for all patients and +4.5 (-20.9, 29.9) for patients with LVH. LVMi reduction from baseline to month 30 in patients with baseline LVH treated with migalastat was statistically significant.

Conclusion: In patients switched from ERT, the renal and cardiac effects of migalastat persist over 30 months, making migalastat a promising first-in-class oral chaperone treatment for male/female patients with amenable mutations.

P06.10

Biochemical peculiarities and clinical aspects in three Romanian patients with classic galactosemia

A. A. Chis¹, A. Nicolescu², C. Deleanu³, S. Tatar¹, R. Pop⁴, R. Vulturari¹;

¹Univ. of Medicine and Pharmacy, Cluj-Napoca, Romania, ²"P.Poni" Institute of Macromolecular Chemistry of the Romanian Academy, Iasi, Romania, ³"C.D. Nenitescu" Institute of Organic Chemistry of the Romanian Academy, Bucharest, Romania, ⁴Iasi, Romania, ⁵"P. Poni" Institute of Macromolecular Chemistry of the Romanian Academy, Iasi, Romania, ⁶"C.D. Nenitescu" Institute of Organic Chemistry of the Romanian Academy, Bucharest, Romania, ⁷Iasi, Romania, ⁸IIIrd Pediatric Clinic, Cluj-Napoca, Romania.

Classic galactosemia is a hereditary disorder of galactose metabolism caused by a deficiency in GALT (galactose-1-phosphate uridyl transferase). Patients diagnosed with this disorder show a potentially fatal phenotype after galactose intake in the first days of life. A galactose-restricted diet quickly resolves this acute symptoms. The exact mechanism(s) causing the complications (cognitive impairment and in females - ovarian insufficiency) and the time window in which the damage occur remain uncertain.

The national newborn screening in our country is limited to PKU and Congenital hypothyroidism, and this is why a fast analysis for urinary biomarkers in patients suspected for genetic metabolic disease is an emergency. We present the biochemical abnormalities, the clinical pictures and evolution in three newborn patients diagnosed with classic galactosemia after the first days of life; concentration of urinary galactose (between 9.890 and 11.897 mmol/molCreatinine) and galactitol (between 4.380 and 9.832 mmol/mol-Creatinine) were measured using an Bruker-Avance-400 MHz Spectrometer; the 1H-NMR spectrum of urine helped in a fast diagnosis but also in comparing the biochemical peculiarities with clinical pictures in our patients.

Metabolic profiling is an essential component that along with genetics, transcriptomics and proteomics data will permit a detailed description of the interactions between metabolites, proteins, transcripts and genes in the disease continuum.

Our cases will contribute to a better understanding of biochemical phenotype and clinical effects. This report highlight the importance of an extensi-

on of New Born Screening (NBS) in Romania and, as well, the importance of early confirmation of the diagnosis for family counseling.

COQ2-associated primary coenzyme Q10 deficiency: functional characterization of the human gene and establishment of genotype-phenotype correlations

E. Trevisson¹, M. A. Desbats¹, V. Morbidoni¹, M. Silic-Benussi², V. Ciminale², F. Pierre³, P. Navas⁴, L. Salviati¹;

¹Clinical Genetics, Department of Women's and Children's Health, University of Padova, Padova, Italy, ²Istituto Oncologico Veneto-IRCCS (IOV), Padova, Italy, Padova, Italy, ³Commissariat à l'Energie Atomique (CEA), Institut de Recherches en Technologies et Sciences pour le Vivant, Laboratoire Chimie et Biologie des Métaux, Grenoble, France, ⁴Centro Andaluz de Biología del Desarrollo, University Pablo de Olavide, Sevilla, Spain.

Introduction: COQ2 encodes para-hydroxybenzoate polyprenyltransferase, that catalyzes the second step of the final reaction sequence of Coenzyme Q10 (CoQ) biosynthesis. A homozygous mutation in COQ2 was the first molecular defect reported in a family with primary CoQ deficiency in 2006, followed by the identification of other 10 families. Their phenotypes vary widely but genotype-phenotype correlations remain to be clarified.

The structure of human COQ2 has been inferred by sequentially cloning the 5' region (amplified from genomic DNA) and the 3' region obtained from cDNA and the reported human sequence shows 4 in frame ATG initiation codons.

Methods: we employed in silico and experimental analyses to characterize the 5' region of COQ2, to analyze the topology and subcellular localization of Coq2p and set up a yeast model to validate COQ2 mutations.

Results: We provided experimental evidence showing that the functional human COQ2 transcript is shorter than what was previously thought and that Coq2 is a mitochondrial protein with the C terminus facing the inter-membrane space. We engineered all the known COQ2 missense alleles into the *S.cerevisiae* orthologue to analyze the respiratory phenotype in the deleted strain. Our model proved to be simple and reproducible and demonstrated the hypomorphic nature of all mutations. We also showed that the residual activity (measured by CoQ content in yeast) clearly correlates with patients' clinical phenotype.

Conclusions: Our data support the hypothesis that the affected tissues display a specific sensitivity to different levels of CoQ10 deficiency.

This study was supported by Ministry of Health Grant GR-2009-1578914

P06.12

Unusual phenotype with a novel homozygous SLC25A1 mutation

O. Wormser¹, I. Cohen¹, Y. Yogeve¹, O. Staretz-Chacham², O. S. Birk^{3,4};

¹Morris Kahn Laboratory of Human Genetics, National Institute for Biotechnology in the Negev (NIBN), Ben Gurion University, Beer-Sheva, Israel, ²Pediatric Metabolic Unit, Soroka Medical Center, Ben Gurion University, Beer Sheva, Israel, Beer-Sheva, Israel, ³Genetics institute, Soroka Medical Center, Ben Gurion University, Beer Sheva, Israel, Beer-Sheva, Israel.

Five infants of two related consanguineous Bedouin families presented with a syndrome of neonatal-onset encephalopathy with severe muscular weakness, intractable seizures, respiratory distress and delayed psychomotor development, culminating in early death. Muscle biopsy showed evidence of complex V mitochondrial disease, and brain imaging demonstrated ventriculomegaly with thinning of corpus callosum. Homozygosity at loci of genes known to be associated with mitochondrial complex V deficiency was ruled out using polymorphic markers. Whole exome sequencing data of an affected individual were filtered for known benign variants using open access databases (ClinVar, HapMap, EVS and 1000 genomes) and our in-house data of over 100 ethnically matched exomes. Segregation analysis ruled out all the putatively deleterious homozygous mutations found, except for a single homozygous variant: NM_005984: c.713A>G in *SLC25A1*, resulting in a p.N238S missense mutation. The mutation fully segregated in the family as expected in recessive heredity. Mutations in *SLC25A1* have been shown to be associated with a rare neuro-metabolic disorder of combined D,L-2-hydroxyglutaric aciduria (DL-2HGA; OMIM #615182). To the best of our knowledge this is the first study showing a mutation in *SLC25A1* causing documented mitochondrial complex V deficiency.

P06.13

Congenital disorder of glycosylation type Iq: Report of a patient with an SRD5A3 mutation identified on whole exome sequencing and review of the literature

A. Hanson-Kahn¹, K. Liker¹, L. Slattery², M. Manning¹;

¹Stanford University, Stanford, CA, United States, ²Lucile Packard Children's Hospital, Palo Alto, CA, United States.

Congenital disorders of glycosylation are multisystem disorders caused by abnormal glycosylation of proteins. Many subtypes have been described. Patients with type Iq, caused by mutations in the SRD5A3 gene, have ophthalmologic abnormalities, ataxia, intellectual disability, speech delay and hypotonia. We report the first patient with type Iq who was diagnosed by clinical whole exome sequencing.

The patient was referred for evaluation of nystagmus noted at 3 months, optic nerve atrophy, hypotonia and global developmental delay. Pregnancy and delivery were uncomplicated. The patient rolled over at 8 months, sat at 10 months and walked at 24 months. She has no words at 2 years. ERG, brain MRI and EEG are normal. She is an only child, and her parents are first cousins.

Whole exome sequencing identified a c.57G>A (p.W19X) variant in SRD5A3, which has thusfar only been described in 5 patients. Our patient's features are similar to the other individuals described, although she does not have ataxia. Transferrin isoelectric focusing was consistent with a type I profile. Ophthalmologic findings in patients with c.57G>A seem to be restricted to optic nerve atrophy, nystagmus and strabismus. Ataxia is less common, and cerebellar malformation may be absent. Intellectual disability is described as being mild.

We review the literature about the Iq subtype, further delineate the clinical phenotype of the c.57A>G mutation, and propose that testing for congenital disorders of glycosylation type Iq be considered in any patient with nystagmus, strabismus or optic nerve atrophy, hypotonia and mild intellectual disability.

P06.14

Gene defects underlying the congenital lactic acidosis

I. Bravo-Alonso, R. Navarrete, A. Vega, B. Merinero, C. Pérez-Cerdá, M. Ugarte, B. Pérez, P. Rodríguez-Pombo;

Centro de Diagnóstico de Enfermedades Moleculares (CEDEM), Centro de Biología molecular Severo Ochoa (CSIC-UAM), CIBERER-ISCHII, IDIPAZ, Universidad Autónoma de Madrid, Madrid, Spain.

Congenital Lactic Acidosis (CLA) is the biochemical hallmark of a heterogeneous number of non-genetic and genetic conditions. A large number of defects related to the disruption of normal pyruvate metabolism and/or mitochondrial function, with a growing list of mitochondrial diseases caused by different nuclear gene defects, makes the molecular diagnosis a labor-intensive work that requires a systematic multidisciplinary approach.

Herein, we present data relative to the massive-parallel sequencing, using the Illumina® clinical-exome TruSight™ One Sequencing panel, of a cohort of 29 patients, all selected for having neonatal/infantile encephalopathy with CLA. The clinically significant deemed variants found were confirmed by subsequent Sanger sequencing. In thirteen out of the 29 patients, we yield the molecular diagnosis, with mutations in PDHA1 (3), PDHX (1), PHKA2 (1), ACAD9 (1), TK2 (1), NDUFS4 (1), FOXRED1 (1), GFM1 (1), TSFM (1), PDSS1 (1) and COQ2 (1) genes. In silico predictions supported a pathogenic role in each case. Segregation analysis in parents' DNA confirmed their carrier condition. The overall rate of positive diagnosis was 45%. In absence of previous diagnostic work-up, an impaired real-time oxygen consumption rate in cultured intact patients' fibroblasts is been used as standard method to evaluate the mitochondrial functionality when samples were available.

Underscoring the genetic heterogeneity of congenital lactic acidosis, our findings implicate 11 different genes in 29 patients. We conclude that targeted exome sequencing enhances the ability to identify the underlying gene mutation when a well-sustained clinical suspicion has been previously established.

Lack of association between increased mitochondrial DNA4977 deletion and ATP levels of sputum cells from chronic obstructive pulmonary disease patients vs healthy smokers

Y. Müsteri Öltulu¹, A. Karimova², D. Ustek³, M. Kara⁴, B. Tutluoglu⁵, H. Azakli³, I. Onaran²;

¹Health Sciences Faculty, Department of Nutrition and Dietetics, Biruni University, Istanbul, Turkey, Istanbul, Turkey, ²Department of Medical Biology and Genetics, Cerrahpasa Faculty of Medicine, Istanbul University, Istanbul, Turkey, Istanbul, Turkey, ³Istanbul Medipol University, Department of Medical Genetics, School of

Medicine, Istanbul, Turkey, Istanbul, Turkey, ⁴Department of Genetics, School of Medicine, Mugla University, Mugla, Turkey, Mugla, Turkey, ⁵Department of Pneumology, Cerrahpasa Faculty of Medicine, Istanbul University, Istanbul, Turkey, Istanbul, Turkey.

Introduction: In this study we looked at smokers with and without chronic obstructive pulmonary disease (COPD) patients in order to evaluate the incidence of 4977 bp mtDNA (mtDNA4977) deletion and mtDNA copy number in sputum cells and in peripheral blood leukocytes (PBLs) in relation to mitochondrial function and oxidative stress status.

Materials and Methods: Twenty-five COPD patients who were current smokers, 22 smokers and 23 healthy nonsmokers (for only PBLs studies) participated in this study. The 4977-bp deletion was detected using a quantitative real time PCR.

Results: The frequency of the mtDNA4977 was significantly higher in the sputum cells of patients with COPD compared to smokers without COPD (p<0.0001). This difference was not observed in PBLs. Levels of cellular oxidative stress were significantly higher in the sputum cells of subjects with COPD than in the smoker group. However, mtDNA copy number, mitochondrial membrane potential ($\Delta\Psi_m$) and cellular ATP levels in PBLs and sputum cells were not significantly different between the studied groups. The Pearson analysis revealed no correlations between the accumulation of mtDNA4977, and intracellular ATP content and $\Delta\Psi_m$ values of the sputum cells, although there was a positive correlation between increased mtDNA4977 and the levels of cellular oxidative stress in COPD patients (r:0.80, p<0.0001).

Conclusions: Our studies may suggest that the accumulation of mtDNA4977 in the sputum cells of smokers with COPD does not seem to have an important impact on mitochondrial dysfunction in relation to ATP production and $\Delta\Psi_m$ when compared to those of healthy smokers.

P06.16

Treatment of the CTNS W138X nonsense mutation with nonsense suppressor drugs

E. J. Brasell¹, L. Chu², D. Iglesias³, Y. Yamanaka¹, P. Goodyer²;

¹McGill University, Montreal, QC, Canada, ²McGill University Health Centre, Montreal, QC, Canada, ³Genome Quebec, Montreal, QC, Canada.

Introduction: Cystinosis is caused by biallelic mutations of the cystinosin (CTNS) gene, encoding a lysosomal cystine transporter. Intralysosomal cystine accumulation drives progressive organ dysfunction. In Quebec, about 50% of cystinosis patients harbor the W138X nonsense mutation causing a stop codon in exon 7. Nonsense mutations trigger nonsense-mediated decay (NMD) of mutant transcripts and inhibit protein translation.

Materials and Methods: Aminoglycosides, such as geneticin (G418), have nonsense suppressor activity, which permits translational read-through of premature stop codons. To test the effect of G418 on the W138X mutation, we treated CTNS^{W138X/W138X} human fibroblasts for 24h in culture and examined CTNS expression and intracellular cystine levels. Using ZFN technology, we also generated a Ctns nonsense mutant mouse (Y226X) for in vivo studies of aminoglycoside-like compounds.

Results: After 24h treatment with G418, CTNS mRNA transcript levels in CTNS^{W138X/W138X} fibroblasts increased to normal levels. Furthermore, G418 reduced intracellular cystine levels by 60%. These results suggest that G418 reduces NMD of CTNS^{W138X/W138X} transcript and allows production of functional CTNS. In addition, we confirmed that Ctns^{Y226X/Y226X} mice have decreased levels of Ctns transcript and intracellular cystine accumulation, as well as glucosuria and early swan-neck lesions of the proximal tubule by 6 months of age.

Conclusions: G418 promotes read-through of the CTNS W138X mutation, producing sufficient CTNS protein for cystine efflux from lysosomes. This suggests that nonsense suppressor compounds may offer an effective therapeutic strategy for cystinosis involving nonsense mutations. Our Ctns^{Y226X/Y226X} mice provide a pre-clinical model for screening next-generation nonsense suppressor drugs.

Fellowship: Cystinosis Research Foundation.

P06.17

Association of ENPP1 polymorphism K121Q with type 2 diabetes mellitus and stroke in Ukrainian population

O. Obukhova, V. Harbuzova, I. Marchenko;

Sumy State University, Sumy, Ukraine.

Introduction: T2DM is a complex polygenic disorder in which common genetic variants interact with environmental factors to unmask the disease. ENPP1 is an II transmembrane glycoprotein that inhibits insulin signaling by direct interaction with the insulin receptor beta subunit. This inhibition is enhanced by the minor Q allele of the K121Q polymorphism (rs1044498)

in the gene *ENPP1*, and causes insulin resistance and diabetes. A stroke is a medical condition that can affect diabetes. Patients with diabetes who suffer a stroke are at greater risk of both disability and death.

Materials and Methods: Venous blood of 163 patients with T2DM and 110 healthy individuals (control group) was used for genotyping. Analysis of *ENPP1* polymorphism K121Q (rs1044498) was examined by PCR-RFLP with the following restriction fragment length analysis of the allocation of them by electrophoresis in agarose gel. Statistical analysis was performed by using the software package SPSS-17. The value of $P < 0.05$ was considered as significant.

Results: Using the Pearson criterion was reveal association between the K121Q polymorphism of *ENPP1* gene and the development of T2DM in stroke and non-stroke patients. It was shown that in patients with stroke value homozygotes for the major allele (K/K) and minor allele carriers (K/Q+Q/Q) is 48.8% and 51.2%, while in the non-stroke patients -70.5 % and 29.5% respectively ($P = 0.012$).

Conclusions: In diabetic patients with genotype K/Q+Q/Q risk of stroke was significantly higher than in those with K/K genotype in Ukrainian population.

P06.18

Variants Across Multiple Candidate Genes Confer Susceptibility to Diabetic Retinopathy in a North Indian Population

R. Sikka¹, J. Chhablani², A. J. S. Bhanwer³, S. Chakrabarti⁴;

¹Department of Human Genetics, Guru Nanak Dev University, Amritsar, Punjab, India,

²Smt Kanuri Santhamma Centre for Vitreo Retinal Diseases, Hyderabad, Telangana, India,

³Guru Nanak Dev University, Amritsar, Punjab, India, ⁴LV Prasad Eye Research Institute, Hyderabad, Telangana, India.

Over the last two decades, there have been tremendous efforts in characterizing the molecular mechanisms underlying complex disorders like diabetes along with its associated variant, diabetic retinopathy (DR). These approaches were largely based on Genome Wide Association Studies and candidate gene screenings for identifying the associated biomarkers. These studies were limited largely due to population substructuring along with the vagaries of small sample size. In the present study, we performed targeted genome screening of 97 SNPs across in 48 candidate genes involved in the metabolic pathways leading to DR. We analyzed these variants in a cohort of 848 subjects (414 DR cases along with gender and ethnicity matched 434 controls above the age of 50 years) using Sequenom MassARRAY technology. Strong genetic associations were observed in *TCF7L2*; three intergenic variants; *ADIPOQ* and *TLR-4* ($p < 0.05$) with DR. Further, the clinical and anthropometric data revealed that the history of hypertension [$p < 0.001$; OR=13.64 (9.15=20.34)], male gender [$p = 0.003$; OR=1.86 (1.22-2.81)] and BMI [$p < 0.001$; OR=1.31 (1.17-1.46)] were the main risk factors for DR. These results provide strong evidence of association of variants in these genes with susceptibility to DR.

P06.19

Increased DNA methylation caused by obesity as a key factor for insulin resistance development

M. Malodobra-Mazur, D. Bednarska-Chabowska, R. Adamiec, T. Dobosz; Wrocław Medical University, Wrocław, Poland.

Introduction: Insulin resistance and type 2 diabetes are leading problems of modern civilization. In pathogenesis of both disorders key role is played by obesity. Numerous data implicate obesity with DNA hypermethylation including genes regulating insulin sensitivity, however there are only a few reports concerning promoter's methylation of insulin pathway genes. The aim of our work was to assess the rate of global and site-specific DNA methylation of main insulin pathway genes in obese insulin resistant patients. **Methods:** Global and site-specific DNA methylation was analyzed in lymphocytes and adipose tissue of insulin resistant subjects and controls using EpiJect DNA Methylation Analysis Kit. Site-specific DNA methylation was analyzed within promoters of *INSR*, *PIK3R1* and *SLC2A4* using Real-Time PCR. **Results:** Strong positive correlation between global DNA methylation and BMI was displayed in both types of investigated tissues. Simultaneously, DNA methylation positively correlated with glucose level and insulin resistance ratios (HOMA-IR, QUICKI) in both tissues. Furthermore, increased promoter methylation of analyzed genes was noticed in visceral adipose tissue of insulin resistant patients comparing to controls. What's more, the promoter methylation rate of *INSR* and *SLC2A4* positively correlated with glucose level and insulin resistance and negatively with gene expression. Promoters' methylation status of all genes correlated positively with BMI. **Conclusions:** Obtained results indicate the role of DNA hypermethylation in insulin resistance. Aberrant profile of promoters methylation was shown

for numerous genes regulating insulin sensitivity including *ADIPOQ*, *LPL* or *PPAR γ* . Present study showed the association between promoters methylation of main insulin pathway genes and insulin resistance.

Elucidation of the molecular process underlying mutant alpha-galactosidase A degradation in Fabry disease

A. Pockrandt¹, C. Zheng^{1,2}, C. Bohl¹, J. Lukas¹, A. Rolfs^{1,3};

¹Albrecht-Kossel-Institute for Neuroregeneration, Rostock, Germany, ²Leibniz Institute for Catalysis, Rostock, Germany, ³Centogene AG, The Rare Disease Company, Rostock, Germany.

Lysosomal storage disorders (LSD) are a group of variant inherited metabolic diseases caused by protein deficiencies. Lysosomal proteins undergo intracellular processing and trafficking. Mutant proteins in Gaucher and Niemann-Pick Typ C1 disease are exposed to the ER-associated degradation (ERAD). In the present study we intend to investigate on the molecular process underlying inadvertent pre-mature degradation of mutant α -galactosidase A enzyme (α -gal A, OMIM * 300644) in Fabry disease (OMIM # 301500).

We used MALDI TOF mass spectrometry to identify ubiquitinated lysine moieties 130, 240 and 426 of α -gal A that would lead to proteasomal targeting. Substitution of these three lysines reduced ubiquitination of the enzyme. Furthermore, we over-expressed mutant α -gal A in HEK293H cells and applied inhibitors of cellular ubiquitination and the proteasome, summarised as Ubiquitin/Proteasome System inhibitors (UPSi) in order to prevent the degradation process. Usage of two UPSi, MG132 and Rosiglitazone, led to an twofold increased enzyme level suggesting a potential clinical relevance for this compound class. In search of intracellular binding partners via immunoprecipitation the direct physical interaction of α -gal A to different ER resident chaperones (e.g. Calnexin and BiP/GRP78) was confirmed. Further studies will be performed to identify E3 ubiquitin ligase outfit involved in mutant α -gal A ubiquitination and degradation in disease state.

P06.23

Use of next generation sequencing for the diagnosis of familial hypercholesterolemia (FH)

S. Martínez-Figueroa, R. Roig, L. Garrido, A. Beteta, À. García-Osuna, F. Blanco-Vaca; Hospital de la Santa Creu i Sant Pau, Barcelona, Spain.

Introduction: More than 1500 mutations causing FH are known. Their detection is classically performed by Sanger sequencing and MLPA of the LDLR. Between 2008 and 2012, we used a microarray (LIPOchip®) for detecting the (around 250) most frequent mutations in the Spanish population. Because of the high potential mutation heterogeneity, during 2013 we tested the Next Generation Sequencing (NGS) Roche 454 based SEQPRO LIPO RS®. **Material and Methods:** The SEQPRO LIPO RS kit amplifies 48 amplicons covering the coding regions of the LDLR, PCSK9 and LDLRAP1 and 2 regions of APOB. The SEQPRO LIPO RS software automatically generates variants lists that were compared to a Mutation Database to provide pathogenic significance. 160 samples of FH patients from Catalonia were screened with this kit.

Results: DNA was obtained from patients diagnosed used the Dutch MedPed criteria. 27 samples were diagnosed as possible FH (values between 3 and 5), 55 as probable FH (values of 6 and 7), 55 as definite FH (values ≥ 8). No values were indicated for 23 patients. Mutations were found in 66 samples, representing 41% of all samples. Forty-five different mutations were found, 32 of them being unique, all in the LDLR gene except one mutation in APOB (p.R3527Q). Most mutations were amino acid changes or lead to null alleles. Carriers of mutations whose pathogenicity was already demonstrated showed a higher Dutch Medped than carriers of variants of unknown significance (9.34 vs 6.44).

Conclusion: This NGS-based kit was proven adequate for FH mutation detection.

High dietary folate during pregnancy leads to pseudo-MTHFR deficiency, changes in choline metabolites and short-term memory impairment in offspring

R. H. Bahous¹, N. M. Jadavji², M. Cosín-Tomás³, L. Deng⁴, J. Lu⁵, O. Malysheva⁶, M. Pallàs⁷, P. Kaliman^{7,8}, M. Caudill⁶, R. Rozen^{1,4};

¹Department of Human Genetics, McGill University, Montreal, QC, Canada, ²Department of Neuroscience, Carleton University, Ottawa, ON, Canada, ³Pharmacology Unit, Faculty of Pharmacy, Institut de Neurociència Universitat de Barcelona (IBUB), Nucli Universitari de Pedralbes, Barcelona, Spain, ⁴Department of Pediatrics, McGill University Health Center, Montreal, QC, Canada, ⁵Department of Medicine, McGill University, Montreal, QC, Canada, ⁶Division of Nutritional Sciences and Genomics, Cornell University, Ithaca, NY, United States, ⁷Institute of Biomedical Investigation of Barcelona, Spanish National Research Council, Barcelona, Spain, ⁸Center for Mind and Brain, University of California Davis, Davis, CA, United States.

Introduction: Severe deficiency of methylenetetrahydrofolate reductase (MTHFR) in mice is associated with short-term memory impairment and disturbed choline metabolism. Folate intake has increased in the general population, particularly in women of childbearing age, due to food fortification and use of high dosage vitamin supplements. The goal of this study was to determine whether high dietary folate during pregnancy and lactation would affect brain function in offspring.

Materials and Methods: Female mice were placed on control diets or folic acid-supplemented diets prior to mating, which were maintained during pregnancy and lactation. Embryos were collected at E17.5 or pregnancy was carried to term. Male offspring were evaluated for memory impairment at 3 weeks of age using the novel object recognition test.

Results: Pups born to mothers on supplemented diet showed visual short-term memory impairment. In the livers of mothers and pups, MTHFR protein levels were significantly decreased and the ratio of the phosphorylated (less active): non-phosphorylated isoform was increased. Phosphocholine was decreased in livers of pups and glycerophosphocholine was decreased in offspring hippocampus. In the embryos of females on the supplemented diet, we observed growth delay, decreased MTHFR protein in livers and a decrease in some choline metabolites (choline, betaine and phosphocholine).

Conclusions: We suggest that high folate intake during pregnancy leads to pseudo-MTHFR deficiency, disturbs choline metabolism and results in memory impairment in offspring. These findings contribute to increased awareness of the unintended negative consequences of folic acid oversupplementation.

Grants: Fellowship (Faculty of Medicine-McGill) to RB and CIHR grant to RR.

P06.25

Evaluation of neopterin as a potential biomarker of Gaucher disease

C. Drugan, T. Drugan, N. Miron, C. Cătandă;

Iuliu Hațieganu University of Medicine and Pharmacy, Cluj-Napoca, Romania.

Introduction: Gaucher disease, one of the most prevalent lysosomal storage disorders, is caused by a recessively inherited deficiency of the lysosomal enzyme glucocerebrosidase, encoded by the *GBA1* gene. We investigated the usefulness of neopterin, as a potential biomarker in Gaucher disease and analysed its evolution in response to enzyme replacement therapy.

Materials and methods: We measured plasma neopterin levels in 31 patients with non-neuronopathic Gaucher disease, before and after the onset of enzyme replacement therapy and compared the results with those of 18 healthy controls. Plasma chitotriosidase activity served as a reference biomarker, against which we evaluated the evolution of neopterin.

Results: In treatment-naïve patients, neopterin levels were significantly increased (mean 11.90±5.82 nM), compared with controls (6.63±5.59 nM), and returned to normal levels (6.92±4.66 nM) after average interval of 3.8 years of macrophage-targeted recombinant enzyme substitution. Receiver operating characteristic analysis of the diagnostic value of neopterin indicated a cut-off value of 7.613 nM, corresponding to an area under the curve of 0.780 and indicating a good discrimination capacity, with a sensitivity of 0.774 and a specificity of 0.778.

Conclusions: Plasma neopterin levels reflect the global accumulation of Gaucher cells and the extent of chronic immune activation in this disorder. Circulating neopterin may be considered an alternative storage cell biomarker in Gaucher disease, especially in chitotriosidase-deficient patients.

P06.26

Glycogen Storage Disease type IXa: a new variant in PHKA2 detected by Next Generation Sequencing

C. Rodríguez Jiménez¹, F. Santos¹, Á. Campos¹, C. Camarena², D. Lledín², E. Sevilla¹, A. Carazo¹, E. Vallespín¹, Á. Del Pozo¹, R. Mena¹, P. Lapunzina¹, S. Rodríguez Nóvoa¹;

¹INGEMM, Madrid, Spain, ²Hospital La Paz, Madrid, Spain.

INTRODUCTION: Glycogen storage disease (GSD) type IX (MIM: 30600) results from a deficiency in hepatic phosphorylase kinase (PHK) activity, accounting for ~1/100000 births. PHK is a decahexameric enzyme composed of four subunits, α , β , γ and δ encoded by four different genes: PHKA2, PHKB, PHKG and CALM, respectively. Mutations in PHKA2 (MIM 300798) cause the most common subtype, X-linked recessive GSD IXa (75% of all GSD IX). Herein, we report a patient with clinical symptoms compatible with GSD VI or IX.

PATIENT AND METHODS: A four-year old patient with hepatomegaly, growth retardation, elevation of liver enzymes, hyperlipidaemia and mild fasting hypoglycaemia with hyperketosis was remitted to our service. PYGL, PHKA1, PHKA2, PHKB and PHKG2 were analyzed by Next Generation Sequencing (NGS).

RESULTS: We identified the previously undescribed hemizygous variant PHKA2:exon18: c.1963G>A. In silico analyses showed two possible consequences: 1st -missense variant, p.Glu655Lys, affecting a highly conserved amino acid and predicted to be likely pathogenic; 2nd - Splicing variant: MaxEnt, NNSPLICE, GeneSplicer, SliceSiteFinder-like predict that this variant disrupt the ex18 canonical splice donor site, probably resulting in an aberrant protein. The variant was absent in the mother, thus, it is likely to have arisen as "de novo" event.

CONCLUSIONS: NGS helped us to improve GSD clinical diagnosis, allowing the simultaneous analysis of several genes. The novel hemizygous variant PHKA2:c.1963G>A, could explain the GSD IXa phenotype observed in our patient. Functional studies should be performed to determine and confirm the pathogenic mechanism, in order to provide genetic counselling to the family.

P06.27

Identification of two new variants at the codon 281 of HFE-1 gene

V. Geromel, N. Couprie, P. Mouty, D. Martinez, L. Raymond, G. Egea;

BIOMNIS, Lyon, France.

In France, HFE hereditary hemochromatosis counts for 95 % of hereditary iron overload. The homozygosity for the p.Cys282Tyr mutation in the HFE gene leads to hepcidin deficiency, enhanced body iron storage and clinical impact. In Biomnis, the detection of the p.Cys282Tyr allele is based on real-time PCR using Taqman® probes.

Two compound heterozygous states for the p.Cys282Tyr mutant and either the p.His63Asp or the p.Ser65Cys variant alleles are commonly screened although they are associated with mild iron level increase. In recent years several new mutations in HFE gene have been described: for instance a novel C282Y/R226G compound heterozygous state has been found displaying the biochemical hemochromatosis phenotype.

In the course of our genotyping technique for p.Cys282Tyr allele, we have detected abnormal profiles for two patients. A Sanger sequencing has been performed and two new variants have been identified at the 281 codon. For patient 1, the p.Thr281Lys has been found associated with the p.Cys282Tyr and p.His63Asp at the heterozygous states, and for patient 2, the variant p.Thr281Met turned out to be linked to the p.His63Asp allele at the heterozygous state.

Both new mutations do not affect the normal Cys225S-S282Cys disulfide bridge in the HFE protein. However while the p.Thr281Lys allele in patient 1 could show the same specificities as a neutral and hypomorphic variant, the p.Thr281Met allele, related to a marked hemochromatosis phenotype in patient 2, could be consistent with a deleterious character. Further investigations of that mutant protein will be required.

P06.28

Phenylalanine hydroxylase deficiency in southern Italy: genotype-phenotype correlations, BH4 responsiveness and identification of a novel mutant PAH allele

R. Trunzo, R. Santacroce, A. Leccese, G. De Girolamo, M. Margaglione;

Laboratory of Human Genetics, Foggia, Italy.

Hyperphenylalaninemia (HPAs), the most common inborn error of metabolism (1:10.000), are recessively inherited and caused by mutations in the gene encoding phenylalanine hydroxylase (PAH). PAH converts L-Phenylalanine into L-Tyrosine. PAH block results in accumulation of L-Phe and

toxic metabolites. The mutational spectrum of PAH gene in Southern Italy have been documented elsewhere, but in particular from Campania and Sicily. We sequenced the PAH gene and genotype-phenotype correlations and genotype-based prediction of BH4 responsiveness in 37 PKU patients from Puglia were done. The mutational spectrum included 30 variants with c.1066-11G>A being the most frequent (12,16%). One new variant, c.870 T>G was found. The genotype-phenotype correlation was concordant in 90%. The genotype-based prediction to BH4-responsiveness was around 40% in our patients; thus, this information could be useful for the selection of candidates for BH4 therapy. The present study enlarges the molecular epidemiology of PAH mutations, particularly with respect to Southern Italy. Our data reinforce the wide heterogeneity of PAH mutations in PKU patients and moreover, reveal a good correlation, with patients carrying null mutations in both alleles showing the highest degree of concordance with the most severe phenotypes as previously reported.

Finally, the increasing information obtained in this and other studies will improve the prediction of the evolution of the disease and the diagnostic applicability of mutational analysis. The genotyping of patients became important, not only because of the definitive diagnosis and prediction of the optimal diet, but also to point out those patients that could benefit from new therapeutic approach.

P06.29

Molecular diagnosis of familial hypobetalipoproteinemia

R. Roig, S. Martínez, A. Beteta, F. Blanco;

Hospital de la Santa Creu i Sant Pau, Barcelona, Spain.

Introduction: Familial hypobetalipoproteinemia (FHBL) is a rare autosomal codominant disease characterized by < 5th percentile of the age- and sex-specific levels of LDL-cholesterol. Most cases are caused by mutations in the APOB gene and, less frequently, by ANGPTL3 mutations. Some FCHL patients with APOB mutations, but not with ANGPTL3 mutations, present with hepatic steatosis and intestinal lipid malabsorption. The molecular characterization of these entities is thus often needed for clinical diagnosis and genetic counseling.

Aims: To perform molecular diagnosis of FHBL in 20 suspected cases.

Materials and Methods: DNA was extracted from whole blood samples of 20 probands and subjected to PCR and Sanger sequencing of exons and flanking exon-intron of the APOB gene. Probands without APOB mutation were subjected to ANGPTL3 screening.

Results: From the 20 probands with the suspected disorder, 10 of them presented APOB mutations. Of these, 9 were in exons and 1 in a splicing zone. A prematurely stop codon was generated in all these probands thus encoding truncated apoB-100 proteins. Two of the 10 probands without APOB mutations presented mutations in ANGPTL3. One was a 5pb deletion (c.363_367delCTCAA) generating a prematurely stop codon that impairs ANGPTL3 function.

Conclusions: APOB gene mutations were found in the half of the analyzed probands while ANGPTL3 gene mutations were found in the 20% of probands without APOB gene mutation. The identification of unresolved cases could be improved by studying other genes potentially causing inherited hypolipidemia.

P06.31

In vitro expression analysis of eight phenylalanine hydroxylase variants: correlation with metabolic phenotypes and structural properties

R. Trunzo¹, R. Santacroce¹, G. De Girolamo¹, A. Leccese¹, M. Margaglione¹, N. Blau²;

¹Laboratory of Human Genetics, Foggia, Italy, ²Dietmar-Hopp Metabolic Center, Heidelberg, Germany.

Hyperphenylalaninemia is a genetic disease prevalently caused by a wide range of mutations in phenylalanine hydroxylase (PAH) gene. In vitro expression analysis of mutations offers the opportunity to elucidate the molecular mechanisms involved, investigating the severity of biochemical phenotype, and how a mutation exerts its deleterious effects on the enzyme.

To study the effects of mutations on PAH activity, we used an in vitro expression system in combination with liquid chromatography applied with ESI-MS/MS for the quantification of tyrosine produced from phenylalanine to assess the residual activities of 8 missense variants (Y204C, L212P, L249P, L249F, R270K, R261P, S196Y and T380M) associated with PAH deficiency. The assays showed a decreased activity ranging from 7% to 51% that of the wild-type protein, with the exception of Y204C, which revealed no significant impact on enzyme function (94±6%). Three mutations (L249F, S196Y, and T380M) were associated with low-intermediate levels of activity (21-51%). Mutations L212P, L249P, R270K, and R261P showed very low residual activity (7-17%).

Moreover, in western blot analysis, all of the mutant proteins with rather

low activity (L212P, R270K, R261P) also presented with reduced amounts of protein. Instead, L249P, S196Y, T380M with low activity showed substantial amount of protein. In particular, L249P showed a clear contrast between strong reduction of activity (7±0,11) and high protein expression.

Results from the experimental modulation of mutant residual activity have major implications, both for our understanding of genotype-phenotype correlations and for the discussion of molecular basis of BH4 responsiveness, useful for the development of novel therapeutic approaches.

P06.32

Targeted next generation sequencing in patients with inborn errors of metabolism

D. Yubero¹, J. Armstrong², A. García-Cazorla², B. Perez-Dueñas², F. Palau², R. Artuch², Inborn Errors of Metabolism working group;

¹Fundació Sant Joan de Déu, Barcelona, Spain, ²Hospital Sant Joan de Déu, Barcelona, Spain.

Introduction: Next generation sequencing technologies (NGS) have allowed to promote a cheaper and faster genetic diagnosis. However, due to the uncertainties of NGS, the need of a holistic approach to inborn errors of metabolism (IEM) diagnosis is still unambiguous. To evaluate the NGS utility on the clinical field, targeted genic panel approach was designed for the diagnosis of a set of IEM. The aim of the work was to compare the diagnostic yield of NGS in patients presenting consistent clinical and biochemical suspicion of IEM with those with no specific biomarkers.

Materials and methods: Subjects studied (n=146) were classified in 2 categories: Group 1 (n=81), patients with consistent clinical and biochemical suspicion of IEM; Group 2 (n=65), cases with clinical suspicion of IEM but with unspecific or negative biomarkers. 175 genes (defects in amino acids, organic acids, free fatty acid oxidation, neurometabolic and complex molecules metabolism) were studied through HaloPlex Target Enrichment System and Illumina sequencing.

Results: Definitive genetic diagnosis was achieved in 73 out of the 146 patients (50 %); in 12/146 (8.2 %) only one mutation or variants with uncertain significance were detected in candidate genes; and in 61/146 (41.8%), no mutations were found. For group 1, the diagnostic yield was 78% (63 out of 81). This rate went down to 15.4% (10 out of 65) in group 2 (X² = 76.171; p < 0.0001).

Conclusions: Genetic diagnosis in our cohort was fast and effective, especially in the group having both clinical and biochemical indication for the diagnosis.

P06.33

Second tier next-generation sequencing for inborn errors of metabolism after positive newborn screening results.

E. Lundman¹, A. Stray-Pedersen¹, J. Strand¹, J. Gaup¹, T. Tangeraas¹, J. Jørgensen¹, T. Rootwelt^{1,2}, R. D. Pettersen¹;

¹Oslo University Hospital, Oslo, Norway, ²University of Oslo, Oslo, Norway.

Introduction: Newborn screening (NBS) in Norway is mandated for 20 Inborn Errors of Metabolism (IEM). Rapid genotyping after a positive NBS result may have a major impact on follow-up and treatment. Using NBS screening samples we evaluated next generation sequencing using a large gene panel as 2nd tier tests for IEM.

Materials and Methods: Six samples with known diagnoses (1 PKU+TFP, 1 CPT2, 2 PA and 2 MMA) were included, 5 with known genotype. DNA (~1.8ng) extracted from the NBS dried blood spots was amplified with the IonAmpliSeq IEM panel (570 genes) and sequenced on IonTorrent PGM. Using Ion Reporter software, the detected variants were filtered to only show variants within the 32 relevant NBS-IEM genes, in exonic or splice regions, with 5000Exomes Global MAF<0.01.

Results: In total 1740-2122 variants were detected in each sample, with 2-12 variants remaining after initial filtering. In the 5 previously genotyped samples, all disease-causing variants were confirmed. In one MMA sample with unknown genotype, only three potential variants remained after filtering, including the two which likely account for the phenotype: NM_052845.3(MMAB):[c.291-1G>A(c);c.571C>T]. The results were available within 3 days after DNA extraction.

Conclusion: The tested workflow may reduce turn-around-time for genotyping substantially, and show the possibility of quickly confirming positive metabolic screening even with large genes and multiple disease-genes involved. Bioinformatic filtering before variant evaluation avoids incidental findings outside the screening mandate genes and drastically shortens analysis time. A smaller gene panel may reduce costs and allow higher coverage of the gene variants of interest.

A newly identified mitochondrial tRNA modification due to QRSL1 mutations causes infantile mitochondrial disease.

N. Akiyama¹, K. Murayama², M. Shimura², T. Fushimi², K. Ichimoto¹, M. Mori², Y. Kishita⁴, Y. Tokuzawa⁴, M. Kohda⁴, T. Suzuki⁵, Y. Okazaki⁴, A. Ohtake⁶;

¹Department of Clinical Genetics, Chiba Children's Hospital, Chiba, Japan, ²Department of Metabolism, Chiba Children's Hospital, Chiba, Japan, ³Department of Pediatrics, Matsudo City Hospital, Chiba, Japan, ⁴Research Center for Genomic Medicine, Saitama Medical University, Saitama, Japan, ⁵Department of Chemistry and Biotechnology, Graduate School of Engineering, University of Tokyo, Tokyo, Japan, ⁶Department of Pediatrics, Saitama Medical University, Saitama, Japan.

Background: Defects of tRNA modification (tRNA modopathy) are known as a cause of a variety of diseases. We present two cases of infantile mitochondrial disease with pathogenic mutations in QRSL1 (hGatA) involved in Glu-tRNAGln amidotransferase (Glu-Adt), which is composed of three subunits, hGatC, hGatA and hGatB.

Patients and methods: A girl (Pt250) suddenly suffered from hypoglycemia and lactic acidosis on day 1. Subsequently tachypnea, hypertrophic cardiomyopathy, adrenal insufficiency and hearing loss appeared. She died of cardiac failure at 5 months. Another girl (Pt860) developed cyanosis and lactic acidosis on day 3. She died of interstitial pneumonia at 2 months. We performed enzyme analysis, whole exome sequencing and their validation tests.

Results: The enzyme analysis showed combined respiratory chain deficiencies (I, III, and IV) in both cases. The whole exome sequencing revealed Pt250 harbored a homozygous mutation c.398G>T (p.G133V) and Pt860 harbored a compound heterozygous mutation c.398G>T (p.G133V) and c.350G>A (p.G117E) in QRSL1. In vitro reconstitution of Gln-tRNAGln formation using recombinant hGatCAB showed strongly decreased transamidation activity.

Conclusions: Our study is the first to demonstrate that QRSL1 mutations lead to a defect in the human mitochondrial translation and are a cause of severe infantile mitochondrial disease.

ISCA2 mutation causes hereditary spastic paraplegia

I. Dorboz¹, F. Renaldo², A. Slama³, J. Benoist², M. Elmaleh², V. Desportes⁴, O. Boespflug-Tanguy²;

¹INSERM, Paris, France, ²Robert Debré Hospital, Paris, France, ³Bicetre Hospital, AP-HP, Le Kremlin Bicêtre, Paris, France, ⁴CHU Lyon, Hôpital Femme Mère Enfant, Bron, Lyon, France.

Iron-sulfur (Fe-S) clusters are ubiquitous cofactors composed of iron and inorganic sulfur. [Fe-S] clusters participate in electron transfer, substrate binding, iron, sulfur storage, regulation of gene expression, and enzyme activity. Various biogenesis components are functionally impaired leading to human disease. An early onset lethal encephalopathy has been recently described in relation to mutations of ISCA2. This protein is essential with ISCA1 and IBA57 for protein assembly required for [4Fe-4S]. We describe a new ISCA2 mutation in a 12-year-old boy from a consanguineous Turkish family. He presented with a slowly progressive spastic paraplegia. At the age of 15 months he developed pyramidal signs in the lower limbs, however there was no dystonia or cerebellar signs. Brain MRI showed diffuse white matter abnormality, with areas of cavitation. Examination at the age of 8 years shows improvement in clinical signs but not in MRI with an extension of white matter abnormalities. Activities of the respiratory chain complexes were normal in fibroblasts whereas PDH activity was in the low range. Exome sequencing combined to homozygosity mapping revealed a homozygous mutation in ISCA2 c.154C>T/p.Leu52Phe, parents were heterozygous for the variant. The mutation was predicted to be deleterious and was not found in the public databases. The reason for the clinical and biological differences between our patient and those previously described is not clear. However a variable phenotype expression was already describe in other Iron-sulfur clusters proteins such as IBA57 and NFU1, suggesting that other potential factors that might contribute variability in modulating phenotype

A GWAS of first phase glucose stimulated insulin secretion during an intravenous glucose tolerance test reveals new physiology of genetic variants associated with type 2 diabetes

N. van Leeuwen¹, A. R. Wood², A. Jackson³, A. Jonsson⁴, N. Wang⁵, U. Smith⁶, L. Boquete Vilarino², A. Stancakova⁷, M. Walker⁸, R. Hanson⁹, T. M. Frayling², Genome Utilisation for IntraNEous glucose stimulated insulin Secretion Studies GUINNESS consortium;

¹LUMC, Leiden, Netherlands, ²University of Exeter Medical School, Exeter, United Kingdom, ³University of Michigan School of Public Health, Ann Arbor, MI, United States, ⁴University of Copenhagen, Copenhagen, Denmark, ⁵Keck School of Medicine of USC, Los Angeles, CA, United States, ⁶University of Gothenburg, Gothenburg, Sweden, ⁷University of Eastern Finland and Kuopio University Hospital, Kuopio, Finland, ⁸Newcastle University, Newcastle upon Tyne, United Kingdom, ⁹The National Institute of Diabetes and Digestive and Kidney Diseases, Phoenix, AZ, United States.

Introduction: The mechanism underlying deterioration of insulin secretory capacity which plays an important role in the development of type 2 diabetes (T2D) is not fully understood. To identify genetic factors involved we meta-analyzed all studies where first phase insulin secretion has been investigated through intravenous glucose tolerance tests (IVGTT) and where GWAS (n=4834) or metabochip (n=741) data was available.

Methods: The traits Acute Insulin Response to glucose (AIR), Peak Insulin (PI) and Disposition Index (DI) were defined. Variants were imputed using the 1000G reference panel and tested for association using linear regression adjusted for age and sex and in an additional analysis also for BMI.

Results: A common T2D variant in *MTNR1B* was associated with the IVGTT traits at genome wide significance (PI p=2.5×10⁻²⁶, AIR p=4.3×10⁻¹⁹, DI p=3.3×10⁻¹⁷) and variants in *CDKAL1* with both PI(p=4.9×10⁻¹⁵) and AIR(p=9.5×10⁻¹³), these variants also influenced oral glucose stimulated insulin secretion (OGTT). Other common T2D variants were associated at p<0.01 revealing potential mechanisms for these variants. Variants in *IGF2BP2* and *ADCY5* influenced the IVGTT but had little effect on the OGTT suggesting they exert direct effects on the pancreas rather than systemic effects. Putative novel associations were observed on chromosome 7, 11 and 2 (p<5×10⁻⁸) but these variants need further validation.

Conclusion: Our genome wide analysis on the largest dataset for intravenously measured insulin secretion showed that T2D risk alleles at the *MTNR1B* and *CDKAL1* loci were strongly associated with our measures and it provides new insight into physiological mechanisms of other diabetes risk variants.

P06.37

The importance of both galactocerebrosidase enzyme analysis and GALC gene testing for diagnosis of Krabbe leucodystrophy

D. Cregeen, E. Green, O. Chiu, M. Jackson;

Viapath, Guy's Hospital, London, United Kingdom.

Krabbe disease is a very rare autosomal recessive lysosomal storage disorder caused by deficiency of the enzyme galactocerebrosidase (galactosylceramidase). Traditionally diagnosis relied on measurement of enzyme deficiency using a radiolabelled natural substrate; a method in use at our laboratory for well over 30 years. Subsequently a more convenient fluorimetric substrate has been implemented in some laboratories, however there are known (albeit infrequent) issues with this methodology including false positive and negative results. Most laboratories are now using GALC gene analysis as a first or second line test for Krabbe disease. A recurrent 30kb GALC deletion has been identified in some populations however many GALC variants are family specific and therefore definitive enzyme analysis (either pre- or post- DNA testing) can be invaluable for confirmation of a diagnosis. Sanger sequencing of the GALC coding region has been carried out in 32 families at our centre to date. We present several patients with novel pathogenic variants and also several patients with a false positive enzyme deficiency caused by a non-pathogenic sequence variant (c.550C>T) which is thought to confer reduced enzyme activity *in vitro* (possibly more frequently observed with the fluorimetric enzyme methodology). The possibility of pseudodeficiency and the preponderance of novel variants in Krabbe patients highlights the importance of both galactocerebrosidase enzyme analysis and GALC gene testing for diagnosis of this disorder.

Pharmacological intervention in Fabry disease and the role of proteostasis

S. Seemann¹, M. Ernst², L. R. Trenkner¹, G. Fuellen², J. Lukas¹, A. Rolfs^{1,3};

¹Albrecht Kossel Institute, Medical University Rostock, Rostock, Germany, ²Institute for Biostatistics and Informatics in Medicine and Ageing Research, Medical University Rostock, Rostock, Germany, ³Centogene AG, The Rare Disease Company, Rostock, Germany.

Fabry disease is a lysosomal storage disorder resulting from a mutation in the gene encoding for the lysosomal enzyme α-galactosidase A (GLA). These mutations result in a lack or a reduction of enzyme activity. Missense mutations often lead to a destabilized but still catalytically active enzyme. Small molecules have been shown to support protein folding and to reduce the re-

jection of the enzyme by the ER associated degradation, which consequently leads to enhanced transport to the lysosomes.

We identified small molecules that showed the capability to elevate the activity of mutant α -galactosidase A in human fibroblasts from Fabry patients carrying the p.R301Q mutation. Also, synergistic effects of compounds could be shown arguing for a differential mode of action. In order to investigate more closely the specific mode of action of the proteostasis regulators we found to be effective, HTA-2.0 microarrays will be performed to compare transcriptomics data of treated and untreated p.R301Q fibroblasts. Resulting transcriptional fingerprints of the effective small molecules will be integrated and visualised on a proteostasis network based on biological function or physical interaction. To establish this network we reviewed several hundred proteostasis components with the help of commercial and non-commercial databases like Selventa and String.

We will finally identify sub-networks and single protein molecules within the proteostasis network as effective modulators of gene function and, respectively, as potential targets for a specific therapeutical intervention. The methodology is a generalizable tool to be transferred also to other lysosomal disorders and to identify new targets for treatment approaches.

Identification of the functional miRNA/miRNAs in the pathogenesis of MODY3

O. F. Baltacı¹, S. Colakoglu², G. Gullu², A. Karabay Korkmaz¹, E. Berber²;

¹Istanbul Technical University, Istanbul, Turkey, ²Marmara University, Istanbul, Turkey,

³Istanbul Arel University, Istanbul, Turkey.

Introduction: MODY3 is a progressive hyperglycemia, associated with HNF1A gene. The HNF1A gene encoded transcription factor HNF1A regulates expression of genes including glucose metabolism and glucose transport genes, insulin gene. MODY3 is misdiagnosed as Type1 Diabetes due to the similar clinical features. miRNAs are involved in the development of diabetes, diabetic complications, insulin expression. The present study explores the functional miRNAs in the pathogenesis of MODY3 by determining the HNF1A regulated miRNA/miRNAs in MIN6 cells.

Materials and Methods: Glucose stimulated MIN6 cells, expressing HNF1A endogenously, were transfected with the human HNF1A cDNA expression vector for overexpression and with siRNA binding to HNF1A mRNA to silence HNF1A expression. Overexpression and silencing were confirmed with RT-qPCR and Western Blotting. The HNF1A regulated miRNA/miRNAs was determined by RNA-Seq of the total RNA extract in the HNF1A overexpressed and silenced cells.

Results: 238 known and 91 novel miRNAs showed significantly differential expression when total RNA extract expression from HNF1A overexpressed and silenced cells were compared. Previously known miR-129-1-3p, miR-129-2-3p, miR-200b-3p, miR-296-3p, and miR-378a-5p, associated with diabetes in the literature, showed the most significant differential expression.

Conclusion: This study revealed presence of HNF1A regulated known and novel miRNAs in MIN6 cells. The most significantly differentially expressed 5 miRNAs are selected as candidate miRNA molecules in the pathogenesis of MODY3. Validation of the candidate miRNAs and their effect on insulin secretion in MIN6 cells are in progress. Further studies in the serum samples of MODY3 patients will reveal their role as a biomarker in the diagnosis.

Functional Characterization of p.T10M and p.S345K mutations in HNF1A Gene in MODY patients

O. Yalcin Capan¹, O. F. Baltacı¹, E. Selcuk², E. Berber¹;

¹Istanbul Arel University, Istanbul, Turkey, ²Istanbul Technical University, Istanbul, Turkey.

Introduction: Maturity-onset diabetes of the young (MODY) is a monogenic form of diabetes mellitus characterized by abnormal beta cell function, autosomal dominant inheritance, hyperglycemia, lack of auto-immunity in non-obese young patients. MODY3 associated with HNF1A gene mutations is the most common form of MODY. HNF1A is a transcription factor that regulates a number of liver-specific genes and genes involved in glucose metabolism. **Materials and Methods:** The functional properties of HNF1A gene variations (p.T10M, p.S345K) which were identified in Turkish MODY patients were analyzed. The effects of the candidate mutations on HNF1A transactivation function were determined by dual luciferase reporter assay. The effects of mutations on the nuclear localization of HNF1A were analyzed by immunofluorescence confocal microscopy. DNA binding activity of mutant HNF1A and wild type proteins were also compared by colorimetric DNA-protein binding assay.

Results: Dual luciferase assay results showed that both p.T10M and p.S345K mutant proteins have similar transactivation activity as the wild type HNF1A. Immunostaining studies revealed that p.T10M mutant protein localizes in the nucleus as the wild type HNF1A while p.S345K mutant protein is in the cytoplasm. DNA binding ability of p.T10M mutant protein was reduced, but p.S345K mutant similar compared to wild type.

Conclusion: Preliminary results showed that both mutant HNF1A proteins have reduced activities and malfunctions compared to wild type. Future studies will show whether they also effect the insulin secretion from pancreatic cells. This project (113S218) was supported by TÜBİTAK (The Scientific and Technical Research Council of Turkey).

Reprogramming of patients-derived fibroblasts to pluripotency for modeling inherited disorders of propionate metabolism

E. Richard¹, S. Brasil¹, M. Ugarte¹, L. R. Desviat¹, B. Pérez¹;

¹Universidad Autónoma de Madrid, Madrid, Spain.

Recent advances in induced pluripotent stem cell (iPSC) technologies have transformed our ability to elucidate the pathogenic mechanisms of disease development and to test new therapeutic strategies. iPSCs are capable of self-renewal and have the potential to differentiate into any cell type which can now help to overcome the limitations of fibroblasts as cellular model for inherited metabolic disorders. This work has focused on the generation and characterization of iPSCs from two patients-derived fibroblasts with methylmalonic aciduria cblB type (MIM #251110) and one with propionic acidemia PCCA type (MIM #606054) using CytoTune Sendai vectors which include the four Yamanaka factors (Oct4, Sox2, Klf4 and c-Myc). The iPSCs generated have been characterized and presented the hallmarks for these cells: (1) typical iPSC-like morphology and growth characteristics, (2) conservation of the mutations identified in the three patients, (3) positive staining for alkaline phosphatase activity, (4) expression of pluripotency-associated markers (OCT4, NANOG and SOX2) and surface markers (SSEA3, SSEA4, TRA1-60, and TRA1-81), (5) demethylation of the OCT4 and NANOG promoters, (6) normal karyotype and (7) differentiation potential into all three primary germ cell layers *in vitro*. Our next step will be the iPSC differentiation into neurons, hepatocytes and cardiomyocytes serving as an *in vivo* platform for modeling these two disorders of propionate metabolism. Grants: PI13/01239 and SAF2013-43005

P06.44

Functional characterization of four novel genetic variants causing methylmalonic aciduria and propionic acidemia in Serbian patients

M. Stojiljkovic¹, K. Klaassen¹, M. Djordjevic², A. Sarajlija², S. Brasić², B. Kecman², S. Grković², J. Kostić¹, P. Rodriguez-Pombo³, L. R. Desviat², S. Pavlovic¹, B. Perez²;

¹IMGGE, University of Belgrade, Belgrade, Serbia, ²Mother and Child Health Care Institute of Serbia „Dr Vukan Cupic“, Belgrade, Serbia, ³Centro de Diagnóstico de Enfermedades Moleculares, CBMSO, UAM, CIBERER, Madrid, Spain.

Methylmalonic aciduria (MMA) and propionic acidemia (PA), inborn metabolic diseases inherited in an autosomal-recessive manner, are the most frequent organic acidurias. However, each of them is classified as rare disease since their incidences are estimated at ~ 1:50 000 for MMA and ~ 1:100 000 -150 000 for PA. Specific mitochondrial enzymatic deficiencies in the catabolism of branched-chain amino acids cause MMA and PA.

Four MMA and one PA patients from Serbia were analyzed. We detected five previously described variants: p.Asn219Tyr, p.Arg369His, p.Val553Glyfs*17 in *MUT*, p.Thr198Serfs*6 in *MMAA*, p.Ile144_Leu181del in *PCCB* gene and four novel genetic variants: p.Leu549Pro, p.Glu564*, p.Leu641Pro in *MUT* and p.Tyr206Cys in *PCCB* gene.

In silico and eukaryotic expression studies confirmed pathogenic effect of all novel variants. Aberrant enzymes p.Leu549Pro *MUT*, p.Leu641Pro *MUT* and p.Tyr206Cys *PCCB* did not show residual activity in activity assays. In addition, activity of *MUT* enzymes was not rescued in the presence of vitamin B12 precursor *in vitro* which was in accordance with non-responsiveness or partial responsiveness of patients to vitamin B12 therapy.

Our study brings the first molecular genetic data and phenotypic characteristics for MMA and PA patients for Serbia and the whole South-Eastern European region. Therefore, our study contributes to the better understanding of molecular landscape of MMA and PA in Europe and to general knowledge on genotype-phenotype correlation for these rare diseases.

Mitochondria are the powerhouses of all eukaryotic cells which produce energy in a process called oxidative phosphorylation (OXPHOS). Complex I (CI), the first and the biggest of five multi-protein complexes that compose the mitochondrial OXPHOS system, consists of both mitochondrially and nucleus-encoded subunits. Because of its size and its dual genetic origin, biogenesis of CI is a complex event that requires a set of not yet completely characterized assembly factors. Mutations in genes encoding either CI structural subunits or assembly factors result in isolated CI deficiency, which represents the most common cause of OXPHOS dysfunction.

Using whole exome sequencing and targeted exome sequencing, we identified *TMEM126B* as a disease-causing gene in three unrelated patients presenting with exercise intolerance and muscle weakness due to isolated CI deficiency. *TMEM126B* is a putative CI assembly factor that is not well characterized and its mutations led to the accumulation of CI assembly intermediates in patient fibroblasts. Lentiviral complementation with the wild-type cDNA restored the assembly of CI confirming the pathogenic nature of the identified mutations and establishing *TMEM126B* as a novel mitochondrial disease gene.

Mitochondrial dysfunction and aberrant methylation in nuclear genes

L. Mayorga¹, S. Laurito¹, E. Campoy¹, H. Eiroa², **M. Roqué¹**;

¹Institute of Histology and Embryology CONICET National University of Cuyo, MENDOZA, Argentina, ²J.P Garrahan Children's Hospital, Buenos Aires, Argentina.

Introduction: It is known that environment has an impact on epigenomes, especially of cancer cells. It is, however, not clear how this occurs. A hallmark of cancer cells is energy reprogramming whereby glycolysis is preferred over OXPHOS. We propose that mitochondria might play a role in epigenome modifications. The aim of this study was therefore to investigate the role of mitochondrial dysfunction in aberrant methylation of nuclear genes. **Methods:** Methylation analyses of 26 nuclear genes were performed by MS-MLPA on: -leucocytes and muscle samples from 23 mitochondrial disease patients; -human skeletal muscle (HskM) cell line treated with Rotenone, an OXPHOS inhibitor. OXPHOS function was determined by Trimethylrodamine ester stain and quantifications on confocal microscopy were performed using ImageJ. Methylation was analyzed by GeneMarker v1.95.

Results: muscle samples from patients presented higher frequency of aberrantly methylated genes than leucocytes ($p=0,02$). Caspase8 was the most frequently methylated gene in muscle (76,9% vs 0% in leucocytes). Unexpectedly, experiments in OXPHOS inhibited HskM cells revealed changes in the methylation of a single gene: Caspase8. The methylation status of this gene was augmented when the mitochondrial membrane potential came down due to Rotenone action and reverted when Rotenone was removed.

Conclusions: Our observations indicate that mitochondria's dysfunction is related to methylation alterations in nuclear genes. These epigenetic findings could contribute in the practice, to explain the wide phenotypic spectrum of mitochondrial diseases. In addition, this suggests that mitochondria have a potential role in the link between environment and epigenome. **Grant:** National University of Cuyo, Argentina.

Next Generation Sequencing (NGS) technologies are revolutionizing the diagnostic and research screening for rare diseases, particularly for those genetically and clinically heterogeneous like primary mitochondrial disorders. NGS approaches are particularly suitable for investigating the causative mutations in small families and even in single individuals, for which the traditional linkage analysis is limited. These technologies, in fact, are contributing to deepen the knowledge on the heterogeneous genetic causes of mitochondrial diseases and to significantly reduce the percentage of cases lacking a molecular diagnosis, with several new disease genes discovered. In this study we analyzed a cohort of 125 patients, that failed to show mutations in mtDNA and in specific nuclear genes after traditional Sanger's sequencing, performing a combined, two-step strategy, based on targeted genes panel as a first NGS screening, followed by whole exome sequencing (WES) in still unsolved cases. This approach has allowed us to reach a molecular diagnosis in the 20% of these difficult cases, but it has also revealed unexpected and conceptually new findings. These include the possibility of marked variable penetrance of recessive mutations, the identification of large-scale DNA rearrangements, which explain spuriously heterozygous cases, and the association of mutations in known genes with clinical phenotypes never described before. Importantly, WES on selected cases allowed us to discover pathogenic mutations in genes encoding non-mitochondrial proteins, an observation that widens the complex genetic heterogeneity of mitochondrial disease and suggests a new area of investigation in mitochondrial medicine.

Baranov^{1,2};

¹Saint Petersburg State University, St-Petersburg, Russian Federation, ²FSBSI „The Research Institute of Obstetrics, Gynecology and Reproductology named after “DO. Ott”, St-Petersburg, Russian Federation, ³City Hospital №40, St.Petersburg, Russian Federation, ⁴North-Western State Medical University named after I.I.Mechnikov, St-Petersburg, Russian Federation, ⁵City Hospital №40, St-Petersburg, Russian Federation, ⁶Children's Municipal Hospital №19 after K.A. Rauhfus, St-Petersburg, Russian Federation, ⁷CAF Foundation, Moscow, Russian Federation.

Improvement of medical care by implementation of new molecular technologies is one of the major challenges of healthcare in the Russia. This approach is of special importance for molecular-genetic analysis of children with monogenic endocrine pathology as well as members of their families. NGS diagnostic panel of exon amplification of candidate genes involved in pathogenesis of hyperinsulinism and MODY was developed. It included the following candidate - genes: HNF1A, GCK, HNF4A, HNF1B, PDX1, NEUROD1, KLF11, CEL, PAX4, INS, BLK, EIF2AK3, RFX6, WFS1, ZFP57, FOXP3, KCNJ11, ABCC8, GLUD1, HADH (SHAD), SLC16A1, UCP2, INSR, AKT2, GCG, GCGR, PPARG, PTF1A. NGS was carried out for 21 patients by „HiSeq 2500“ („Illumina“, USA). The results of DNA sequencing were used for bioinformatic filtering with the following available programs: „GeneTalk“, „destroyed“, „reporter ion“, „to sift“, „PolyPhen2“, „PAP1“. Verification of the final results was done by direct Sanger sequencing with ABI3130 genetic analyzer. Pathogenic mutations and thus molecular-genetic diagnosis were so far confirmed only in 3 families. The mutations identified so far were in heterozygous state of GCK gene and included: c.772C>A; c.199C>A; c.754A>G. According to our data MODY mutations distribution in Russian population seems to be rather similar to this one for other population. Identified mutations proved molecular basis of the disease, and might be useful for understanding the mechanism of disease and its potentially more efficient treatment.

The study was done in Biobank of the Research Park of SPbSU and implemented under the Alfa-Endo Charity Program and the Russian Science Foundation grant №14-50-00069

Novel variants in BCKDHA and BCKDHB genes cause maple syrup urine disease syndrome in Serbian patients

K. Klaassen¹, M. Stojiljkovic¹, M. Djordjevic², A. Sarajlija², S. BrasiF, B. Kecman², S. Grkovic², J. Kostic¹, P. Rodriguez-Pombo³, L. R. Desviat³, B. Perez², S. Pavlovic¹; ¹Institute of Molecular Genetics and Genetic Engineering, University of Belgrade, Belgrade, Serbia, ²Mother and Child Health Care Institute of Serbia „Dr Vukan Cupic“, Belgrade, Serbia, ³Centro de Diagnóstico de Enfermedades Moleculares, Centro de Biología Molecular, Universidad Autónoma de Madrid, CBMSO, UAM, CIBERER, Madrid, Spain.

Maple syrup urine disease syndrome (MSUD) is a rare metabolic disease resulting from deficient function of the branched-chain alpha-ketoacid dehydrogenase complex (BCKD), responsible for degradation of branched-chain amino acids leucine, isoleucine and valine. BCKD is composed of four components, E1a, E1b, E2, and E3, whereas variants in genes coding for E1a (BCKDHA), E1b (BCKDHB) and E2 (DBT) lead to MSUD (MIM# 248600).

In this study, we analyzed 4 Serbian patients diagnosed with MSUD according to biochemical data and clinical symptoms. We used Sanger sequencing for targeted analysis of BCKDHA, BCKDHB and DBT genes. In BCKDHA gene, we detected two previously described variants, c.1312T>A (p.Tyr438Asn) and c.861_868delAGGCCCCG (p.Gly288Valfs*11), and also two novel missense variants, c.581A>G (p.His194Arg) and c.892G>A (p.Val298Met). In BCKDHB gene, we detected one previously described variant, c.410C>T (p.Ala137Val), and a novel deletion, c.857_871del15 (p.Glu286_Met290del). All novel missense variants were predicted to be damaging by PolyPhen2, SIFT, PROVEAN and MutPred algorithms, and the protein sequence alignment using Clustal Omega pointed out to evolutionary conservation of affected residues. Protein modeling using I-TASSER showed that both novel BCKDHA variants lead to improper folding of the protein and thus result in an unstable protein.

This study provided the first data about molecular genetics of Serbian patients presenting with MSUD clinical symptoms, thus enabling molecular genetic diagnostics and genetic counseling of this disease in the country.

Acknowledgments: This work has been funded by grants from MESTD, Serbia (III 41004 and 451-03-02635/2011-14/14), Ministry of Economy and Competitiveness, Spain (PI13/01239 and PRIAIBSE-2011-1126) and European Commission (EU-FP7-REGPOT-316088).

P06.52

Massive parallel sequencing-based genetic confirmation of metabolic disorders detected by the neonatal screening program

R. Navarrete, F. Leal, A. Vega, C. Medrano, I. Bravo-Alonso, L. R. Desviat, P. Rodriguez-Pombo, B. Merinero, M. Ugarte, C. Pérez-Cerdá, B. Pérez; Centro de Diagnóstico de Enfermedades Moleculares, Centro de Biología Molecular, Universidad Autónoma de Madrid, CIBERER, IdiPAZ, Madrid, Spain.

The main purpose of expanded newborn screening (NBS) is to diagnose genetic disorders at an earlier step to start treatment before the appearance of clinical symptoms. In metabolic disorders, quantification of amino acids and acylcarnitines in dried blood spots by tandem mass spectrometry allows the detection of more than 30 different pathologies. The entire diagnosis process requires further sample collection for a second-tier test and genetic confirmation. In this work, we present our experience with the use of massive parallel sequencing (MPS) for genetic analysis of 84 consecutive DNA samples from newborns referred to confirm the results of the Spanish NBS program. The analysis was done by a customized panel to capture the sequence of the more frequent actionable metabolic disorders. Additionally, Illumina clinical-exome TruSightOne® combined with a gene virtual capture was used. Biallelic pathogenic mutations were found in 53 patients while only one mutation was detected in 24, in PAH, ACADM, ACADVL, GCDH, MCCC1, MCCC2, and SLC22A5. No mutations were found in some newborns with hyperphenylalaninemia or biochemical suspicion of VLCADD or GCDH deficiency. Pathogenic mutations (loss-of-function or previously described mutations) were found in 128 alleles while variants of unknown clinical significance were detected in 18 alleles. In two newborns suspected to have a variant condition of MSUD and argininemia, pathogenic mutations were detected for the first time in BCAT2 and SLC7A1 respectively. The results show the usefulness of MPS as second-tier test for diseases confirmation and for differential diagnosis of metabolic disorder. Grant: PI13/01239

Exome analysis in consanguineous families with neonatal diabetes suggests novel aetiological genes and new insights into beta-cell function

E. De Franco, J. A. L. Houghton, H. Lango Allen, S. E. Flanagan, C. Shaw-Smith, M. Wakeling, T. Laver, A. T. Hattersley, S. Ellard; University of Exeter Medical School, Exeter, United Kingdom.

A genetic diagnosis of neonatal diabetes (NDM) guides clinical management and can lead to improved treatment. Approximately 15% of patients born to consanguineous parents don't have mutations in known genes. The aim of this study was to identify novel recessive causes of NDM to gain insights into mechanisms underlying pancreatic beta-cell development and function. We performed exome sequencing and autozygosity mapping in 10 patients with NDM born to consanguineous parents in whom the known causes had been excluded.

We identified homozygous likely pathogenic variants in 5/10 patients. Two genes, *TMEM167A* and *CD274*, have not previously been linked to human disease. *TMEM167A* encodes a protein important for vesicular transport and interacts with the product of a known NDM gene (*IER3IP1*). *CD274* is essential for immune regulation and the knockout mouse phenotype supports an aetiological role. Three patients had mutations in previously reported disease genes: *EPG5* (regulates autophagy), *SPATA5* and *COQ9* (both important for mitochondrial function). Importantly for our patient, individuals with *COQ9* mutations can be successfully treated with oral CoQ10 therapy. In addition to NDM, these three patients had clinical features overlapping previously reported cases. Although the possibility of a dual aetiology cannot be excluded, these genes encode proteins in pathways known to be affected in the pathophysiology of diabetes, supporting their role in NDM. Identification of further patients is required to confirm these findings.

In conclusion, our approach was highly successful finding the likely genetic diagnosis in 5/10 patients and highlighting the possible role of five genes in beta-cell function/development.

P06.54

Production of induced Pluripotent Stem cells (iPSc) from patients with „neutral lipid storage disease with myopathy“: perspectives for a model of disease in vitro.

D. Degiorgio^{1,2}, S. Missaglia³, M. Castagnetta¹, E. M. Pennisi⁴, M. Mogni¹, D. A. Coviello¹, D. Tavian^{3,5};

¹Laboratory of Human Genetics, E.O. Ospedali Galliera, Genoa, Italy, ²Department of Experimental Medicine, University of Genoa, Genoa, Italy, ³Laboratory of Cellular Biochemistry and Molecular Biology, CRIBENS, Catholic University of the Sacred Heart, Milan, Italy, ⁴Department of Neurology, San Filippo Neri Hospital, Rome, Italy, ⁵Psychology Department, Catholic University of the Sacred Heart, Milan, Italy.

Mutations in *PNPLA2* gene causes the „Neutral Lipid Storage Disease with Myopathy“, a very rare disorder characterized by a defect in the degradation of cytoplasmic triglycerides and accumulation as lipid droplets (LDs). This lipid dysmetabolism may determine progressive myopathy (100%), cardiomyopathy (44%), diabetes (24%), hepatomegaly (20%), chronic pancreatitis (14%) and short stature (15%). No specific therapy is available today. The fibroblasts from 2 patients and 1 healthy subject have been reprogrammed into induced pluripotent stem cells (iPSCs), through infection using the Sendai viral reprogramming kit. Both patients have a homozygous *PNPLA2* mutation: in the first one the c.541_542delAC causes a prematurely truncated protein, whereas in the second one the c.662G>C determines the amino-acid change p.(R221P). The iPSC were initially selected by their morphology and the expression of the enzyme alkaline phosphatase. We demonstrated their pluripotency properties evaluating by immuno-staining the expression of markers TRA-1-81, SSEA4 and OCT4, and their in vitro differentiation into three-germ layers (β-III tubulin, ectoderm; SMA, mesoderm; FOXA2, endoderm). The comparative gene expression profiles (by qRT-PCR) of SOX2 and NANOG in iPSC and their corresponding fibroblasts, shows the preferential gene expression in iPSC clones. The evaluation of additional genes (*ZFP42*, *OCT4*, *hTERT*, *LIN28*, *DPPA2* and *TDGF1*) is ongoing. The immunohistochemical evaluation showed the presence of LDs in fibroblasts and also in iPSC of the patients. The perspective to differentiate iPSCs into striatum/cardiac muscle lineages, will allow us to define a disease model to investigate the pathogenetic mechanisms and to evaluate specific approaches for new pharmacological treatments.

Ohridski“, Department of Analytical Chemistry, Faculty of Chemistry and Pharmacy, Sofia, Bulgaria, ⁵Faculty of Natural Sciences, Ss. Cyril & Methodius University- Skopje, Skopje, Macedonia, The Former Yugoslav Republic of, ⁶Department of Clinical Genetics, University Pediatric Hospital, Medical University Sofia, Sofia, Bulgaria, ⁷Department of Medical Genetics, Medical University - Sofia, Sofia, Bulgaria.

Introduction: Inborn errors of metabolism (IEM) constitute a large group of monogenic disorders disrupting metabolic pathways. Clinical presentation varies widely - from early onset (and sometimes fatal) disease in the newborn to progressive chronic form with onset in adult life. Massive parallel sequencing technology has the potential to uncover causative genetic variants in affected individuals and gives clues for their proper therapy.

Materials and methods: NGS targeted resequencing of large gene panels was used for genetic profiling of 13 probands with suspected IEM and healthy parents in a family where the proband was not available for DNA analysis. Nine patients presented typical symptoms and / or specific metabolic profile; others were with unclear or insufficient clinical data.

Results: In 7 affected probands causative gene mutations were found (data shown in table). Sanger sequencing was performed for confirmation of the results.

Conclusion: NGS of focused gene panels gives high diagnostic yield when applied to well-defined patient groups. Identification of causative mutations is possible even in families with missing probands and may help for their appropriate genetic counseling and medical management. Despite this, about 40% of patients may need WES/WGS to reveal a diagnosis.

Patient	Gene	Results from NGS genotyping		Clinical observation	Inheritance
		Mutation 1	Mutation 2		
1	HADHA	p.Glu510Gln	p.Arg291Ter	newborn with cardiomyopathy and suspected Pompe disease	Autosomal recessive

Next Generation Sequencing: a good standard for mitochondrial disorders diagnosis

G. Grieco¹, M. Valente¹, S. Brandini², V. Battaglia², A. Olivieri², S. Gagliardi¹, I. Ricca¹, S. Zucca¹, A. Torroni², C. Cereda¹;

¹Center of Genomics and post-Genomics, C. Mondino National Institute of Neurology Foundation, Pavia, Italy, ²Department of Biology and Biotechnology, „L. Spallanzani“ University of Pavia, Pavia, Italy.

Background: Mitochondrial diseases are a group of clinically and genetically heterogeneous disorders with variable penetrance, expressivity, and different age of onset. Most disease-causing mtDNA mutations are heteroplasmic and the degree of heteroplasmy varies in different tissues. Thus, the determination of mutant loads in affected tissues is important in making the diagnosis and correlating clinical phenotype. Next Generation System (NGS) approach also allows simultaneous analyses of a group of genes or of the whole exome, thus, the mutations in causative gene(s) can be identified in one-step.

Objective: Aim of this study was to make genetic analysis in a much faster and more efficient way; and to identify the specific degree of heteroplasmy. **Methods:** Nextera XT Illumina platform was used and NGS analysis has been performed on 52 DNA blood samples.

Results: Data analysis confirmed the classical mutation 8344R in a sample used as a positive control and showed the presence of risk factors as 7080,

13889 and 12634. The most interesting data concerned a sample which, with the restriction fragment length polymorphism (RFLP) methodology, did not show the presence of the 3243R mutation which, on the other hand, was observed at 13.6% with NGS technology.

Discussion: Our results confirmed that NGS was more sensitive and specific respect to other methods to study mtDNA. The use of deep sequencing allowed to identify both low-level of heteroplasmy and the presence of rare mutations.

P06.57

Descriptive report of the adult only-visceral phenotype of Niemann-Pick disease type C.

L. López de Frutos^{1,2,3}, J. J. Cebolla^{1,2,3}, P. Irún^{1,2,3}, P. Giraldo^{1,2,3};

¹Spanish Foundation of Gaucher Disease and Other Lysosomal Disorders (FEETEG), Zaragoza, Spain, ²Instituto de Investigación Sanitaria Aragón (IIS Aragón), Zaragoza, Spain, ³Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), Zaragoza, Spain.

Niemann-Pick C disease (NPC) is a rare autosomal recessive lipid storage disorder with a heterogeneous presentation. It is characterized by visceral, neurological and psychiatric manifestations. Most of patients develop symptoms in early childhood; however, several phenotypes were identified in adults. The adult only-visceral phenotype is uncommon nevertheless is referred in some publications.

This study reports adult probands state NPC only-visceral phenotype and its characterization. Firstly, plasma biomarkers as Chitotriosidase activity (ChT), CCL18/PARC and 7-Ketocholesterol (7-KC) concentrations were assessed through biochemistry approaches. Lastly, genetic characterization of NPC1 and NPC2 were carried out.

In the last two years, 146 probands were recruited. 36 of them were identified at least one genetic variation reported as pathogenic or unknown significance (VUS) in NPC, 8/36 showed only-visceral symptoms; 3 of them were children who were excluded from the study. Focused in this 5 adult visceral cases, they were 38(27-47) [mean(min-max)] years old. ChT was 119(13-653) nmol/mL/hour. CCL18/PARC and 7-KC concentrations were 157(65-178) and 210.5(>2-333)ng/mL respectively. Variants identified in NPC1, reported as pathogenic or VUS, were: p.C177T, c.463+19A>G, p.Q775P, p.N916S, p.I1061T and p.A1151T. NPC2 gene does not show any variations. All genetic variations were found in heterozygosity and only one subject presented two variants.

Those results underline the need to perform complementary studies to evaluate the possible penetrance of some variations inherited in heterozygosis. It is necessary to analyze more patients with this only-visceral phenotype to establish some relationship between this form and some genetic variants.

Work financed by a grant from Actelion Pharmaceuticals and FEETEG.

Microarray expression profile analysis in Niemann-Pick type C fibroblasts: preliminary results of a pilot study

K. Hetmańczyk¹, R. Iwanicka-Nowicka^{2,3}, A. Fogtman², M. Kobłowska^{2,3}, M. Filocomo⁴, S. Lualdi⁴, B. Żyżyńska-Granica⁵, P. Włodarski⁶, A. Ługowska¹;

¹Department of Genetics, Institute of Psychiatry and Neurology Institute of Psychiatry and Neurology, Warsaw, Poland, ²Laboratory of Microarray Analysis, Institute of Biochemistry and Biophysics, Polish Academy of Sciences, Warsaw, Poland, ³Laboratory of Systems Biology, Faculty of Biology, University of Warsaw, Warsaw, Poland, ⁴Centro di Diagnostica Genetica e Biochimica delle Malattie Metaboliche, Istituto G. Gaslini, Genova, Italy, ⁵Department of Pharmacodynamics, Medical University of Warsaw, Warsaw, Poland, ⁶Department of Histology and Embryology, Medical University of Warsaw, Warsaw, Poland.

Introduction: Niemann-Pick type C (NPC) disease is a rare lysosomal disorder due to mutations in the genes NPC1 or NPC2. Proteins NPC1 and NPC2 are essential for intracellular transport of free cholesterol. Affected individuals accumulate free cholesterol and glycosphingolipids in late endosomes and early lysosomes. So far, the pathomechanism of NPC is not fully understood.

Aim of our study was to examine the expression levels of genes engaged in cellular metabolic pathways in cell lines obtained of NPC patients and controls.

Materials and Methods: Total RNA was isolated from 10 NPC1 patients cell lines and 9 cell lines from control persons. Biotin-labeled cRNA samples were hybridized to HumanHT-12 v4.0 Expression Bead Chip. Row data obtained after microarray experiments were then analyzed with the Partek Genomic Suite v6.6 and Ingenuity Pathway Analysis program.

Results: Statistically significant alterations in expression were observed for three genes: SOD1 coding for superoxide dismutase 1 (mean fold change, MFC, 2.5), CTSK coding for cathepsin K (MFC 2.5), and CTSB coding for ca-

thepsin B (MFC 1.5). We have found that in NPC cells the up-regulated genes were related to oxidative stress, autophagy, and apoptosis.

Conclusions: These preliminary results indicate that in humans activation of autophagy may enhance cell stress and eventually trigger the apoptotic pathway. This was already reported in NPC1 deficient mice as well as impaired proteolysis, which underlies autophagic dysfunction.

Our further work will include the validation of obtained data by qRT-PCR in human NPC fibroblasts.

Burghel" Clinical Hospital, Department of Urology, Bucharest, Romania.

Background. Obesity is one of the world's pandemics. This research wishes to determine high-risk polymorphisms associated with obesity for the Romanian population. It is the first large obesity-related genome-wide association study in Romania.

Materials. Methods. A GWAS was performed on a Romanian cohort of 2024 males aged over 50 y.o. (408 obese, 894 overweight, 647 normalweight). The research included 700000 SNPs. Genotyping results were analyzed in correlation with obesity, obesity parameters (weight, BMI) and complications (diabetes, flebitis, hypertension, prostate cancer). Lifestyle risk-factors were considered (environment, smoking, alcohol, coffee). Allele frequencies were calculated and compared with literature.

Results. Intron 1 of the FTO gene (16q12.2) had the strongest signal (10⁻⁴ - 10⁻⁵ p values) when associated with weight, BMI and obesity level (18 highly correlated SNPs). A locus on chromosome 7 (7q31.1) showed lower associations (3 SNPs). FTO SNPs also revealed strong correlations with diabetes, especially in obese. Hypertension was found associated with polymorphisms on chromosomes 4, 12 and 13 (BANK1, PPP3CA, AT2B, FRY genes) but not obesity-mediated. Lifestyle risk-factors associated-SNPs also showed correlations with obesity, diabetes and hypertension. One variant in the FRY gene (13q13.1) yielded associations with both smoking and hypertension. Over 50 SNPs were correlated with prostate cancer, 28 revealing the strongest results (chromosomes 4,8,13,16,2,6).

Conclusions. The results revealed several gene clusters correlated with obesity and comorbidities. The implications of these variants for the Romanian population need to be further analyzed, replication studies having to be undertaken for confirmation.

The research is part of EU FP7 ProMark project.

Introduction: X-linked ornithine carbamoyltransferase deficiency (OTCD) is the most common urea cycle defect. Human *OTC* gene is expressed almost exclusively in the liver. We present the results of molecular genetic analyses in a newborn male with typical biochemical markers of OTCD who died due to severe hyperammonemia and multiorgan failure seven days after birth.

Methods: Genomic DNA from blood and cDNA from postmortem liver were amplified by PCR, and respective PCR products were analyzed by Sanger sequencing. The extent of the genomic deletion was determined by sequencing PCR products containing the deletion boundaries, and confirmed by MLPA.

Results: Amplification of genomic DNA did not yield any PCR product of exon 2, Sanger sequencing did not reveal any other changes in the remaining exons. A 2,325 bp large deletion starting 2,113 bp upstream of exon 2 and ending 73 bp in intron 2 was identified in genomic DNA. Congruently,

deletion of exon 2 was also observed in liver mRNA (r.78_216del, predicted p.Cys271Ilefs*10). In addition, an unexpected splicing variant with deletion of exons 2-4 (r.78_386del, p.Cys27_Arg129del) was observed indicating possibly the presence of distant acting splicing regulatory elements in the 2,325 bp genomic DNA deletion.

Conclusions: This study demonstrates the important role of mRNA analysis for interpretation of genetic variants observed in genomic DNA and indicates that the *OTC* gene may carry splicing regulatory elements within the region spanning 2,325 bp between intron 1 and intron 2. P06.61

New mutations of the Twinkle mitochondrial helicase resulting in Perrault syndrome

B. A. Fekete, K. Pentelényi, A. Domokos, P. Balicza, A. Kékesi, A. Gál, M. J. Molnár; Institute of Genomic Medicine and Rare Disorders, Semmelweis University, Budapest, Hungary.

Perrault syndrome is a rare disease characterized by sensorineural hearing loss, ovarian dysfunction in females and neurological symptoms. The phenotypic heterogeneity is accompanied with genetic heterogeneity with the most commonly affected genes being HARS2, HSD17B4, LARS2 and CLPP. In one single report mutations in C10orf2 have been associated with the disease as well.

Hereby we present the case of a 20-year-old female with early onset progressive hypacusis and primer hypogonadism, which are the hallmarks of the Perrault syndrome phenotype. Additional clinical features are dysarthria, severe weakness in the limb muscles, truncal and limb ataxia, polyneuropathy and psychiatric symptoms. Serum lactate was elevated. MRI found: medulla oblongata and spinal cord atrophy. Genetic analysis of the HSD17B4 gene did not find pathogenic mutations. In her muscle tissue multiple mtDNA deletions were present. NGS analysis of the genes responsible for intergenomic communication detected compound heterozygous c.1196A>G and c.1358G>A mutations in the C10orf2 gene. The segregation analysis by Sanger sequencing found these mutations in her parents in heterozygous status.

Our observation confirms that Twinkle protein dysfunction is associated with Perrault syndrome. The severe neurological and psychiatric symptoms of our patient and the presence of medulla oblongata and spinal cord atrophy expand the phenotypic spectrum of the disorders caused by Twinkle mutations.

therapeutical approaches in lysosomal storage diseases - identification of novel small molecule drugs in Fabry, Gaucher, Pompe and Niemann-Pick type C disease

J. Lukas¹, S. Seemann¹, A. Pockrandt¹, C. Zheng¹, M. Sharif², A. Pews-Davtyan², M. Beller², A. Rolfs^{1,3};

¹Albrecht-Kossel-Institute for Neuroregeneration, Rostock, Germany, ²Leibniz Institute for Catalysis, Rostock, Germany, ³Centogene AG, The Rare Disease Company, Rostock, Germany.

Lysosomal storage diseases (LSDs) form a group of rare, inherited, progressive disorders of lysosomal catabolism. The diseases are based on mutations in genes mainly encoding for soluble (or membrane-associated) lysosomal hydrolases as is the case for Fabry (FD), Gaucher (GD) and Pompe (PD) diseases. Integral membrane proteins and transporters can also be affected as in Niemann-Pick Type C (NPC) disease.

Several therapeutic interventions have been developed within the last two decades. Among the clinically approved therapies are namely bone marrow transplantation and enzyme replacement therapy. However, alternative treatment strategies need to be elaborated, because these conventional methods are limited by several means, e.g. non-responsivity of the central nervous system, the unavailability of ERT for certain diseases, etc.

We developed distinct cell culture models to test for candidate small molecule drugs for a clinical application in LSDs. Generally, the aim of our research was the identification and mechanistical examination of different compounds to act on a preferably broad range of distinct genotypes in LSDs and, consequently, attenuate disease course. Using a HEK293 cell-based system for the expression of mutant forms of α -galactosidase A (FD) and α -glucosidase (PD) enzymes we identified novel compounds and compound combinations from various structural and functional molecule classes being able to increase cellular activity of the mutant protein.

A compound derivatisation and testing program has been initiated for known pharmacological chaperones in GD and NPC using patient fibroblast cells aiming at (1) optimising their activities and (2) getting insights into structure/function relationship of the compounds.

Effect of sepiapterin on three novel missense mutation forms of phenylalanine hydroxylase in hepatoma cells

M. Pecimonova¹, A. Soltysova^{1,2,3}, E. Polak¹, M. Stojiljkovic⁴, Z. Levarski¹, J. Krahulec¹, L. Kadasi^{1,2,3}

¹Faculty of Natural Sciences, Department of Molecular Biology, Comenius University, Bratislava, Slovakia, ²Institute for Clinical and Translational Research, Biomedical Research Centre, Slovak Academy of Sciences, Bratislava, Slovakia, ³Institute of Virology, Biomedical Research Centre, Slovak Academy of Sciences, Bratislava, Slovakia, ⁴Institute of Molecular Genetics and Genetic Engineering, University of Belgrade, Belgrade, Serbia.

Phenylketonuria and its milder form, hyperphenylalaninemia, are metabolic, autosomal recessive genetic disorders, associated with the deficiency of enzymatic activity of enzyme phenylalanine hydroxylase (PAH). This enzyme catalyzes the essential conversion of L-phenylalanine to L-tyrosine in the presence of molecular oxygen, iron, and 6(R)-L-erythro-5,6,7,8-tetrahydrobiopterin (BH4) which functions as a natural cofactor of PAH. BH4 has chaperone-like effect on PAH enzyme, which is functional only in tetrameric form and may also have a potential effect on PAH mRNA expression in hepatoma cells.

Until now, more than 950 variants were identified in the PAH gene. Novel missense mutations p.F233I, p.R270I and p.F331S in this gene were found in the Slovak population. Previously, we performed PAH functional assays for testing the impact of these mutations on the functionality of PAH protein using prokaryotic expression system.

In this work, we focused on the expression of PAH mutated proteins in eukaryotic cell line HepG2 in the presence of sepiapterin which acts as the precursor of BH4. However some authors report that BH4 has no effect on PAH mRNA expression and has only effect on proper protein folding, other research papers report that PAH mRNA expression is increased in presence of BH4. Therefore we performed Real Time PCR and Western blot analyses to investigate the impact of sepiapterin on the level of mRNA and mutated PAH proteins.

This project was sponsored by grant APVV-0240-12.

P06.64

Phenylketonuria, clinical and molecular aspects in a group of Romanian patients

R. C. Vulturari¹, M. Mager²

¹Univ. of Medicine and Pharmacy, Dept. of Cell and Molecular Biology, Cluj-Napoca, Romania, ²Univ. of Medicine and Pharmacy, Dept. of Neurology, Cluj-Napoca, Romania.

Phenylketonuria is an autosomal recessive disease that, if is untreated, will impair cognitive development resulting from a neurotoxic effect of hyperphenylalaninemia (HPA); the associated clinical phenotype varies and the potential genotype-phenotype correlations would help in understanding the pathophysiology of this disease. Its metabolic phenotype is accountable to multifactorial origins both in nurture [where the normal nutrition introduces L-phenylalanine] and in nature, where mutations (>520 alleles) occur in the PAH gene. The allelic variation at the PAH locus yield greater or lesser risk of impaired cognitive development according to the degree of HPA. The clinical evaluation of a group of 20 PKU patients (with different stage of treatment) from neurology section of Cluj Children Hospital, Romania, was done according to The München development scale for the children with mental age below 3 years, with The Simon-Binet test for children with mental age 3-7 years and with The Raven's Progressive Matrices for those above 7 years. Biochemical phenotypes associated were included in severe PKU when the level of Phe is above 1200 µmol/l, moderate PKU (Phe: 600-1200 µmol/l) or mild HPA for Phe: 120-600 µmol/l. The leukocyte DNA was isolated and using polymerase chain reaction with subsequent restriction analysis, we identified patients homozygous for mutation R408W (more than 50%), patients compound heterozygotes for R408W/L48S, R408W/R413P, R261Q/IVS12+1>a, Y268C/ IVS12+1>a, or R408W/R261Q mutations. Our data provide that the highest degree of concordance genotype-phenotype was found in patients with null/null genotypes and evidence that a simple genotype-phenotype correlation does exist in this group of patients.

Plasma and tissue miRNA signatures to understand the pathophysiology in propionic acidemia

A. Rivera-Barahona¹, A. Fulgencio-Covián¹, B. Pérez^{1,2}, C. Pérez-Cerdá², M. Ugarte², E. Richard^{1,2}, L. R. Desviat^{1,2}

¹Centro de Biología Molecular, Madrid, Spain, ²Centro de Diagnóstico de Enfermedades Moleculares, Madrid, Spain.

miRNAs are regulatory short non-coding RNAs involved in many cellular processes and pathological conditions, thus they have emerged as potential biomarkers and therapeutic targets in human diseases. In this work we have

analysed the miRNA profile in plasma samples from patients with the rare metabolic disorder propionic acidemia (PA) and in different tissues from the hypomorphic murine model. PA is characterized by the toxic intracellular accumulation of propionyl-CoA due to propionyl-CoA carboxylase (PCC) enzyme deficiency and usually presents as a neonatal form with patients developing neurological deficits and cardiomyopathy in the long-term. We have used a qRT-PCR miRNome panel to analyse the expression of 752 miRNAs in *Pcca*^{-/-} (A138T) mouse liver and in plasma samples from PA patients and controls. In mouse, we have found 14 significantly dysregulated miRNAs from which three also exhibited altered plasma levels in PA patients. In mouse tissues we selected miR-34a-5p, miR-338-3p and miR-350 to investigate their potential targets in relation to PA pathology. The levels of the three miRNAs were found increased in brain and heart of the hypomorphic mice at different ages, correlating in some cases with a decrease in specific predicted targets such as BCL2, MEK1, p38, JNK and ATP5G1, involved in apoptosis, stress-signalling and mitochondrial function. Taken together, our results point out to the role of miRNAs in PA pathophysiology and underscore their potential use as biomarkers of the disease.

New insights into renal amino acid reabsorption

C. Vilches¹, M. López de Heredia¹, S. Boday², M. Espino^{1,2}, E. Boiadjieva³, E. Prat^{1,4}, L. González¹, R. Artuch⁵, F. Verrey^{6,3}, M. Palacín^{2,6}, V. Nunes^{4,1,4}, *authors sharing leadership; ¹Human Molecular Genetics Laboratory, IDIBELL, U730 CIBERER, L'Hospitalet de Llobregat, Barcelona, Spain, ²Institute for Research in Biomedicine (IRB Barcelona), U731 CIBERER, Barcelona, Spain, ³Institute of Physiology and Zurich Center for Integrative Human Physiology, University of Zurich, Zurich, Switzerland, ⁴Genetics Unit, Physiological Sciences II Department, Medicine Faculty, University of Barcelona, L'Hospitalet de Llobregat, Barcelona, Spain, ⁵Clinical Biochemistry Department and Institute of Research Pediatrics, U703 CIBERER, Barcelona, Spain, ⁶Biochemistry and Molecular Biology Department, Biology Faculty, University of Barcelona, Barcelona, Spain.

Introduction: The generation of mouse models for heteromeric amino acid transporters has been proved to be a powerful tool to understand the renal amino acid transport in mammals and subsequently our knowledge about aminoacidurias.

Materials and Methods: We have generated and characterized a double-loss-of function mouse model for the two basolateral amino acid transporters LAT2 and TAT1 (hereafter, dKO). Animals were treated with a high protein content diet, amino acids were quantified in urine and plasma samples to assess renal function, and expression of amino acid transporters was analyzed by RT-qPCR in the dKO, the single KOs and control mice.

Results: We found a decreased reabsorption of aromatic and neutral amino acids and to a lesser extent, of basic ones and proline, which is exacerbated under rich protein diet. A strong renal phenotype in the dKO versus single ones supports a coordinated function of LAT2/4F2hc and TAT1 on the basolateral transport in renal reabsorption. The expression analyses demonstrate the upregulation of one particular isoform of the basolateral transporter y+LA T1, and in a lesser extent of SNAT3.

Conclusion: There is cooperation between LAT2/4F2hc and TAT1 in the renal reabsorption, where TAT1 supplies neutral amino acids for LAT2 exchanger. The dKO model presents a significant remaining tubular reabsorption of neutral amino acids suggesting the existence of compensation by other basolateral transporters. y+LAT1 and SNAT3 seem to be two of them. Altogether, our results provide new insights into the in vivo mechanisms of amino acid reabsorption in the kidney.

Use of shRNAs on patients' cells as a long-term substrate reduction therapy approach for Sanfilippo C disease

N. Benetó¹, I. Canals^{1,2}, L. Vilageliu¹, D. Grinberg¹

¹Dept. Genetics, Fac. Biology, University of Barcelona, CIBERER, IBUB, Barcelona, Spain, ²Stem Cells, Aging and Neurodegeneration Group, Lund Stem Cell Center, University Hospital, Lund, Sweden.

Sanfilippo C syndrome is a rare lysosomal storage disorder caused by mutations in the HGSNAT gene, which encodes an enzyme involved in heparan sulphate (HS) degradation. The enzyme deficiency causes the storage of partially degraded HS molecules inside the lysosome. The disease has an autosomal recessive inheritance pattern and is characterized by a severe and progressive neurodegeneration for which no effective treatment exists. Previously, we demonstrated, on Sanfilippo C patients' fibroblasts, that the use of siRNAs targeting EXTL2 and EXTL3, genes involved in HS synthesis, could be effective as a short-term substrate reduction therapy (SRT). Here, we have used five different lentiviruses encoding shRNAs targeting EXTL2, to analyse the effect of a long-term treatment. All the shRNAs caused

a notable reduction in the mRNA levels (around 90%) of the EXTL2 gene six days post-infection. Moreover, immunocytochemistry analyses showed a clear decrease of the HS amounts after treatment.

Due to the good results obtained on patients' fibroblasts, now we are using the most effective shRNAs on induced pluripotent stem cells (iPS cells) derived from patients' fibroblasts. We have set up the conditions for the differentiation of those iPS cells to neurons, the most affected cell type in this disease, and we are going to perform the same assays on them.

Our results confirm the usefulness of shRNAs as a long-term SRT, becoming a promising approach for a future therapeutic option for Sanfilippo C syndrome.

Identification of rare genetic variants in patients with non-syndromic early-onset obesity using a pooled DNA sequencing approach

F. Bou¹, C. Serra-Juhé^{1,2,3}, G. Martos-Moreno^{4,5,6}, B. Rodríguez-Santiago⁷, R. Flores^{1,2,3}, J. Argente^{4,5,6}, L. Pérez-Jurado^{1,2,3};

¹Genetics Unit, Universitat Pompeu Fabra, Barcelona, Spain, ²Hospital del Mar Research Institute (IMIM), Barcelona, Spain, ³Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), Instituto de Salud Carlos III, Barcelona, Spain, ⁴Departments of Pediatrics & Pediatric Endocrinology, Hospital Infantil Universitario Niño Jesús, Universidad Autónoma de Madrid, Madrid, Spain, ⁵La Princesa Research Institute, Madrid, Spain, ⁶Centro de Investigación Biomédica en Red de Fisiopatología de la Obesidad y Nutrición (CIBEROBN), Instituto de Salud Carlos III, Madrid, Spain, ⁷Quantitative Genomic Medicine Laboratories (qGenomics), Barcelona, Spain.

Studies trying to elucidate the pathophysiology of obesity consistently describe a highly heterogeneous disorder at the clinical and molecular level, with high heritability. At least 10 genes, mostly with recessive inheritance, have been reported to cause monogenic severe obesity, and there are a few more candidates of strong effect in association studies.

The aim of this study was to establish the contribution of rare genetic variants in candidate genes to early-onset obesity (BMI>3SDS, <3y). Using a pooled DNA sequencing approach, which allows analyzing many samples with reduced costs, we screened 15 candidate genes for obesity in a cohort of 480 patients and 480 controls (BMI<P50). We focused on very rare variants found in single or few individuals per cohort.

Seven of the 15 genes (*BDNF*, *FTO*, *MC3R*, *MC4R*, *NEGR1*, *PPARG* and *SIM1*) were differentially represented between patients and controls; we identified 30 rare variants in patients and 5 in controls (p=0.0001). The difference of probably pathogenic variants (15 in patients vs 1 in controls) was also significant (p=0.0005); all were single allele changes and none of the individuals carried more than one variant.

Our data reveal a higher burden of rare and probably pathogenic heterozygous variants in several candidate genes in patients with severe early-onset obesity compared to controls. Our results reinforce the role of the melanocortin pathway and bring to light other genes that may carry highly penetrant obesogenic single allele variants, like *FTO*, *PPARG* and *BDNF*.

Rare copy number variants reveal novel genes and pathways involved in early-onset obesity

C. Serra-Juhé^{1,2,3}, G. Martos-Moreno^{4,5,6}, F. Bou¹, B. Rodríguez-Santiago⁷, R. Flores^{1,2,3}, J. González^{8,9}, J. Argente^{4,5,6}, L. Pérez-Jurado^{1,2,3};

¹Genetics Unit, Universitat Pompeu Fabra, Barcelona, Spain, ²Hospital del Mar Research Institute (IMIM), Barcelona, Spain, ³Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), Instituto de Salud Carlos III, Barcelona, Spain, ⁴Departments of Pediatrics & Pediatric Endocrinology, Hospital Infantil Universitario Niño Jesús, Universidad Autónoma de Madrid, Madrid, Spain, ⁵Hospital de la Princesa Research Institute, Madrid, Spain, ⁶Centro de Investigación Biomédica en Red de Fisiopatología de la Obesidad y Nutrición (CIBEROBN), Instituto de Salud Carlos III, Madrid, Spain, ⁷Quantitative Genomic Medicine Laboratories (qGenomics), Barcelona, Spain, ⁸Centre de Recerca en Epidemiologia Ambiental (CREAL-ISGlobal), Barcelona, Spain, ⁹Centro de Investigación Biomédica en Red de Epidemiologia y Salud Pública (CIBERESP), Barcelona, Spain.

Introduction: Obesity is a multifactorial disorder with high heritability (50-75%), probably higher in early-onset and severe cases. Although rare monogenic forms and several genes and regions of susceptibility, including CNVs, have been defined, the genetic causes underlying the disease still remain largely unknown.

Methods: We studied a cohort of Spanish children with severe (BMI>3SDS) non-syndromic early-onset (<3y) obesity (EOO). We obtained molecular karyotypes of 157 cases. Large (>100kb) and rare (<1/2,000 controls) CNVs were validated, segregated in the family, and studied in a larger sample (323

EOO cases/480 controls). Additionally, mutation analysis of the genes altered by CNVs (n=16) was completed in both cohorts by NGS using a pooled DNA strategy.

Results: A higher burden of duplication-type CNVs was detected in EOO cases versus controls (OR=1.85, p-value=0.008). Likely pathogenic CNVs included duplications of glutamate receptor (*GRIK1*, *GRM7*), the X-linked gastrin-peptide receptor (*GRPR*) and the *NPY* genes, all inherited from obese parents. Results were replicated by MLPA in the extended cohort. By NGS focusing the analysis on rare variants, we identified a missense mutation in *NPY*, a nonsense mutation in *GRIK1*, and 5 missense mutations in *GRPR* in EOO cases, but no mutations in controls.

Conclusions: Our data reveal a higher burden of rare CNVs and point mutations in patients with EOO compared to controls. Genes altered by CNVs are candidates for contributing to the pathogenesis of morbid EOO. Among these, *NPY*, *GRPR* and two glutamate receptors are likely involved in highly penetrant, monogenic and familial obesity.

Vitamin E treatment in Smith-Lemli-Opitz syndrome patients - experiences of follow up

K. Koczok¹, L. Horváth², G. P. Szabó³, Z. Korade⁴, N. A. Porter⁵, I. Balogh¹;

¹Department of Laboratory Medicine, Division of Clinical Genetics, University of Debrecen, Debrecen, Hungary, ²Department of Pharmaceutical Surveillance and Economy, University of Debrecen, Debrecen, Hungary, ³Department of Pediatrics, University of Debrecen, Debrecen, Hungary, ⁴Department of Psychiatry, Vanderbilt University, Nashville, TN, United States, ⁵Department of Chemistry, Vanderbilt University, Nashville, TN, United States.

Introduction: Smith-Lemli-Opitz syndrome (SLOS) is a multiple malformation syndrome caused by 7-dehydrocholesterol reductase enzyme deficiency. Decreased cholesterol, elevated 7-dehydrocholesterol (7-DHC) and oxidative derivatives of 7-DHC are putative pathophysiological factors of SLOS. According to literature vitamin E is effective in reducing 7-DHC-derived oxysterols in cultured SLOS fibroblasts. We have started a study on clinical effects of vitamin E in SLOS in 2014.

Materials and Methods: Seven SLOS patients were enrolled in the study receiving 230 mg (age: 4-10 years) or 2x230 mg (above 10 years) RRR-alpha-tocopheryl acetate beside cholesterol supplementation. Plasma vitamin A and E concentrations were monitored regularly by HPLC. Behavioral effects of the therapy were determined using the Aberrant Behavior Checklist (ABC) at baseline, after 6 and 12 months. During follow-up, upon anecdotal reports of the parents, we created another questionnaire focusing on sleeping habits and photosensitivity as well in addition to behavior.

Results: Patients were vitamin E deficient prior to therapy, while vitamin A concentrations were normal in all but one patient. Absorption of the vitamin was satisfactory, plasma vitamin E concentrations showed normalization in all patients. According to ABC improvement in irritability and stereotypic behavior was detected in one patient. Using our questionnaire positive effects on self-injurious and stereotypic behavior, improvement of sleeping habits and photosensitivity were observed in four patients.

Conclusions: Vitamin E deficiency is likely to be the consequence of higher utilization and not inadequate absorption and can be normalized using high treatment doses. Our results suggest potential benefit of vitamin E treatment in SLOS.

Sandhoff disease : a case report with new mutation

S. Seyhan, H. Önder Yılmaz, A. Cansu, A. H. Çebi, M. İkbāl; Karadeniz Technical University Medicine Faculty, Trabzon, Turkey.

Sphingolipidoses are inherited lysosomal storage diseases which are result of the accumulation of sphingolipids therefore progressive neurodegenerative findings revealed. In Sandhoff disease there are lack of activities of total hexosaminidase (A and B components) with beta subunit gene mutation and it lead to the accumulation of GM2 gangliosides in neural tissue. It is divided into three types acute (infantile), juvenile (late infantile) and adult (chronic). The incidence of sphingolipidoses in Turkish Society is 4,1/100.000 in live birth. In Sandhoff disease the accumulation of sphingolipids in macular retinal ganglion cell causes typical „Japanese flag“ formation of the image.

In this study, we present a 3-years-old-male who was brought to our pediatric neurology clinic because of fatigue, slow movement, inactivity since his birth. On physical examination we determine decreased deep tendon reflexes, mild coarse facies and cherry spot on ocular fundus. Delays in all developmental stages were detected in Denver-2 test. Parents are relative. Due to diagnosis of Lysosomal enzyme levels in white blood plasma cells

hexosaminidase A and B levels were determined as 20% lower limit we made HEXB gene whole exom sequence analysis. As a result we determine the patient p.S210P(c.628T>C)(homozygous). The analysis of known mutations that are sent from the patient's parent were determined as p.S210P(c.628T>C)(heterozygous). We present this case because it is a new mutation in the HEXB gene.

Characterization of HEK293 cell lines stably expressing mutated hSRD5A3 variants to mimic SRD5A3-CDG

A. Buczkowska¹, P. Link-Lenczowski², L. Borowski¹, A. Fogtman¹, M. Kobłowska¹, D. J. Lefeber³, A. Dziembowski¹, E. Swiezewska¹;

¹Institute of Biochemistry and Biophysics Polish Academy of Sciences, Warsaw, Poland, ²Jagiellonian University Medical College, Krakow, Poland, ³Department of Neurology, Translational Metabolic Laboratory, Radboud University Medical Center, Nijmegen, Netherlands.

Attachment of carbohydrate chains to proteins is a common post-translational modification occurring ubiquitously in mammalian cells. N-Glycosylation pathways use the lipid carrier dolichol (Dol) as an obligate precursor. Mutations in the genes encoding enzymes involved in the synthesis of Dol cause deficiencies in cellular function and lead to a variety of debilitating diseases called congenital disorders of glycosylation type I. One of the variants, SRD5A3-CDG, is caused by nonsense mutations in the gene encoding polyprenol reductase, *SRD5A3*, which plays a crucial role in the dolichol cycle by catalyzing conversion of polyprenol to dolichol. Decreased content of dolichyl phosphate affects the assembly of the Dol linked Glc₃Man₉GlcNAc₂ glycan and its transfer to proteins upon N-glycosylation.

Flp-In technology was used to obtain several HEK293T cell lines expressing miRNA silencing endogenous *SRD5A3* and simultaneously complemented with mutated variants of *SRD5A3*. Biochemical analysis of model cell lines demonstrated that expression of mutated *SRD5A3* led to aberrations in lipid metabolism and in protein glycosylation. Additionally, using microarray analysis, we investigated the differences in gene expression profiles between HEK293 cell lines expressing mutated *SRD5A3* and control. This analysis revealed more than 100 genes with modulated expression (up/down-regulated) compared to the mock transfected cells. Functional identification of these genes is in progress.

Results of these analyses will help to understand the variability of the clinical symptoms observed for SRD5A3-CDG patients.

This work was partially supported by grant [UMO-2012/06/M/NZ3/00155] funded by the National Sciences Center of Poland.

P06.74

Molecular diagnosis of Wilson disease by Next Generation Sequencing

V. Parrillas, E. Sevilla, C. Rodríguez, C. Camarena, E. Vallespín, A. Carazo, V. Montaña, R. Mena, J. Silla, P. Lapunzina, S. Rodríguez Novoa; Hospital Universitario La Paz, Madrid, Spain.

Introduction: Wilson's disease (WD, OMIM #277900) is an autosomal recessive disorder of copper metabolism that produces intracellular copper accumulation in liver, brain, kidney and cornea and may lead to hepatic cirrhosis and neurological damage. WD affects from 1/30000 to 1/100000 individuals worldwide. *ATP7B* gene (MIM #606882), responsible for WD, is a copper transporter P-ATPase that plays a key role in incorporating copper into ceruloplasmin and moving excess copper out of the liver. Over 200 different mutations have been identified in the *ATP7B* gene.

Materials and Methods: Patients with clinical evidence of Wilson's disease were remitted to our service for genetic testing. Analysis of the *ATP7B* was

done by Next Generation Sequencing (NGS). Multiplex Ligation-dependent Probe Amplification (MLPA) was performed in all patients in order to detect deletions/duplications in the *ATP7B* gene.

Results: Twenty unrelated patients were analyzed. Four of them carried pathogenic variants at *ATP7B*. Table shows their biochemical characteristics and genotypes. Three patients were simple heterozygous for known mutations in *ATP7B*. One patient was compound heterozygous.

Conclusions: Most of the patients with mutations in the *ATP7B* gene are simple heterozygous. This data can suggest the importance of conducting a thorough analysis of gene promoter *ATP7B* as well as finding new targets for molecular diagnosis of EW.

P06.75

Diagnostic tests for hereditary xanthinuria

I. Sebesta^{1,2}, B. Stiburkova^{2,3}, J. Krijt⁴;

¹Institute of Medical Biochemistry and Laboratory Diagnostics, First Faculty of Medicine, Charles University, Prague, Czech Republic, ²Institute of Inherited Metabolic Disorders, Prague, Czech Republic, ³Institute of Rheumatology, Prague, Czech Republic, ⁴Institute of Inherited Metabolic Disorders, First Faculty of Medicine, Charles University, Prague, Czech Republic.

Introduction: Hereditary xanthinuria is an autosomal recessive inherited metabolic disorder due to deficiency of the xanthine dehydrogenase/oxidase (XDH/XO - type I), and is characterized by low concentration of uric acid (UA) in blood and urine and high concentration of urinary xanthine. Type II results from a combined deficiency of XDH/XO and aldehyde oxidase. Patients present with hematuria, renal colic, urolithiasis or even acute renal failure. Molybdenum cofactor deficiency (type III) is characterized by the lack of sulfite oxidase as well as XDH/XO and aldehyde oxidase activities. About 150 cases have been described so far.

Materials and Methods: Hypouricemic patients were found from 3 800 blood and urine samples. Following tests were set up: a) evaluation of UA in serum and urine with exclusion of secondary causes of hypouricemia b) estimation of urinary xanthine, c) allopurinol loading test and finally XDH/XO activity assay in plasma with molecular genetic analysis.

Results: Nine Czech cases were detected, which is one of the largest group worldwide, in the terms of the number of patients. All individuals had profound hypouricemia as the first sign. Urinary concentrations of xanthine were in the range of 170-598 mmol/mol creatinine (ref.range: < 30 mmol/mol creatinine). XDH/XO activities in plasma in two cases were 0 and 0.37 pmol/h/mL of plasma (ref.range: 3.2-9.2 pmol/h/mL of plasma). The nonsense heterozygous mutation p.R825X was found in two patients.

Conclusions: Hereditary xanthinuria is probably not so rare as previously thought. Patients with unexplained hypouricemia need detailed purine metabolic investigation.

P06.76

Lethal Zellweger spectrum syndrome due to a novel mutation in the PEX3 gene

E. M. Honey¹, M. Dercksen², L. J. Mienie², B. C. Vorster²;

¹University of Pretoria, Pretoria, South Africa, ²North-West University, Potchefstroom, South Africa.

Background: Zellweger spectrum syndromes (ZSSs) are a heterogeneous group of autosomal recessive neurodegenerative disorders that affect multiple organ systems. A high incidence of ZSSs in the South African population has been observed in the last 20 years. Most of these patients were diagnosed in the first 8-10 weeks after birth and lived an average of 2 years. Three cases however presented with a severe phenotype and these patients died soon after birth.

Patient: A neonate, presenting with facial and finger dysmorphism as well as

Probands	Genotype of ATP7B (NM_000053.3.4)						Biochemical parameters

lactic acidosis after birth, was recently referred to the Potchefstroom laboratory for inborn errors of metabolism, South Africa for a metabolic work-up. The patient unfortunately died a day after birth.

Results: Initial metabolic investigations on plasma indicated an elevated level of C26 as well as C24/C22 and C26/C22 ratios. In addition, increased pipercolic acid was also observed. A ZSS was suspected after plasma bile acids analysis revealed elevated dihydroxycholestanic acid, trihydroxycholestanic acid and C29-dicarboxylic bile acid. Complementation studies, for accessing peroxisomal biogenesis disorders on fibroblasts, were done and revealed PEX3 gene as a probable candidate. The sequenced mutation analysis of the PEX3 gene showed that the patient had a novel homozygote frameshift mutation namely c.203_204dup (p.Val69Glnfs*9).

Conclusions: It was concluded that this pathogenic mutation results in the expression of a non-functional truncated protein and consequently a severe and fatal phenotype. Our findings on and experience in ZSSs gives merit to the investigation of peroxisomal biogenesis disorders in neonates presenting with dysmorphia and metabolic decompensation.

P07 Immunology and hematopoietic system

Somatic mutation in the HLA genes in a patient with acute myeloid leukemia (AML) prior to hematopoietic stem cell transplantation (HSCT): a case report

V. V. Zakharova, O. A. Shragina, M. A. Maschan, E. V. Orekhova, M. A. Kournikova, E. V. Raikina;
Dmitry Rogachev Federal Research Centre of Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation.

Introduction: The most important factor that can influence HSCT outcome is HLA matching. Recent publications have pointed somatic mutations resulting in copy-neutral loss of heterozygosity (CN-LOH) for part or full HLA haplotype.

Patient: A 15-year old female previously diagnosed with AML-M5 was referred to clinic with leukemia relapse. Bone marrow showed 97% of blasts. Cytogenetic analysis detected CALM-AF10 fusion gene. FLT3, NPM1 mutations were negative. Unrelated donor search was initiated. But, after two blocks of re-induction chemotherapy she didn't achieve remission and developed sepsis, pneumonia. So, haploidentical HSCT was a treatment of choice. Unfortunately, the evidence of disease progression made it impossible. Patient had to choose palliative care.

Result: HLA-typing by SBT and NGS indicated that the patient was homozygous: A*02:01-B*18:01-Cw*07:01-DRB1*11:04-DQB1*03:01. Confirming result was obtained in registry of unrelated stem cell donors. Mother's typing by SBT: A*03:01,26:01-B*35:03,56:01,-Cw*12:03,01:02-DRB1*11:01,07:01-DQB1*03:01,03:03. There was no common haplotype between mother and daughter. The maternity was confirmed by STR. Testing of patient by SSP revealed a second haplotype (Bw6): A*03:01-B*35:03-Cw*12:03-DRB1*11:01-DQB1*03:01.

Conclusion: We found HLA-diploid normal cells in minority and malignant cells with acquired uniparental disomy. SSP unlike sequencing doesn't depend on balanced PCR amplification of the two alleles present at a locus and might detect the two haplotypes. Bw6 loss confirms the hypothesis from previous cases where Bw6 alleles have been found to the target of HLA malignant eradication. This case shows that LOH may lead to erroneous typing results. Homozygotes should be confirmed by SSP, typing of buccal swabs, blood samples in remission or creating a family tree by typing the parents.

P07.02

Unique concurrence of monosomy of chromosome 7 and KMT2A gene rearrangement in a patient with AML

Z. Litwinska¹, A. Pietrzyk², E. Studniak³, R. Guzicka-Kazimierzczak³, B. Zdziarska³;
¹Department of General Pathology, Pomeranian Medical University, Szczecin, Poland,
²Cytogenetic Unit, Pathology Department, Pomeranian Medical University, Szczecin, Poland,
³Department of Hematology, Pomeranian Medical University, Szczecin, Poland.

Acute myeloid leukemia (AML) is a type of myeloid lineage malignancy, heterogeneous in terms of morphology, immunophenotype as well as cytogenetic, molecular genetics and clinical features. Chromosomal rearrangements, detected in classical cytogenetic analyses and FISH have a significant impact on detecting and classifying type of AML as well as choice of treatment and determining prognosis. Both monosomy of chromosome 7 and KMT2A gene rearrangements are aberrations of remarkable prognostic value.

We present a case of 38-year-old male patient referred to Hematology Department with suspicion of AML. The bone marrow sample was aspirated with white blood cell count measuring 30x10³/μL. Classical cytogenetic analysis was performed according to the standard protocol. Patient's karyotype was

determined as: 45,XY,-7,t(9;11)(p21;q23)[19/20]/ 46,XY[1/20]. 90% of evaluated metaphases presented monosomy of chromosome 7 and translocation t(9;11)(p21;q23) resulting in fusion gene KMT2A-MLL3. Both aberrations were confirmed by FISH.

Monosomy of chromosome 7 occurring with translocation t(9;11)(p21;q23) is extremely rare in AML, with only few cases ever described. As both cell clones were assessed to be in a similar percentage, it was difficult to decide which one of them was the primary abnormality. It is problematic to predict the course of disease in our patient as monosomy of chromosome 7 is linked with adverse prognosis and this specific KMT2A-MLL3 fusion gene is a factor of moderate prognosis, contrary to majority of KMT2A rearrangements, correlated with poor outcome.

The concurrence of these two aberrations, differently affecting prognosis, poses a diagnostic and therapeutic challenge and requires further clinical and cytogenetic follow-up.

P07.03

A comprehensive next generation sequencing gene panel focused on unexplained anemia

F. E. Smith¹, D. Brawand¹, L. Steedman¹, M. W. Oakley¹, C. Wall¹, P. Rushton¹, M. Allchurch², K. Sibson³, C. Hemmaway², D. Rees⁴, S. Thein⁵, B. Clark¹;
¹Viapath at King's College Hospital, London, United Kingdom, ²Haematology, Queen's Hospital, Romford, United Kingdom, ³Haematology Department, Great Ormond Street Hospital, London, United Kingdom, ⁴King's College Hospital, London, United Kingdom, ⁵National Heart, Lung and Blood Institute/NIH, Bethesda, MD, United States.

Congenital anemia is difficult to diagnose once common causes have been excluded; for example 80% cases of congenital non-spherocytic hemolytic anemia are undiagnosed once pyruvate kinase and G6PD deficiencies have been excluded using phenotypic analysis. We describe a next generation sequencing strategy, targeting 147 genes, to facilitate the diagnosis of these conditions. The coding regions, splice sites and 200 bp into the untranslated regions were examined in each gene. All clinically significant variants were confirmed by Sanger sequencing, including confirmation in any appropriate family members.

Illumina MiSeq data was analysed using a bespoke bioinformatics pipeline, which has been validated to a UK certified standard. The pipeline implements detection of genetic variants using multiple base callers and discovery of copy number variants based on sequencing depth. Variants are annotated with information from ClinVar, and population frequency data (ExAC and 1000 genomes project). All genes are sequenced in every individual but data analysis can easily be restricted to virtual subpanels, excluding analysis of genes not requested. We present three cases; one hereditary pyropoikilocytosis, one congenital dyserythropoetic anaemia and one haemoglobinopathy due to a beta globin locus control region deletion; highlighting the diagnostic utility of the panel as well as the underlying bioinformatics analysis. Identifying pathogenic variants in unexplained anaemia cases is important as it facilitates prognosis and treatment, and allows prenatal diagnosis to be offered in future. To date the panel has assessed 35 cases of anemia with unknown cause and has made a definitive diagnosis in 29 (83%).

P07.04

MVK, NLRP3, TNFRSF1A and MEFV gene mutation profile of patients with autoinflammatory diseases: report of 286 pediatric patients from Northern Anatolia

E. Altundag¹, G. Ogur¹, U. Abur¹, H. Mutlu Albayrak¹, M. Celiksoy², A. Paul¹, M. Karadag¹, A. Yildiran²;
¹Ondokuz Mayıs University Medical Faculty Department of Genetics, Samsun, Turkey,
²Ondokuz Mayıs University Medical Faculty Department Of Pediatric Allergy And Immunology, Samsun, Turkey.

INTRODUCTION: The spectrum of MEFV, TNFRSF1A, MVK and NLRP3 gene mutations of autoinflammatory diseases in different ethnic groups is yet not fully studied. Here we present results from 286 pediatric patients from Northern Turkey.

MATERIAL-METHOD: MEFV (exons 2,3,5,10), TNFRSF1A (exon 2-7), MVK (exon 2-11) and NLRP3 (exon 3) were sequenced in 286 pediatric patients. Two groups were studied: one included 194 patients with AID and the other, 92 FMF patients without MEFV gene mutations (FMF-WT).

RESULTS: In AID group, 10% NLRP3, 6% TNFRSF1A, 21% MVK and 32% MEFV mutations were detected. Overall mutation rate was %38; the rate was 3% for pathological mutations.

In FMF-WT group, 20% NLRP3 and 29% MVK mutations were detected. When Tell-Hashomer criteria was included, 36% patients yielded NLRP3 mutations (no mutation for TNFRSF1A). Overall mutation rate was %41 and pathological mutation, was %3.

MEFV sequencing in AID yielded mutations in %32 patients (34% M694V, 17% E148Q, 13% V726A, 9% M680I, 7% P369S, 20% others).

Briefly, 118 out of 286 patients (41%) yielded mutations including low pe-

netrance variants. 9 (3%) showed pathological mutations (five V377I heterozygous, one heterozygous N205S c.614A>G novel mutation for MVK; two I313V mutations for NLRP3 and one N116S mutation for TNFRFS1A). DISCUSSION: This is the first study relevant to MEFV, NLRP3, MVK and TNFRFS1A gene mutation profile in pediatric AID from Turkey. The results are similar to studies in literature in terms of distribution of all variants. However lower rates were observed for pathological mutations. Mutation spectrum was also limited in our study.

P07.05

Effects of gliadin and genetic background in tight junction structure integrity

A. Jauregi-Miguel¹, I. Santin², K. Garcia-Etxebarria¹, I. Romero-Garmendia¹, L. Plaza-Izurrieta¹, J. Bilbao¹;

¹University of Basque Country, Leioa, Spain, ²BioCruces Research Institute, Barakaldo, Spain.

Tight junction structures (TJ) are crucial for intestinal epithelium homeostasis as they control the paracellular flux and maintain the apico-basal polarity of intestinal cells. In celiac disease (CD), disrupted barrier function and increased paracellular permeability are observed, and these could be due to TJ disassembly caused by gliadin-induced innate and adaptive immune responses. Gene expression analysis showed a deregulation of TJ-related pathways in small intestinal mucosa in CD and interestingly, altered expression of several genes including TJP1 (TJ assembly), INADL (apico-basal polarity) and PPP2R3A (negative control of cell growth and division) were not reversed after >2 years on gluten free diet, suggesting genetic involvement. To determine the effect of gliadin and the genetic background on epithelial barrier integrity, we performed functional and expression studies in an intestinal epithelium model, the Caco-2 subclone C2BBE1. Incubation with pepsin-trypsin digested gliadin (PTG) for 4 hours was able to inhibit the formation of cell monolayers but not to disrupt the integrity of those previously formed. When genes crucial for TJ formation were silenced by siRNA, PTG stimulation resulted in the alteration of the TJ pathway and other connected networks, specially Toll-like receptor signaling. Downregulation of central genes in the TJ pathway (TJP1, TJP2 or TJP3) resulted in increased expression of several chemokines. Constitutive altered expression of TJ genes in CD might result in an immature gut barrier that could in turn enhance CD-related gliadin toxicity and result in the activation of proinflammatory cytokine response.

P07.06

Ancestry-based stratified analysis of Immunochip data identifies novel associations with celiac disease

K. Garcia-Etxebarria¹, A. Jauregi-Miguel¹, I. Romero-Garmendia¹, L. Plaza-Izurrieta¹, M. Legarda², I. Irastorza², J. Bilbao¹;

¹University of Basque Country, Leioa, Spain, ²Cruces University Hospital, Barakaldo, Spain.

Celiac disease (CD), an autoimmune disorder affecting 1% of the population, is triggered by gluten in genetically susceptible individuals. At least half of the genetic component of CD remains unknown and the functional consequences of associated SNPs are still unclear. To identify candidate genes in CD, we reanalyzed the whole Immunochip CD cohort (139,553 SNPs; 12,041 cases and 12,228 controls) using a new approach that clusters individuals based on immunoancestry prior to disease association analysis, corrected by stratification of those 30 immunogroups. We detected 636 new associated SNPs ($p < 7.02E-07$) located in 5 novel genomic regions. To test whether we could identify putative candidate genes, we performed expression analyses of genes from the top novel region (chr2:134533564-136169524), an extended locus and a gene marked by an isolated SNP, in duodenum biopsies of active and treated CD patients and non-celiac controls. In the novel region, CCNT2 and R3HDM1 were constitutively underexpressed in disease, even after gluten removal. Moreover, several genes within this region were coexpressed in patients, but not in controls. Other novel genes, like KIF21B, REL and SORD showed altered expression in active disease. Apart from the identification of novel CD loci, these results suggest that ancestry-based stratified analysis is a useful approach for association studies in complex diseases.

P07.08

Molecular analysis of 29 prevalent translocations and agent of acute leukemia in patients with blood cancer

F. Ghasemian Sorbeni¹, E. Sakhinia², A. Esfahani³, S. Montazersaheb⁴, N. Karimi ansari⁵, A. Anarini⁵;

¹Department of Genetics Ahar branch, Islamic Azad university, Ahar, Iran, Islamic Republic of, ²Connective Tissue Disease Research Center, Department of Medical Genetics, Tabriz University of Medical Sciences, Tabriz, Iran, Islamic Republic of, ³Hematology and Oncology Research Center, Shahid Ghazi Hospital, Tabriz University of Medical Sciences, Tabriz, Iran, Islamic Republic of, ⁴Stem Cell Research Center, Tabriz University of Medical Sciences, Tabriz, Iran, Islamic Republic of, ⁵Tabriz Genetic Analysis Center (TGAC), Tabriz University of Medical Sciences, Tabriz, Iran, Islamic Republic of.

Introduction: Chromosomal translocations are major portion of molecular rearrangement that detected on leukemic subtypes and depending on type of fusion genes, involved in the leukemogenesis. Therefore, accurate screening of this rearrangements is very important in leukemia type identification and appropriate therapeutic approaches.

Materials and Methods: To identify chromosomal rearrangements in patients with acute myeloid leukemia (AML) and acute lymphoblastic leukemia (ALL), we used a multiplex RT-PCR protocol in which more than 80 chromosomal breakpoint containing different variants of 29 prevalent translocations were monitored. Of note, a deletion and one duplication, in 8 parallel nested-PCR reactions, in the presence of optimized primers was also assessed. Results: In a retrospective analysis on pooled samples from 20 afflicted AML and ALL patients, at least one chromosomal rearrangement was detected by multiplex RT-PCR in 50% of AML and 45% of ALL cases. The efficiency of multiplex RT-PCR method used here was investigated by analysis of available cell lines as positive control for translocations and sequencing of PCR products.

Conclusions: Here, we notified that the use of multiplex RT-PCR method could promisingly identify the molecular abnormalities involved during translocation of either AML or ALL patients. Another prominent of this method is that even in low amount of sample can be considered as a potential diagnostic method.

P07.09

Identification of congenital blood chimerism in one of the Chinese fraternal twins with mix-filed agglutination in ABO blood grouping

X. Ye, G. You, J. Wang, Q. Fu;

Shanghai Children's Medical Center, Shanghai, China.

Introduction: Chimeras are defined as individuals whose cells are derived from two or more zygotes. Here we report a case of congenital blood chimerism identified by implementing various genotyping technologies in a Chinese patient.

Materials and Methods: The patient with ventricular septal defect from Shanghai Children's Medical Center was one of fraternal twins and had no history of transfusion and transplantation. Blood grouping was performed with standard gel centrifugation test cards. ABO genotyping was determined with polymerase chain reaction followed with direct sequencing and clone sequencing. Short tandem repeats analysis was further performed on the blood sample.

Results: The patient's red cells were mix-filed agglutination with anti-A antibody, which showed a double populations of O and A red blood cells, whereas his parents were normal type B and type A respectively. Molecular typing showed that normal B101/002 and A102/001 genotypes were identified in his parents respectively, however, the patient exhibited the A102,001,002 three alleles. Moreover, short tandem repeats analysis of the patient revealed three alleles for D5S818, D2S1338, D19S433, vWA, D12S391 and D18S51 loci. We hypothesized that an exchange of blood cells between the fetuses occurred in utero and the additional alleles were contributed by his twin sibling.

Conclusions: Using various molecular methods, we identified the blood chimerism in a Chinese patient and provided a basis for further study of this case. Our research also implicated that performing genotyping techniques could reveal the genetic background of blood chimerism and take a deep understanding of the rare case of tetragametic chimerism.

P07.11

Cytokine Genes Polymorphisms and Susceptibility to Upper Respiratory Tract Infections and Otitis Media in childhood

O. Miljanovic¹, S. Teofilov¹, D. Likić², Z. Magić³, B. Cikota-Aleksić⁴;

¹Centre for medical genetic and immunology, Clinical centre of Montenegro, Podgorica, Montenegro, ²Institute for Public Health of Montenegro, Podgorica, Montenegro,

³Institute of Medical Research – Military Medical Academy, Belgrade, Serbia, Belgrade, Serbia, ⁴Institute of medical research – Military Medical Academy, Belgrade, Serbia, Beograd, Serbia.

Introduction: Frequent upper respiratory tract infections (URI) and development of susceptibility to URI in childhood, results from complex interactions among host genetic factors, exposure to pathogens, and environmental influences. The goal of this study was to investigate the association of single-nucleotide polymorphisms (SNPs) in cytokine genes and susceptibility to URI in childhood.

Materials and Methods: The study enrolled 82 children susceptible to URI and OM and 61 children not susceptible to URI, as a control group, who were exposed to similar environmental/host risk factors (atopic manifestations, day-care attendance, passive smoking, breastfeeding). DNA of all children was studied for specific SNPs in cytokine genes. Genotyping for IL10 1082A→G, IL10 -3575T→A, TNFA -308G→A, IL2 -330T→G and IL6 -597G→A were performed on 7500 Real Time PCR System, using TaqMan pre-designed assays, while genotyping for CD14 -159C→T was performed by using PCR and restriction enzyme digestion with Hae III.

Results: The incidence of IL10 -1082 polymorphic genotypes (GA/GG) was significantly higher in children susceptible to URI and OM, than in control group (RR 1.145, 95 % CI 1.011-1.298; p=0.047). Children with high-producing IL10 -1082 (GA/GG) genotypes, exposed to passive smoking, day-care attendance, lack of breastfeeding and with allergic manifestations, were more likely to develop susceptibility to URI and OM.

Conclusion: This study pointed out that IL10 -1082 polymorphic genotypes (GA/GG) are associated with increased risk for susceptibility to URI and OM in childhood. Avoidance of environmental risk factors may modify the risk for URI and OM susceptibility children with IL10 -1082 polymorphic genotypes.

Erythrocytosis is a rare disorder characterised by increased red cell mass and elevated haemoglobin concentration and haematocrit. Several causative genes have been identified in pathways including oxygen sensing, erythropoiesis and oxygen transport. Despite screening for such genes, in many patients no causative variant is identified. In this study, we combined whole genome sequencing (WGS) and targeted next generation (NGS) sequencing approaches to identify novel genes for idiopathic erythrocytosis.

WGS was performed on samples from 10 idiopathic erythrocytosis patients as part of the WGS500 project resulting in 4 novel candidate genes for erythrocytosis, EPO, GF1b, KDM6A and BHLHE41 being proposed. In order to evaluate the likely pathogenicity of these, we sought to replicate these variants by screening a cohort of 125 patients using a custom targeted NGS panel comprising the exonic regions of 21 genes, including the 4 novel genes arising from WGS500, 8 known erythrocytosis genes and 9 others associated with relevant biological pathways.

As a result, 32 exonic rare variants across 36 patients (29%) were detected, of which 10 were known erythrocytosis-causing variants and 22 were novel variants, some with high likelihood of functionality, for which familial segregation, replication and functional studies are underway to further evidence of causality. Of particular interest is the discovery of an additional rare variant in EPO suggesting that this gene should be actively surveyed in idiopathic erythrocytosis patients. Finally we propose that the NGS panel could be used as a clinical tool, to improve accuracy of diagnosis of idiopathic erythrocytosis.

Clinical, genetic and biological characteristics of HbS_Oman: a severe unrevealed form of sickle cell disease

M. Al Awadi;

Genetics and Developmental Medicine Department, Sultan Qaboos University Hospital, Muscat, Oman.

Background: Hemoglobin Soman results from double mutations in the β globin chain; the classic β S mutation (β 6 Glu→Val), and a second mutation in the same chain (β 121 Glu→Lys) identical to that of HbOArab. In the literature only 6 carriers have been described. HbS-Oman carriers can have severe clinical presentation matching sickle cell disease.

Objective: Study the clinical pheno-genotype, and cell biology of both carriers of HbSOman and compound heterozygotes HbS-SOman.

Design/Method: A cross sectional study that includes all identified carriers of HbSOman and compound heterozygotes. Demographic and clinical phenotype data were collected, including family pedigrees that were tracked to the same grandmother indicating a founder effect. Hematological parameters and HPLC were performed.

Results: We identified 53 carriers, 27 males and 26 females and 6 HbS-SOman patients, 4 males and 2 females, age range between 2-75 years. Hemoglobin range was 7.5-14.7 g/dl (11.9±1.6), and SOman 9.5-25.3% (15.9±3.7) for carriers, while Hb ranged from 3.2-7.8 g/dl (5.2±2.4) and SOman 6-24.6% (11.6±6.6) for compound heterozygotes. Clinical severity index correlated with the SOman percent in the carriers with a cut-off value of 14% and with decreased production of α -chains due to deletional or non-deletional mutations; however, there were no such correlations in the compound heterozygotes who presented in early infancy with severe transfusion-dependence. Other genetic modifiers seem to have no effect.

Conclusion HbSOman is a severe form of SCD; carriers can be severely symptomatic and compound heterozygotes present as thalassemia major with early transfusion dependence. HSOman cells have increased sickling and hemolytic characteristics.

New Insights into the HLA-G Non-Coding Polymorphisms Affecting Expression Pattern and Clinical Outcome

C. Ribeyre¹, C. Picard^{1,2}, C. René³, L. Abi-Rached⁴, P. Gouret⁵, J. Paganini⁶, J. Di Cristofaro¹;

¹UMR7268 CNRS-AMU-EFS, Marseille, France, ²Immuno-genetics laboratory,

Etablissement Français du Sang Alpes Méditerranée, Marseille, France, ³Department of Immunology, CHRU de Montpellier, University Hospital Saint-Eloi, Montpellier, France,

⁴Aix Marseille Université, URMITE, UM63, CNRS 7278, IRD 198, INSERM 1095, Marseille, France, ⁵Xegen, Gémenos, France.

HLA-G is an immunotolerogenic molecule whose expression is modulated in pathological situations (cancers, infectious, inflammatory and autoimmune diseases). Higher HLA-G expression correlates with a reduction in transplant rejection. HLA-G displays a high level of polymorphism in its 5' and 3'untranslated regions, we previously showed that haplotypes formed by these SNPs can predict sHLA-G levels and lung transplantation outcome. Yet, the mechanisms modulating HLA-G expression or clinical outcome are not fully understood. The aim of this study is to predict transcription factor binding sites each haplotype. To fully characterize HLA-G variation in coding and untranslated regions, we typed 500 healthy individuals by NGS. Data were analyzed by the Xegen Company. Using all SNPs, including 19 SNPs in transcription factor-binding sites, we could define 35 haplotypes, 24 with estimated frequencies below 0.3%, and 11 with estimated frequencies above 1%, the latter representing 96% of the 1,000 haplotypes investigated and their structure was similar to previously observed. Analysis of transcription factor-binding site content revealed that all haplotypes carry multiple sites for SP1. Similarly, while all haplotypes display a progesterone receptor-binding site, a mutation in this region characterizes the haplotype associated with poor lung transplantation outcome. Other haplotypes displayed specific binding sites for Oct-1, C/EBP α , TEF-1, Elk or STAT. These results support that NGS technology offers a pertinent solution for complete HLA analysis in clinical context and that nucleotide variations in transcription factor-binding sites can account for the modulation of HLA-G expression and clinical outcomes.

Whole Exome Sequencing in a large cohort of patients affected with Inherited Thrombocytopenia

C. Marconi¹, R. Bottega², B. Serena³, F. Palombo¹, V. Bozzi², M. Faleschini⁴, D. DeRocco², C. Cagioni⁵, C. Gnan², P. Noris², A. Savoia^{4,2}, C. L. Balduini², A. Pecci³, T. Pippucci¹, M. Seri¹; ¹University of Bologna -Department of Medical and Surgical Sciences, Bologna, Italy, ²Institute for Maternal and Child Health – IRCCS Burlo Garofolo, Trieste, Italy, ³Department of Internal Medicine, University of Pavia-IRCCS Policlinico San Matteo Foundation, Pavia, Italy, ⁴Department of Medical Sciences, University of Trieste, Trieste, Italy, ⁵Department of Internal Medicine, University of Pavia-IRCCS Policlinico San Matteo Foundation, P, Italy.

Inherited Thrombocytopenias (IT) are a group of heterogeneous disorders caused by almost 30 genes. Although many genes have been identified since the introduction of Whole Exome Sequencing (WES), almost half of IT patients still remains without a molecular diagnosis. As IT are characterized by a wide genetic heterogeneity, identification of novel disease-genes is still challenging. In our cohort of 274 affected families characterized at the molecular level, 5 genes are responsible for about 50% of cases, while the remaining genes are responsible each for less than 2% of cases. To overcome this difficulty and describe novel IT genes, we performed WES in 107 patients (86 families) affected with autosomal dominant IT of unknown molecular origin. We compared the cumulative variant allele frequencies (sum of the allele frequencies of each variant) of each gene in our IT cases to that of a control cohort, consisting of the Exome Aggregation Consortium non-Finnish European samples (33.370 individuals) and we found 7 genes, affecting 22 families, significantly enriched in rare variants ($f < 1 \cdot 10^{-5}$) in IT cases. Two genes (ACTN1, ETV6) are known to be causative for IT. The identified variants was confirmed to be pathogenic through segregation analysis and functional studies. For the other 5 genes, which are novel candidate genes, segregation analysis and screening of further IT patients are ongoing. Conclusions: the availability of a large patients cohort can overcome the problems due to genetic heterogeneity and led to the identification of 5 strong candidate IT genes in our cohort.

P07.16

Evaluation of Micro particle Production by JAK2V617F positive the Endothelial Cells

H. Hekimoglu, I. Uslu, S. Sözer Tokdemir; *Institute of Experimental Medicine, Istanbul University, Istanbul, Turkey.*

Introduction: A cytoplasmic tyrosine kinase (JAK), is encoded by Janus Kinase 2 gene (JAK2), plays an important role in growth and differentiation of hematopoietic cells. A point mutation, characterized as V617F, is found mostly in Philadelphia-chromosome negative myeloproliferative neoplasms (MPN). Recently, micro particles (MP) were related with the thromboembolic complications. This study focuses on the role of JAK2^{V617F} in MP production from endothelial cells (EC).

Materials and Methods: Lentiviral vectors, carrying JAK wild type or mutant in addition to green fluorescent protein (GFP), were transfected to Human Embryonic Kidney cells by Lipofectamine. The viral particles were collected by ultracentrifugation and infected into Human Umbilical Vein EC. In order to isolate MPs, the infected EC culture supernatants were centrifuged and concentrated. The spectrophotometric evaluation of the MP was performed. After labeling of MPs with CD31, the flow-cytometry analysis were performed with applying 0.5-0.9 µm microbeads to set up MP gates.

Results: In this study, we have successfully infected the lentiviral vectors into EC. The analysis of the infected EC supernatants was demonstrated that the MPs were composed of RNAs. Labeling the MPs with EC marker CD31 revealed the origin MPs to be EC and both JAK2 and JAK2^{V617F} increased the MP production 2 fold compared to GFP control.

Conclusion: This study provides insight to understand the possible effects of JAK2^{V617F} on EC regarding to the MP production. Further studies might be helpful to understand the role of JAK2^{V617F} on EC and as well as the role of MPs for thrombus formation.

Resolving KIR genotypes and haplotypes simultaneously using Single-Molecule, Real-Time Sequencing

J. M. Ekholm¹, C. W. Pyo², K. Eng¹, R. Hall¹, C. Vierra-Green³, S. Spellman³, D. Roe⁴, D. E. Geraghty⁴, M. Maier⁵, S. Ranade⁵;

¹PacBio, Menlo Park, CA, United States, ²Clinical Research Division, Fred Hutchinson Cancer Research Center, Seattle, WA, United States, ³Center for International Blood and Marrow Transplant Research, Minneapolis, MN, United States, ⁴National Marrow Donor Program, Minneapolis, MN, United States.

The killer immunoglobulin-like receptors (KIR) genes belong to the immunoglobulin superfamily and are widely studied because of the critical role

they play in coordinating the innate immune response to infection and disease. Resolution of the complete KIR repertoire remains challenging as the region is repetitive and extremely polymorphic, both on the population and sequence level. All together, the KIR genes cluster spans ~150 kb of chromosome 19q13.4.

Highly accurate, contiguous, long reads, like those generated by SMRT Sequencing, when combined with target-enrichment protocols, provide a straightforward strategy for generating complete de novo assembled KIR haplotypes. Here we generated complete diploid haplotypes of the KIR region for 8 individuals on the PacBio RS II platform. The haplotypes ranged in size from 75 kb to 250 kb and captured complete, phased sequence information, with one exception in which a gap of 1 kb was found. This particular example was later determined to be the largest and most complex haplotype in the cohort. Large structural variations within the region were also observed, with two haplotypes showing deletions spanning both the centromeric and telomeric regions and one other haplotype containing a large tB01 insertion.

These data represent the first demonstration of de novo assembled KIR haplotypes derived from diploid human genomes using single-molecule sequencing. The resulting sequences demonstrate the extensive diversity and heterogeneity of the KIR region, which makes investigation into this locus uniquely suited for long-read single-molecule sequencing.

The characterization of KMT2A (MLL) chromosomal breakpoints

M. Macejova¹, L. Zejskova¹, R. Plachy¹, T. Jancuskova¹, D. W. Hardekopf², J. Stika¹, M. Ondrackova¹, N. Kosyakova², T. Liehr², A. Zavrelava², P. Zak³, V. Petecukova⁴, J. Novak⁴, T. Kozak⁴, S. Pekova¹, S. Pekova¹, M. Karas⁵;

¹synlab genetics s.r.o., Prague, Czech Republic, ²Institute of Human Genetics, Jena University Hospital, Jena, Germany, ³4th Department of Internal Medicine – Hematology, Charles University Hospital and Faculty of Medicine, Hradec Kralove, Czech Republic, ⁴Internal Clinic of Hematology University Hospital Kralovske Vinohrady, Prague, Czech Republic, ⁵Department of Hemato-oncology, University Hospital Plzen, Plzen, Czech Republic.

Introduction: Chromosomal rearrangements involving the human KMT2A gene (MLL, mixed lineage leukemia) are associated with development of acute leukemia. The presence of certain MLL rearrangements is an independent prognostic factor and patients are usually treated according to high-risk protocols. Minimal residual disease (MRD) detection provides an objective assessment of treatment response. However, MRD assays using MLL fusion transcripts as molecular markers usually do not provide sufficiently sensitive detection of residual leukemic cells.

Methods: For the identification of MLL breakpoint sequences we used two different approaches. First approach was long-range PCR followed by sequencing of the PCR products. Second approach included combination of conventional chromosome microdissection, next-generation sequencing and sequencing of the final PCR products. Leukemia/patient-specific sequences of the chromosomal breakpoint were used to develop MRD assays and enabled us to perform sensitive monitoring of MRD using qPCR in 9 acute leukemia patients.

Results: We identified unique breakpoint sequences in 9 patients with acute leukemia. Using first approach we detected MLL/AF6, MLL/AF9 (2 patients), MLL/AF10, MLL/ENL (2 patients) and MLL/ELL. Second approach was used for identification of MLL/AF10 and MLL/AF4 breakpoints. Identification of unique breakpoint sequences was followed by the design of sufficiently sensitive MRD assays. The MRD levels of residual leukemic cells correlated with clinical outcome.

Conclusion: MLL breakpoints could be identified by various methods (inverse PCR, panhandle PCR). Our results show other approaches for identification of unique MLL breakpoint sequences, which can be utilized for the design of the leukemia-specific assay for MRD monitoring in patients with acute leukemia.

P07.19

The role of partially methylated domains in normal and neoplastic hematopoietic cells

A. Merkel¹, M. Durran Ferrer², J. I. Martín-Subero², S. C. Heath¹, the BLUEPRINT consortium;

¹Centro Nacional d'Anàlisi Genòmica (CNAG-CRG), Barcelona, Spain, ²Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain.

Leukemia is the 12th most common cancer in Europe, affecting approximately 13 in 100000 people. As part of the European epigenome project BLUEPRINT, we have recently conducted a survey of DNA methylation in over 170 samples from diverse hematopoietic cell types including various leukemia subtypes.

Globally, we find that cells of the lymphoid lineage modulate their methylation more than those of the myeloid lineage. Although many sites of dynamic DNA methylation coincide with tissue specific regulatory regions, a significant proportion (particularly in terminally differentiated lymphoid cells) is associated with large partially methylated domains (PMDs) - a tendency that is amplified in the related malignancies.

They appear compact heterochromatin, associated with repressive histone marks, low transcriptional activity and late replication timing. At the same time, these regions coincide with active regions of open chromatin in embryonic stem cells, indicating that they might have originated from areas under 'lockdown' from the pluripotent state to ensure cell fate.

We propose that PMDs represent higher order chromatin structures that are established early during lymphoid differentiation as part of lineage commitment. Over time and with increasing number of cell replications these regions experience passive loss of methylation ultimately forming large domains of low and intermediate methylation. We find that in lymphoid leukemias these regions are further enlarged and contribute to low global methylation, presumably caused by the high proliferation rate that is a hallmark of most cancers. As such, we believe the chromatin structures underlying PMDs are of significant importance for cell identity and integrity.

MonoMac syndrome, a rare cause of neutropenia

M. T. Bataneant, Maria Puiu, Patricia Urtila, Mihaela Baica, Mihaela Lelik, Maria Pop, Margit Serban, M. Puiu, P. Urtila, M. Baica, M. Lelik, M. Pop, M. Serban; University of Medicine and Pharmacy, Timisoara, Romania.

Introduction. Congenital neutropenias usually are characterized by bacterial recurrent severe infections but chronic viral infection is not a part of the clinical picture of this group of rare diseases.

Case presentation. A male without significant family history of chronic infections or malignancy, who had at 4 years of age generalized warts with an evolution of 4 years was diagnosed accidentally at 11 years of age with mild neutropenia (700/mm³) and mild decreased platelet count (130.000/mm³). Bone marrow aspiration showed normal cellularity without any dysplastic feature. He was treated with Prednisone and G-CSF without response. Secondary causes of neutropenias were excluded by absence of drug administration history, negative serology for HBV, HCV, HIV, CMV, EBV and negative ANA, dsDNA, ANCA antibodies. Immunologic tests showed IgA=0,46g/l (0,7-4,32), IgG=6 g/l (6,44-11,96), IgM=2,12 g/l (0,52-3,57), B1f=270 (300-500), T1f=2548 (1400-2000), CD4+=1093 (700-1100), CD8+=1381 (600-900), NK=79 (200-300). WHIM syndrome was suspected but no mutation in CXCR4 gene was founded. Vinh described in 2010 a new disease-MonoMac syndrome, characterized by monocytopenia with mycobacterial and viral infection caused by mutation in GATA2 gene. Reanalyzing the hemoleucogram we founded persistent decreased count of monocyte cells < 100/mm³. The genetic test identified mutation c.1192 C>T R398W in GATA2 gene.

Conclusion: Even if neutropenia is not a part of the clinical definition of the MonoMac syndrome, we must think to it when neutropenia is associated with chronic viral infection and low count of monocyte cell. 50% of these patients will develop myelodysplastic syndrome and myeloblastic leukemia, so bone marrow transplantation is indicated before developing of these complications.

P07.21

Skin lesions and arthralgias in a large pedigree with a partially anakinra-responsive and possibly IL-18 driven NLRC4-related autoinflammatory disease

N. M. L. Volker-Touw¹, H. D. de Koning², T. van Kempen³, K. Oberndorff⁴, J. Giltay¹, C. G. F. de Kovel¹, M. Boes⁵, M. A. M. van Steensel⁶, G. T. J. van Well⁷, A. Simon⁸, J. Frenkel⁹, M. E. van Gijn¹;

¹Department of Genetics, University Medical Center Utrecht, Utrecht, Netherlands, ²Dept. of Dermatology, Radboud University Medical Center, Nijmegen, Netherlands, ³Dept. of Rheumatology and Clinical Immunology, University Medical Center Utrecht, Utrecht, Netherlands, ⁴Dept. of Pediatrics, Atrium-Orbis Medical Centre, Sittard, Netherlands, ⁵Dept. of Pediatric Immunology and Laboratory of Translational Immunology (LTI), University Medical Center Utrecht, Utrecht, Netherlands, ⁶Dept. of Dermatology, Maastricht University Medical Center, Maastricht, Netherlands, ⁷Dept. of Pediatrics, Maastricht University Medical Center, Maastricht, Netherlands, ⁸Dept. of General Internal Medicine, Radboud University Medical Center, Nijmegen, Netherlands, ⁹Dept. of Pediatrics, University Medical Center Utrecht, Utrecht, Netherlands.

Autoinflammatory disorders (AID) are characterized by chronic or recurrent systemic sterile inflammation. It is a genetically heterogeneous group of diseases. Recently, gain of function mutations in *NLRC4* have been described to be associated with AID.

We performed whole exome sequencing in the members of a large 6 generation pedigree with a hitherto unknown AID. Medical data were collected retrospectively. IL-1 β and IL-18 concentrations were analyzed in plasma. Skin biopsies were obtained of lesional and uninvolved skin from three patients for routine histology and immunohistochemical staining of IL-1 β and IL-17. Exome sequencing revealed a novel heterozygous c.1333T>C p.(Ser445Pro) variant in *NLRC4*. The variant segregated with the 13 affected family members (LOD-score 3.58). Prediction software programs (Sift, Polyphen) indicated pathogenic properties. Moreover the variant is located next to the recently described p.(His443Pro) pathogenic mutation. In affected family members, the clinical phenotype was influenced by weather conditions, stress, and infection. Severity of the clinical phenotype varied considerably. In a subset of the patients, the clinical symptoms resolved promptly after anakinra treatment, while other patients responded only partially. Biopsies of lesional skin showed a unique lymphocytic-histiocytic infiltrate in the dermis, unlike the histology of previously described autoinflammatory skin disease. Plasma concentrations of IL-18 were extremely elevated in all patients, even without an inflammatory episode (median 4,324 pg/ml; ref. 0-34 pg/ml).

In conclusion, in this study we describe a novel variant in *NLRC4* in a large pedigree with a partially anakinra-responsive AID, and expanded the clinical phenotype associated with *NLRC4*-inflammasome mediated AID.

P07.22

Physiological repression of PARP1 transcription during pro-inflammatory macrophages development results from differentiation-associated cell cycle arrest in G0/G1 phase

A. Robaszekiewicz, E. Wisnik;

University of Lodz, Institute of Biophysics, Department of Environmental Pollution Biophysics, Lodz, Poland.

ADP-ribosylation - post-transcriptional modification of proteins carried out by PARP1 is capable of shifting gene expression up and down. In human pro-inflammatory macrophages (M1) PARP1 acts as a repressor of genes encoding cytokines and as indicated in our study the differentiation process of CD34+ hematopoietic stem cells and premonocytic cell line THP1 into macrophages is associated with the loss of PARP1. Therefore, we searched for the mechanism responsible for PARP1 repression during pro-inflammatory macrophage development. The differentiation of HSC and THP1 was induced with GM-CSF and PMA, respectively. The expression of PARP1 was determined with real-time PCR and western blot. The contribution of miRNA was verified using Ago2 inhibitor - aurintricarboxylic acid, RNA synthesis was monitored with nascent RNA capturing, cell cycle was analyzed with flow cytometry. Chromatin association with transcription factors was monitored with ChIP.

The reduction of PARP1 protein in macrophages results from transcription repression of PARP1 gene as these cells demonstrate lower Pol2 occupancy around TSS and de novo synthesis of PARP1 mRNA. Moreover, Ago2 inhibitor failed to rescue PARP1 decrease indicating that miRNA does not contribute to mRNA degradation. The treatment of proliferating macrophage precursors with mimosine, which mimicks differentiation-induced cell cycle arrest in G0/G1 phase, triggered comparable decrease in PARP1 expression. Further analysis revealed the cell cycle-dependent modulation of Sp1 interaction with PARP1 promoter as a mechanism responsible for the differentiation-induced PARP1 transcriptional repression.

Acknowledgements: The study was funded by Polish National Science Centre grant UMO-2013/11/D/NZ2/00033.

P07.23

A Phelan-McDermid syndrome case with immunological findings

A. G. Zamani¹, E. H. Sayar², S. G. Güner², M. S. Yıldırım¹, & Reislif²;

¹Necmettin Erbakan University, Meram Medical Faculty, Department of Medical Genetics, Konya, Turkey, ²Necmettin Erbakan University, Meram Medical Faculty, Department of Pediatric Immunology, Konya, Turkey.

Phelan-McDermid syndrome (PHMDS) can be caused by a heterozygous contiguous gene

deletion at chromosome 22q13. At least 500 cases of 22q13.3 deletion syndrome are known. Characteristic signs and symptoms of the syndrome include normal to accelerated growth, moderate to profound intellectual disability, decreased muscle tone (hypotonia), and absent to severely delayed speech.

A 15-year-old speechless, mentally deficient, unable to walk male underwent genetic evaluation. He had no eye contact. Clinical examination showed a small forehead, long eyelashes, epicanthal folds and lowset ears, large and broad hands and feet with short terminal phalanges. The brain

MRI indicated thinning of the corpus callosum (between the body and the splenium), widespread cortical atrophy and dilation of the lateral ventricles, mild widespread reduction of the white matter. We can not get metaphase peripheral blood culture. Then cytogenetic analysis were performed from fibroblast cultures. FISH was performed with DiGeorge/VCFPS Probe TUPLE1(22q11.2)/ARSA control probe (22q13.3) (Cytocell,UK). The ARSA (control) probe (22q13.3) did not hybridize and the diagnosis of the 22q13 deletion syndrome was confirmed. Although there is no history of frequent infections, all of immunoglobulin levels, except IgE, revealed to be markedly decreased. Besides, lack of memory B cells, total T and helper T lymphocyte ratio were also found lower than normal from immunological analysis of peripheral lymphocyte by flow cytometry. In this report, the remarkable clinical and immunologic findings were presented and discussed in detail.

P07.24

Exome sequencing of 160 patients with primary immunodeficiencies: translational genomics with direct clinical implications

P. Arts¹, A. Simons¹, E. Yilmaz², A. R. Mensenkamp¹, W. A. van Zelst-Stams¹, M. van Deuren³, M. van der Flier⁴, A. Simon³, J. A. Veltman¹, F. L. van de Veerdonk⁴, A. Hoischen¹, M. G. Netea³;

¹Department of Human Genetics, Radboud University Medical Center, Nijmegen, Netherlands, ²Department of Medical Biology, Faculty of Medicine, Akdeniz University, Antalya, Turkey, ³Department of Internal Medicine and Radboud Center for Infectious Diseases, Radboud University Medical Center, Nijmegen, Netherlands, ⁴Department of Pediatric Infectious diseases, Department of Pediatrics, Radboud University Medical Center, Nijmegen, Netherlands.

Introduction: Primary immunodeficiencies (PIDs) are severe medical conditions caused by non-redundant defects of innate or adaptive immune responses, leading to recurrent, severe infections. Severely affected PID patients with an unknown genetic defect were selected for diagnostic exome-sequencing.

Methods: 160 PID cases were included in this study. First, variation in 294 genes known to cause PIDs are studied using an *in silico* filter during exome data-analysis. Next, 102 patients without a genetic diagnosis after step 1 gave permission for exome-wide analysis of the data. In selected cases *in vitro* stimulations of identified cytokine production capacity defects and provided additional functional evidence for the diagnosis.

Results: Diagnostic exome analysis revealed (likely) pathogenic mutations in known PID genes in 32 cases (20%). Exome-wide analysis led to identification of additional causative mutations in 10 cases, for which underlying genes have a known role in specific immunological pathways. One example with direct clinical implication of this approach was the characterization of the genetic, and functional defects in 3 patients with autoimmune lymphoproliferative syndrome type V and (*de novo*) *CTLA4* mutations. Several studies suggest abatacept as treatment for patients with *CTLA4* deficiency. **Conclusion:** Exome sequencing can provide a genetic diagnosis in a significant number of patients with PIDs. It is important to perform exome-wide analyses after an analysis of the known PID genes because many new PID genes are only just being discovered. The molecular diagnosis provided novel insight in therapeutic options for a subset of our patients.

P07.25

Enrichment of rare disease causing variants in population isolates: the Finnish Disease Heritage example

¹Institute for Molecular Medicine Finland (FIMM), Helsinki University, Helsinki, Finland, ²Department of Internal Medicine, Oulu University Hospital, Oulu, Finland, ³Department of Internal Medicine, Kuopio University Hospital, Kuopio, Finland, ⁴Department of Internal Medicine, Tampere University Hospital, Tampere, Finland, ⁵Department of Virology, University of Tampere, School of Medicine, Tampere, Finland, ⁶Children's Hospital, Helsinki University Central Hospital, University of Helsinki, Helsinki, Finland, ⁷Helsinki University Hospital, Helsinki, Finland, ⁸Hematology Research Unit, Biomedicum Helsinki and Hematology Division, Comprehensive Cancer Center, University of Helsinki and Helsinki University Hospital, Helsinki, Finland, ⁹Program in Medical and Population Genetics, Broad Institute of MIT and Harvard, Cambridge, MA, United States, ¹⁰Rare Disease Center, Children's Hospital, University of Helsinki and Helsinki University Hospital, Helsinki, Finland, ¹¹Adult Immunodeficiency Unit, Inflammation Center, University of Helsinki and Helsinki University Hospital, Helsinki, Finland.

The correlation between the genetic structure of the population and the distribution of genetic disorders supports a population perspective in medical genetics, especially in the field of rare monogenic disorders. The benefits are even higher if applied to population isolates.

Finland presents a characteristic population history with a restricted number of founders, isolation, several population bottlenecks, and recent expansion

of the population. This has led to the enrichment of some deleterious variants and loss of others, creating a phenomenon called the Finnish Disease Heritage (FDH).

By definition, FDH disorders are more frequent in Finland than elsewhere. Within each disorder the majority (if not all) of the Finnish patients share the same founder Fin_{major} mutation, again over-represented in Finland. Nonetheless, FDH disorders are rare (1:10,000-1:100,000). Today, FDH comprises 36 disorders (32 autosomal recessive, two autosomal dominant, and two X-chromosomal) with a disease spectrum spreading to all branches of medicine, but more consistently in pediatrics. Some FDH disorders can be effectively treated, assuming the correct diagnosis has been performed.

Investigating by whole-exome sequencing the molecular defects behind rare immune disorders in Finnish patients, we identified rare homozygous FDH Fin_{major} variants in the *CUBN* (megaloblastic anemia) and *RECQL4* genes (Rapidilino syndrome).

In addition, we found a previously known disease-associated *AICDA* variant causing primary antibody deficiency (HIGM2) as part of a founder haplotype. The variant is strongly enriched in Finland (~38.5 fold) compared to other populations with European ancestries, suggesting it as a potential Fin_{major} mutation and HIGM2 as a newly found FDH disorder.

P07.26

Functional study of Peptidylarginine deiminase type 4 as a genetic risk factor for Rheumatoid arthritis

A. Suzuki¹, Y. Kochi¹, H. Matsumura¹, E. Kanno¹, K. Yamamoto^{1,2};

¹RIKEN, Yokohama, Japan, ²Univ. of Tokyo, Tokyo, Japan.

Rheumatoid arthritis (RA) patients frequently have autoantibodies to citrullinated peptides, suggesting the involvement of the citrullinating enzymes, peptidylarginine deiminases (PADIs), in RA. Previous linkage studies showed that a RA-susceptibility locus included four PADI genes, however it was not clear which PADI gene confers RA susceptibility. Peptidylarginine deiminase type 4 (PADI4) was identified as a susceptibility gene for RA in a trans-ethnic meta genome-wide association study (GWAS). PADI4 is one of the PADI gene family and converts arginine residue to citrulline residue. PADI4 is highly expressed in immune tissues and cells, especially bone marrow, macrophages, neutrophils and monocytes. Peptidylcitrulline is an important molecule in RA, because it is an antigen of ACPA and only PADI enzymes (translated protein from PADI genes) can provide peptidylcitrullines by modification of protein substrates. To understand the importance of PADI4 gene in the progression of RA, we used *Padi4*^{-/-} mice and showed that PADI4 is significantly affected to progress of collagen induced arthritis (CIA) RA model mice. In *Padi4*^{-/-} CIA mice sera, the concentrations of serum anti-CII IgM, IgG, and levels of inflammatory cytokines decreased significantly rather than in WT CIA mice. We demonstrated that *Padi4* expression was induced by CII immunization. In *Padi4*^{-/-} mice, inflammatory cytokine levels were significantly decreased compared with those in wild-type mice. Interestingly, *Padi2* expression was induced in immune cells of *Padi4*^{-/-} mice in compensation for the defect in *Padi4*. As the results, we suggested that PADI4 enhanced collagen-initiated inflammatory responses.

P07.27

Newborn screening for severe combined immunodeficiency (SCID) using T-cell receptor circles (TRECs) and high-throughput sequencing (HTS).

J. M. Strand¹, K. Gu², T. G. Abrahamsen^{2,3}, E. Lundman¹, H. Gaup¹, H. Erichsen², T. Øverland², A. Rønnestad², T. E. Hartmann Bjørndalen⁴, H. S. Sorte⁵, T. Tangeraas^{1,2}, J. Jørgensen¹, C. L. Salvador^{1,6}, A. D. Rowe^{1,6}, T. Rootwelt^{1,2}, R. D. Pettersen¹, A. Stray-Pedersen¹;

¹Norwegian National Unit for Newborn Screening, Division of Paediatric and Adolescent Medicine, Oslo University Hospital, Oslo, Norway, ²Department of Paediatrics, Division of Paediatric and Adolescent Medicine, Oslo University Hospital, Oslo, Norway, ³Institute of Clinical Medicine, University of Oslo, Oslo, Norway, ⁴Department of Obstetrics and Gynecology, Women's Division, Division of Paediatric and Adolescent Medicine, Oslo University Hospital, Oslo, Norway, ⁵Department of Medical Genetics, Oslo University Hospital, Oslo, Norway, ⁶Department of Medical Biochemistry, Oslo University Hospital, Oslo, Norway.

Introduction: Children with SCID are apparently healthy at birth, but may acquire life-threatening infections during first months of life. Newborn screening (NBS) for SCID was started as a prospective research project based on informed, written consent in 2015. We are also conducting a retrospective study using samples from patients with known immunodeficiencies to test cut-off values and 2nd tier HTS sequencing.

Materials and Methods: TRECs are analyzed by RT-PCR in DNA extracted from the same dry blood spot card as the ordinary NBS program. Cut-off was set to 40 TREC/ μ l, and only samples under cut-off and with normal β -actin

levels are positive on the 1st tier. 2nd tier testing of known immunodeficiency genes using the IonAmpliSeq PID panel on Ion Torrent PGM is performed to increase positive predictive value.

Results: Of the 720 children tested so far, the average level is 250 TREC/ μ l. 11 samples, all from NICU patients, have fallen below cutoff, without suspicion of a SCID diagnosis. In the retrospective project, screening samples from 7 patients with known immunodeficiency due to defects in IL2RG, JAK3, IL7R, PGM3, LIG4, RECQL4 and ADA had TRECs of 0, 0, 0, 11, 0, 60, and 0/ μ l, respectively. 2nd tier HTS was able to confirm the molecular alterations in 5,5 of the 7. The PID gene panel lacked coverage of the remaining mutations, and needs refinement before implementation.

Conclusion: TRECs as 1st tier, and HTS SCID gene panel as 2nd tier, promise rapid detection of newborns with SCID and other severe T-cell deficiencies.

P07.28

High-throughput multiplexed digital droplet PCR for detection of severe combined immunodeficiency in newborn screening

N. Vidal-Folch, D. Milosevic, R. Majumdar, D. K. Gavrilov, D. Matern, K. Raymond, P. Rinaldo, S. Tortorelli, R. S. Abraham, D. Oglesbee; Department of Laboratory Medicine and Pathology, Mayo Clinic College of Medicine, Rochester, MN, United States.

Introduction: Measurement of T-cell receptor excision circles (TREC) is widely used for detection of Severe Combined Immunodeficiency (SCID) in newborn screening programs (NBS). Currently, qPCR is predominantly used to quantify TREC in dried blood spots (DBS). qPCR requires normalization to controls and is susceptible to variations in amplification efficiency. We evaluated digital droplet PCR (ddPCR) as a novel method for SCID detection. Materials and Methods: DNA was extracted from one 3mm DBS punch using wash steps and denaturation at 99°C. Simultaneous quantification of TREC and RNaseP (internal control) was performed using AutoDG and QX200 ddPCR Bio-Rad system. A total of 10 diagnosed patient DBS (1 X-linked SCID, 1 RAG1 Omenn syndrome, 2 idiopathic T-cell lymphopenia (iTCL), 1 chr22q11.2 deletion negative TCL, 2 DiGeorge syndrome, 1 CHARGE syndrome, 1 ataxia telangiectasia and 1 cartilage hair hypoplasia) and 80 normal DBS (age \leq 7days, gestational age \geq 36weeks) were screened for TREC levels. Results are expressed in TREC/ul blood.

Results: All previously diagnosed patient DBS were confirmed to contain \leq 15 TRECs. Normal DBS ranged 46-276, average of 132 TRECs. Dilution experiments showed LLOQ at 14 TRECs. LOD was 11 TRECs. Precision experiments showed $<20\%$ CV for intra-assay (at 54 TRECs) and inter-assay (at 60 TRECs) reproducibility. A reference range study is currently ongoing.

Conclusions: We have developed a highly sensitive and accurate multiplexed ddPCR method for absolute quantification of TREC in DBS without the need for standard curve. The method is cost-effective, high-throughput and suitable for NBS testing.

P07.29

Altered expression of DNA repair enzymes involved in molecular signaling pathway dependent on p53 in systemic lupus erythematosus

M. D. Olivares^{1,2}, J. Perez-Hernandez^{1,2}, V. Lendinez-Tortajada¹, M. J. Forner², F. J. Chaves^{1,3}, J. Redon^{2,4}, R. Cortes^{1,2};

¹Genotyping and Genetic Diagnosis Unit, INCLIVA Biomedical Research Institute, Valencia, Spain, ²Cardiometabolic and Renal Unit, INCLIVA Biomedical Research Institute, Valencia, Spain, ³CIBER of Diabetes and Associated Metabolic Diseases (CIBERDEM), Institute of Health Carlos III, Barcelona, Spain, ⁴CIBER Physiopathology of Obesity and Nutrition (CIBEROBN), Institute of Health Carlos III, Madrid, Spain.

Introduction: In systemic lupus erythematosus (SLE) apoptosis is thought to be defective, producing increased extracellular DNA and dsDNA antibodies. The p53 pathway is crucial in apoptosis regulation. We investigated if expression of enzymes (OGG1 and SIRT1) and transcription factor (FOXO1) involved in p53 pathway were altered in SLE, and associated with immune activation.

Material and Methods: We studied 32 SLE patients (10 with active lupus nephritis (LN), 12 with inactive LN, and 10 SLE in absence of LN); and 20 healthy controls. The mRNA levels for p53, SIRT1, OGG1 and FOXO1 were quantified by RT-qPCR in the urinary cellular pellet.

Results: Urinary mRNA levels of p53, OGG1 and FOXO1 were significantly diminished in active LN ($p<0.01$, $p<0.01$ and $p<0.05$, respectively), whereas in the other patient groups were similar to control group. However, the expression of SIRT1 in the urinary sediment had a significant increase ($p<0.01$) in active group compared to controls. Furthermore, the three patient groups showed an inverse correlation between FOXO1 and OGG1 mRNA levels with antibodies anti-dsDNA ($r=-0.47$ and $r=-0.55$, $p<0.01$), and Systemic Lupus Activity Index (SLEDAI) ($r=-0.22$ and $r=-0.41$, $p<0.05$). Whereas urinary expression of SIRT1 had a direct correlation with anti-dsDNA ($r=0.87$,

$p<0.001$) in active LN.

Conclusions: These data show a transcriptional dysregulation in DNA repair enzymes SIRT1 and OGG1, and transcription factor FOXO1 involved in the p53 molecular pathway in SLE patients. In addition, mRNA quantification in the urinary sediment could be a non-invasive method to establish its association with the renal impairment in SLE.

P07.30

Screening of KLF1 gene variants in cases with increased levels of fetal hemoglobin

A. Karamani¹, **C. Chassanidis**², E. Boutou², E. Voskaridou³, A. Balassopoulou²; ¹School of Biology, National and Kapodistrian University of Athens, Athens, Greece, ²Molecular Genetics Laboratory, Thalassemia and Hemoglobinopathies Center, Laiko General Hospital, Athens, Greece, ³Thalassemia and Hemoglobinopathies Center, Laiko General Hospital, Athens, Greece.

Introduction: KLF1 is a transcription factor, promoting shift in expression from γ to β -globin. This process is carried out either directly, by activating transcription of β -gene, or indirectly by activating transcription repressors for silencing γ -genes. Variations of KLF1 lead to increased expression of fetal hemoglobin (Hb F), showing clinical benefits for thalassemia patients, making it an ideal target for gene intervention to increase HbF levels and thus ameliorating the patient's phenotype.

Material and Methods: This study aimed to identify possible variations of KLF1 gene, in β -thalassaemia heterozygotes and normal controls presenting high levels of HbF $>4\%$. DNA from 47 blood samples was obtained (32 heterozygotes/ 15 normal) and analyzed by PCR and Sanger sequencing of KLF1 gene.

Results: An already characterized alteration (-148G>A) detected for the first time in the Greek population (β -thalassaemia heterozygote, HbF 19,5%) in coexistence with one published variation of unknown significance (c.544T>C, p.Phe182Leu). Two alternations, not yet recorded (g.1980C>A, c.831A>C), were found in β -thalassaemia heterozygotes, (HbF: 5,9% and 10,1%) and a frequent polymorphism (c.304T>C, p.Ser102Pro) was present in the majority of tested samples. γ -genes investigation prior to this of KLF1 revealed the polymorphism -158C>T (HBG1, Cretan-type) for the first time in an Albanian origin sample.

Conclusions: KLF1 analysis in a small cohort of samples revealed variations that could possibly contribute in differential HbF expression. More extensive analysis of the above gene along with other non globin genes-modifying factors of HbF expression- has to be conducted especially in β -thalassaemia patients in order to unravel the mechanism of Hb F regulation.

P08.01

The clinical significance of 15q11.2 BP1-BP2 duplications: - Where do we stand?

S. Serafim^{1,2}, B. Marques¹, S. Pedro¹, F. Brito¹, J. Dupont², P. Dias², O. Moldovan², R. Silveira-Santos², S. Custódio², A. Sousa², A. B. Sousa², J. de Sá², A. Queiroz², M. L. Vicente², H. Correia¹;

¹Instituto Nacional de Saúde Dr. Ricardo Jorge, Lisboa, Portugal, ²Hospital de Santa Maria, Centro Hospitalar Lisboa Norte EPE, Lisboa, Portugal, ³Hospital de Faro E.P.E., Faro, Portugal, ⁴Hospital Garcia de Orta, Almada, Portugal, ⁵Hospital Amato Lusitano, Castelo Branco, Portugal.

The 15q11.2-q13 region has been well characterized, being associated with a range of syndromatic copy number variants (CNVs), and comprises five established break points sites (BP1 to BP5).

While the clinical effect for BP1-BP3, BP2-BP3 and BP4-BP5 CNVs is well established, the same cannot be said for BP1-BP2 CNVs.

Recently the 15q11.2 BP1-BP2 deletion has been reviewed, emerging as a microdeletion syndrome with low penetrance and variable expressivity being the CNV frequently inherited from a healthy parent. This microdeletion is considered to be a risk factor for several neurodevelopment disorders. For the reciprocal duplication the picture has been less conclusive.

Aiming for a better understanding of the clinical significance of this CNV, we collected patients with intellectual disability and/or other clinical features, referred for microarray testing, gathering clinical details for the ones with the duplication. Data was collected from two genetic laboratories.

With a total of 1545 patients, we identified eleven carrying the duplication at 15q11.2 BP1-BP2. It was possible to assess inheritance in only four cases, all inherited from a healthy parent. All patients presented intellectual disability, and facial dysmorphism was the second most common feature observed. Microcephaly, autism, congenital abnormalities, dystonia and cataplexy

where reported individually.

The magnitude of the effect of 15q11.2 duplication remains elusive, and the outcome unclear, posing a major challenge to genetic counseling. Nevertheless, we expect the collection of more of these cases will establish this gain, as it happened with the reciprocal deletion, as a microduplication syndrome with low penetrance and variable expressivity.

P08.02

Copy number variation at chromosome 16p13.11 in Estonian patients

M. Andresson¹, P. Tammur¹, O. Žilina¹, K. Kuuse¹, M. Nõukas², T. Reiman^{1,3,4};
¹Tartu University Hospital, United Laboratories, Department of Genetics, Tartu, Estonia,
²Estonian Genome Center, University of Tartu, Tartu, Estonia, ³University of Tartu,
 Institute of Biomedicine and Translational Medicine, Department of Biomedicine, Tartu,
 Estonia, ⁴University of Tartu, Institute of Clinical Medicine, Department of Pediatrics,
 Tartu, Estonia.

There are many copy number variations (CNVs) that are associated with susceptibility for neurodevelopmental disorders. One such novel CNV is deletion and duplication at chromosome 16p13.11 whose clinical significance is becoming more ascertained.

CNVs at 16p13.11 show broad phenotypic manifestations and incomplete penetrance. They are significantly enriched in individuals affected by developmental delay/intellectual disability, autism, epilepsy, dysmorphic features and congenital anomalies. Pathogenic 16p13.11 CNVs vary in size, but harbour the critical region called interval II (chr16: 15.48-16.32 Mb, GRCh37/hg19).

We investigated the burden of CNVs at 16p13.11 (HumanCytoSNP-12 v2-1 BeadChips; Illumina Inc.) in a sample of 3,212 individuals with a range of neurodevelopmental conditions, clinically referred for chromosomal microarray analysis. Cases were compared with 14,747 controls from the Estonian Genome Center. We identified 16 patients with CNV within the 16p13.11 region, representing ~ 0.5 % of the patients analyzed, as compared to ~ 0.15 % in the Estonian general population. Eight cases were with deletion and eight with duplication in that region, including one prenatally diagnosed case.

We found that patients with CNV in 16p13.11 present with varied clinical features as previously described. These features are incompletely penetrant. All deletions and duplications identified encompass the critical region of the CNV. The sizes of the rearrangements vary between 0.3-2.7 Mb.

Our findings confirm that genomic abnormalities at chromosome 16p13.11 predispose to a range of neurocognitive and developmental disorders in individuals who carry them

P08.03

Phenotypic variability associated with the recurrent 1q21.1 copy number variant: eight new cases

A. Perez-Granero^{1,2,3}, N. Govea^{1,3,2}, M. Grimalt^{1,3}, E. Miravet^{1,3}, J. Rosell^{1,3,2};
¹Hospital Universitari Son Espases, Palma, Spain, ²Institut de Investigacions Sanitàries de Palma (IDISPA), Palma, Spain, ³GCV Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), Madrid, Spain.

Introduction: The chromosome 1q21.1 locus is a region with a high susceptibility to recurrent deletions and duplications. These disorders have incomplete penetrance and variable expressivity. Hence the clinical significance of this copy-number variation (CNVs) can be difficult to evaluate (from development delay, mild to moderate intellectual disability, autism, psychiatric and behavioural problems to normal phenotype).

Materials and Methods: Our laboratory has examined 664 samples by targeted array comparative genomic hybridization using an (Cytochip ISCATM 8x60 v2.0 Illumina). Samples were received from patients with mental retardation, epilepsy, autism and/or congenital anomalies. When parental samples were available, the familial study was performed.

Results: We have identified 5 patients with microdeletion and 3 patients with microduplication 1q21.1. One patient with microdeletion was referred for microcephaly and the other 4 patients for developmental abnormalities or mental retardation. In two cases the parents are also affected. We have only one case of parental samples and the deletion was of paternal origin. Two patients with microduplication were referred for epilepsy and the other one by autism. All have macrocephaly. In two cases we have the parental samples and the duplication was of maternal origin in both cases.

Conclusions: In our group of patients the recurrent 1q21.1 CNV is the most frequent anomaly (1,2 %). The macrocephaly is constant in patients with duplication 1q21.1. The family study is inherited origin in all our studied cases. The clinical variability and the incomplete penetrance make genetic counselling very difficult, especially in prenatal diagnosis.

P08.04

Identifying candidate genes for 2p15p16.1 microdeletion syndrome using clinical, genomic and functional analysis

H. Bagheri¹, C. Badduke¹, Y. Qiao¹, R. Colnaghi², A. Diana², I. Abramowicz², C. Dunham³, J. Wen¹, R. Wildin⁴, M. Nowaczyk⁵, J. Eichmeyer⁶, A. Lehman³, B. Maranda⁷, S. Martell¹, X. Shan¹, S. Lewis¹, M. O'Driscoll², C. Gregory-Evans¹, E. Rajcan-Separovic¹;
¹University of British Columbia, Vancouver, BC, Canada, ²Human DNA Damage Response Disorders Group, Genome Damage & Stability Centre, University of Sussex, Brighton, United Kingdom, ³BC Children's Hospital, Vancouver, BC, Canada, ⁴National Human Genome Research Institute, Bethesda, Maryland, USA, Bethesda, MD, United States, ⁵Department of Pathology and Molecular Medicine, McMaster University Medical Centre, Hamilton, ON, Canada, ⁶St. Luke's Children's Hospital, Boise, ID, United States, ⁷Medical Genetics, Université de Sherbrooke, Sherbrooke, QC, Canada.

Introduction: The 2p15p16.1 microdeletion syndrome has a core phenotype consisting of intellectual disability, microcephaly, hypotonia, delayed growth, common craniofacial features, and digital anomalies. So far, more than 20 cases with this syndrome have been reported in literature; however, the size of the deletions and their breakpoints vary making the identification of candidate genes challenging. Recent reports pointed to four genes (XPO1, USP34, BCL11A and REL) which were included, alone or in combination, in the smallest deletions causing the syndrome.

Results: Herein, we describe 8 new cases with 2p15p16.1 deletion and review all published cases. We demonstrate functional deficits for the above 4 candidate genes using patient lymphoblast cell lines (LCLs) and knockdown of their orthologs in zebrafish. All genes were dosage sensitive based on reduced protein expression in LCLs. In addition, deletion of XPO1, a nuclear exporter, co-segregated with nuclear accumulation of one of its cargo molecules (rpS5) in patient LCLs. Other pathways associated with these genes (e.g. NF-kB and Wnt signaling as well as DNA damage response) were not impaired in patient LCLs. Knockdown of xpo1a, rel, bcl11aa and bcl11ab resulted in abnormal zebrafish embryonic development including microcephaly, dysmorphic body, hindered growth, small fins as well as structural brain abnormalities.

Conclusions: Our multifaceted analysis strongly implicates XPO1, REL, and BCL11A as candidate genes for the 2p15p16.1 microdeletion syndrome.

P08.05

Haploinsufficiency of ZNF385B and neurological manifestations in 2q31 microdeletion syndrome

N. Okamoto¹, K. Shimajima², T. Yamamoto²;
¹Department of Medical Genetics, Osaka Medical Center and Research Institute for Maternal and, Osaka, Japan, ²Tokyo Women's Medical University Institute for Integrated Medical Sciences, Tokyo, Japan.

Microdeletion of 2q31 involving the HOXD gene cluster is a rare syndrome. The deletion of the HOXD gene cluster is thought to result in skeletal anomalies in these patients. HOX genes encode highly conserved transcription factors that control cell fate and the regional identities along the primary body and limb axes. Several patients with this syndrome have neurological manifestations. We experienced a new patient with 2q31 microdeletion encompassing the HOXD gene cluster and some neighboring genes including the ZNF385B. The patient showed digital anomalies, growth failure, epileptic seizures, and severe intellectual disability. MRI showed delayed myelination and a low signal intensity in the bilateral basal ganglia. Abnormal MRI findings in the 2q31.1 microdeletion syndrome have been reported in some other patients. They were also haploinsufficient for ZNF385B. The ZNF385B is a zinc finger protein expressed in brain. We suggest that haploinsufficiency of ZNF385B is responsible for the neurological features of this syndrome.

P08.06

2q37.3 deletions among children with intellectual disability, autism and/or congenital malformations

I. A. Demidova^{1,2,3}, S. G. Vorsanova^{1,2,3}, K. Vasin^{2,1,3}, M. A. Zelenova^{2,1,3}, N. S. Shmitova², N. S. Shmitova², O. S. Kurinnaia^{1,2,3}, Y. B. Yurov^{2,1,3}, I. Y. Iourou^{2,1,3};
¹Research and Clinical Institute for Pediatrics named after YE Veltishev at the Pirogov Russian National Research Medical University, Ministry of Health, Moscow, Russian Federation, ²Mental Health Research Center, Moscow, Russian Federation, ³Moscow State University of Psychology and Education, Moscow, Russian Federation.

Introduction. 2q37.3 deletion syndrome is considered to be a rare chromosomal disorder associated with variable clinical features, among which are intellectual disability (ID), autistic features, brachydactyly, short stature, hypotonia and obesity. Some facial features are characteristic for the syndrome (i.e. round face, frontal bossing, arched eyebrows, deep-set eyes, upslanted palpebral fissures, epicanthal folds, thin upper lip, minor ear anomalies). Haploinsufficiency of HDAC4 seems to be the most critical for the phenotypic spectrum. Here, we have attempted to assess chromosome

2q37.3 deletions and HDAC4 haploinsufficiency per se in children with intellectual disability, autism and/or congenital malformation.

Materials and Methods. Molecular karyotyping by SNP/oligonucleotide microarray (resolution: >1kbp) was used to analyze 300 children with ID, autism spectrum disorders and congenital malformations.

Results. Cytogenetically visible 2q37 deletions were detected in 2 cases. Molecular karyotyping confirmed the presence of these deletions (5Mb and 8.5Mb). Furthermore, a CNV within 2q37.3 (44kbp) leading to HDAC4 loss was detected in a patient. All affected female patients had ID, autism and minor ear anomalies. One had widely set nipples and hypotonia. Another one had a short stature. Two patients presented with ocular hypertelorism. HDAC4 haploinsufficiency was observed in all three cases.

Conclusions. We show that 2q37 deletions can be common in children with ID, autism, congenital malformations tending to a frequency as high as 1%. Therefore, one can suggest that 2q37.3 deletions are likely to be more common among these children than previously recognized. Supported by the Russian Science Foundation (Grant #14-35-00060).

P08.07

7p21 Interstitial duplication - male patient with global developmental delay, autism, dysmorphisms and epilepsy

J. B. Melo^{1,2,3}, S. I. Ferreira¹, A. Jardim¹, A. Mascarenhas¹, M. C. Robalo⁴, I. M. Carreira^{1,2,3};

¹Laboratório de Citogenética e Genómica, Faculdade de Medicina da Universidade de Coimbra, Coimbra, Portugal, ²CIMAGO – Centro de Investigação em Meio Ambiente, Genética e Oncobiologia, Coimbra, Portugal, ³CNC-IBILI, Universidade de Coimbra, Coimbra, Portugal, ⁴Hospital Pediátrico, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal.

Duplications involving the short arm of chromosome 7 are rare events, and most occur in association with rearrangements of other chromosomes as a consequence of missegregation of a balanced translocation in a carrier progenitor. The majority of the patients described have a 7p terminal duplication in association with other imbalance, making 7p interstitial duplications even more rare events. The ones described have variable sizes, usually with cytogenetically visible imbalances, with few characterized by array-Comparative Genomic Hybridization.

Here we report a 12 year old male with global developmental delay, facial dysmorphisms, hypotonia and epilepsy that was analyzed by Agilent 180K oligonucleotide array-CGH, with an average probe spacing of 17Kb. The analysis revealed a 5.5 Mb interstitial duplication in chromosome 7p21.2p21.1(14,624,128-20187,355)[hg19].

Common to all reported patients with 7p duplications is the presence of intellectual disability and variable facial dysmorphisms, while manifestations like cardiac anomalies, skeletal anomalies and hypotonia are present only in some of the patients. The reported patient is the third reported with autism, after the report of a 7p21.1p22.2 de novo duplication, larger but overlapping the one reported, and a 7p11.2p14.1 proximal duplication. This is the first report of a 7p21 interstitial duplication associated with epilepsy.

Establishing the exact boundaries of 7p pure interstitial duplications, identifying the genes involved and their functional characterization might lead to pinpoint candidate genes responsible for specific manifestations. A detailed clinical characterization of the patients will also help in this genotype-phenotype correlation in order to define critical regions responsible for the different manifestations.

P08.08

8p rearrangements detected by array-CGH in a 1500 cohort of patients with intellectual disability

L. M. Pires¹, S. I. Ferreira¹, M. Val¹, N. Lavoura¹, J. Saraiva², I. M. Carreira^{1,3,4}, J. B. Melo^{1,3,4};

¹Laboratório de Citogenética e Genómica, Faculdade de Medicina, Coimbra, Portugal, ²Serviço de Genética Médica, Hospital Pediátrico, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal, ³CIMAGO – Centro de Investigação em Meio Ambiente, Genética e Oncobiologia, Coimbra, Portugal, ⁴CNC-IBILI, Universidade de Coimbra, Coimbra, Portugal.

Array-Comparative Genomic Hybridization (array-CGH) has increased the diagnostic yield in patients with intellectual disability (ID), autism spectrum disorders (ASD) and multiple congenital anomalies due to its improved resolution. The short arm of chromosome 8 (8p) is structurally complex because of the existence of two olfactory gene clusters flanking a 5Mb region of 8p23.1, several low copy repeats (LCRs) and common inversion polymorphisms that makes this region prone to various recurrent genomic rearrangements that include: 8p23.1 deletions or duplications, 8p23.1 paracentric inversions, pericentric inversions, 8p translocations, 8p inverted duplication with associated terminal deletion, among others. In addition to these 8p pathogenic imbalances, others have been reported as copy number variants (CNVs) without apparent clinical significance. In our cohort of 1500 patients,

with ID and/or ASD studied by Agilent 180K oligonucleotide array-CGH, we have detected 14 patients with 8p imbalances (5 deletions, 8 duplications and one inverted duplication). Single gene deletions were observed in 3 patients and larger interstitial deletions in 2 patients (one with a 3,4Mb 8p21.2 deletion and the other with two adjacent deletions in 8p23.1 and in 8p23.1p21.3). Interstitial duplications were identified in 8 patients, including a 6,3Mb 8p21.3p21.1 duplication, a 960Kb 8p23.1 duplication, a 274Kb 8p22 duplication, 4 patients with a small 160Kb duplication inherited from healthy parents classified as a CNV of unknown clinical significance and one patient with a single gene duplication. In brief, our results are in accordance with published data suggesting existence of multiple hotspots in 8p causing complex rearrangements and variety of phenotypes.

P08.09

ADNP mutations are a frequent cause of autosomal dominant intellectual disability

A. Riess¹, U. Moog², S. Waldmüller¹, P. Bauer¹, O. Riess¹, S. Karch³, E. Schröck⁴, N. Di Donato⁴, A. Rump⁴, L. Mackenroth⁴, A. Tzschach⁴;

¹Institute of Medical Genetics and Applied Genomics, University Hospital Tübingen, Tübingen, Germany, ²Institute of Human Genetics, University of Heidelberg, Heidelberg, Germany, ³Center for Child and Adolescent Medicine, Heidelberg University Hospital, Heidelberg, Germany, ⁴Technische Universität Dresden, Institute of Clinical Genetics, Dresden, Germany.

Heterozygous loss-of-function mutations in the activity dependent neuro-protector homeobox gene ADNP, which encodes a transcription factor involved in the SWI/SNF remodelling complex, were recently shown to be associated with moderate to severe intellectual disability (ID). Additional clinical abnormalities which included short stature, muscular hypotonia and facial dysmorphisms had enabled the delineation of a new entity termed Helsmoortel-van der Aa syndrome (OMIM 615873). Since its first report in 2014, studies in large ID cohorts identified mutations in 14 unrelated patients, suggesting that ADNP mutations are a comparatively frequent cause of autosomal dominant ID.

We report on three unrelated German patients (two boys and one girl) in whom ADNP mutations were detected by next-generation sequencing. Clinical problems that are in accordance with those of previously reported patients included severe ID, muscular hypotonia, short stature and hypoplastic corpus callosum. Borderline microcephaly, which had so far only been reported in a minority of patients, was present in two of our patients. One patient had unilateral iris coloboma, which has hitherto not been reported in association with ADNP mutations.

Our findings corroborate the assumption that ADNP mutations are one of the more frequent causes of ID in sporadic patients, and they expand the clinical spectrum of the probably underdiagnosed Helsmoortel-van der Aa syndrome.

P08.10

Clinical and quantitative PCR confirmation of copy number variations detected by array CGH

A. C. Ceylan¹, E. Z. Taşkıran¹, P. Ö. Şimşek Kiper², G. E. Utine², K. Boduroğlu², M. Alikışifoğlu^{1,2};

¹Hacettepe University, Faculty of Medicine, Department of Medical Genetics, Ankara, Turkey, ²Hacettepe University, Faculty of Medicine, Department of Pediatrics, Department of Pediatric Genetics, Ankara, Turkey.

Introduction: Copy Number Variations (CNV) are known to underlie several diseases such as intellectual disability, autism spectrum disorders, and schizophrenia. It is also well known that CNVs play important roles in microdeletion syndromes. Several methods were developed to detect CNVs. One of these methods, array Comparative Genomic Hybridization (aCGH), is now the recommended first-tier test for molecular diagnosis in patients with cognitive disorders. aCGH detects genome-wide CNVs, however, findings should be validated. Thus, the aim of this study was to verify CNVs detected by aCGH in patients with cognitive disorders.

Materials and methods: aCGH (Agilent® 8x60K) analyses for 150 patients with cognitive disorders detected 19 CNVs - either of unknown clinical significance or of likely pathogenicity. Afterwards, these CNVs were verified by SYBR Green-based quantitative-PCR (qPCR).

Results: Verification was done in 18 CNVs. Of these, 4 CNVs turned out to be false positives. Two CNVs were de novo. Clinical correlation of the CNVs revealed that these 16 CNVs were among the already known microdeletion and/or microduplication syndromes. In order to draw attention to the importance of verification, two patients will be presented: One with a confirmed and paternally inherited deletion at 2q37, and the other with a false positive duplication at 1q21.3.

Conclusion: The current study has shown that CNVs detected by aCGH

should always be verified, for example by qPCR, especially when there is an impact on clinical phenotype. Verification is also important for the family for accurate genetic counseling.

P08.11

Implementation of arrayCGH in a Portuguese tertiary hospital: 5 years and over 1400 cases

R. Silveira-Santos, A. Sousa, S. Custódio, S. Serafim, J. Dupont, O. Moldovan, P. Dias, A. Medeira, I. Cordeiro, A. B. Sousa;
Serviço de Genética Médica, Departamento de Pediatria, Hospital de Santa Maria - CHLN, Lisboa, Portugal.

Successful application of arrayCGH to prenatal and postnatal genetic diagnosis led to a significant increase in the detection rate of chromosomal abnormalities. Here, we reflect on our 5-year experience (2011 to 2015) with the implementation of arrayCGH.

Different array platforms were used with increasing probe density and, since 2013, included SNPs to investigate patients whose phenotype was consistent with an imprinting disorder or an autosomal recessive disorder caused by autozygosity. We examined 1414 patients belonging to 1261 families (95 prenatally, 1319 postnatally), who were referred mostly for intellectual disability, autism and/or congenital abnormalities.

In 10/95 (11%) prenatal and in 365/1319 (28%) postnatal cases we identified possibly relevant copy number variations (CNV) or regions of absence of heterozygosity (AOH). Overall there were 1125 relevant CNVs that required further investigation originating 468 reportable CNVs (203 deletions, 265 duplications), ranging in size from 43kb (intragenic deletion of *MBD5*) to 154Mb (X aneuploidy). After segregation analysis and/or confirmatory tests, 266 variants were classified as pathogenic and 202 as of uncertain clinical significance. We also detected an AOH containing a gene associated with Bardet-Biedl syndrome, consistent with the patient's phenotype, and a case of partial UPD(14).

Large size rearrangements can be benign and, conversely, very small size CNVs may be pathogenic. The global analysis of our array database suggests a postnatal cut-off of 30kb and, for prenatal reporting, a 150kb cut-off for deletions and a 200kb for duplications. However, we recommend analyzing each case on an individual basis and in close connection with the clinicians.

ARV1 - a new candidate gene for intellectual disability and seizures

R. Segel^{1,2}, A. Aran^{1,2}, H. Fridman¹, P. Renbaum¹, S. Gulsuner³, S. Zeligson¹, T. Walsh³, M. King³, E. Levy-Lahad^{1,2};

¹Shaare Zedek Medical Center, Jerusalem, Israel, ²Hadassah Medical School, the Hebrew University, Jerusalem, Israel, ³Departments of Medical Genetics and Genome Sciences, University of Washington, Seattle, WA, United States.

Intellectual disability (ID) and seizures are genetically heterogeneous. We report two male siblings with severe ID and seizures, born at term to consanguineous Palestinian parents. Both have non-verbal communication and severe ID without regression, seizures started in the first year of life. Hearing and vision are normal. Both are normocephalic, brain MRI demonstrated mild cortical atrophy in the older brother only. Lactate, ammonia, Acyl-carnitine, liver function and lipid profile were normal.

Whole Exome sequencing of the affected siblings, both parents and two unaffected sisters revealed only one variant that was homozygous in both affected children, heterozygous in the sisters: *ARV1* p.G189R (c.G565A). This residue is highly conserved in all vertebrates, Gerp score of 4.7. This variant has not been reported in 1000 Genome or EVS, Only 2 heterozygotes reported in ExAC (frequency e-051.648), predicted as damaging by Polyphen (0.998), and likely pathogenic in Clinvar, based on a single indication of this variant in a family with an unspecified neurodegenerative disease (Alazami 2015).

ARV1 is an endoplasmic reticulum transmembrane protein, first identified as essential for sterol esterification in yeast. *Arv1*^{-/-} mice exhibit a dramatic lean phenotype. In mammalian cells, *Arv1* is required for normal cholesterol, bile acid and triglyceride homeostasis, its knockdown increases lipid-mediated cell death. The effects of the G189R mutation on these functions will be presented.

Our results suggest *ARV1* mutations cause functional brain abnormalities, should be considered as a candidate gene for ID with seizures, and provide further evidence of the role of sterol metabolism in neurological function.

Clinical utility of whole exome sequencing: case report of a child with global neurodevelopmental delay focused on autism spectrum disorder

A. Vallmajó¹, D. Casellas¹, A. Castan¹, M. García¹, B. Rodríguez-Santiago², M. Obón¹;
¹Hospital U de Girona Dr. Josep Trueta, Girona, Spain, ²qGenomics Laboratory, Barcelona, Spain.

Introduction: Autism Spectrum Disorders (ASD, OMIM#209850) are a group of heterogeneous neurobehavioral syndromes without an accurate molecular genetics protocol after a non-conclusive karyotype, fragile-X and CGH-array tests results. Here we report the case of a two-years-old child, born at 41 weeks gestation after induced labor for oligohydramnios, with a global neurodevelopmental delay focused on ASD, a suggestive hereditary family history and normal karyotype, fragile-X and CGH-array tests. Whole exome sequencing was performed to depict the complex genetics autism spectrum disorder.

Material and methods: Exome sequencing and selective analysis of ASD known genes was applied at first. Then a second analysis extended to remaining OMIM genes was carried out (qGenomics Laboratory)

Results: ASD related genes analysis did not reveal any significant finding, but the extended study to other OMIM genes identified a likely pathogenic mutation in *GDI1* gene (c.389-1G>-C; hemizygous splicing variant). This gene has been strongly associated with intellectual disabilities (ID) although there is only evidence from 3 published families with X-linked ID and *GDI1* mutations (one nonsense, two missense) (Strobl-Wildemann G, et al. Am J Med Genet A. 2011).

Conclusions: The mutation found in the studied family provides more evidence about the *GDI1* role in X-linked ID. Furthermore, *GDI1* seems to be related also to another clinical feature, ASD. Our findings suggest including *GDI1* in ASD panels as well as in X-linked intellectual disabilities. Finally, our work underlines the utility of whole exome sequencing instead of specific gene panels for an accurate diagnosis and complete genetic counselling.

P08.14

Targeted gene panel to investigate intellectual disability and autism spectrum disorders comorbidity

E. Leonardi, A. Gasparini, M. Carraro, E. Bettella, R. Polli, F. Cesca, S. Sartori, S. C. E. Tosatto, A. Murgia;
University of Padua, Padova, Italy.

Intellectual disability (ID) and autism spectrum disorder (ASD) are clinically and genetically heterogeneous diseases. Recent whole exome sequencing studies indicated that genes associated with different neurologic disorders are shared among these disorders or converge on common functional pathways.

The aim of this study was to design a customized multiplex PCR-based gene panel to investigate the genetic bases of ID and ASD comorbidity. The gene panel covers 74 genes, including a subset of genes that are found recurrently mutated in ID or ASD conditions, genes shared among ID and ASD disease network and ID/ASD genes that are directly connected to these. We analyzed 18 clinically selected patients with ID and ASD without syndromic features, negative for Fragile-X test and array CGH. For all 18 patients, 85-97% of the targeted regions achieved read depths of at least 20x, with average read depths ranging from 91x to 612x. 22 rare single nucleotide variants (SNV) were found in the exonic sequences of 16 out of the 18 patients: most of them are predicted to be deleterious and have very low frequency or are not present in public databases. Although familial segregation analysis will be helpful to determine the pathogenic nature of the variants, likely causative variants have been assigned for 8 (44%) of the patients. These results confirm the diagnostic value of the targeted gene panel for investigating children with ID and ASD.

P08.15

Effectiveness of whole-exome sequencing and costs of the traditional diagnostic trajectory in children with intellectual disability

G. R. Monroe¹, G. W. Frederix², S. M. C. Savelberg¹, T. I. de Vries¹, K. J. Duran¹, J. J. van der Smagt¹, P. A. Terhal¹, P. M. van Hasselt³, H. Y. Kroes¹, N. M. Verhoeven-Duijf¹, I. J. Nijman¹, E. C. Carbo¹, K. L. van Gassen¹, N. V. Knoers¹, A. M. Hövels², M. M. van Haelst¹, G. Visser², G. van Haafden¹;

¹Utrecht University Medical Center, Utrecht, Netherlands, ²Utrecht Institute of Pharmaceutical Sciences, Utrecht, Netherlands, ³Wilhelmina Children's Hospital, Utrecht, Netherlands.

Introduction: This study investigated whole-exome sequencing (WES) yield in a subset of intellectually disabled patients referred to our clinical diagno-

stic center and calculated the total costs of these patients' diagnostic trajectory in order to evaluate early WES implementation.

Materials and Methods: We compared 17 patients' trio-WES yield with the retrospective costs of diagnostic procedures by comprehensively examining patient records and collecting resource use information for each patient, beginning with patient admittance and concluding with WES initiation. We calculated cost savings using scenario analyses to evaluate the costs replaced by WES when used as a first diagnostic tool.

Results: WES resulted in diagnostically useful outcomes in 29.4% of patients. The entire traditional diagnostic trajectory average cost was \$16,409 per patient, substantially higher than the \$3,972 trio-WES cost. WES resulted in average cost savings of \$3,547 for genetic and metabolic investigations in diagnosed patients and \$1,727 for genetic investigations in undiagnosed patients.

Conclusion: The increased causal variant detection yield by WES and the relatively high costs of the entire traditional diagnostic trajectory suggest that early implementation of WES is a relevant and cost efficient option in patient diagnostics. This information is crucial for centers considering implementation of WES and serves as input for future value-based research into diagnostics.

P08.16

A 1.77 Mb deletion in 3p26.3 encompassing CNTN6 and CNTN4 genes: case report

F. Brito¹, B. Marques¹, S. Pedro¹, S. Serafim¹, R. Goncalves², J. Freixo², H. Correia¹;

¹Instituto Nacional de Saúde Dr. Ricardo Jorge, Lisboa, Portugal, ²Hospital D. Estefânia, Centro Hospitalar de Lisboa Central EPE, Lisboa, Portugal.

Chromosome microarray analysis is a powerful diagnostic tool and is being used as a first-line approach to detect chromosome imbalances associated with intellectual disability, dysmorphic features and congenital abnormalities. This test enables the identification of new copy number variants (CNVs) and their association with new microdeletion/microduplication syndromes in patients previously without diagnosis. We report the case of a 7 year-old female with moderate intellectual disability, severe speech delay and auto and hetero aggressivity with a previous 45,XX,der(13;14)mat karyotype performed at a younger age. Affymetrix CytoScan 750K chromosome microarray analysis was performed detecting a 1.77 Mb deletion at 3p26.3, encompassing 2 OMIM genes, *CNTN6* and *CNTN4*. These genes play an important role in the formation, maintenance, and plasticity of functional neuronal networks. Deletions or mutations in *CNTN4* gene have been implicated in intellectual disability and learning disabilities. Disruptions or deletions in the *CNTN6* gene have been associated with development delay and other neurodevelopmental disorders. The haploinsufficiency of these genes has been suggested to participate to the typical clinical features of 3p deletion syndrome. Nevertheless inheritance from a healthy parent has been reported, suggesting incomplete penetrance and variable phenotype for this CNV. We compare our patient with other similar reported cases, adding additional value to the phenotype-genotype correlation of deletions in this region.

Modeling of chromosomal diseases related to intellectual disability using genome editing of induced pluripotent stem cells from a patient with CNTN6 gene microdeletion

T. A. Shnyder¹, A. G. Menzorov^{1,2}, N. M. Matveeva¹, V. S. Fishman¹, I. E. Prityazhnyuk¹, T. V. Karamysheva¹, A. A. Kashevarova^{3,4}, N. A. Skryabin^{3,4}, E. A. Sazhenova³, I. N. Lebedev^{3,4,5}, O. L. Serov^{1,2};

¹Institute of Cytology and Genetics SB RAS, Novosibirsk, Russian Federation, ²Novosibirsk State University, Novosibirsk, Russian Federation, ³Institute of Medical Genetics, Tomsk, Russian Federation, ⁴National Research Tomsk State University, Tomsk, Russian Federation, ⁵Siberian State Medical University, Tomsk, Russian Federation.

Introduction: Previously we have described three patients with intellectual disability and some dysmorphic features. Patients had microdeletion or microduplication at 3p26.3, affecting a single gene, *CNTN6* (Kashevarova et al., 2014). In *Cntn6* knock-out mice lack of this gene causes abnormal dendritogenesis. We decided to produce patient-specific neurons to study molecular mechanisms of *CNTN6* deletion effect in humans.

Materials and Methods: Induced pluripotent stem cells (iPSCs) were produced from patient skin fibroblasts with 3p26.3 microdeletion and healthy donor using standard protocol with four transcription factors. Array-based comparative genomic hybridization (aCGH), RT-PCR and FISH analyses were used to confirm microdeletion in iPSCs. CRISPR/Cas9 system was used to knock-out *CNTN6* allele. Neuronal differentiation of iPSCs was performed by NGN2 overexpression (Zhang et al., 2013).

Results: Eight iPSC lines had diploid karyotype (46,XY). Pluripotency was

assessed by generation of embryoid bodies and teratoma formation in SCID mice. We confirmed microdeletion and lack of *de novo* chromosome aberrations by aCGH. In addition, we produced targeted missense mutation in the remaining intact *CNTN6* allele using CRISPR/Cas9 system to "enhance" effects of *CNTN6* deletion. iPSCs neuronal differentiation was directed by overexpression of transcription factor NGN2. According to preliminary data, nearly all cells were positive for neuron specific markers and had electrophysiological parameters comparable to those of a healthy donor.

Conclusions: Patient-specific iPSC-derived neurons with *CNTN6* deletion and complete knock-out could be used as a unique model for studying effects caused by *CNTN6* copy number changes.

Eight further individuals with intellectual disability and epilepsy carrying biallelic CNTNAP2 aberrations allow delineation of the mutational and phenotypic spectrum

M. Smogavec¹, A. Smith², J. Hoyer³, D. Lederer⁴, M. Nassogne⁵, E. E. Palmer^{6,7}, M. Deprez⁴, V. Benoit⁴, I. Maystadt⁴, C. Noakes⁸, A. Leal⁹, A. Reis³, D. Shears⁸, K. Brockmann⁹, C. Zweier³;

¹Institute of Human Genetics, University Medical Center, Georg August University, Göttingen, Germany, ²Oxford Medical Genetics Laboratories, Churchill Hospital, Oxford, United Kingdom, ³Institute of Human Genetics, Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany, ⁴Centre de Génétique Humaine, Institut de Pathologie et Génétique, Charleroi (Gosselies), Belgium, ⁵Pediatric Neurology Unit, Saint-Luc University Hospital, UCL, Brussels, Belgium, ⁶GOLD (Genetics of Learning and Disability) Service, Hunter Genetics, Waratah, Australia, ⁷University of New South Wales, Sydney, Australia, ⁸Department of Clinical Genetics, Churchill Hospital, Oxford University Hospitals NHS Trust, Oxford, United Kingdom, ⁹Interdisciplinary Pediatric Center for Children with Developmental Disabilities and Severe Chronic Disorders, University Medical Center, Georg August University, Göttingen, Germany.

Introduction: Heterozygous copy number variants (CNVs) or sequence variants in the contactin associated protein 2 gene *CNTNAP2* have been discussed as risk factors for a wide spectrum of neurodevelopmental and neuropsychiatric disorders. Biallelic aberrations in this gene are causative for an autosomal-recessive disorder with epilepsy, severe intellectual disability (ID) and cortical dysplasia (CDFES), however, due to the limited number of reported individuals, the full mutational and clinical spectrum has still to be characterized.

Methods and Results: Targeted sequencing, chromosomal microarray analysis or multi gene panel sequencing identified homozygous mutations, compound heterozygous CNVs or compound heterozygous CNVs and mutations in eight individuals from six unrelated families. All aberrations were inherited from healthy, heterozygous parents and are predicted to be deleterious for protein function. Epilepsy occurred in all patients with onset in the first three and a half years of life. Further common aspects were severe ID (7/8), regression of speech development (5/8), and behavioural anomalies (7/8). Interestingly, cognitive impairment in one of two affected brothers was in comparison relatively mild with good speech and simple writing abilities. Cortical dysplasia that was previously reported in CDFES, was not present in MRIs of six individuals and only suspected in one.

Conclusion: By identifying novel homozygous or compound heterozygous, deleterious CNVs and mutations in *CNTNAP2* in eight individuals from six independent families with moderate to severe ID, early onset epilepsy and behavioural anomalies, we considerably broaden the mutational and clinical spectrum associated with biallelic aberrations in *CNTNAP2*.

P08.19

Coffin-Lowry syndrome, a familial "female only" case; natural history and variability of Coffin-Lowry syndrome in females

A. Kattentidt¹, R. Kersseboom¹, T. Rinne², E. van der Zon¹;

¹Zuidwester, Spijkenisse, Netherlands, ²Department of Clinical Genetics, Radboud University Medical Centre, Nijmegen, Netherlands.

Coffin-Lowry syndrome (CLS) is a rare X linked semi-dominant mental retardation syndrome, in males characterized by severe intellectual disability, growth retardation, distinct facial features and progressive kyphoscoliosis. In females, the phenotype is less explicit and ranges from the full phenotype as seen in males, to completely absent. The diagnosis in females can be challenging. Furthermore, data on the natural history in affected females is still scarce.

We describe a familial case of CLS with two affected adult females and no affected males. The molecular analysis of the *RPS6KA3* gene revealed a heterozygous frameshift mutation in exon 11, once previously reported in the literature. Both sisters presented well-known features of CLS: intellectual

disability, facial dysmorphic features and soft, fleshy hands. Both females were affected by a psychiatric disorder, including psychotic disorder and depression. Interestingly, there was a strongly intrafamilial variability in the severity of psychiatric disease and psychosocial functioning. Both parents were asymptomatic. The genetic testing to determine whether the mother is an asymptomatic carrier is ongoing.

To our knowledge this is one of the very few families with affected females only. This case demonstrates the variability of clinical phenotype and natural history of CLS in adult females. Furthermore, we illustrate the challenges of treatment of a psychiatric disorder in females with CLS.

Clinical, chromosomal and molecular characterization of a cohort of 160 patients with corpus callosum agenesis with or without intellectual disability

C. Depienne^{1,2,3}, C. Nava^{1,2}, A. Rastetter¹, S. Heide^{1,2}, C. Mignot^{2,4}, B. Keren², F. Lesne², A. Faude², L. Boutaud², C. Alby², C. Bole², P. Nitchké², T. Billette de Villemeur², M. Moutard⁵, T. Attié-Bitach², D. Héron^{2,4};

¹Inserm U 1127, CNRS UMR 7225, Sorbonne Universités, UPMC Univ Paris 06 UMR S 1127, Institut du Cerveau et de la Moelle épinière, ICM, Paris, France, ²Département de Génétique, Hôpital Pitié-Salpêtrière, APHP, Paris, France, ³Service de cytogénétique, Hôpitaux universitaires de Strasbourg, Strasbourg, France, ⁴Centre de Référence Déficiences Intellectuelles de Causes Rares, Hôpital Pitié-Salpêtrière, APHP, Paris, France, ⁵Institut Imagine, Hôpital Necker, APHP, Paris, France, ⁶Service de Neuropédiatrie, Hôpital Trousseau, APHP, Paris, France.

Corpus callosum agenesis (CCA) corresponds to complete or partial absence of the corpus callosum, the main brain structure connecting the two hemispheres, and is the most frequent brain malformation in humans. CCA is usually diagnosed antenatally, and prenatal counseling is therefore a crucial issue, especially in apparently isolated CCA. To determine the type and frequency of genetic anomalies and to identify new genes involved in CCA, we recruited prospectively a cohort of 150 patients with CCA and intellectual disability (ID), and several families with CCA without ID. Clinical examination has allowed establishing a diagnosis for 10 patients, whereas a chromosomal abnormality was identified in 20 patients. Next, we have sequenced 423 candidate genes selected for their known or putative association with CCA in humans (345) or mouse models (79) in 100 probands. A pathogenic mutation was identified in 18 patients in 8 different genes (ARID1B, ZBTB18, TUBA1A, FOXG1, SPTAN1, ARX, MED12, DYNC1H1). In addition, we have sequenced the exome of 5 trios, 4 sib pairs, and 3 families with CCA without ID segregating as a dominantly inherited trait. Our results show that next generation sequencing approaches are powerful diagnostic tools for CCA and confirm the large genetic heterogeneity of this condition, in which many genes are still unknown. Moreover, the identification of genes involved in CCA without ID will change the paradigm of prenatal genetic counseling.

Customized high resolution arrayCGH for neurodevelopmental disorders: our experience

M. Rinci¹, Z. Krsnik¹, K. Gotovac², T. Liehr³, F. Borovecki², L. Brecevic¹;
¹Croatian Institute for Brain Research, School of Medicine University of Zagreb, Zagreb, Croatia, ²Department for Functional Genomics, University Hospital Centre Zagreb, University of Zagreb School of Medicine, Centre for Translational and Clinical Research, Zagreb, Croatia, ³Jena University Hospital, Friedrich Schiller University, Institute of Human Genetics, Jena, Germany.

Array comparative genomic hybridization (aCGH) is a powerful tool for detecting relative small genomic imbalances. Here we report on the design and potential of a targeted aCGH for the evaluation of patients with neurodevelopmental disorders. An array was designed on Agilent's SureDesign web application in 8X60K format, covering 6,803 genes, with a probe spacing of 0.66-20 kb.

Overall 39 patients were analyzed and 479 genes had aberrant copy number (CNV). These genes were screened by an algorithm for brain specific gene expression (publicly available data). Expression heat maps were found for 316 genes: 93 were below the expression threshold of 5.5, 134 had expression level up to 9, and 86 had high expression level up to 13, respectively. Comparing custom array with commercially available Agilent 8X60K platforms, the custom one is superior in terms of numbers of specific genes covered. Furthermore, comparing the resolution of arrays (33 kb SurePrint 3G, 60 kb ISCA), our design has much higher average resolution of 8.2 kb and therefore has a capability to detect smaller CNVs. Considering that our custom array was able to detect imbalances in 220 genes that are expressed in brain, the design presented showed to be a powerful tool for detecting

genomic imbalances in genes that are involved in neurodevelopmental disorders. This preliminary data are strong indications that implementation of targeted custom aCGH in research may reveal new candidate genes underlying neurodevelopmental disorders.

Epilepsy and its correlation with psychomotor development degree in the Spanish cohort of Wolf-Hirschhorn syndrome

J. Nevado^{1,2}, R. Blanco³, I. Málaga³, J. J. Granizo⁴, P. Barruz¹, P. D. Lapunzina¹;
¹INGEMM, Hospital Universitario la Paz-IdiPaz, MADRID, Spain, ²CIBERER, Madrid, Spain, ³Hospital Central de Asturias, Oviedo, Spain, ⁴Hospital Infanta Cristina, MADRID, Spain.

Wolf-Hirschhorn syndrome (WHS) is a contiguous gene syndrome caused mainly by deletion of the short arm of chromosome 4. Epilepsy represents a major clinical challenge during early years in WHS, with significant impact on quality of life. The main aim of this work it will be to describe social, demographic and clinical features of a cohort of WHS in Spain trying to establish whether or not the level of psychomotor development in this cohort correlates with size of the deletion and other clinical features.

Methods: Using high-resolution SNP-array, we finely mapped CNVs in around 40 individuals with WHS. Seizure and other phenotypes data were collected through a comprehensive questionnaire supplemented with available medical records, and statically analyzed.

Results: We show a complete description of a cohort of WHS in our country. Although main clinical features were similar to other previous studies, our cohort showed a better degree of psychomotor development than other ones. In fact, seizures in this cohort were preferentially under a febrile context (91%), and related to communication skills; more than 60% was able to communicate (non-verbal), 46% say words, and 27% to make short sentences, in a context that positively correlates with shorter deletions.

Conclusions: We founded a direct relationship between size of the deletion, severity of the epilepsy and the level of psychomotor development delay. Our preliminary results suggested that epilepsy in WHS may be a complex event and may it involve the synergistic effects of loss of two or more genes. Granted by Endoscreen S2011/BMD-2396

¹NGS Laboratory, NIMGenetics, Madrid, Spain, ²Hospital Universitario Quirón, Madrid, Spain, ³Clínica Universidad de Navarra, Pamplona, Spain, ⁴Hospital Universitario Reina Sofía, Córdoba, Spain, ⁵Hospital Universitario de la Princesa, Madrid, Spain, ⁶Hospital El Ángel, Málaga, Spain, ⁷Hospital Universitario Materno Infantil de Canarias, Las Palmas, Spain, ⁸Instituto Neurológico Dr. Mateos, Oviedo, Spain, ⁹Complejo Hospitalario Universitario de Albacete, Albacete, Spain, ¹⁰Centro de Estudios Genéticos de Andalucía, Granada, Spain, ¹¹Hospital Universitario de Getafe, Madrid, Spain, ¹²Hospital Sant Joan de Déu, Barcelona, Spain, ¹³Hospital Miguel Servet, Zaragoza, Spain, ¹⁴Hospital Ruber Internacional, Madrid, Spain.

Introduction: Whole exome sequencing (WES) has entered the medical practice as an effective diagnostic test transforming the molecular diagnosis and clinical management of undiagnosed genetic diseases. Exome trio analysis is a very effective strategy to identify de novo, hemizygous, newly homozygous and in compound heterozygous potentially causal variants of rare genetic disorders.

Methods: We performed exome sequencing using Ion AmpliSeq™ Exome RDY technology (Life Technologies) with Ion Proton™ and Ion S5-XL™. Sequencing reads were analysed using Torrent Suite software. Trio annotated variants using ION Reporter were prioritized with an in-house analytical pipeline to identify causative genetic variants.

Results: We present the analysis of the first 130 trios referred to NIMGenetics. Patients were mainly children with syndromic intellectual disability (55%). The genetic etiology was potentially elucidated in 55 probands harboring 38 causal variants and 22 likely causative variants, achieving a 43% molecular diagnostic rate. Among these patients, 36 harbored de novo variants, 6 hemizygous maternally inherited variants, 4 in compound heterozygous variants, 7 newly homozygous variants and 3 variants inherited from parents. Patients with syndromic intellectual disability (54%, 38/70) and specific neurological disorders (53%, 9/17) showed higher molecular diagnostics rates than patients with non-neurological disorders (27%, 3/11)

and non-syndromic intellectual disability (19%, 6/32).
 Conclusions: In our cohort exome trio analysis provide a diagnostic yield of 43% in patients whom traditional molecular diagnostics strategies were uninformative. The implementation of WES as a first-tier diagnostic approach will provide a higher diagnostic yield and a cost-efficient option particularly in rare syndromic intellectual disabled patients.

P08.25

Offspring of an FMR1 premutation carrier: son with a deletion of FMR1 exon 1 and daughter with a full mutation

A. Baumer, E. Wey, R. Abbas, S. M. Azzarello-Burri, A. Rauch; Institute of Medical Genetics, Schlieren, Switzerland.

The vast majority (approx. 99%) of fragile X syndrome patients present with a trinucleotide repeat expansion (>200 CGG repeats) in the 5' UTR of the FMR1 gene. Deletions and point mutations are detected in less than 1% of patients. Deletions affecting single exons or the entire FMR1 gene arise either de novo, are transmitted from mothers carriers of the same deletion, or derive from a maternal pre- or full-mutation allele.

We report on the transmission of a mutant FMR1 allele from a premutation carrier mother to her two children. The healthy mother is carrier of an FMR1 allele with an expansion in the premutation range (approximately 84 CGG repeats). A deletion of the entire exon 1 was detected in her 2-year-old son diagnosed with fragile X syndrome. The analyses were based on a RP PCR and a methylation sensitive MLPA assay, including CNV analysis. A prenatal investigation for her daughter showed that she is carrier of a full mutation with approximately 285 CGG repeats. This latter analysis was performed on chorionic villi using RP PCR. The results for both siblings showed no evidence for mosaicisms.

This case report draws attention to the fact that premutations may not only result in repeat expansions but also in deletions affecting the FMR1 gene.

The FOXG1 syndrome is a rare autosomal dominant developmental encephalopathy. In the literature, 53 patients with a point mutation in the FOXG1 gene have been reported (until December 2015). Through international collaboration, we collected data from 30 new patients with a heterozygous FOXG1 point mutation, including 18 novel mutations, and present detailed phenotypic description and neuroimaging. We performed systematic statistical analysis and genotype-phenotype correlation in patients with FOXG1 syndrome based on the molecular and clinical data of a total of 83 patients with a point mutation in FOXG1. Our analysis shows a higher phenotypic variability than expected. The most characteristic clinical features in patients with a FOXG1 mutation are: (1) severe microcephaly, including primary microcephaly, (2) short stature, (3) moderate to severe psychomotor delay, with some patients achieving unsupported walking and speech, (4) preservation of social interaction, (5) frequent neurological abnormalities including hypotonia, stereotypies, dyskinesia, strabismus, bruxism, and spasticity, (6) variable forms of epilepsy, (7) abnormal sleep pattern, (8) gastrointestinal features, (9) development of scoliosis or kyphoscoliosis, and (10) brain anomalies. Our results show a correlation between location and coding effect of the FOXG1 mutation. The most severe phenotype is associated with truncating mutations in the 5' domain and the fork head domain, the mildest phenotype is associated with missense mutations in the fork head conserved site 1. These data serve for improved interpretation of new FOXG1 sequence variants and well-founded genetic counselling.

Introduction: Intellectual disability (ID) and specific language impairment (SLI) cover a wide range of conditions with heterogeneous phenotypes and etiologies, making them challenging for clinical geneticists. Mutations in forkhead box protein P1 (FOXP1), a transcription regulator, are associated with ID and SLI, with or without autistic features (MIM: 613670). Multiple FOXP1 patients have been described, though so far, no specific phenotype emerged.

Materials and Methods: We report on the clinical and molecular data of 21 novel and well-characterized patients with FOXP1 mutations and review the 25 previously reported FOXP1 patients to delineate the condition.

Results: Phenotypic analysis shows a combination of neuromotor delay, ID, SLI, and typical facial features including a high broad forehead, bent downslanting palpebral fissures, ptosis, blepharophimosis, and a short nose with bulbous tip. Relative macrocephaly, strabismus, a wide mouth with downturned corners, and pronounced nasolabial folds appear more variable. Behavioural problems and autistic features are common. Brain, cardiac and urogenital malformations seem associated. Molecular data show de novo mutations in all cases, either monogenic or part of a more extended interstitial 3p deletions. Subgroup analysis reveals sensorineural hearing loss and more severe ID in patients with interstitial 3p deletions.

Conclusions: FOXP1-related ID syndrome is a recognizable entity that seems more frequent than expected. We expand the phenotypic description with typical facial features and associated organ system involvements. This will enable clinicians to make a gestalt diagnosis and will be helpful to evaluate genotype-phenotype correlations when interpreting large NGS data obtained in patients with ID and/or SLI.

Hospital Universitario La Paz, Madrid, Spain.

Background and aims: FOXP1 is a member of the Forhead Box P (FOXP) sub-family of transcription factors, which also includes FOXP2. Disruptions of FOXP2, the closest relative to FOXP1, have been involved in the etiology of familial verbal dyspraxia.

In the last few years, 11 individuals with FOXP1 variants have been reported, supporting the implication of this gene in the pathogenesis of human cognitive disorders including language impairment. These patients show autism spectrum disorders, intellectual disability, global developmental delay and moderate to severe speech delay.

We report on three new individuals with de novo FOXP1 variants showing features that are consistent with this new clinical entity (MIM 613670).

Method: Whole genome aCGH was carried out in patients 1 and 2 using a custom-designed 60K oligonucleotide array (KaryoArray@v3.0).

Whole exome sequencing was performed as a trio in patient 3 to identify de novo mutations related to the phenotype after a normal result using aCGH. Results: Patient 1 had a 379 Kb de novo deletion that only affected FOXP1. Patient 2 carried a 6.28 Mb de novo deletion including FOXP1 and other ge-

nes. In patient 3 a de novo nonsense mutation (p.R525X) was identified. Discussion and conclusions: These cases contribute to the characterization of the emerging phenotype associated with protein-disrupting FOXP1 variants. Screening for FOXP1 variants should be considered when evaluating individuals with developmental delay, intellectual disability, autism and severe language defects. This study is supported by Instituto de Salud Carlos III grant PI13/02010

Pathogenic long indels identified in patients with intellectual disability

S. Pajusalu^{1,2}, R. Pfundt³, L. E. L. M. Viissers³, M. P. Kwin⁴, T. Reimand^{1,2,4}, K. Õunap^{1,4}, J. A. Veltman^{3,5}, J. Y. Hehir-Kwa⁷;
¹Department of Genetics, United Laboratories, Tartu University Hospital, Tartu, Estonia, ²Department of Biomedicine, Institute of Biomedicine and Translational Medicine, University of Tartu, Tartu, Estonia, ³Department of Human Genetics, Donders Institute, Radboudumc, Nijmegen, Netherlands, ⁴Department of Pediatrics, Institute of Clinical Medicine, University of Tartu, Tartu, Estonia, ⁵Department of Clinical Genetics, Maastricht University Medical Centre, Maastricht, Netherlands.

Whole exome sequencing (WES) continues to facilitate the genetic diagnosis of patients with intellectual disability (ID). Sensitive methods exist for the identification of single nucleotide variants (SNVs) and indels less than 20bp in size. However, the discovery of long indels 20 - 200bp in size, remains challenging even in non-repetitive regions of the genome such as exons. As a result the role of small deletions (long indels) is currently unknown and under reported in many studies.

We analysed the WES data from 98 patients with ID to identify pathogenic long indels located in exons of 650 ID genes using Pindel and Platypus. All patients had previously screened negative for WES based SNV, small indel and large copy number variants. To assess the sensitivity of the calling algorithms we compared variants discovered in the patient cohort to 35 exonic indels described in the Genome of the Netherlands dataset with an allele frequency greater than 5%, 20-200bp in size.

We were able to detect 74% (n=26) of common exonic indels, serving as an estimated detection sensitivity. Further analysis of the rare variants within the patient cohort identified two indels predicted to explain the patients' clinical syndrome (diagnostic yield 2%). A 42bp homozygous deletion of exon-intron border in PGAP3 gene, and a 114bp heterozygous complex indel disrupting the MECP2 gene.

Despite the fragmented nature and short read length of WES data, using specific software tools for long indel detection increases diagnostic yield in patients with ID.

P08.32
De novo 16p13.3 duplication in a girl with intellectual disability, behavioural abnormality and dysmorphic features - characterisation of 16p13.3 duplication without CREBBP gene

D. Gieruszczak-Biatek^{1,2}, A. Skorka^{1,2}, M. Kucharczyk², M. Mlynek², M. Kugauda^{1,2};
¹The Medical University of Warsaw, Warsaw, Poland, ²The Childrens Memorial Health Institute, Warsaw, Poland.

The availability and use of CGH with high-resolution microarrays has greatly improved the detection of micro-deletion and duplications in patients with developmental delay and congenital anomalies. Here we report the molecular karyotyping and phenotypic description of a new patient with 16p13.3 duplication. Our patient presented with intellectual disability, behavioural abnormality and dysmorphic features. Whole-genome oligonucleotide microarray (PerkinElmer CGXTM HD 4x180K Oligo Array) analysis revealed a 2.41 Mb duplication on chromosome 16p13.3 (chr16:788,264-3,203,164; hg19) encompassing 124 genes (including 71 OMIM genes) as well as the critical regions for alpha thalassaemia with intellectual disability (AT-ID), tuberous sclerosis 2 (TSC2), and polycystic kidney disease 1 (PKD1). FISH studies in both parents gave normal results, proving the de novo occurrence of this aberration in the child. According to the literature, 16p13.3 duplication consists of a contiguous gene syndrome with variable phenotypic expression, and CREBBP is the critical gene responsible for the main clinical features of 16p13.3 microduplication. To date, there is no evidence of other genes in this region contributing to the phenotype. It is suggested that other genes play additive or modulator role justifying some of the features found in individuals with dup 16p13.3. In the presented girl, the 16p13.3 duplication is responsible for the clinical phenotype, although it does not include the CREBBP gene. We indicate another possible candidate genes, contributing additional information for this microduplication syndrome and providing new data supporting further genotype-phenotype studies.

This study was supported by the MNiSW Grant No. 0193/IP1/2013/72.

Syndromic or non-syndromic intellectual disability (ID) has multiple underlying etiologies including in particular monogenic rare disease. Most of these causes are currently unknown. In the last five years, the development of whole exome sequencing (WES) has led to identify many new genes responsible of ID. Using WES we identified the same de novo missense heterozygous mutation (p.Glu209Lys) in the PACS2 gene in two patients presenting with moderate ID, neonatal seizures and similar recognizable facial dysmorphism (bulbous nasal tip, wide mouth, thin upper lip and everted lower lip). A moderate neutropenia is observed in one of them. This mutation involves a highly conserved amino acid in an acid domain constituted by ramified amino acids, leading to possible polarity and protein conformation changes. The PACS2 gene encodes for a protein mainly expressed in brain, heart, kidney, pancreas and testis. PACS2 is involved in controlling the exchanges between the endoplasmic reticulum (ER) and mitochondria, in ER homeostasis and in apoptosis induction. Cellular studies have demonstrated that PACS2 knockout would lead to ER dissociation and mitochondria fragmentation, as well as a defect in tBid-mediated apoptosis. PACS2 is also a paralog to PACS1 (54% of identical sequence) previously reported in a human disorder characterized by ID. These data allow considering PACS2 as a new gene responsible for ID with recognizable facial features. The identification of other individuals will be the next step for the description of this new syndrome.

P08.34
Characterisation of emerging pathological CNVs in adults with intellectual disabilities and co-morbid psychiatric disorders

K. Wolfe, A. Strydom, A. McQuillin, N. Bass;
University College London, London, United Kingdom.

Chromosomal copy number variations (CNVs) are highly implicated in the aetiology of neurodevelopmental disorders. Research in pediatric cohorts with developmental delay/intellectual disabilities (ID) has led to the identification of new CNV syndromes. Many adults with ID harboring rare CNV syndromes remain unidentified, precluding description of later onset psychiatric phenotypes.

In an attempt to further characterise very rare emerging CNV syndromes we undertook genome wide chromosomal microarray analysis and comprehensive psychiatric phenotyping of adults with idiopathic ID recruited from ID psychiatry services across England.

Of the 202 adults recruited to the study 11% had CNVs classed as likely pathogenic by the clinical diagnostic laboratory. These included a 1.7Mb deletion at 2q13 and a 2.4Mb duplication at 4p16.3, both of which are poorly characterised in adulthood. We undertook further targeted recruitment of children and adults with CNVs in these regions to expand the phenotypic data on these emerging pathological CNVs.

Study of adults with idiopathic ID and psychiatric disorders has enabled the phenotypic characterisation of two CNVs associated with co-morbid pathologies. Ongoing characterisation of rare CNVs in adulthood could inform clinical management of children with emerging CNV syndromes.

Six individuals with intellectual disability, cerebral white matter abnormalities and motor impairment are homozygous for a splice site mutation in the ABCC9 gene

G. Å. M. Hansen¹, B. Nygård¹, H. Hjeltnes¹, R. Glad¹, M. Falkenberg Smeland¹, V. Marton¹, C. Jonsrud¹, M. Van Ghelue^{1,2};

¹Department of Medical Genetics, Division of Child and Adolescent Health, University Hospital of North Norway, Tromsø, Norway, ²Department of Clinical Medicine, Faculty of Health Sciences, The Arctic University of Tromsø, Tromsø, Norway.

Two families with members displaying substantial motor impairment, mild intellectual disability and periventricular white matter abnormalities on cerebral MRI were referred to our department. Four affected siblings in family 1 had been thoroughly investigated for neuromuscular disorders, including mitochondrial disease. Two siblings in family 2 were previously diagnosed with tuberous sclerosis due to cerebral MRI abnormalities. A trio from each family was analysed using the TruSight One sequencing panel, targeting 4813 disease associated genes on an Illumina MiSeq platform. All six patients (10-31 years old) were homozygous for a splice site mutation c.1320+1G>A in ABCC9. ABCC9 encodes sulfonylurea receptor 2 (SUR2), which is a regulatory subunit of the K-ATP-sensitive potassium (KATP) channel. These SUR2-containing KATP channels are enriched in the sarcolemma, where they sense intracellular ADP content and trigger the opening or closing of potassium channels. These channels are critical in cells during periods of high energy demand. The outcome ABCC9 of the c.1320+1G>A variant is an in frame deletion (r.1165_1320del) resulting (if translated) in a SUR2 protein lacking 52 amino acids (p.Ala389_Gln440del). This compromised SUR2 protein might explain some of the clinical findings in these patients. Whereas heterozygous mutations in ABCC9 are known to cause Cantu syndrome (hypertrichotic osteochondrodysplasia, OMIM#239850), we speculate if the homozygous mutation identified in these two families may cause a new, distinct syndrome.

P08.36

Haploinsufficiency of histone acetylase modifier BRPF1 is responsible for mild intellectual disability with ptosis and might participate to clinical manifestations of the 3p deletion syndrome

F. Mattioli¹, E. Schaefer², K. Yan³, A. Magee⁴, G. Vieville⁵, K. Dieterich⁵, C. Philippe⁶, X. Yang⁷, J. Mandel¹, A. Piton¹;

¹IGBMC, Strasbourg, France, ²Service de génétique médicale, Strasbourg, France, ³Goodman Cancer Center & Department of Medicine McGill University, Montreal, QC, Canada, ⁴Northern Ireland Regional Genetics Service, Belfast City Hospital, Belfast, Ireland, ⁵Hôpital Couple – Enfant, Grenoble, France, ⁶Medical Genetics Service, Sainte-Justine Hospital, Montréal, QC, Canada, ⁷Goodman Cancer Center & Department of Medicine McG, Montréal, QC, Canada.

Intellectual disability (ID) is a common neurodevelopmental disorder characterized by an extreme genetic heterogeneity with more than five hundred genes now described as implicated in mendelian forms. We performed exome sequencing in a large family with five affected individuals presenting with mild ID, ptosis, growth retardation and hypotonia with a suspected autosomal dominant mode of inheritance. We identified a 2-bp deletion causing a frameshift in BRPF1, a gene not yet implicated in ID. The mutated transcript is expressed in fibroblasts and leads to a truncated protein. The BRPF1 protein activates two histone acetyltransferases (KAT6A and KAT6B) causing syndromic ID in human when mutated. We have therefore investigated how the truncation can affect BRPF1 interaction with its partners KAT6A and KAT6B, as well as its histone H3 binding ability. BRPF1 is located in the 3p25 region, involved in a deletion syndrome characterized by ID with additional features, and presumably due to the loss of the SETD5 gene. The identification of a truncating mutation in the BRPF1 gene perfectly cosegregating with ID in one large family with phenotype overlapping the 3p25 deletion syndrome suggests that BRPF1 might also participate to the cognitive and dysmorphic phenotype of this syndrome, and especially ptosis, hypotonia, and growth retardation, as these clinical features are present in patients with 3p25 deletion only when BRPF1 is included. In addition, we also report few other patients with similar phenotype carrying BRPF1 deletions or point mutations, confirming the involvement of the gene in syndromic mild ID.

Trio-based exome sequencing of 10 patients with intellectual disability (ID) previously identified a *de novo* missense mutation in YY1¹, a transcription factor with an important role in various biological processes, such as proliferation, differentiation, embryogenesis, apoptosis, and tumor development. Our study aimed to determine the role of YY1 mutations in ID. Additional patients with *de novo* mutations in YY1 were collected through targeted re-sequencing of YY1, further exome sequencing studies, and through GeneMatcher² and Decipher³. In total, eight patients with *de novo* mutations in YY1 (four missense and four truncating mutations) and three patients with small deletions encompassing YY1 were identified. All patients showed below average IQ that ranged from moderate ID to mild learning problems. Other recurrently observed features included intrauterine growth retardation, feeding problems, behavioral problems, and dystonia. In four patients, typical facial dysmorphisms were present: facial asymmetry with a broad forehead, fullness of the upper eyelids, and a Gingko leaf-like shape of the upper lip. To gain insight into the effects of YY1 mutations on downstream signaling, we profiled lymphoblastoid cell lines from patients with mutations and deletions of YY1 through RNA-seq and ChIP-seq for YY1 and enhancer chromatin marks. In conclusion, we show that *de novo* mutations in the transcription factor YY1 are recurrently observed in patients with ID, and we present a characterization of the main gene network nodes affected by YY1 mutations and deletions.

Identification of new candidate genes in intellectual disability and epilepsy

J. Halvardson¹, J. Zhao¹, A. Zaghlool¹, C. Wentzel¹, P. Georgii-Hemming², E. Månsson³, H. Ederth Sävmarker⁴, G. Brandberg⁵, C. Soussi Zander¹, A. Thuresson¹, L. Feuk¹;

¹Uppsala University, Uppsala, Sweden, ²Karolinska Institute, Stockholm, Sweden, ³Örebro University Hospital, Örebro, Sweden, ⁴Gävle Hospital, Gävle, Sweden, ⁵Falun Pediatric Clinic, Falun, Sweden.

It has been estimated that at least 20-30% of intellectual disability (ID) patients are co-diagnosed with epilepsy, representing a strong over-representation of epilepsy in ID patients compared with the general population prevalence of 0.5-1 %. Here we present the results of exome sequencing in 39 trio families where the index patient is diagnosed with both ID and epilepsy. The families have no history of disease and have previously been screened for copy number variation using arrays.

In 39 patient-parent trios we identified 29 *de novo* mutations in coding sequence. Analysis of *de novo* and inherited variants using standard guidelines for interpretation of coding variants yielded a molecular diagnosis in 11 families (28.2%). Variants in genes of unknown clinical significance were further investigated using protein and co-expression networks, as well as previously published exome sequencing results in neurodevelopmental disorders. Both network analysis and a number of previously published *de novo* mutations implicate the gene HECW2 as a novel candidate gene in ID and epilepsy.

Our results also highlight the utility of network analysis and comparison to previous large-scale studies as a way to prioritize candidate genes for further studies. This study adds to the increasingly growing list of causative and candidate genes in ID and epilepsy and highlights HECW2 as a new candidate gene in neurodevelopmental disorders.

The French HUGODIMS consortium experience on intellectual disabilities

S. Béziau¹, S. Küry¹, T. Besnard¹, X. Latypova¹, A. Denommé², B. Cogné¹, S. Schmitt¹, P. Boisseau¹, M. Vincent¹, S. Mercier¹, B. Isidor¹, HUGODIMS;
¹CHU de Nantes, Nantes, France, ²CHU d'Angers, Angers, France.

Background: Intellectual disabilities (ID) constitute a heterogeneous group of syndromic and non-syndromic disorders of variable prevalence. The number of genes accounting for the vast majority of ID is so important that a targeted analysis is questionable. Numerous studies pointed to the relevancy of exome sequencing of patients/parents trios to increase diagnostic yield.

Purpose: Our goal was to determine the efficiency of exome sequencing to unravel the molecular cause of ID in patients with severe phenotype seen by clinical geneticists from Western France hospitals.

Method: Following a trio-based exome sequencing strategy, we investigated 75 patients with severe ID which could not be explained by fragile X syndrome, copy number variations (CGH array) or even by known candidate genes.

Results: For almost 50% of the cases tested so far, we have been able to explain the molecular cause of the disease or highlight new ID candidate genes.

Conclusions: Our work confirmed that the trio-based whole-exome sequencing is a powerful approach for diagnosis and research. New identified genes highlighted the importance of several signaling pathways such as the NMDAR one, in the occurrence of neurodevelopmental disorders.

P08.40

MED13L haploinsufficiency syndrome - four additional cases emphasizing the variability of the phenotype

P. M. Tørring¹, L. B. Ousager¹, C. Brasch-Andersen¹, M. J. Larsen¹, L. N. Krogh¹, U. Dunkhase-Hein², M. Kibæk³, L. Laulund³, N. Illum³, M. Zollino⁴, C. R. Fagerberg¹;
¹Dept. of Clinical Genetics, Odense University Hospital, Odense C, Denmark, ²Dept. of Pediatrics, Hospital of Southern Jutland, Aabenraa, Denmark, ³Dept. of Pediatrics, Odense University Hospital, Odense C, Denmark, ⁴Istituto di Genetica Medica, Università Cattolica Sacro Cuore, Rome, Italy.

Introduction: *MED13L* haploinsufficiency syndrome has recently been described and is characterized by moderate intellectual disability (ID), speech impairment, and dysmorphic facial features, in some cases accompanied by congenital heart defects. We present four additional patients with *MED13L* haploinsufficiency syndrome and review the literature for phenotypical and genetic aspects of previously described patients.

Materials and methods: In the search for genetic aberrations in individuals with ID, two of the patients were identified by chromosomal microarray analysis, and one by exome sequencing. One of the individuals, suspected of *MED13L* haploinsufficiency syndrome, based on clinical features, was identified by sanger sequencing of *MED13L*.

Results: All four patients had *de novo* *MED13L* aberrations, including two intragenic *MED13L* microdeletions, one nonsense and one frameshift *MED13L* mutation. Phenotypically, they all had ID, speech and motor delay, open mouth appearance, and macrostomia. Two patients were diagnosed with autism, and three had macroglossia. None had congenital heart defects.

The literature was reviewed with respect to clinical features and genetic aberrations.

Conclusions: Even if most clinical features of *MED13L* haploinsufficiency syndrome is rather non-specific, the syndrome may be suspected in patients with developmental delay, speech impairment, and macroglossia, macrostomia, or open mouth appearance.

The PUF60 gene encodes for the Poly-U Binding Splicing Factor 60 kDa which belongs to the spliceosome. Recently, PUF60 haploinsufficiency has been discussed as the best candidate gene for the 8q24.3 microdeletion syndrome phenotype, in seven patients with developmental delay (DD), post-natal proportionate growth retardation, and facial dysmorphism. Variable features comprised ocular coloboma, joint laxity and/or dislocation, vertebral anomalies, branchial anomalies, cardiac, and renal defects. To date, a unique patient has been reported with a *de novo* probably pathogenic mutation in PUF60 (p.His169Tyr) associated with DD, microcephaly, craniofacial and cardiac defects. We report on three additional patients carrying a *de novo* heterozygous mutation in PUF60 identified by whole exome sequencing (WES), including a splice-site mutation (c.24+1G>C), a nonsense (p.Arg448*), and a missense change (p.Val483Ala). All four mutated patients share a core facial gestalt that was present in patients with 8q24.3 microdeletions, associated with DD. Other findings included feeding difficulties (3/4), cardiac defects (3/4), IUGR (3/4), hip dislocation (2/4), vertebral anomalies (1/4), distal anomalies (3/4), bilateral micropthalmia and irido-retinal colobomas (1/4), and branchial arch defect (1/4). These results confirm the major role of PUF60 in the 8q24.3 microdeletion phenotype since patient with a microdeletion share common manifestations with patients carrying a point mutation. PUF60 can be added to the list of genes causing a recognizable form of syndromic intellectual disability, as well as to the list of syndromic colobomas.

Diagnosis of intellectual disability by sequencing all genes known in pathology.

B. Keren¹, C. Mignot², C. Nava¹, E. Lejeune², C. Mach³, C. Estrade³, V. Olin³, A. Lafitte³, S. Karagic³, A. Jacquette², P. Charles², S. Whalen², I. Marey², S. Heide³, F. Mochel⁴, A. Afenjar⁴, D. Doummar⁵, T. Billette de Villemeur⁵, A. Guet⁵, D. Rodriguez⁵, M. Marie-Laure⁵, Y. Marie⁶, S. Chantot-Bastarud⁷, R. Touraine⁸, F. Lesne⁸, A. Faudet⁸, F. Soubrier⁸, D. Héron², C. Depienne¹;
¹Département de Génétique, ICM UPMC, Inserm UMR_S1127/CNRS UMR 7225, GH Pitié-Salpêtrière, APHP, Paris, France, ²Département de Génétique, centre de référence déficience intellectuelle de causes rares, filière Déficience, GH Pitié-Salpêtrière, APHP, Paris, France, ³Département de Génétique, GH Pitié-Salpêtrière, APHP, Paris, France, ⁴Département de Génétique, centre de référence déficience intellectuelle de causes rares, filière Déficience, GH Armand-Trousseau, APHP, Paris, France, ⁵Service de Neuropédiatrie, GH Armand-Trousseau, APHP, Paris, France, ⁶ICM, plateforme de génotypage et séquençage, GH Pitié-Salpêtrière, Paris, France, Paris, France, ⁷Laboratoire de Cytogénétique, GH Armand-Trousseau, APHP, Paris, France, ⁸Service de Génétique, CHU Nord, Saint-Etienne, France.

The etiologies of intellectual disability (ID) are very heterogeneous. For this reason, exome sequencing is increasingly used in the diagnosis of ID.

We sequenced 151 index cases with the Illumina TruSight One panel which targets the coding sequences of 4813 genes involved in human pathology. Our aim was a diagnostic yield close to exome sequencing but less expensive. All patients had a negative diagnostic work-up before sequencing including chromosome microarray analysis.

A definitive or likely diagnosis was found for 42 index cases (28%) in 39 different genes: 30 were autosomal dominant (*de novo* or with a low mosaicism in one parent), 6 were autosomal recessive, 6 were X-linked. We also made 4 partial diagnoses which do not explain the whole phenotype. Besides, 10 variants were classified as variants of unknown significance. Finally, we identified 7 incidental findings irrelevant with the indication.

In our series, 56 patients had autism and ID with normal motor development and autistic regression. In these patients, we achieved a unique diagnosis (1.7%); therefore our diagnostic yield was 42% among our 95 patients with ID and no autism. We had also 35% diagnoses in our 40 patients with ID and epilepsy.

Overall, this technique provides a significant advance in the diagnostic strategy of patients with ID. However, it highlights the need to better characterize its clinical indications. Mostly, our experience suggests that ID as part of an autistic syndrome is currently not a good indication due to the supposed multifactorial nature of this pathology.

P08.43

A novel mutation (c.132 G>C) in PQBP1 gene is linked to severe to mild intellectual disability in five male cousins

M. M. Alwasayah^{1,2}, B. Al-wasiyah³, C. Trujillo⁴, H. Bouazzi⁵;

¹Azizah Maternity & Children Hospital, Jeddah, Saudi Arabia, ²Center of Excellence in Genomic Medicine Research (CEGMR), King Abdullaziz University, Jeddah, Saudi Arabia, ³King Abdullaziz University, Jeddah, Saudi Arabia, ⁴Erfan & Bagedo Hospital, Jeddah, Saudi Arabia, ⁵Necker-Enfants malades Hospital, Paris descartes University, Paris, France.

Introduction: Ten percent of intellectual disabilities are related to genes on the X chromosome. Among the 1200 genes of the X chromosome, 115 of them so far are X-linked intellectual disability genes (X-LID). PQBP1 gene is well known to be involved in syndromic and non-syndromic X-LID. Here we report a French family with 5 affected males who showed severe to mild intellectual disability associated with developmental delay. Subsequent genetic analysis with X exome sequencing has revealed a novel missense mutation, c.132G>C. Which was predicted to be deleterious by Polyphen-2 software. This mutation was inherited by all the affected relatives. The mothers and the grandmother have been found heterozygous for the mutation. **Material and methods:** NGS for XLID was performed for 2 patients using SOLID 5500 sequencer (Life technologies, Grand Island, NY, USA). Sorting and calling of SNP/InDel were performed using SAMTOOL and GATK software. All sequence variants were prioritized by scoring phylogenetic conservation and functional impact (SIFT and Polyphen-2). Candidate variants were confirmed by Sanger sequencing.

Results: Sequencing of X-exome from all patients identified three missense variants (c.731G>A/G244Q, c.86-88del/K29del and - c.132G>C- R10P) respectively in three different genes (TLR8, SPANXN4, and PQBP1).

Conclusion: We have identified three candidate genes for this family (PQBP1, TLR8 and SPANXN4), whose mutations are respectively (p.R10P, pG244Q and pK29del). To our knowledge these mutations are new, they segregate with the disease phenotype, and are absent in healthy subjects. The only gene known for its involvement in the ID is PQBP1

P08.44

Homozygote RTTN mutation in a patient with microcephaly and intellectual disability

E. Yasar¹, G. Yigit², Y. Li², J. Altmuller³, P. Nurnberg³, S. Karatoprak⁴, U. Kornak^{5,6,7}, B. Wollnik², I. Tekedereli¹;

¹Medical Genetics Division, Inonu University School of Medicine, Malatya, Turkey, ²Institute of Human Genetics, University of Gottingen, Gottingen, Germany, ³Cologne Center for Genomics, University of Cologne, Cologne, Germany, ⁴Child and Adolescent Psychiatry Division, Inonu University School of Medicine, Malatya, Turkey, ⁵Institute of Medical Genetics and Human Genetics, Charité - Universitaetsmedizin Berlin, Berlin, Germany, ⁶Max Planck Institute for Molecular Genetics, Berlin, Germany, ⁷Berlin-Brandenburg Center for Regenerative Therapies, Charité - Universitaetsmedizin Berlin, Berlin, Germany.

Introduction: Primary microcephaly is an important clinical symptom associated with various genetic disorders and can be found isolated or as one of the features of a syndrome. Microcephaly and intellectual disability usually present together and more than 300 OMIM entries are described with the coexistence of these two features. In this report we describe a patient with microcephaly, deficiency of speech development, delayed motor skills, seizures and a homozygous RTTN gene mutation.

Materials and Methods: Cranial MRI, EEG, echocardiography, abdominal USG, visual evoked potential (VEP) and brainstem auditory evoked response (BAER) tests were performed. Karyotyping, FISH analysis and whole exome sequencing (WES) were performed.

Results: The index patient was 9 years and presented with primary microcephaly, developmental delay, recurrent seizures, and intellectual disability. Cranial MRI showed pachygyria, neuronal migration anomaly and cerebrotubular atrophy. EEG showed frontotemporal epilepsy. Echocardiography, abdominal ultrasonography, VEP and BAER tests were normal. The patient had normal karyotype and FISH analysis for Prader Willi/Angelman Syndrome. WES analysis revealed a causative homozygous missense (c.2796A>T) RTTN gene mutation.

Conclusions: RTTN gene encodes rotatin protein which is localized at the ciliary basal bodies. In mice, rotation protein defects result in abnormal axial rotation and neural tube differentiation. Even though specific functions in human are still unknown, it is suggested that rotatin has similar effects on the development of the neural tube and the notochord. Since clinical variability in patients carrying autosomal recessive RTTN mutations has been described, it is important to further define the clinical spectrum of RTTN-associated disorders.

P08.45

Epilepsy is not a mandatory feature of STXBP1 associated Ataxia-Tremor-Retardation Syndrome

S. Beck-Weedl¹, A. Riess¹, U. Grasshoff¹, M. Sturm¹, F. Akmut¹, M. Schöning², A. Tzschach³, O. Riess¹, J. Gburek-Augustat²;

¹Institute of Medical Genetics and Applied Genomics, University of Tuebingen, Tuebingen, Germany, ²Children's Hospital; Paediatric Neurology and Developmental Medicine, University of Tuebingen, Tuebingen, Germany, ³Institute of Clinical Genetics, Technische Universität Dresden, Dresden, Germany.

Introduction: Mutations in the *STXBP1* gene were first described to cause Ohtahara syndrome (Early infantile epileptic encephalopathy, EIEE) characterized by very early infantile epileptic encephalopathy with frequent tonic spasms and a suppression-burst pattern on electroencephalogram. In the following years a wider phenotype was recognized having milder forms of epilepsies.

Material and Methods: More than 150 patients with intellectual disability (ID) and movement disorders, in whom genomic imbalances and fragile X syndrome had been excluded, were screened for exonic variants using the TruSight One enrichment panel (Illumina).

Results: Here, we present three female patients with an ataxia-tremor-retardation syndrome caused by a *de novo* dominant *STXBP1* mutation. Two of the girls were diagnosed through next-generation-sequencing as mutations in *STXBP1* were not suspected. The third patient was diagnosed by targeted genetic testing due to its clinical features strikingly similar to the first two girls. All patients showed intellectual disability and movement disorders. Additional behavioral disturbances such as hyperactivity, stereotypic behavior, hand biting and hyperventilation burst were also recognized in affected patients with *STXBP1* mutations

Conclusion: In summary, the characteristic feature of our three patients is the lack of epilepsy which is in contrast to the majority of the patients. Hence, epilepsy is not a mandatory feature of patients with a *STXBP1* mutation.

P08.46

A microdeletion at Xp11.22 detected by whole exome sequencing confirms SHROOM4 association with Stocco dos Santos syndrome and XLID in a large Greek kindred

B. Hagnefelt¹, C. Konialis¹, K. Lilakos², S. Karapanou¹, C. Pangalos¹;

¹InterGenetics-Diagnostic Genetics Center, Athens, Greece, ²Department of Haematology, University of Athens Medical School, Athens, Greece.

Introduction: The direct implication of several X-linked genes in XLID has been questioned, mainly due to the lack of replication of the particular finding and to inherent difficulties in validating *de novo* variants. We present the identification of a microdeletion encompassing the SHROOM4 gene, detected through whole exome sequencing in a large Greek kindred with syndromic XLID, thus establishing the involvement of SHROOM4 in Stocco dos Santos Syndrome and syndromic XLID.

Materials and Methods: A 45 yr old male, presenting with mild dysmorphic features, kyphosis, short stature, moderate intellectual disability and with four other similarly affected male relatives, was referred for genetic testing. Common genetic causes had been previously excluded. Whole exome sequencing (WES) was performed on an Ion Proton PI chip, followed by variant prioritization utilizing a custom analysis pipeline, including CNV detection through a modified coverage analysis plug-in.

Results: Combined analysis of WES data from the proband revealed a highly probable deletion of the Xp11.22 chromosomal region, approximately 1,85Mb in size encompassing OMIM genes SHROOM4 and BMP15. Subsequent aCGH analysis confirmed the presence of the microdeletion in 3 other similarly affected males in the family and the expected maternal segregation in the kindred.

Conclusions: The findings presented herein provide important evidence confirming, the hitherto debatable, involvement of the SHROOM4 gene in syndromic XLID and its association with Stocco dos Santos syndrome. Furthermore, the employed data analysis pipeline illustrates the power of WES analyses for the detection of constitutional CNV's, particularly those associated with X-linked genetic disorders.

P08.47

A novel splicing mutation in the IQSEC2 gene that modulates the phenotype severity in a family with intellectual disability

I. Madrigal¹, M. Alvarez-Mora¹, J. Rossell², L. Rodriguez-Revenga¹, O. Karlberg³, S. Sauer⁴, A. Sävänen³, M. Mila¹;

¹Hospital Clinic, Barcelona, Spain, ²Hospital Universitari Son Espases, Palma de Mallorca, Spain, ³Molecular Medicine and Science for Life Laboratory, Uppsala University, Uppsala, Sweden, ⁴Max-Planck Institute for Molecular Genetics, Berlin, Germany.

Introduction: The IQSEC2 is known to have a significant role in cytoskeletal organization, dendritic spine morphology and synaptic organization.

Material and Methods: We studied a non-consanguineous family with five affected individuals with unexplained mild to severe ID and one with learning disabilities, studied by next generation sequencing.

Results: Here we report on the first splicing variant in IQSEC2 (g.88032_88033del; NG_021296.1) that co-segregates in a family diagnosed with an X-linked form of ID. In a percentage of the cells, the variant activates an intraexonic splice acceptor site that abolishes 26 amino acids from the highly conserved PH domain of IQSEC2 and creates a premature stop codon 36 amino acids later in exon 13. Interestingly, the percentage of aberrant splicing seems to correlate with the severity of the disease in each patient. The impact of this variant in the target tissue is unknown, but we can hypothesize that these differences may be related to the amount of abnormal IQSEC2 transcript.

Conclusions: To our knowledge, we are reporting a novel mechanism of IQSEC2 involvement in ID. Variants that affect splicing are related to many genetic diseases and the understanding of their role in disease expands potential opportunities for gene therapy. Modulation of aberrant splicing transcripts can become a potent therapeutic approach for many of these diseases.

Mutation spectrum of KMT2D gene in Kabuki syndrome

V. Gatinois^{1,2,3}, G. Sarrabay^{1,2,3}, G. Boursier^{1,4}, A. Fabre¹, E. Sanchez², D. Genevieve^{2,3,5}, I. Toutou^{1,2,3}, M. Barat-Houari^{1,2};

¹Laboratoire de génétique des maladies rares et autoinflammatoires - Hôpital A. de Villeneuve - CHU de Montpellier, Montpellier, France, ²Unité INSERM U1183 - Hôpital St Eloi - CHU de Montpellier, Montpellier, France, ³Université de Montpellier, Montpellier, France, ⁴UMR CNRS 9214 / Inserm U1046 - Université de Montpellier, Montpellier, France, ⁵Service de Génétique Médicale - Hôpital A. de Villeneuve - CHU de Montpellier, Montpellier, France.

Introduction: Kabuki syndrome is a rare genetic disease involving multiple malformations, intellectual deficiency and a distinctive facial phenotype. Genetic transmission of Kabuki syndrome is mainly autosomal dominant with an estimated incidence of 1 in 32,000 births. In most cases, a KMT2D point mutation is responsible of the syndrome.

Materials and Methods: A large cohort of French Kabuki patients was collected. For each of them, a previous clinical assessment was performed and 260 probands with a high confidence were selected. KMT2D analysis was done by Sanger sequencing. Highlighted variants were scored into a 5-categories classification of pathogenicity based on scientific literature, public mutation databases, population frequencies, mutation nature, family segregation and prediction tools.

Results: We identified more than 200 unique pathogenic or likely pathogenic mutations among which 50 were never published before. Truncating mutations were the most common type of variations. Missense mutations showed a non homogenous distribution with high density in exons 50 to 53 encoding the highly conserved SET domain of KMT2D protein. Most of mutations were de novo and a very few cases showed a dominant inheritance from a parent with all or any clinical evidences of the proband. Some of these de novo mutations were recurrent highlighting the existence of mutational hot spots on KMT2D.

Conclusions: This large cohort allowed us to collect and classify a large number of unpublished mutations. This work has been shared on a public LOVD-database (<http://databases.lovd.nl/shared/genes/KMT2D>) in order to improve both interpretation of KMT2D variants and management of Kabuki patients.

KAT6A truncating mutation in a girl with global developmental delay and a distinctive phenotype

M. Palomares Bralo^{1,2,3}, S. García Miñaur^{1,2,3}, L. Fernández^{1,2,4}, E. Vallespín^{5,6,4}, Á. del Pozo Maté^{1,6,4}, K. Ibáñez Garikano^{5,6,4}, J. Silla^{1,6,4}, F. Santos-Simarro^{1,6,4}, R. Mena^{5,6,4}, R. Martín Arenas¹, P. Tirado Requero⁷, E. Mansilla^{1,6,4}, J. Nevado^{1,6,4}, L. Alba Valdivia⁵, M. de Torres^{1,6,4}, P. Lapunzina Badia^{1,6,4};

¹INGEMM, Hospital Universitario La Paz, Madrid, Spain, ²Instituto de Investigación Hospital Universitario La Paz, Madrid, Spain, ³Centro de Investigación Biomédica en Red Enfermedades Raras, Madrid, Spain, ⁴Centro de Investigación en Red Enfermedades Raras, Madrid, Spain, ⁵INGEMM, Hospital Universitario La Paz, Madrid, Spain, ⁶Instituto de Investigación Hospital Universitario La Paz, Madrid, Spain, ⁷Servicio de neurología infantil. Hospital Universitario La Paz, Madrid, Spain.

Background and aims: Implementation of exome sequencing in individuals with intellectual disability syndromes has enabled the identification of de novo heterozygous mutations in up to 40% of patients with severe ID. Recently, heterozygous truncating mutations in KAT6A have been reported in 10 individuals by two independent groups as the cause of a distinct ID syndrome. Common features included global developmental delay, hypotonia, speech delay, microcephaly and/or craniosynostosis and craniofacial dysmorphisms. Here we present a girl with a de novo heterozygous mutation in KAT6A with a phenotype that resembles the one reported in previous cases, reinforcing the association between KAT6A mutations and a new recognizable syndrome.

Method: Whole exome sequencing was performed as a trio in this family in an attempt to identify de novo mutations causing the ID and the peculiar phenotype observed in this girl. At 22 months she presented with growth and developmental delay, congenital heart defects, microcephaly and distinctive facial features. Initial investigations (cerebral MRI, skeletal survey, abdominal US scan, metabolic screen, standard chromosome analysis and a 60K customized aCGH) were all normal.

Results: A de novo mutation in KAT6A was detected: NM_001099412.1:c.4228_4232delAAAGA(p.Lys1410Glyfs*7). This change was confirmed by Sanger sequencing.

Discussion and conclusion: This case contributes to delineate the phenotype of a new intellectual disability syndrome associated with KAT6A mutations and highlights the potential of whole exome sequencing for the identification of causal mutations in individuals with intellectual disability where no diagnosis has been reached after routine investigations.

KCNK9 imprinting syndrome - a treatable disorder?

J. M. Graham¹, N. Zadeh², E. Tan³, M. Deardorff⁴, L. Sagi-Dain⁵, S. Shalev⁶;

¹Cedars Sinai Medical Center, Los Angeles, CA, United States, ²CHOC Children's Hospital, Orange, CA, United States, ³KK Women's and Children's Hospital, Singapore, Singapore, ⁴Children's Hospital of Philadelphia, Philadelphia, PA, United States, ⁵Emek Medical Center, Afula, Israel, ⁶Rapaport Faculty of Medicine, Technion, Haifa, Israel.

Barel et al. (2008) mapped a new KCNK9 imprinting syndrome to chromosomal region 8q24 in a large Arab Israeli family, and demonstrated that this syndrome is caused by a specific missense mutation 770G>A in exon 2, replacing glycine at position 236 by arginine (G236R) in the maternal copy of KCNK9 within this locus. KCNK9 (also called TASK3) encodes a member of the two pore-domain potassium channel (K2P) subfamily. This gene is normally imprinted with paternal silencing, thus a mutation in the maternal copy of the gene will result in disease, whereas a mutation in the paternal copy will have no effect. Exome sequencing in 4 other patients with developmental delay and central hypotonia revealed de novo G236R mutations. These patients demonstrated congenital hypotonia, variable cleft palate, normal MRIs and EEGs, delayed development, and severe feeding problems. Associated facial dysmorphic features included dolichocephaly with bitemporal narrowing, short philtrum, tented upper lip, palatal abnormalities, and small mandible. Features in older members of the original Arab Israeli family included intellectual disability of variable severity, severe feeding difficulties in infancy with dysphagia of liquids and dysphonia with a muffled voice into early adulthood, generalized hypotonia, weakness of proximal muscles, elongated face with narrow bitemporal diameter, and reduced facial movements. We describe the clinical features in the 4 recently recognized patients and compare them with those found in members of the original Arab-Israeli family and suggest this may be a treatable disorder.

P08.51

About a case with a novel KIRREL3 variant: further clinical delineation of the associated phenotype

E. Ranza¹, M. Guipponi¹, J. L. Blouin¹, P. Makrythanasis¹, C. Gehrigh¹, C. Menache², A. Bottani¹, A. Martin³, M. E. Williams³, S. E. Antonarakis^{1,4};

¹HUG, University Hospitals of Geneva, Geneva, Switzerland, ²Neuropediatrics, Clinique des Grangettes, Chêne-Bougeries, Switzerland, ³Department of Neurobiology and Anatomy, University of Utah School of Medicine, Salt Lake City, UT, United States, ⁴Department of Genetic Medicine and Development, University of Geneva, Geneva, Switzerland.

KIRREL3 is a cell-adhesion molecule of the immunoglobulin superfamily, that has been implicated in cerebral development, synaptic maintenance and plasticity. It interacts with neuronal proteins, including the synaptic scaffolding protein CASK, which is associated with an X-linked intellectual disability (ID) syndrome (OMIM#300749).

To date, only a few patients with pathogenic variants in *KIRREL3* have been reported (OMIM#612581): their phenotype was described as mild to severe ID, without further details, highlighting the need for a better clinical delineation of this syndrome.

Here, we report a case of a 12 year-old male with moderate ID, obesity, ADHD and behavioural problems, mostly hyperphagia. The patient also had mild dysmorphic features, such as enophthalmia, bulbous nose, short philtrum, thin upper lip and wide spaced teeth with two missing superior canines. Brain MRI revealed wide asymmetrical ventricular spaces.

Array-CGH, *FMR1* testing and 15q11.2 DNA methylation were all normal. Exome sequencing followed by targeted analysis of a panel of 990 ID genes, identified a novel *de novo* missense variant in *KIRREL3* c.2019G>A:p.(Met673Ile) which was classified as likely pathogenic according to the latest ACMG guidelines. The functional impact of the mutant *KIRREL3* on synapse development in neuronal cells is currently ongoing.

This study will provide insight into the clinical spectrum associated with pathogenic variants in *KIRREL3* and the molecular mechanisms underlying *KIRREL3*-related neurodevelopmental disorders.

P08.52

Efficacy of GenIDA, a family-oriented international online registry and clinical database for genetic forms of intellectual disability and/or autism, to collect medically relevant information on the Koolen - de Vries Syndrome

F. P. Colin¹, K. P. J. Schellekens², T. Mazzucotelli¹, T. Kleefstra², D. A. Koolen², J. L. Mandel^{1,3,4};

¹Translational medicine and neurogenetics dept., Institut de génétique et de biologie moléculaire et cellulaire (IGBMC) – INSERM U964 – CNRS UMR7104 – University of Strasbourg, Illkirch, France, ²Department of Human Genetics, Radboud University Medical Centre, Nijmegen, Netherlands, ³Genetic diagnostic laboratory, CHU, Strasbourg, France, ⁴Collège de France, Chaire de génétique humaine, Paris, France.

Intellectual disability (ID) and autism spectrum disorders (ASD) are overlapping disorders that constitute a major public health problem with a cumulated frequency of about 2.5%. Progress in genome analysis has allowed the identification of many recurrent CNVs and more than 600 genes implicated in monogenic forms of ID/ASD. However, information on the clinical spectrum and natural history is often lacking behind. These data are essential for improved clinical management of patients and genetic counselling of family members.

Therefore, we initiated a unique database model for specific genetic causes of ID/ASD, called GenIDA (genida.unistra.fr), whereby clinical information is entered and updated by the family of the affected individual based on a structured clinical questionnaire that is available in multiple languages. We have used Koolen - de Vries syndrome (KdVS) as a test case for the GenIDA approach. KdVS is a multi system condition characterized by (neonatal) hypotonia, moderate ID, epilepsy, congenital abnormalities and characteristic facial dysmorphism. We transferred a large existing family-based KdVS clinical dataset (>70 cases) and asked parents to update the data on the GenIDA website.

This project shows the willingness of parents to participate in studies dealing with rare diseases affecting their child. Direct comparison with data collected by clinicians allowed us to evaluate the quality of the data entered by families, search for novel and/or more penetrant comorbidities (i.e. behavioral problems like hyperactivity were significantly more reported) and generate a first natural history analysis.

Unreported mutation found by whole exome sequencing in the KPTN gene is causative for Macrocephaly in an Iranian infant

H. Galehdari¹, G. Shariati², A. Saberi³, M. Hamid⁴, E. Jahangiri¹, F. Seifi¹, N. Mazaheri¹, M. Zamani¹, J. Zeighami¹, M. Sarvari¹;

¹Genetics, Ahwaz, Iran, Islamic Republic of, ²Narges Genetic Diagnostic Lab, Ahwaz, Iran, Islamic Republic of, ³Jondishapur University, Ahwaz, Iran, Islamic Republic of, ⁴Pasteur Institute, Tehran, Iran, Islamic Republic of.

Mutation in *KPTN* gene have been identified as causative for autosomal recessive mental retardation and clinically characterized by significantly below average general intellectual functioning associated with impairments in adaptive behavior and manifested during the developmental period. Most consistent features are global developmental delay, macrocephaly with frontal bossing, high levels of anxiety, repetitive speech, and mild to severe speech deficits. Recent reports suggest that *KPTN* mutations are associated with a broader phenotypic spectrum. We used next generation sequencing to find out disease causing gene confirmed by Sanger sequencing. We identified a novel nonsense mutation(c.609 G>A) in 14 years old Iranian patient with autistic behavior; macrocephaly, skull deformity, speech impairment and symptoms included hydrocephaly have been showed by MRI at birth. This mutation was neither found in ExAC nor 1000G and ClinVar.

P. M. de Brouwers⁵, M. Guipponi^{1,3}, F. A. Santoni^{1,3}, E. Frengen⁹, J. Ahmed⁴, H. van Bokhoven⁵, S. Riazuddin^{9,10}, S. E. Antonarakis^{1,3};

¹Department of Genetic Medicine and Development, University of Geneva, Geneva, Switzerland, ²Department of Otorhinolaryngology-Head & Neck Surgery, School of Medicine, University of Maryland, Baltimore, MD, 21201, USA, Baltimore, MD, United States, ³Service of Genetic Medicine, University Hospitals of Geneva, Geneva, Switzerland, ⁴Institute of Basic Medical Sciences (IBMS), Khyber Medical University, Peshawar, Pakistan, ⁵Department of Human Genetics, Donders Institute for Brain, Cognition and Behaviour, Radboud University Medical Center, Nijmegen, Netherlands, ⁶Department of Neurology, Oslo University Hospital, Oslo, Norway, ⁷National Centre of Excellence in Molecular Biology, University of the Punjab, Lahore, Pakistan, ⁸Department of Medical Genetics, Oslo University Hospital, University of Oslo, Oslo, Norway, ⁹Allama Iqbal Medical College, University of Health Sciences, Lahore, Pakistan, ¹⁰Shaheed Zulfiqar Ali Bhutto Medical University, Pakistan Institute of Medical Sciences, Islamabad, Pakistan.

LINGO1, a transmembrane receptor, is predominantly expressed in central nervous system and is involved in the inhibition of neuronal myelination, through activation of the NgR1 signaling pathway. Various GWAS and expression studies have implicated increased expression of this gene with Multiple Sclerosis, Essential Tremor and Parkinson's disease. We have studied two unrelated Pakistani consanguineous families from different areas of the country. Eleven patients of both families presented with moderate to severe intellectual disability, speech and motor delay. Out of 11 patients, four presented with microcephaly and seven with generalized tonic-clonic seizures. We performed exome sequencing in order to identify the potential causal variant. We have identified a homozygous missense variant (NM_032808.6:c.869G>A:p.(Arg290His)) in family one and different homozygous variant in family two (NM_032808.6:c.863A>G p.(Tyr288Cys)) in LINGO1, that were predicted to be pathogenic by SIFT, PolyPhen and MutationTaster, and segregated with the phenotype in the respective families. NgR1 signaling pathway mediated by LINGO1-NgR1 complex, negatively regulates oligodendrocyte differentiation and neuronal survival. Previously mouse and zebrafish models have been described and presented the role of LINGO1 in abnormal neuronal development and central nervous system myelination. Taken together, our results indicate that LINGO1 missense variants cause autosomal recessive intellectual disability. However, further functional studies are warranted to dissect the exact role of the identified variants.

P08.55

Recurrence of *MEF2C* heterozygous mutation in siblings indicating parental germline mosaicism

I. K. Nielsen¹, I. S. Pedersen², V. Q. Le², A. Ernst², J. R. Ostergaard²;

¹Department of Clinical Genetics, Aalborg University Hospital, Aalborg, Denmark, ²Section of Molecular Diagnostics, Clinical Biochemistry, Aalborg University Hospital, Aalborg, Denmark, ³Department of Pediatrics, Aarhus University Hospital, Aarhus, Denmark.

Introduction: The autosomal dominant mental retardation syndrome-20 (MRD20) is caused by a heterozygous mutation in the *MEF2C* gene and characterized by severe intellectual disability with absent speech, limited walking abilities, hand stereotypies, epilepsy, and lack of major malformations. *MEF2C* is essential for early neurogenesis, neuronal migration and differentiation of the brain. To date, all individuals reported have been simplex cases, resulting from de novo deletions or point mutations. We report a case with putative gonadal mosaicism in a parent leading to siblings with MRD20.

Material and methods: Female siblings (2 and 10 yrs) of healthy unrelated parents. The children had a similar phenotype with severe intellectual disability, absent spoken language, few seizures, stereotypic hand movements, unstable wide-based gait, and minor facial dysmorphism.

Whole exome sequencing was carried out and mutations were validated by Sanger sequencing.

Results: A pathogenic heterozygous frame-shift mutation in *MEF2C*, NM_001193347.1:c.582delT was detected in lymphocytes from both girls. The mutation was not found in lymphocytes from any of the parents. The parents did not wish to have any other samples taken in order to confirm a somatic or germline parental mosaicism.

Conclusions: Finding the same mutation in siblings, and not in the parents, indicates parental gonadal mosaicism. To the authors' knowledge, this has not been described before for MRD20, suggesting that the recurrence risk, for parents with a child with MRD20, might be higher than by chance alone. Considerations of (and testing for) mosaicism might be considered a helpful tool in the genetic counseling of these families.

MEF2C mutations in the clinic - a case series

C. Breen^{1,2}, J. Innes^{1,2}, J. Clayton-Smith^{1,2}, E. A. Jones^{1,2}, H. Kingston^{1,2}, W. Reardon^{1,2}, B. Kerr^{1,2}, S. Douzgou^{1,2};

¹Manchester Centre for Genomic Medicine, Manchester, United Kingdom, ²Institute of Human Development Faculty of Medical & Human Sciences, University of Manchester, Manchester, United Kingdom.

Patients with chromosome 5q14.3q15 microdeletions involving the phenocritical *MEF2C* gene present with features including early and severe developmental delay including absence of speech and hypotonia; many remain unable to walk unaided. A facial gestalt includes a high and wide forehead,

pronounced eyebrows, down turned corners of the mouth, and a prominent philtrum. *MEF2C* mutations are estimated to account for 1% patients with severe mental retardation and 2% Rett-like patients, with a phenotype similar to those with the microdeletion.

We report 5 new patients seen by our team, 4 with deletions including *MEF2C* and one with a point mutation. We compare this additional phenotypic data with that reported in the literature, and including a patient with the deletion of both *MEF2C* and the adjacent *RASA1* who also presents with capillary malformation, confirming a previously reported association. We also discuss the facial phenotype of our patients, with reference to the recent literature around *MEF2C* as a transcription factor in craniofacial development.

P08.57

Novel *PGAP1* gene mutation in patients with mental retardation in a Turkish family

L. Özer¹, D. Trujillano², E. Ünsal³, S. Aktuna³, F. Akyiğit¹, P. Çelikkol¹, A. Rolf⁴, V. Baltacı⁵;

¹Mikrogen Genetic Diagnosis Center, Ankara, Turkey, ²Centogene, Rostock, Germany, ³Istanbul Yeni Yüzyıl University School of Medicine, Department of Medical Biology and Genetics, Istanbul, Turkey, ⁴Centogene, Rostock, Turkey, ⁵Istanbul Yeni Yüzyıl University School of Medicine, Department of Medical Biology and Genetics, İSTANBUL, Turkey.

Introduction: Pathogenic variants in the *PGAP1* gene were reported as causative for autosomal recessive mental retardation type 42 and hereditary spastic paraplegia type 67. **Materials and Methods:** Here we represent a Turkish family with two affected children who were born as the first (14 years old male) and second child (11 years old male) of consanguineous family. Growth and motor delay, delayed language development, short stature, intellectual disability, stereotypic movements, autistic features, large ears, abnormality of the pinna, flattened nasal bridge, shortening of all distal phalanges, clinodactyly of 5th finger were noted in two patients. The second child had epileptic seizures which were not seen in first child. Cranial MRI of first child revealed bilateral myelinisation delay at temporal lobes, thinning of corpus callosum. Whole exome sequencing (WES) was performed for patients and their parents. **Results:** WES analysis revealed homozygous previously unreported variant in exon 25 of the *PGAP1* gene, c.2349delins14 (p.His783Glnfs*2) in patients. Both parents are heterozygous carrier of the detected variant. **Conclusions:** We present a novel *PGAP1* variant in a Turkish family. Few cases were reported about *PGAP1* mutations in patients with intellectual disability. Our case presentation will be helpful to define the phenotype of the patients with *PGAP1* mutations and to confirm the clinical findings of previous studies and also to shed light on the further studies.

Table 1. Reported Cases with *PGAP1* Mutations:

P08.58

Microdeletion located in Xq22 in a girl. Confirmation of a specific phenotype

F. Giuliano¹, H. Karmous-Benailly¹, M. Dayem-Quere¹, C. Desaldealer², C. Costet-Fighiera², G. Pitelet³;

¹Department of Medical Genetics, Centre Hospitalier Universitaire de Nice, Nice, France,

²Department of Pediatrics, Hôpitaux Pédiatriques de Nice, CHU Lenval, Nice, France,

³Consultation of Ophthalmology, Clinique Saint George, Nice, France.

Alteration of proteolipid protein 1 gene (PLP1) mapped in Xq22 is usually known to lead to an X-linked hypomyelination disorder, Pelizaeus Merzbacher disease (PMD; MIM =312080). Mutations and duplications are the main causes of PLP dysfunction in affected patients. Rare deletions have been described, all of them of small size.

Five females with microdeletion, exactly mapped in Xq22 are reported [Yamamoto et al, 2014], but do not share the similar features as PMD male patients. However, they appear to share a similar phenotype, including severe developmental delay, major sleep disturbance, similar facial features, ophthalmologic abnormalities and feeding difficulties. Cerebral MRI may show thin corpus callosum and for some delayed myelination.

We identified a female patient with de novo copy number aberration located in Xq22. We compare our clinical, biological and radiological data with the five affected ones previously described by Yamamoto et al, aiming to demonstrate that Xq22 deletions in female should be considered as responsible for a specific phenotype.

P08.60

Diagnostic challenges due to mosaics

C. Rusu¹, A. Sireteanu², M. Gramescu¹, R. Popescu¹, E. Gorduza²;

¹University of Medicine and Pharmacy, Iasi, Romania, ²Regional Institute of Oncology, Iasi, Romania.

We present 4 different cases to illustrate diagnostic challenges and genetic counseling issues raised by mosaics.

Case 1: 10 years old male, first child of a young, healthy, unrelated couple. No family history. Physical examination reveals: hypertelorism, hypospadias and developmental delay. Brain MRI identified Dandy-Walker malformation. Clinical suspicion of Opitz G/BBB syndrome was raised, but molecular test was normal. In time, areas of dry skin along Blaschko lines became evident and new DNA test identified an X chromosome microdeletion in mosaic.

Case 2: 13 years old female, the only child of a young, healthy, unrelated couple. As an infant she presented with milia, cleft palate, lobulated tongue and digital anomalies, features highly suggestive for OFD1 syndrome, but molecular testing was normal. With age, pigmentary areas along Blaschko lines became evident, suggesting the presence of a mosaic.

Case 3: 3 years old macrosomic female that associates mild dysmorphic face, blindness, deafness, seizures and severe intellectual disability. The presence of the mosaic was suggested by 2 small skin defects. Blood investigations have been normal, but DNA investigations from oral cells revealed 12p tetrasomy and established the diagnosis of Pallister-Killian syndrome.

Case 4: 5 years old male with mild dysmorphic face, very deep palmar and plantar creases, cryptorchidism and developmental delay. The karyotype revealed trisomy 8 in mosaic (5 lines).

In conclusion, we present 4 cases with mosaics to illustrate suggestive features and to discuss challenges related to laboratory diagnosis and genetic counseling.

P08.61

Genetic analysis of delayed motor mental development and Unverricht-Lundborg disease in a large highly consanguineous family from Turkey

E. Yucesan¹, F. Tuncer¹, M. Calik², N. Bebek², U. Ozbek¹, S. Ugur Iseri¹;

¹Institute for Experimental Medicine, Istanbul, Turkey, ²Harran University, Harran Faculty of Medicine, Sanliurfa, Turkey, ³Istanbul University, Istanbul Faculty of Medicine, Istanbul, Turkey.

Combined analysis of homozygosity mapping and whole exome sequencing (WES) are powerful tool to detect pathogenic variants associated with recessive disorders. Herein, WES and SNP array used for clarifying delayed motor mental development (DMMD). We also conducted genetic test for Unverricht-Lundborg Disease (ULD) in family for different individuals.

Introduction

We ascertained consanguineous family presenting two different phenotype, DMMD, Unverricht-Lundborg Disease (ULD) respectively. In this study, we applied two-step approach, where SNP array analysis, defining homozygosity regions were used to limit exome variants to specific chromosomal regions. Also mutation analysis of CSTB for ULD.

Materials and Methods

We analyzed consanguineous family with two affected children having DMMD. Other two affected children diagnosed with ULD. 2 affected sibs were genotyped using SNP array. Homozygous regions were detected using PLINK. WES was performed for 2 affected sibs. In addition, analysis of CSTB gene was performed for promoter region via longPCR, as mutations in CSTB have been implicated in ULD.

Results

According to previous results, homozygous haplotypes were valid for 6 distinct chromosomes. Variants filtered from WES data solely for homozygous regions. Amongst, novel variants with pathogenic affect on protein were prioritized. Evaluating homozygous haplotypes for filtered variants, segregation analysis in the family is continuing.

LongPCR analysis revealed repeat expansion of almost 60 copies in promoter region in ULD

Conclusions

Parallel methods used to explain genetic background of DMMD and preliminary analysis are still continuing. Also we detected repeat expansion in CSTB gene's promoter for affected sibs.

Background: N-terminal acetylation is a common protein modification in eukaryotes associated with numerous cellular processes. Inherited mutations in NAA10, encoding the catalytic subunit of the major N-terminal acetylation complex NatA have been associated with diverse, syndromic X-linked recessive disorders, while de novo missense mutations have been reported in one male and one female individual with severe intellectual disability but otherwise unspecific phenotypes. Thus, the full genetic and clinical spectrum of Naa10 deficiency is yet to be delineated.

Methods and Results: Whole exome or panel sequencing identified three different novel and one known missense mutation in NAA10, de novo in eleven females, and due to maternal germ line mosaicism in another girl and her more severely affected and deceased brother. Common phenotypes in the affected females included severe intellectual disability and postnatal growth failure with pronounced microcephaly. In vitro enzymatic assays for the novel, recurrent mutations p.(Arg83Cys) and p.(Phe128Leu) revealed a reduced catalytic activity. X-inactivation was random in four of six tested females. Conclusions: We report on 12 females with mutations in NAA10 and thus further expand the mutational and clinical spectrum. The core phenotype of X-linked Naa10 related N-terminal-acetyltransferase deficiency in both males and females includes developmental delay, severe intellectual disability, postnatal growth failure with severe microcephaly and skeletal or cardiac anomalies. Genotype-phenotype correlations within and between both genders are complex and may include various factors such as location and nature of mutations, enzymatic stability and activity, and X-inactivation in females.

P08.63

Genetic disease amongst children referred to an East London neurodevelopmental clinic over fifteen years

S. K. Best¹, M. Bajaj¹, E. Rosser²;

¹Wellington Way Children's Centre, Barts Health NHS Trust, London, United Kingdom,

²Clinical Genetics Department, Great Ormond Street Hospital for Children NHS Foundation Trust, London, United Kingdom.

Introduction: Tower Hamlets in East London is an ethnically diverse area with high levels of consanguinity. Patients referred to the neurodevelopmental clinic with developmental delay or congenital abnormalities bet-

ween 1999 and 2013 were evaluated for underlying diagnoses and the use of genetic testing.

Methods: Clinical notes were reviewed. Genetic test results were obtained. Excel analysis and Chi-squared testing was performed. Undiagnosed patients were labelled "likely" genetic disease if they had 2/3 of: developmental delay, congenital abnormality or parental consanguinity, and "highly likely" if they had 3/3. Undiagnosed patients with obvious alternative causes were not labelled.

Results: 749 patients were included. 53.8% (403) had undergone genetic testing, of which 26.2% (164) had a confirmed genetic diagnosis. 40.7% of those undergoing genetic testing had a confirmed genetic diagnosis (128/403). A further 123 patients were thought likely/very likely to have an undiagnosed genetic disorder, of which 77 (62.6%) had known consanguineous parents. Confirmed genetic diagnosis was statistically significantly more common amongst the consanguineous population than the known non-consanguineous population (43/128 vs 75/333, $p < 0.025$).

The proportion undergoing genetic testing increased over time. Microarray testing was the most common test used and became more prevalent after 2010.

84 different genetic diseases were confirmed. Syndromic disorders and aneuploidies were most common.

Conclusions: Genetic disease was common amongst children referred to the neurodevelopmental clinic and genetic testing is important in their evaluation. Consanguinity significantly increases the likelihood of causal genetic disease. Neurosusceptibility microdeletions/microduplications are under-represented as microarray testing was not routinely available throughout this period.

P08.64

Mosaic Xq26.2q26.3 duplications associated with intellectual disability and congenital malformations: a new chromosomal syndrome?

S. G. Vorsanova^{1,2,3}, Y. B. Yurov^{2,1,3}, M. A. Zelenova^{2,1,3}, O. S. Kurinnaia^{1,2,3}, K. Vasin^{2,1,3}, V. S. Kravets^{1,3,2}, M. Gordeeva¹, I. Y. Iourov^{2,1,4}

¹Research and Clinical Institute for Pediatrics named after YE Veltishev at the Pirogov Russian National Research Medical University, Ministry of Health, Moscow, Russian Federation, ²Mental Health Research Center, Moscow, Russian Federation, ³Moscow State University of Psychology and Education, Moscow, Russian Federation, ⁴Department of Medical Genetics, Russian Medical Academy of Postgraduate Education, Ministry of Health, Moscow, Russian Federation.

Introduction. Recurrent mosaic duplications are exclusive in the available literature. This is especially the case in terms of clinically relevant X chromosome duplications in females. However, a growing amount of reports on somatic genome variations causing intellectual disability and congenital malformations allows speculations that mosaic (sub)chromosomal rearrangements might be more common and clinically relevant than previously recognized.

Materials and Methods. Molecular karyotyping using SNP/oligonucleotide microarray (resolution: >1 kbp) was performed in a cohort of 402 children with intellectual disability, autism, epilepsy and/or congenital malformations.

Results. Four girls (~1%) have exhibited mosaic duplications spanning Xq26.2q26.3.

The age varied from 1 year 1 month to 6 years. Shared features included intellectual disability/developmental delay, microcephaly, broad philtrum and wide nasal bridge, long lashes, ptosis; one patient demonstrated autistic features. The overlapping region for all duplications included 8 genes: *GPC3*, *MIR19B2*, *MIR106A*, *PHF6*, *HPRT1*, *MIR503*, *MIR424*, *PLAC1*. Although non-mosaic duplication in this region involving genes *PHF6* and *HPRT1* has been described in the literature previously, the lack of phenotypic resemblance to the detected cases and an original bioinformatics analysis allow the speculation that mosaic duplications Xq26.2q26.3 might be a new chromosomal syndrome associated with intellectual disability and congenital malformations.

Conclusions. Our study demonstrates that mosaic duplications Xq26.2q26.3 are relatively common in children with intellectual disability, autism, epilepsy and/or congenital malformations. Furthermore, our findings demonstrate the possibility that mosaic chromosomal rearrangements can be a cause for a new chromosomal syndrome. Supported by the Russian Science Foundation (grant: 14-15-00411).

P08.65

Mendeliome sequencing increases the diagnostic yield in patients with unexplained intellectual disability by 30% (a single center experience)

A. Rump¹, L. Mackenroth¹, A. Kahlert¹, J. Lemke², K. Hackmann¹, E. Betcheva-Krajcir⁴, A. Krüger¹, R. Opitz³, F. Kuhlee¹, A. Tzschach¹, E. Schröck¹, N. Di Donato¹

¹Institut für Klinische Genetik, Medizinische Fakultät Carl Gustav Carus, Technische Universität Dresden, Dresden, Germany, ²Institut für Humangenetik, Universitätsklinikum Leipzig, Leipzig, Germany, ³Abteilung für Gynäkologie und Geburtshilfe, Universitätsklinikum Carl Gustav Carus, Technische Universität Dresden, Dresden, Germany.

Introduction: Despite extensive use of chromosomal microarrays, up to 50% of children with developmental delay still remain undiagnosed. Therefore, we applied mendeliome sequencing to 57 index patients with developmental delay or intellectual disability (ID) and pre-excluded genomic imbalances.

Method: Genomic DNA samples of 28 parent-child trios plus 29 individuals were analyzed for mutations in 4813 genes, using the TruSightOne gene panel on the MiSeq platform (Illumina, San Diego, CA). Sequence variants were called by two independent platforms: the GATK pipeline installed on the MiSeq and the CLC Biomedical Genomics platform (Qiagen, Hilden, Germany). All variants with putative effect on amino acid level were screened for clinical and molecular concordance (i.e. disease-association of the gene, published mutation) and all modes of inheritance (dominant de novo, autosomal recessive, X-recessive) were considered. The results were discussed in a team of clinicians and molecular geneticists and relevant variants were validated by Sanger-sequencing.

Results: Using the mendeliome in a diagnostic setting, we established a diagnosis in 16 of the 57 index patients (28%). For seven further patients, we found one or two possibly causative candidates (13%). 5 patients (9%) showed incidental findings which either made treatment or surveillance necessary (homozygous *MUTYH*-mutations, *SDHA*-mutation) or led to an increased risk for a recessive disease in children (*PAH*- or *CFTR*-mutations). Conclusion: Mendeliome sequencing significantly increases the diagnostic yield in patients with ID unsolved by previous routine testing (array-CGH, karyotyping). However, variant interpretation remains challenging and requires standardized procedures for using the new technology in a standard diagnostic setting.

P08.66

Evaluation of non-coding copy number variants in neurodevelopmental disorders

R. Asadollahi, A. Mihai, B. Oneda, R. Baldinger, R. Reissmann, P. Boonsawat, M. Papik, M. Zweier, S. Azzarello-Burri, A. Baumer, P. Joset, K. Steindl, A. Rauch;

Institute of Medical Genetics, University of Zurich, Zurich, Switzerland.

The genome-wide significance of non-coding CNVs has not been studied in neurodevelopmental disorders (NDDs). Therefore, by high-resolution chromosomal microarray analysis, we investigated all non-coding CNVs in 121 patients with undiagnosed NDDs. We detected 548 rare non-coding variants with a median size of 8 kb, of which 94 (~17%) were seen < 3 times in our total in-house arrays and had medium to high regulatory scores. The scoring system was based on the evolutionary conservation and affected non-coding RNAs, cis-regulatory elements and histone modification markers. Considering the pattern of inheritance and/or literature assessment, we classified 9 of 94 (~9.6%) as strong candidates of which 6 were true positive. From these variants, two (25 kb de novo and 122 kb inherited losses) were within the regulatory enriched intronic parts of *ALCAM* and *GRM5* respectively, both involved in major neuronal processes. We also detected a 21 kb maternally inherited X-chromosomal gain in a boy, overlapping the non-coding last exon of the gene *SYAP1* and strong regulatory elements in cis. Furthermore, we found a 44 kb loss affecting strong regulatory elements near the *DAAM1* and *DACT1* involved in the Wnt signaling pathway which co-segregated with the phenotype in a family with three affected members. Of note, in the latter two cases, whole exome sequencing did not reveal any pathogenic variant. Accordingly, we were able to illustrate a genome-wide overview of rare non-coding CNVs in patients with NDDs as well as non-coding CNVs possibly contributing to the phenotypes of 4 (3.3%) of the patients.

Purpose: The purpose of the current study was to assess the penetrance of NRXN1 deletions.

Methods: We compared the prevalence of NRXN1 deletions identified among 19,263 clinically referred cases to that of 15,264 controls. The burden of additional clinically relevant CNVs was used as a proxy to estimate the relative penetrance of NRXN1 deletions.

Results: We identified 41 (0.21%) previously unreported exonic NRXN1 deletions ascertained for DD/ID, significantly greater than in controls [OR=8.33 (95% CI 2.98-23.25), p< 0.0001]. Ten (22.7%) of these had a second clinically relevant CNV. Subjects with a deletion near the 3' end of NRXN1 were significantly more likely to have a second rare CNV than subjects with a 5' NRXN1 deletion [OR=19.30 (95% CI 3.50-147.24), p<0.0001]. The prevalence of intronic NRXN1 deletions was not statistically different between cases and controls (p=0.613). The majority (63.2%) of intronic NRXN1 deletion cases had a second rare CNV, a five-fold greater prevalence than for exonic NRXN1 deletion cases (p=0.003).

Conclusions: The results support the importance of exons near the 5' end of NRXN1 in the expression of neurodevelopmental disorders. Intronic NRXN1 deletions do not appear to substantially increase the risk for clinical phenotypes.

P08.68

Intragenic duplication of the PARK2 gene contributes to developmental delay

P. Dello Russo, **C. Gnan**, **A. Franzoni**, **N. Passon**, **F. Baldan**, **L. Allegri**, **G. Damante**; Azienda Ospedaliero Universitaria S.Maria della Misericordia, Udine, Italy.

Introduction: Autism spectrum disorder (ASDs) are childhood neurodevelopmental disorders genetically heterogeneous, with evidence for hundreds of susceptibility loci. Recently it has been reported that CNVs within or surrounding genes involved in the ubiquitin pathways, including *UBE3A*, *PARK2*, *RFWD2* and *FBXO40*, were detected as possible cause for ASD. Furthermore *PARK2* gene was identified as candidate gene for attention-deficit/hyperactivity disorder. The precise function of this gene is unknown yet; however the parkin protein seems implicated in dopaminergic transmission.

Recently was identified a 314kb copy number gain in the long arm of chromosome 6q26 including only exon 2 of *PARK2* gene associated to a 3-month-old female with neurological problems.

We report a ten-year-old boy who showed behavior problems, language difficulties, psychomotor retardation, cognitive impairment, and no dysmorphic features.

Materials and Methods: Array-CGH assay was carried out (Agilent Human Genome CGH oligonucleotide array 180k, Agilent Technologies, Santa Clara, CA, USA) following the manufacturer's instructions on a DNA sample isolated from peripheral blood cells.

Quantitative PCR was performed using 7300 Real Time PCR System (Applied Biosystems, Foster City, CA, USA) on the samples of our proband and his parents to determine the inheritance of chromosomal aberration.

Results: Array-CGH revealed a duplication of 231kb in the chromosome 6q26 which only included two exons (exon 3 and 4) of *PARK2* gene. He had no other pathogenetic CNV. Real Time PCR revealed that the rearrangement was paternally inherited.

Conclusion: Our patient supports the positive association between *PARK2* gene damages and neurocognitive and developmental anomalies.

P08.69

Effect of intranasal insulin on development in Phelan-McDermid syndrome: a randomized, double-blind, placebo-controlled trial

R. J. Zwanenburg¹, **G. Bocca**², **S. A. J. Ruiter**³, **J. H. Dillingh**⁴, **B. C. T. Flapper**², **E. R. van den Heuvel**⁵, **C. M. A. van Ravenswaaij-Arts**¹;

¹Department of Genetics, UMCG, Groningen, Netherlands, ²Department of Paediatrics, UMCG, Groningen, Netherlands, ³Centre of Expertise for Child Development Care and Research, Groningen, Netherlands, ⁴Department of Clinical Pharmacy and Pharmacology, UMCG, Groningen, Netherlands, ⁵Department of Mathematics and Computer Science, Eindhoven University of Technology, Eindhoven, Netherlands.

Introduction: Phelan-McDermid (PMS) or 22q13.3 deletion syndrome is a rare neurodevelopmental disorder. Clinical features include moderate to severe intellectual disability and behavioural problems in the autism spectrum. Other researchers had observed a beneficial effect of intranasal insulin on development and behaviour in a pilot study in six children with PMS. To validate this effect, we conducted a randomized, double-blind, placebo-controlled clinical trial using a stepped-wedge design.

Material and methods: Twentyfive children aged 1 to 16 years with a 22q13.3 deletion including the SHANK3-gene participated in the clinical trial for a period of 18 months. Starting 6 months before the trial, children were systematically assessed for development and behaviour every 6 months. The 2nd, 3rd and 4th assessments were followed by daily nose sprays containing either insulin or placebo for a 6-month period. A 5th assessment was done directly after the end of the trial.

Results: Intranasal insulin did not cause serious adverse events. It increased the level of developmental functioning by 0.4-1.4 months per 6-month period that, while not statistically significant in this small group, was considered clinically relevant. A stronger, significant effect was observed in children older than 3 years, who usually show a decrease of developmental growth.

Conclusions: Although the application of intranasal insulin is a promising therapeutic approach, clinical trials in larger study populations are required to prove the therapeutic effect of intranasal insulin in PMS.

P08.70

Diagnostic flow-chart to improve the detection rate and to uncover the genetic heterogeneity in Pitt-Hopkins syndrome: experience on 260 subjects

M. Zollino, **S. Ricciardi**, **S. Frangella**, **D. Orteschi**, **M. Murdolo**, **P. Doronzio**, **S. Lattante**, **G. Marangi**;

Institute of Genomic Medicine, Università Cattolica del Sacro Cuore, Roma, Italy.

Pitt-Hopkins syndrome (PTHS) is defined by the association of severe intellectual disability, a typical facial gestalt and additional features, including breathing abnormalities. It is caused by haploinsufficiency of the TCF4 gene. The PTHS phenotype overlaps with different conditions, including mainly Angelman, but also Mowat-Wilson, Christianson and Rett syndromes.

A total of 260 subjects were referred because of clinical suspicion of PTHS. The genetic diagnosis was obtained in 40/260 (15%) as follows: TCF4 intragenic variants (30); large 18q21 deletions (2); partial TCF4 deletion (1); balanced de novo translocations (2); MECP2 variants (2); UBE3A variant (1); ZEB2 variants (2).

All patients were first distinguished into two categories, depending on clinical presentation. Group A included 125 subjects who all had severe ID with nearly absent speech and high clinical score for PTHS; group B included the remaining 135 subjects with mild to moderate ID and low clinical score for PTHS.

All patients with a proven genomic mutation were in group A, increasing test sensitivity from 15% to 32%.

A clinically driven flowchart is suggested in PTHS phenotype, including step by step the following tests: 1)TCF4 analysis; 2) array-CGH; 3) conventional cytogenetics; 4) NGS gene panel analysis (TCF4, CNTNAP2, NRXN1, UBE3A, SLC9A6, MECP2, CDKL5, FOXG1, MEF2C, ZEB2, ATRX); 5) whole exome se-

quencing (WES). Variants detected by WES are presented separately, since a limited number of patients has been analyzed. Nosological implications are discussed. Supported by Telethon grant nr: GEP 14089.

P08.71

Two unrelated cases with rare mosaic deletions affecting TCF4 gene, exhibiting different phenotypes

A. Alexandrou¹, G. A. Tanteles^{2,3}, I. Papaevripidou¹, A. Ketoni¹, N. Salameh¹, P. Evangelidou¹, C. Sismani¹, V. Christophidou-Anastasiadou^{2,3};

¹Cytogenetics and Genomics Department, The Cyprus Institute of Neurology and Genetics, Nicosia, Cyprus, ²Clinical Genetics Department, The Cyprus Institute of Neurology and Genetics, Nicosia, Cyprus, ³Archbishop Makarios III Medical Centre, Nicosia, Cyprus.

Pitt-Hopkins syndrome (PTHS) is a rare neurodevelopmental disorder characterized by a distinctive phenotype. PTHS phenotype is caused by mutations or variable size deletions involving TCF4 gene (18q21) implying haploinsufficiency of this gene. Mosaic structural rearrangements are extremely rare events and pose great challenges for interpretation. There is very limited literature on mosaic deletions affecting TCF4 gene in which patients are described to manifest the full spectrum of the disorder. Herein, we report two unrelated individuals bearing deletions in a low mosaic state.

The first case is the non-affected father of a patient with a PTHS spectrum phenotype. A deletion of 263.4 kb was identified in the patient removing exons 4-9 of TCF4 gene. The deletion was inherited from the father who carries the deletion in a mosaic state (~20%). This is the first PTHS case reported in the literature of a deletion affecting TCF4 inherited from a clinically unaffected parent.

The second case involves a patient with a phenotype consistent with PTHS. Array-CGH revealed a very low mosaic (15%) 18q21.2q21.33 deletion of 10.17Mb in size harbouring the TCF4 gene which was confirmed by FISH analysis (11%). Family studies are ongoing.

Our findings and review of the literature support that deletions affecting TCF4 independent of their size appear to have no significant effect on the severity of the syndrome. However, it is also demonstrated that mosaic 18q21 deletions can have a normal phenotype which contradicts previous observations that mosaic status of such deletions cause similar phenotypes.

P08.72

Characterization of patient with de novo frameshift PUF60 mutation suggests that disruption of this gene is sufficient for most symptoms of Verheij syndrome

M. Hančárová¹, M. Havlovicová¹, D. Prchalová¹, V. Stránecký², Z. Sedláček¹;

¹Department of Biology and Medical Genetics, Charles University 2nd Faculty of Medicine and University Hospital Motol, Prague, Czech Republic, ²Institute of Inherited Metabolic Disorders, Charles University 1st Faculty of Medicine and General University Hospital, Prague, Czech Republic.

Verheij syndrome (OMIM 615583) is associated with rare *de novo* 8q24.3 microdeletions. Patients show developmental delay, short stature, microcephaly, coloboma, and craniofacial, skeletal, cardiac and renal defects. Initially two patients were described with deletions of 15-24 Mb, later followed by five patients with much shorter deletions, the smallest encompassing only three genes, *SCRIB*, *PUF60* and *NRBP2*. A *de novo* loss-of-function missense *PUF60* mutation was also found in a similar patient who however lacked coloboma and renal abnormalities. These observations and knockdown of *PUF60* and/or *SCRIB* in zebrafish suggested that the two genes influenced different symptoms, together exacerbating the phenotype of the syndrome. We report a 16-year-old boy with autism, moderate intellectual disability, speech delay, growth retardation, short stature, microcephaly, cardiac and renal defects, skeletal anomalies and a facies with bitemporal narrowing, thick eyebrows, long philtrum, broad nasal root and thin upper lip. Karyotyping and microarray analysis yielded no findings. Whole exome sequencing of the family trio identified a private heterozygous *de novo* deletion of four nucleotides in *PUF60* (NM_078480.2:c.407_410delTCTA,p.1136Tfs*31). The patient showed no eye symptoms but no focused ophthalmological examination has been performed yet. The presence of severe renal hypoplasia in the patient and his overall similarity to the typical picture of the Verheij syndrome suggest that also the renal symptoms can be attributed solely to defects of *PUF60* which may be of key importance for the syndrome. The case illustrates the strength of exome sequencing in deciphering the genetic basis of diseases.

P08.73

First case of concurrent RAI1 mutation and ANKRD11 partial deletion in a girl with features of Smith Magenis and KBG syndromes

I. Bestetti^{1,2}, C. Picinelli¹, M. Crippa¹, M. Mencarelli², L. Larizza¹, D. Milani⁴, P. Finelli^{1,2};

¹Laboratory of Medical Cytogenetics and Molecular Genetics, IRCCS Istituto Auxologico Italiano, Milano, Italy, ²Department of Medical Biotechnology and Translational Medicine, University of Milan, Milano, Italy, ³Molecular Biology Laboratory, IRCCS Istituto Auxologico Italiano, Milano, Italy, ⁴Medical Genetic Unit, Pediatric Highly Intensive Care, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Italy.

Smith Magenis (SMS) and KBG syndromes are rare autosomal dominant disorders characterized by distinctive facial features and intellectual disability (ID), caused by RAI1 and ANKRD11 haploinsufficiency, respectively.

Here we describe a 46,XX girl aged 8 years, who shows mild to moderate facial dysmorphisms, ID, and an autism spectrum disorder. Upon exclusion of 17p11.2 SMS locus deletion by previous genetic investigation, RAI1 mutational screening identified an unreported heterozygous missense mutation (p.G1036R) inherited from the healthy father who shares with his daughter the facial aspect only. MLPA and RT-qPCR analyses on RAI1 revealed a wild type condition, whereas high resolution array-CGH analysis disclosed a rare *de novo* deletion at 16q24.3, never reported in healthy subjects. The deletion affects the last two exons and the 3'UTR of ANKRD11. RT-qPCR performed on the KBG gene revealed the simultaneous existence of wild type and truncated mRNA, each present at 50% of the total amount detected in healthy controls.

Based on these findings and considering that ANKRD11 mutations have been reported in a few clinically borderline Cornelia de Lange (CdLS) patients, a clinical reevaluation of the proband was performed. Neither microcephaly and developmental delay, generally associated to CdLS, nor macrodactilia and short stature, hallmarks of the classic KBG phenotype, were observed. However, the proband shows a composite phenotype mixing up KBG and SMS signs. This peculiar clinical picture might result from the combined effect of RAI1 mutation and ANKRD11 *de novo* deletion, which does not likely imply gene haploinsufficiency, as in classical SMS and KBG syndromes.

P08.74

Copy number variation in RBFOX1 and DOCK8: Neurodevelopmental disorders or benign variants?

S. Albara^{1,2}, K. E. Hermetz², M. Rudd²;

¹Leeds Genetics Lab, Leeds, United Kingdom, ²Emory Genetics Laboratory, Atlanta, GA, United States.

Deletions and duplications involving the genes RBFOX1 and DOCK8 have been implicated in intellectual disability (ID) and autism spectrum disorders (ASD). However, the clinical significance of these CNVs is controversial. We analysed 14 RBFOX1 deletions (20-309 kb), six RBFOX1 duplications (34 kb to 1.34 Mb), and eight DOCK8 deletions (22-227 kb) from unrelated individuals. Our analysis revealed that five DOCK8 deletions were terminal and three were interstitial. Two deletions lie within intron 1, two include only exon 1, and four include multiple exons. Thirteen of the RBFOX1 deletions lie within a single intron; deletion of intron 3 and intron 4 are the most common. Though the clinical information provided is limited, seven individuals with RBFOX1 deletions have a diagnosis of ASD. The clinical significance of duplications is difficult to interpret since intragenic gains can lead to loss-of-function, whereas whole gene duplication can lead to triplosensitivity. Half of the RBFOX1 duplications have one breakpoint upstream of the gene and one breakpoint in intron 2, which is predicted to maintain the reading frame if the duplications are in direct tandem orientation. One RBFOX1 duplication lies entirely within intron 3 and two include only exon 4, which could lead to an out-of-frame transcript. Our analysis sheds light on the genomic structures of small CNVs implicated in neurodevelopmental disorders. Only two CNVs had identical breakpoints, suggesting diversity in RBFOX1 and DOCK8 rearrangements rather than a few common variants. However, the clinical significance of these CNV remains unclear since all CNVs we included were inherited.

Molecular diagnosis improvement in patients with Rett Syndrome using Next-Generation Sequencing.

H. Maortua^{1,2,3}, **A. De la Hoz**^{2,3}, **C. Martínez-Bouzas**^{1,2,3}, **M. I. Tejada**^{1,2,3};
¹Genetic Service, Cruces University Hospital, Barakaldo-Bizkaia, Spain, ²BioCruces Health Research Institute, Cruces University Hospital, Barakaldo-Bizkaia, Spain, ³Clinical group affiliated with the Centre for Biomedical Research on Rare Disease (CIBERER), Madrid, Spain.

Introduction: Rett syndrome (RTT) is a severe neurodevelopmental disorder characterized by intellectual disability, regression of development and progressive microcephaly. RTT is mainly caused by mutations in MECP2; although mutations in other genes (CDKL5 and FOXP1) are also found. However, a number of patients who show a clinical diagnosis of RTT have no mutations in these genes. Recently, Next Generation Sequencing technology (NGS) has changed genetic diagnosis because of its ability to detect rare, de novo mutations.

Material and Methods: We designed a NGS panel with 21 genes (ARX, BDNF, CDKL5, FOXP1, FOXP2, GABRD, HERC2, JMJD1C, KCNQ2, MECP2, MEF2C, MFSB8, PLP1, SCN2A, SHANK3, STXBP1, TBR1, TCF4, UBE3A and WDR45). The panel consists of 11874 amplicons (196.569 Kb), with 98.57% target coverage. Target enrichment was performed by HaloplexHS. Libraries were sequenced on an Ion Torrent PGM platform. SureCall software was used for raw data alignment and variant annotations. Torrent Suite™ and Ion Reporter™ software were then used for variant analysis.

Results: Our custom panel has been validated detecting all the known molecular changes (table below). Furthermore, new variations have been found which are under study.

Conclusion: This custom panel is a powerful and cost-effective tool to diagnose complex disorders with genetic heterogeneity such as RTT syndrome. This work has been funded by Fundació Agrupació.

Gene	Variations
MECP2	16 loss-of-function
MECP2	4 missense
MECP2	4 polymorphism
CDKL5	1 loss-of-function
CDKL5	1 deletion
CDKL5	1 unknown variation
ARX	1 missense
ATRX	1 missense
UBE3A	2 loss-of-function
UBE3A	1 missense

P08.76

First familial Rubinstein-Taybi syndrome case associated with a novel EP300 mutation

M. López¹, **P. de Castro Castro**², **V. Seidel**², **E. Domínguez-Garrido**¹;
¹Fundación Ríoja Salud, Logroño, Spain, ²Hospital General Universitario Gregorio Marañón, Madrid, Spain.

Introduction: RSTS (OMIM RSTS 1, #180849, RSTS 2, #613684) is a rare (1:125000) autosomal dominant neurodevelopmental disorder characterized by broad thumbs and halluces. The vast majority of cases occur sporadically due to de novo heterozygous mutations. RSTS is caused in 50-60% of cases by mutations in the CREBBP gene and by EP300 gene mutations in 5-8%.

Subjects and methods: A 9 year-old female patient was referred from Neuropediatrics for suspected RSTS. DNA was obtained from blood of the patient and her mother. CREBBP and EP300 MLPA, panel based-NGS of CREBBP and EP300 genes and Sanger sequencing confirmation was carried out. Sequence changes were compared to the mother.

Results: The patient and her mother presented with mild learning difficulties, short stature and microcephaly. The mother had broad thumbs, whereas the child had normal thumbs and halluces. A novel heterozygous deletion in exon 31 of EP300 gene (c. 7219_7222del) was found in both the proband and her mother, indicating that the mutation is inherited. This is a clearly pathogenic frameshift mutation (p.S2407fs).

Conclusion: This is the first report of an inherited EP300 mutation in RSTS worldwide, and the first familial RSTS case in Spain, demonstrating that transmission is extremely rare. Since most individuals with RSTS due to EP300 mutation are mildly affected, this entity is likely underdiagnosed. Thus special attention should be paid in them.

Rubinstein-Taybi syndrome type 2: Report of 9 new cases that extend the phenotypic and genotypic spectrum

M. J. Hamilton^{1,2,3}, **R. Newbury-Ecob**⁴, **M. Holder-Espinasse**⁵, **J. A. Hurst**⁶, **E. Clement**⁶, **W. Reardon**⁷, **S. Joss**⁸, **E. Hobson**⁹, **M. Blyth**⁹, **M. Al-Shehhi**⁷, **S. Lynch**⁹, **M. Suri**³;
¹University of Glasgow, Glasgow, United Kingdom, ²West of Scotland Clinical Genetics Service, Glasgow, United Kingdom, ³Department of Clinical Genetics, Nottingham City Hospital, Nottingham, United Kingdom, ⁴Department of Clinical Genetics, University Hospitals Bristol, Bristol, United Kingdom, ⁵Clinical Genetics Service, Guy's and St Thomas' Hospital, London, United Kingdom, ⁶Clinical Genetics Unit, Great Ormond Street Hospital for Children, London, United Kingdom, ⁷Department of Clinical Genetics, Our Lady's Children's Hospital, Dublin, Ireland, ⁸Yorkshire Regional Genetics Service, Chapel Allerton Hospital, Leeds, United Kingdom, ⁹ACoRD, University College Dublin, Dublin, Ireland.

BACKGROUND: Rubinstein-Taybi syndrome is an autosomal dominant neurodevelopmental disorder characterised by growth deficiency, broad thumbs and great toes, intellectual disability and characteristic craniofacial appearance. Mutations in CREBBP account for around 55% of cases, with a further 8% attributed to the paralogous gene EP300. Comparatively few reports exist describing the phenotype of Rubinstein-Taybi due to EP300 mutations. **METHODS:** Clinical and genetic data were gathered from 9 patients from the UK and Ireland with pathogenic EP300 mutations, identified either by targeted testing or exome sequencing. **RESULTS:** All patients had mild or moderate intellectual impairment. Behavioural or social difficulties were noted in eight, including three with autistic spectrum disorders. Typical dysmorphic features of Rubinstein-Taybi were only variably present. Additional observations include maternal pre-eclampsia (2/9), syndactyly (3/9), delayed bone age (2/9), feeding or swallowing issues (2/9), scoliosis (2/9) and hypermobility of the elbow (2/9). Six patients had truncating mutations in EP300, with pathogenic missense mutations identified in the remaining three. **DISCUSSION:** The findings support previous observations that microcephaly, maternal pre-eclampsia, mild growth restriction and a mild to moderate intellectual disability are key pointers to the diagnosis of EP300-related Rubinstein-Taybi syndrome. Variability in the presence of typical facial features of Rubinstein-Taybi further highlights clinical heterogeneity, particularly among patients identified by exome sequencing. Features that overlap with Floating-Harbor syndrome including craniofacial dysmorphism and delayed osseous maturation were observed in 3 patients. Previous reports have only described mutations predicted to cause haploinsufficiency of EP300. This cohort includes the first described pathogenic missense mutations in EP300.

P08.78

Abnormal primary dentition : a clue for the diagnosis of the SATB2-associated syndrome

M. Rio^{1,2}, **G. Barcia**^{1,2}, **J. Bonnefont**^{1,2}, **J. Amiel**^{1,2}, **V. Pingault**^{1,2}, **S. Hanein**³, **A. Munnich**^{1,2};
¹Service de génétique, Hôpital Necker-Enfants Malades, APHP, Paris, France, ²INSERM 1163 Institut IMAGINE Université Paris Descartes-Sorbonne Paris Cité, Paris, France.

The SATB2-associated syndrome (SAS) has been recently proposed as a new clinically recognizable syndrome that results from deleterious alterations of the SATB2 gene in humans. We report the clinical characterization of 5 patients in whom targeted high-throughput sequencing for the diagnosis of intellectual disability or neurocristopathies identified a de novo mutation in the SATB2 gene for three patients and a de novo intragenic deletion for two patients. Age at diagnosis was 5 years (2/5), 7 years (2/5), 8 years (1/5). The 5 patients shared the characteristic features of the SAS: intellectual disability with limited speech development (5/5), cleft (1/5) or high-arched palate (4/5), and dental abnormalities (5/5). 4 patients presented one fracture and osteopenia was seen in two of the patients, confirming that this finding could be added to the list of distinctive findings. All patients had dental abnormalities with macrodontia of primary and permanent teeth, irregular shape of the teeth, dental crowding. Interestingly, anomaly of the primary teeth is a consistent finding detected in the 5 patients. This feature should be a good handle for early diagnosis of SAS and we therefore suggest adding this feature to the list of distinctive features of SAS.

P08.79

Severe presentation of primary microcephaly (Seckel-like syndrome) in a patient born from an incestuous relationship

I. Sudholt, **K. Komlosi**, **S. Diederich**, **D. L. Fend-Guella**, **U. Zechner**, **S. Schweiger**, **O. Bartsch**;
 Institute of Human Genetics, University Medical Center of the Johannes Gutenberg University, Mainz, Germany.

Seckel syndrome is a genetically heterogenous rare recessive disorder with growth retardation, microcephaly, intellectual disability (ID) and a ,bird-

headed' appearance. The differential diagnosis includes autosomal recessive primary microcephaly (MCPH) without additional malformations or neurologic findings.

We report a 30-year-old woman with profound ID, absent speech, stereotypic behavior, diplegia, proportionate growth deficiency (-5 SD), severe primary microcephaly (-10,5 SD) and dysmorphic features including a sloping forehead, prominent large nose, small chin, dorsally rotated ears, short and broad fingers, and small feet. She was a product of an incestuous abuse between father and daughter. In the first 30 years she had the clinical diagnosis of Seckel syndrome with no identified genetic cause. We used panel diagnostics for over 1200 brain related genes (MPIMG-1-Test) on an Illumina MiSeq system and a modified Medical Resequencing Analysis Pipeline for variant calling.

3/40 variants fitted an autosomal recessive model with only STIL associated with the phenotype. A novel homozygous likely pathogenic sequence variant STIL c.3377A>G (p.Tyr1126Cys) was found. Segregation analysis confirmed heterozygosity in the mother. The father (=grandfather) was deceased. Homozygous STIL mutations can cause MCPH7 (OMIM #612703) with non-syndromic primary microcephaly and moderate ID, however, single cases also showed severe ID, short stature, and holoprosencephaly. Possibly additional yet unidentified recessive traits in our patient might have contributed to a more complex phenotype of classical MCPH7. Our case demonstrates the overlap between syndromic and non-syndromic forms, the close connection to Seckel syndromes and the clinical utility of NGS in the diagnosis of atypical presentations.

P08.80

The identification of a 94,5 kb deletion in Xq24 encompassing the SLC25A5 gene confirms its pathogenic role in neurodevelopmental disorders

A. Zonta¹, G. Zacchetti¹, I. Fusco¹, S. Mellone¹, C. Peruzzi², A. Guala³, M. Giordano¹;
¹Human Genetics Laboratory, Dept. of Health Sciences, Piemonte Orientale University, Novara, Italy, ²Child Neurology Unit, Maggiore della Carità Hospital, Novara, Italy, ³Pediatric Unit, Castelli Hospital, Verbania, Italy.

We report on a 16-year-old boy referred for learning disability, deficit in attention and social competence, difficulties in daily activities organization, impulsive and repetitive behaviour, clumsiness and fatigue. The clinical examination reported bilateral epicanthus, left palpebral ptosis and valgus knees. An EEG showed diffuse abnormalities with a poorly organized background. EMG, NCV and CK were normal. His maternal uncle is affected with intellectual disability and epilepsy. His parents are healthy and non consanguineous.

Array-CGH[60K] identified a 94,5 kb deletion at Xq24 (chrX:118.579.289-118.673.787) encompassing the 3' end of the SLC25A43 gene, the SLC25A5 gene and the 3' end of the CXorf56 gene. The same deletion has been found in the proband's mother, maternal grandmother, maternal uncle with intellectual disability and seizures and was not found in another healthy maternal uncle.

Overlapping microdeletions at Xq24 have been found in patients with non syndromic intellectual disability or borderline IQ scores. The smallest region of overlap encompassed the SLC25A43 and SLC25A5 genes, members of the mitochondrial carrier subfamily of solute carrier (SLC) protein genes. Biallelic mutations of genes belonging to the SLC25 family cause a wide range of metabolic disorders with CNS involvement. As a deletion of the SLC25A43 gene has been subsequently found in a healthy subject and the expression of this gene in the brain is low, a pathogenic role for the SLC25A5 has been suggested.

The deletion identified in our patient is the smallest deletion reported so far encompassing the SLC25A5 gene and confirms that its deficiency can cause neurodevelopmental disorders.

P08.81

MBD5 molecular screening on Smith Magenis-like Syndrome patients without the typical 17p11.2 deletion

M. Sciarrillo^{1,2}, C. Picinelli¹, I. Bestetti^{1,2}, A. Sironi¹, N. Kurtas¹, E. Pont³, A. Mihalich³, L. Spaccini⁴, M. Bedeschi⁵, C. Pantaleoni⁶, S. Maitz⁷, A. Selicorni⁷, D. Milani⁸, L. Larizza¹, P. Finelli^{1,2};

¹Laboratory of Medical Cytogenetic and Molecular Genetics, IRCCS Istituto Auxologico Italiano, Milano, Italy, ²Department of Medical Biotechnology and Translational Medicine, University of Milan, Milano, Italy, ³Molecular Biology Laboratory, IRCCS Istituto Auxologico Italiano, Milano, Italy, ⁴Medical Genetics Unit, Buzzi Children's Hospital, Milano, Italy, ⁵Medical Genetic Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Italy, ⁶Infantile Neuropsychiatry, U.O. Developmental Neurology, IRCCS Istituto Neurologico „Carlo Besta“, Milano, Italy, ⁷U.O.S Clinical Genetics and Pediatrics, MBBM Foundation San Gerardo Hospital, Monza, Italy, ⁸Medical Genetic Unit, Pediatric Highly Intensive Care, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Italy.

Smith Magenis Syndrome (SMS) is a complex heterogeneous disorder, caused by RAI1 haploinsufficiency and triggered by 17p11.2 deletion or RAI1 gene mutation. Only 50% of patients with a clinical suspicion of SMS bear the known defects, making its diagnosis challenging and suggesting that other loci may underlie SMS-like phenotypes.

Notably 2q23.1 deletion and brachydactyly mental retardation (BDMR) syndromes, caused by MBD5 and HDAC4 haploinsufficiency respectively, are two SMS phenotypical and molecular overlapping syndromes as the affected patients seem to show a reduced RAI1 transcript levels, implying that MBD5/HDAC4 regulate RAI1.

Here we describe a cohort of 30 SMS-like patients without 17p11.2 deletion, and RAI1 microdeletion or mutation. Array-CGH analysis revealed a 29 kb deletion at 2q23.1 encompassing exons 1 and 2 of MBD5 in one patient, while MBD5 mutational screening identified in a second case an heterozygous missense mutation likely pathogenic, p.A857T. Unexpectedly the deletion was found in a mosaic condition in the healthy father of the first patient, while the missense mutation, previously described in a child with mental retardation, was maternally inherited. The subsequent RT-qPCR showed a MBD5 transcript downregulation in the patient with 2q23.1 deletion, normal RAI1 transcript levels in all the patients and unexpectedly in the SMS-like patient with MBD5 haploinsufficiency too.

Our findings corroborate the hypothesis that other loci can be causative of SMS-like phenotypes and for this reason we are setting up a flow chart aiming at improve the molecular diagnosis in SMS-like patients and shed light on pathogenetic mechanisms.

P08.82

Identification of a RAI1-associated disease network

A. Raymond¹, M. Loviglio¹, C. R. Beck², T. Harel², W. Bi², M. Leleu³, N. Guex^{1,4}, A. Niknejad⁴, E. S. Chen², E. S. Chen², S. Gu², J. White², I. Crespo⁴, J. Yan², W. Charnig², C. A. Shaw², Z. Coban-Akdemir², J. Rougemont³, I. Xenarios^{1,4}, J. R. Lupski²;

¹Center for Integrative Genomics, University of Lausanne, Lausanne, Switzerland, ²Baylor College of Medicine, Houston, TX, United States, ³Ecole Polytechnique Fédérale de Lausanne, Lausanne, Switzerland, ⁴Swiss Institute of Bioinformatics, Lausanne, Switzerland.

Smith-Magenis syndrome (SMS) is a developmental disability/multiple congenital anomaly disorder resulting from haploinsufficiency of RAI1. We investigated a cohort of 149 individuals presenting the constellation of SMS features, and focused on 15 individuals showing neither hemizyosity in the SMS critical region nor variants in RAI1. Using whole-exome sequencing we identified potentially deleterious variants in eight patients. These variants affect KMT2D, ZEB2, MAP2K2, GLDC, CASK, MECP2, KDM5C and POGZ, known to be associated with Kabuki 1, Mowat-Wilson, cardiofaciocutaneous, glycine encephalopathy, mental retardation and microcephaly with pontine and cerebellar hypoplasia, X-linked mental retardation 13, X-linked mental retardation Claes-Jensen type and a recently described intellectual disability syndrome, respectively. Analyses of coexpression networks and biomedical text mining suggest that these pathologies and SMS are part of the same disease network. Further support for this hypothesis comes from transcriptome profiling of 10.5 dpc embryos that shows that the expression levels of both ZEB2 and MAP2K2 are perturbed in Rai1^{-/-} mice. Chromatin conformation capture revealed contacts between RAI1 and the ZEB2 and GLDC flanking loci, as well as between RAI1 and human orthologs of the genes that show perturbed expression in a Rai1^{-/-} mouse model, in particular genes mapping to MMU11. This finding possibly explains the enrichment of MMU11-mapping genes within genes differentially expressed in Rai1^{-/-} mouse embryos. These holistic studies of RAI1 and its interactions allow insight into SMS and other disorders associated with intellectual disability and behavioral abnormalities, demonstrating the utility of a comprehensive genomic approach even in the diagnosis of distinctive disorders.

P08.83

Exome Sequencing Combined with Linkage Analysis Identifies a Novel Gene Associated with a Syndromic Form of Intellectual Disability

Y. Kesim¹, M. Calik², F. N. Tuncer¹, G. Altiocka Uzun³, A. Iscan⁴, U. Ozbek¹, S. Ugur Iseri¹; ¹Institute for Experimental Medicine, Genetics Department, Istanbul, Turkey, ²Harran University, Faculty of Medicine, Department of Pediatric Neurology, Sanliurfa, Turkey, ³Istanbul University, Istanbul Faculty of Medicine, Department of Neurology, Istanbul, Turkey, ⁴Bezmi Alem Vakif University, Faculty of Medicine, Department of Pediatric Neurology, Istanbul, Turkey.

Introduction: Syndromic intellectual disability (ID) comprises a group of clinically and genetically heterogeneous conditions, in which intellectual deficits are associated with other medical and behavioral signs and symptoms. Herein, we present genetic analyses leading to identification of a novel gene associated with syndromic ID in a consanguineous family.

Materials and Methods: All family members including two affected siblings were SNP genotyped in order both to perform genome wide copy number variation (CNV) profiling and linkage analysis. This strategy was accompanied by exome sequencing in the affected sib pairs.

Results: CNV analysis did not detect common pathogenic CNV events in the two affected sibs. SNP derived linkage analysis was overlapped with exome variants, which enabled us to investigate exome variants only in linkage intervals. This collective effort led us to identify a new substitution in a novel gene encoding a member of alpha/beta hydrolase superfamily on chromosome 20. Upon this finding, the first-degree cousin of the affected sib pair having a similar phenotype was also recruited to the study. The variant was also shown to be segregating with the disorder in this new branch of the family. Pathogenicity of the variant is supported further by in silico tools and its absence in public databases and apparently healthy 300 controls from Turkey.

Conclusions: Combined analysis of linkage and exome sequencing has proved to be a powerful approach proved to identify defective genes in consanguineous pedigrees. This study was supported by the grants of TUBITAK (113S331) and Istanbul Development Agency (TR10/15/YNK/0093).

P08.85

A new patient with Treacher Collins syndrome and intellectual disability due to a small deletion of TOCF1 and CAMK2A genes

I. López-Expósito^{1,2,3}, J. Bafalliu^{1,2,3}, M. Ballesta-Martinez^{4,2,3}, A. Vera-Carbonell^{1,2,3}, V. López-Gonzalez^{4,2,3}, G. Soler-Sánchez^{1,3}, M. Sánchez-Soler⁴, E. Guillén-Navarro^{5,2,3}; ¹Centro de Bioquímica y Genética Clínica. Hospital Clínico Universitario Virgen de la Arrixaca, Murcia, Spain, ²Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER). Instituto de Salud Carlos III, Madrid, Spain, ³Instituto Murciano de Investigación Biosanitaria (IMIB), Murcia, Spain, ⁴Sección de Genética Médica. Servicio de Pediatría. Hospital Clínico Universitario Virgen de la Arrixaca, El Palmar, Murcia, Spain, ⁵Consejería de Sanidad, Murcia, Spain.

The Treacher Collins syndrome-1 (TCS1, OMIM 154500) is an autosomal dominant disorder of craniofacial development, caused by heterozygous mutation in the TCOF1 gene on chromosome 5q32, rarely associated to intellectual disability (ID).

Recently, two large deletions (262kb and 1Mb) encompassing TCOF1 have described in two patients with typical features of TCS and ID. The minimal critical region also involved the CDX1, SLC6A7, CAMK2A, ARSI and CD74 genes. Authors suggested that CAMK2A could be responsible for the ID, although a combinatorial effect with the other deleted genes could not be ruled out.

We report on a new patient with TCS1 and ID, with a smaller deletion (ranged from 150kb to 180 Kb) that only included TCOF1, ARSI and CAMK2 genes. The girl was referred for genetic evaluation at four months of age, due to abnormal craniofacial development. MLPA of TCOF1 showed a complete deletion of the gene. At the last evaluation at the age of 10 years, her facial features fit the diagnosis of TCS and she also presented behavioral disorders and intellectual disability. CGH array was performed confirming that ARSI and CAMK2A were also deleted. The function of the ARSI gene is not related with the phenotype of the patient, but CMK2A can play a role in the neuronal development.

In conclusion, our patient presents a novel small deletion that narrows down the minimal critical region for a contiguous genetic disorder with TCS and ID, and strongly supports the hypothesis that haploinsufficiency of CAMK2A gene is responsible for the ID.

P08.86

Clinical description of two cases of Trichothiodystrophy 4 (OMIM#234050) due to homozygous mutation in MPLKIP in two unrelated families from the same geographical area, suggesting a common founder

M. Ballesta-Martinez¹, V. López-Gonzalez², M. Sánchez-Soler¹, L. Rodríguez-Peña¹, B. Rodríguez-Santiago², T. Martínez-Menchón³, J. Ferrando-Barbera⁴, L. Armengol-Dulcet⁵, E. Guillén-Navarro⁵;

¹Sección de Genética Médica. Servicio de Pediatría. Hospital Clínico Universitario Virgen de la Arrixaca, Murcia, Spain, ²qGenomics, Barcelona, Spain, ³Servicio de Dermatología. Hospital Clínico Universitario Virgen de la Arrixaca, Murcia, Spain, ⁴Servicio de Dermatología. Hospital Clinic de Barcelona, Barcelona, Spain, ⁵Consejería de Sanidad, Murcia, Spain.

Trichothiodystrophy (TTD) is a rare autosomal recessive disorder characterized by short, brittle hair with low-sulphur content. TTD patients display a wide variety of clinical features, including cutaneous, neurologic, and growth abnormalities. Common additional clinical features are ichthyosis, intellectual/developmental disabilities, decreased fertility, ocular abnormalities, short stature, and recurrent infections. Within the spectrum of the TTD-related conditions appear a number of syndromes affecting mainly organs derived from the neuroectoderm. There are both photosensitive and nonphotosensitive forms of the disorder: TTD1 (ERCC2), TTD2 or Sabinas syndrome (ERCC3/XPB gene), TTD3 or Pollitt syndrome (GTF2H5 gene), TTD4 or BIDS syndrome (MPLKIP gene), TTD5 or IBIDS syndrome (RNF113A gene), SI-BIDS syndrome, and ONMRS syndrome.

We report two unrelated patients with trichothiodystrophy type 4 from the same geographical area, carrying the same homozygous mutation in MPLKIP gene. First patient is a 7-year-old girl, first child of healthy nonconsanguineous parents (from the same town, 7000 inhabitants). Microcephaly (-4.74 SD), growth retardation, psychomotor delay, and brittle short growing hair. Optic microscopy showed pili torti and break stems. Homozygous c.277delT (p.Ser93Profs) mutation in MPLKIP gene was detected by exome sequencing. Patient 2 is a 2-year-old girl, second child of healthy unrelated parents, with psychomotor delay, microcephaly (-4.66 SD), limited growth and brittle hair. Hair analysis revealed trichoschisis and break stems. Due to highly concordant clinical features and geographical overlap with patient 1, analysis of Ser93Profs mutation on MPLKIP was performed first, detecting the same homozygous mutation, suggesting a founder effect in the area.

P08.87

Mutations specific to the Rac-GEF domain of TRIO cause intellectual disability and microcephaly

R. Pengally¹, S. Greville-Haygate¹, S. Schmidt¹, E. Seaby¹, C. Fagotto-Kaufman¹, R. Jabal-Ameli-Forooshani¹, S. Mehta², M. Parker³, D. Goudie⁴, C. Mercer¹, The DDD Study, A. Debant¹, S. Ennis¹, D. Baralle¹;

Background: Neurodevelopmental disorders have challenged clinical genetics for decades, with over 700 genes implicated and many whose function remains unknown. The application of whole-exome sequencing is proving pivotal in closing the genotype/phenotype gap through the discovery of new genes and variants that help to unravel the pathogenic mechanisms driving neuropathogenesis. One such discovery includes TRIO, a gene recently implicated in neurodevelopmental delay. **Methods:** Whole-exome sequencing was undertaken on a family presenting with global developmental delay, microcephaly and mild dysmorphism. Father/daughter exome analysis was performed, followed by confirmatory Sanger sequencing and segregation analysis on four individuals. Three further patients were recruited through the deciphering developmental disorders (DDD) study. **Functional studies** were undertaken using patient-specific Trio protein mutations. **Results:** We identified a frameshift deletion in TRIO that segregated autosomal dominantly. By scrutinising data from DDD, we further identified three unrelated children with a similar phenotype who harboured de novo missense mutations in TRIO. **Biochemical studies** demonstrated that in 3 out of 4 families, the Trio mutations affected the Dbl homology domain and led to a markedly reduced Trio-mediated Rac1 activation. **Conclusion:** We describe an inherited global developmental delay phenotype associated with a frameshift deletion in TRIO. Additionally, we identify pathogenic de novo missense mutations in TRIO associated with the same overwhelming phenotype; intellectual disability, microcephaly, and dysmorphism with striking digital features. We further functionally validate the importance of the Dbl homology domain in Trio protein function. Our study demonstrates how genomic technologies are yet again proving prolific in diagnosing and advancing the understanding of neurodevelopmental disorders.

P08.88

UNC80 mutation causes a syndrome of hypotonia, severe intellectual disability, dyskinesia and dysmorphism, similar to that caused by mutations in its interacting cation channel NALCN

Y. Perez¹, R. Kadir¹, M. Volodarsky¹, I. Noyman², H. Flusser², Z. Shorer², L. Gradstein³, R. Birnbaum⁵, O. Birk^{1,6};

¹The Morris Kahn Laboratory of Human Genetics, National Institute for Biotechnology in the Negev and Faculty of Health Sciences, Ben Gurion University of the Negev, Beer Sheva, Israel, ²Pediatric Neurology unit, Division of Pediatrics, Soroka University Medical Center, Faculty of Health Sciences, Ben Gurion University of the Negev, Beer Sheva, Israel, ³Zussman Child Development Center, Soroka University Medical Center, Faculty of Health Sciences, Ben Gurion University of the Negev, Beer Sheva, Israel, ⁴Department of Ophthalmology, Soroka Medical Center and Clalit Health Services, Faculty of Health Sciences, Ben Gurion University of the Negev, Beer Sheva, Israel, ⁵Department of Life Sciences and Faculty of Natural Sciences, Ben-Gurion University of the Negev, Beer Sheva, Israel, ⁶Genetics Institute, Soroka University Medical Center, Ben Gurion University of the Negev, Beer Sheva, Israel.

Background: A syndrome of profound hypotonia, intellectual disability, intra uterine growth retardation with subsequent failure to thrive, dyskinesia and epilepsy was diagnosed in Bedouin Israeli families. Mild dysmorphism was evident: plagiocephaly, broad forehead with prominent nose, smooth philtrum and congenital esotropia. We set out to decipher the molecular basis of this syndrome.

Methods: Genome wide linkage analysis and fine mapping were done. Whole exome sequencing data were filtered for candidate variants within locus. Validation and segregation of the mutation was assayed via Sanger sequencing. UNC80 expression pattern was analyzed through RT-PCR.

Results: Homozygosity mapping followed by fine mapping identified a 7.5 Mb disease-associated locus (LOD score 3.5) on chromosome 2. Whole exome and Sanger sequencing identified a single homozygous nonsense mutation within this locus, segregating within the families as expected for recessive heredity and not found in a homozygous state in 150 Bedouin controls: c.151C>T, p.(R51*) in UNC80.

Conclusions: The syndrome described is caused by a mutation in UNC80, truncating most of the 3258 amino acids highly conserved encoded protein, that has no known motifs. UNC80 bridges between UNC79 and the cation channel NALCN, enabling NALCN's role in basal Na⁺ leak conductance in neurons, essential for neuronal function. The phenotype caused by the UNC80 mutation resembles that previously described for homozygous NALCN mutations.

P08.89

UNC80 mutations lead to a recognizable syndrome with persistent hypotonia, encephalopathy, severe intellectual disability and postnatal growth retardation

UNC80, a component of the NALCN sodium channel complex, interacts directly with NALCN and regulates the basal excitability of the nervous system. Loss-of-function mutations of NALCN cause autosomal recessive infantile hypotonia with psychomotor retardation and characteristic facies (IHPRF; MIM #615419). Animal models of UNC80 and NALCN deficiency have similar phenotypes to those reported in humans with biallelic mutations in NALCN. We report 4 affected individuals from 3 unrelated families of different ethnicity (Iraq, Morocco, Norway) with profound persistent hypotonia, severe intellectual disability, postnatal growth retardation +/- microcephaly and seizures due either to homozygous missense mutations (p.P177S,

p.R2536T) or compound heterozygous truncating mutations in UNC80. HEK293T cells transfected with the homozygous p.P1700S mutation showed markedly decreased NALCN currents compared to controls on patch clamp recording. Recently, two other groups reported in total 16 affected individuals from 6 families of Arab ethnicity (3 from Saudi Arabia, 1 from Egypt, and 2 related Negev Beduin families) with homozygosity for either 1 missense (p.V189M) or 3 truncating mutations in UNC80, with phenotypes resembling our patients and patients with NALCN deficiency. Biallelic mutations in UNC80 result in an intellectual disability phenotype reminiscent of the severe end of the Angelman/Rett syndrome spectrum.

P08.90

Whole exome sequencing of 28 individuals with likely autosomal recessive intellectual disability reveals truncating variants in previously reported ID-genes

R. Buchert¹, R. Abou Jamra², A. Baraghithi³, M. Sturm¹, J. Sommerfeld¹, C. Vogel¹, C. Bauer¹, B. Kootz¹, S. Junker¹, A. Jamal⁴, M. Hamdallah⁵, W. Al-Ameri⁶, A. Rieβ¹, P. Bauer¹, O. Rieβ¹, T. Froukh⁷;

¹Institute of Medical Genetics and Applied Genomics, University of Tübingen, Tübingen, Germany, ²Institute of Human Genetics, University Medical Center Leipzig, Leipzig, Germany, ³Department of Biotechnology and Genetic Engineering, Philadelphia University, Amman, Jordan, ⁴private practice, Amman, Jordan, ⁵Farah Hospital, Amman, Jordan, ⁶Ibn Alhytham Hospital, Amman, Jordan.

In a bilateral project between Germany and Jordan, we examined 28 consanguineous Jordanian families with intellectual disability (ID) of probably autosomal recessive inheritance. We conducted whole exome sequencing (WES) for one affected individual per family and filtered for homozygous variants. With this approach we could identify homozygous truncating variants in the previously established ID-genes *NT5C2* (p.Gln447fs5), *ALDH5A1* (p.Gln362*), *GPR56* (p.Trp657*) and *WDR62* (p.Trp836*).

Although family pedigrees suggested autosomal recessive ID, we were able to identify autosomal dominant causes in 2 families. In a consanguineous family with one affected individual, CNV analysis of WES coverage data revealed a de novo deletion on chromosome 4q21.22-21.23 which was previously reported in individuals with ID and fits the phenotype of the examined individual.

In another individual we identified a heterozygous truncating mutation in *TCF4* previously described in Pitt-Hopkins-syndrome. Segregation analysis revealed that the likewise affected sister also carries this variant while both parents are negative for this variant with no traces of somatic mosaicism. Thus, we propose that this variant is the result of a germline mosaic and causative for the phenotype.

In total, with our approach of WES of affected individuals with likely autosomal recessive ID, we identified the underlying causes of intellectual disability in 6 out of 28 families. However, in 2 families the pathogenic changes were due to de novo events. This stresses the importance of taking into account all possible patterns of inheritance including germline mosaics when analyzing WES data.

This project is funded through a grant by DAAD.

P08.91

A new mutation in KMT2A gene in a boy with Wiedemann-Steiner syndrome

M. Soeiro e Sá, P. Dias, A. B. Sousa; Serviço de Genética Médica, Departamento de Pediatria, Hospital de Santa Maria, Centro Hospitalar Lisboa Norte, Centro Académico de Medicina de Lisboa, Lisbon, Portugal.

Wiedemann-Steiner syndrome (WSS) is a rare autosomal dominant intellectual disability (ID) syndrome characterized by hypotonia, growth deficiency, distinctive facial gestalt and hypertrichosis cubiti. It is due to heterozygous mutations in KMT2A (MLL) gene at 11q23.3, encoding a histone methyltransferase. Since the identification of the causative gene in 2012, only 20 cases have been reported, all caused by different mutations.

Herein we describe a 10-year-old boy with moderate ID, short stature (<5th centile), generalized obesity (BMI in the 95th centile), thick hair with frontal upsweep, low posterior hairline, small and vertically narrow palpebral fissures, hypertelorism, bilateral epicanthus, wide nasal bridge, long and smooth philtrum, broad right first digit, bilateral sandal gap, cutaneous syndactyly between the second and third toes and bilateral long vellus hair on the elbows. Hearing and vision were unaffected. Karyotype, array-CGH and FMR1 molecular analysis were normal.

The phenotype suggested WSS and the diagnosis was confirmed with the identification of a heterozygous variant, c.502+1G>T, in KMT2A. The latter was previously unreported but considered likely pathogenic because it affects splicing.

Hairy elbows can be isolated or present in association with a spectrum of other features; when syndromic they are very suggestive of WSS and analysis of KMT2A is warranted. Etiological clarification classifies WSS within the large group of chromatin remodeling defect disorders, which are thought to result from global changes in protein expression during embryonic development leading to multiorgan abnormalities. How this mechanism can produce such a peculiar effect as localized hair growth on the elbows is still unclear.

P08.92

De novo Loss of Function Mutations in the KIAA2022 Gene on Xq13.3 Are Associated with Intellectual Disability, Impaired Language, and Epilepsy in Females

A. Pujol^{1,2}, R. Webster³, M. T. Cho², K. Retterer², F. Millan², C. Nowak⁴, J. Douglas⁴, A. Amadé⁵, G. Raymond⁶, M. Johnson⁶, A. Begtrup², D. McKnight², J. Juusola², O. Devinsky⁷, W. Chung⁸;

¹IDIBELL, Barcelona, Spain, ²GeneDx, Gaithersburg, MD, United States, ³Department of Pediatrics, Columbia University Medical Center, New York, NY, United States, ⁴Boston Children's Hospital, Boston, MA, United States, ⁵University of Michigan, Ann Arbor, MI, United States, ⁶Pediatric Neurology, University of Minnesota, Minnesota, MN, United States, ⁷New York University School of Medicine, New York, NY, United States, ⁸Department of Pediatrics, Columbia University Medical Center, New York, NY, United States.

Intellectual disability (ID) affects about 1%-3% of humans with a gender bias toward males. In the search for genes involved in monogenic ID, molecular characterization of chromosomal rearrangements involving the X-chromosome, and X-chromosome exome sequencing, have been important in the identification of the more than 100 genes to date. We report the results of diagnostic whole-exome sequencing in trios to identify five females carrying de novo predicted pathogenic mutations in KIAA2022 (OMIM: 300524), from 1500 females with ID/developmental delay. The encoded product, X-linked Intellectual Disability Protein Related to Neurite Extension (XPN), is highly expressed in the developing and adult brain and is involved in the regulation of neuronal migration and cell adhesion. Our five females come from unrelated families, and are characterized by severe intellectual disability, developmental delay, epilepsy refractory to treatment, impaired language, autism-spectrum disorder, hypotonia, and ataxic gait with normal brain MRIs. Additional but less common symptoms include gastrointestinal reflux, esotropia and mild dysmorphisms. The phenotypic severity in females is similar to that observed in the 13 previously reported males with pathogenic variants in KIAA2022, who were born from unaffected mother carriers. This report, together with three other recently described symptomatic female patients, contributes to the data supporting KIAA2022 as a cause of intellectual disability in females, and bears direct implications for genetic counseling and testing.

P08.93

A novel mutation in ZMYND11 gene in a girl with severe intellectual disability

O. Moldovan¹, C. Martins Halpern², A. Sousa¹;

¹Serviço de Genética Médica, Departamento de Pediatria, Hospital de Santa Maria, Lisbon, Portugal, ²Unidade de Neuropediatria, Centro de Desenvolvimento, Hospital Garcia de Orta, Lisbon, Portugal.

Introduction: Mental retardation, autosomal dominant 30 (MRD30) (OMIM#616083) is caused by mutations in the ZMYND11 gene. Less than ten cases have been previously reported with mutations in this gene. We describe a girl with severe global developmental delay and dysmorphism. **Materials and Methods:** She was born to healthy and nonconsanguineous parents at 39 weeks gestation. Family history was unremarkable. Her birth weight was 2740g (10th centile), length 47,5cm (25th centile) and head circumference 32cm (3rd centile). Ventricular disproportion and esophageal atresia were suspected in the prenatal scans, but not confirmed after birth. On the other hand, she presented facial dysmorphism, VSD and axial hypotonia. She also had gastro-esophageal reflux, which motivated recurrent episodes of hospitalization for apparent life-threatening events (ALTE), and drug-resistant sleep disturbance. At 1 year and 3 months, her weight and length were above the 75th centile and head circumference was on the 50th centile. She had severe developmental delay with incomplete head control and inability to maintain a sitting position. We performed arrayCGH which revealed no significant CNV, and FISH analysis in buccal mucosa cells and skin fibroblasts to exclude tetrasomy 12p. Finally we decided for trio exome sequencing and a de novo likely-causative variant was detected (c.1259C>A; p.Ser420Tyr) in ZMYND11 gene, predicted to be pathogenic and previously unreported in population databases.

Conclusions: We report a patient presenting a new mutation in ZMYND11 gene which determines the most severe phenotype described to date.

P09.001

Characterization of rearrangements in the 22q11.2 region: A population-based screening of 25,703 newborn Danes.

T. Sparsø¹, L. Olsen¹, S. Weinsheimer¹, M. Bertalan¹, W. Mazin¹, J. Grauholm², M. Hollegard², D. Hougaard², C. B. Pedersen³, P. B. Mortensen³, W. Thompson¹, BROAD investigators, iPSYCH investigators, T. Werge¹;

¹Biological Psychiatry, Sct Hans, Roskilde, Denmark, ²Section of Neonatal Genetics and the Danish Neonatal Screening Biobank, Copenhagen, Denmark, ³National Centre for Register-based Research, Aarhus, Denmark.

Purpose: Genetic rearrangements in the 22q11.2 region are mediated by LCR. Frequency estimates of the 3Mb deletion has so far been based on hospital recruitments and commonly referred to as 1:4000 newborns. A unique source for population-based studies is provided by the iPSYCH initiative (www.ipsych.au.dk). Dried bloodspots from all newborns have been stored since 1982 and today DNA has been extracted from 76,109 individuals (N=25,703 are random samples). Here, we present the first accurate population-based prevalence of both 22q11.2 deletions and duplications. Using the National Health Registry, we provide population-based incidence rate ratio (IRR) estimates for neurodevelopmental disorders in individuals with the 22q11.2 rearrangement. We used incidence density sampling to calculate incidence rate ratio (IRR) estimates for the psychiatric diagnostic categories (ADHD, autism, schizophrenia, and mental retardation). **Results:** Among the 25,703 population-based samples we observed a frequency of 0.027% (1:3672) for 22q11.2 deletions and 0.0622% (1:1606) for the reciprocal duplications. In our samples of ADHD (N=16,715), autism spectrum (N=14,333), schizophrenia (N=2,623) and mental retardation (N=4,097), we found a significant increased IRR for individuals carrying the 22q11.2 deletion (ADHD: IRR=5.00 (p=0.0026), autism: IRR=6.00 (p=0.00309), mental retardation: IRR=14.29 (0<0.00001). Carriers of the reciprocal 22q11.2 duplication showed similar increased risk for neurodevelopmental disorders (ADHD: IRR=3.75 (p=0.00053), autism: IRR=2.86 (p=0.018), schizophrenia: IRR=4.29 (p=0.035), and mental retardation: IRR=4.10 (p=0.00398), however, not as profound as for deletion carriers. **Conclusion:** True population-based frequency of the 22q11.2 deletion is marginally higher than the widely accepted 1:4000. Both the 22q11.2 deletion/duplication confer risk of neurodevelopmental disorders at the population-level.

P09.002

22q11.2 deletion syndrome and HTRA2 p.G399S in a patient with juvenile onset Parkinson disease

P. Prontera¹, V. Napolioni², D. Rogai¹, I. Isidori¹, A. Mencarelli¹, N. Tambasco³, G. Merla⁴, G. Stangoni¹, P. Calabresi^{3,5};

¹Medical Genetics Unit, Perugia, Italy, ²Department of Neurology and Neurological Sciences, Stanford University School of Medicine, Palo Alto, CA, United States,

³Neurologic Clinic, University of Perugia, Perugia, Italy, ⁴Medical Genetics Unit, IRCCS Casa Sollievo della Sofferenza, San Giovanni Rotondo, Italy, ⁵IRCCS Fondazione „S. Lucia“, Rome, Italy.

In a patient with 22q11.2 deletion syndrome who developed at 32 years of age Parkinson Disease (PD), with tremor as the predominant symptom, we performed a WES, on Illumina HiSeq1500 after prepping the samples with a Nextera Rapid Capture Exome kit (Illumina) and an array-CGH analysis (CytoChip 4x180K, BlueGnome) of the trio. The array-CGH better defined the extent of the *de novo* deletion (from 18,894,865 to 21,505,388 [hg19]), while WES did not disclosed mutations in known PD genes, but identified the controversial HTRA2 p.G399S variant in the heterozygous state, inherited from the healthy mother. HTRA2 is a serine protease located in the inter-membrane space of the mitochondria and previous studies demonstrated that HTRA2 p.G399S leads to mitochondrial dysfunction, altered mitochondrial morphology and decreased protease activity. The region 22q11.2 harbors six genes encoding mitochondrial proteins, namely, PRODH, MRPL40, SLC25A1, TANGO2, TXNRD2, and ZDHHC8, that we showed to be down regulated in our patient, by a whole transcriptome analysis on RNA extracted from a fibroblast culture obtained from skin biopsies of the patient and of an age and sex-matched control (Unrestricted Gene expression Human Microarray 4x44K, Agilent Technologies). Even if could be conceivable that a severe mitochondrial dysfunction caused by the concomitant defects in these genes may be the cause of the juvenile PD in our patient, nevertheless this single case report cannot allow for firm conclusions, but it provides additional starting points for future cross-correlations and investigations of genetic epistasis, especially between rare genetic cause of PD.

P09.003

3p- syndrome with deletion of CHL1, CNTN6 and first exon of CNTN4 gene: phenotype and genotype relationship in a 6 yo boy

A. Lafuente, M. Ortiz, J. Juan, G. Pl, A. Zúñiga;
Hospital de la Ribera, Alzira (Valencia), Spain.

The 3p deletion syndrome is a rare contiguous gene syndrome caused by deletions in the 3p25-pter region. The deletions are variable in size, they don't present common break-points and mostly occur de novo, but a few familial cases have been reported. The syndrome is characterized by a recognizable phenotype including low birth weight, growth and mental retardation, developmental delay and characteristic facial appearances. The clinical manifestations in individuals with 3p deletions vary from normal to severe. A milder phenotypic effect or a normal intelligence has also been described for larger, often inherited, deletions of this region and appears to be secondary to the breakpoint's location and the deletion extent.

Proband is a 6 yo male and he is the second child of healthy, non-consanguineous parents. Karyotype was normal male. No family history of congenital anomalies or mental retardation was referred. The child was born after 36 weeks of uneventful pregnancy, by caesarean section. He showed a regular physical and psychomotor development (sitting at 6 months, walking at 14 months). At school learning difficulties were observed and a neuropsychological evaluation showed a borderline I.Q. level and language disorders. CGH microarray analysis showed a sub microscopic 3p26.3 terminal deletion. Parents were normal. The imbalance is less than 2 Mb in size and includes three OMIM gene: CHL1 (607416), CNTN6 (607220) and first exon of CNTN4 (607280). CNTN4 plays an important role in the neuronal network development. CHL1 has been suggested to be responsible for mental defects in patients with 3p- syndrome.

Background: Gilles de la Tourette syndrome (GTS) is a complex neuropsychiatric disorder with a strong genetic influence where copy number variations (CNVs) are suggested to play a role in disease pathogenesis. In a previous small scale CNV study of a GTS cohort (n=111), recurrent exon-affecting microdeletions of four genes, including the gene encoding arylacetamide deacetylase (AADAC), were observed and merited further investigations. Methods: We screened a Danish cohort of 243 GTS patients and 1,571 controls for submicroscopic deletions and duplications of these four genes. The most promising candidate gene, AADAC, identified in this Danish discovery sample was further investigated in cohorts from Iceland, the Netherlands, Hungary, Germany and Italy, and a final meta-analysis including a total of 1,181 GTS patients and 118,730 controls from these six European countries was performed. Subsequently, expression of the candidate gene in the central nervous system was investigated using human and mouse brain tissues. Results: In the Danish cohort, we identified eight patients with overlapping deletions of AADAC. Investigation of the additional five countries showed

a significant association between the AADAC deletion and GTS, and a final meta-analysis confirmed the significant association (P=4.4 x 10⁻⁴; OR=1.9; 95% CI 1.33-2.71). Furthermore, RNA in situ hybridization and RT-PCR studies revealed that AADAC is expressed in several brain regions previously implicated in GTS pathology.

Conclusions: AADAC is a candidate susceptibility factor for GTS and the present findings warrant further genomic and functional studies to investigate the role of this gene in the pathogenesis of GTS.

P09.005

Reduced penetrance of p.Thr585Met RANBP2 mutation in autosomal dominant acute necrotizing encephalopathy

D. R. Carvalho, B. J. A. F. Martins, C. E. Speck-Martins, J. M. Brum, A. La Rocque-Ferreira; SARAH Network of Rehabilitation Hospitals, Brasilia, Brazil.

Acute necrotizing encephalopathy (ANE) is clinically characterized by fever, acute encephalopathy, seizures, and rapid progression to coma within days of onset of a viral illness in otherwise healthy children, with no evidence of central nervous system infection. Brain magnetic resonance imaging (MRI) shows multiple symmetrical lesions affecting primarily the thalami but also brainstem, putamina, periventricular white matter and cerebellum. Most ANE is sporadic and nonrecurrent. A missense mutation in RANBP2 gene has been identified as a major cause of familial and recurrent ANE (MIM 608133), also named autosomal dominant ANE (ADANE). Only few families with ADANE have been reported.

Clinical and radiological findings of six members of a two-generation ADANE family were described. Sequencing revealed the c.1754C>T RANBP2 mutation (p.Thr585Met) in five of them.

DNA was not obtained from radiologically affected boy who died at age 13 months after the second episode of coma. His 18-year-old brother manifests spastic quadriplegia, dystonia and moderate mental retardation as sequelae. Their healthy mother (44 years) is the sister of a 42-year-old heterozygous father of three affected girls and he also never had any symptom. After acute encephalopathy episodes, the 11-year-old sister presents mild dysmetria and cognitive impairment with strabismus, while the 10-year-old sister has spastic diparesis, ataxia and mental retardation. The 7-year-old heterozygous sister manifested unexplained decreased level of consciousness during two viral febrile infections. She had a complete recovery and normal brain MRI.

We reinforce the incomplete penetrance of ADANE and great variability regarding neurologic damage and residual signs.

P09.006

Identification of ADHD candidate genes in large pedigrees combining linkage analysis and whole-exome sequencing

J. Corominas Galbany¹, M. Klein¹, T. Zayats², S. Gross-Lesch³, M. Pauper¹, C. Jacob¹, A. Reif⁴, M. Romanos⁵, A. Arias Vasquez^{1,6}, K. Lesch³, B. Franke^{1,7};

Attention-Deficit/Hyperactivity Disorder (ADHD) is a common neuropsychiatric and multifactorial disorder characterized by inattention, and/or motor hyperactivity and impulsivity. The study of multi-generation pedigrees with multiple affected individuals can point towards novel ADHD-related genes. By combining haplotype analysis and whole exome sequencing (WES), we aim to identify genes carrying rare and/or common variants that contribute to ADHD. Three German pedigrees with multiple ADHD-affected adults were used in this study, in which linkage analysis was carried out on the major part of the individuals and WES data from two or more patients were obtained to detect shared genetic variants. Genotyping data was used to identify haplotype blocks segregating with disease. Linkage analyses were performed using a Multi-Point analysis implemented in Superlink online SNP, for each family and by combining them. Regions with a maximum LOD score higher than 2 were selected as a candidate regions. Genes in these regions containing shared rare genetic variants were selected as candidate genes. A common problem in multifactorial diseases is that the effect of individual markers is too weak to be detected; consequently, multiple genetic markers may be simultaneously analyzed to increase explained

variance. Therefore, gene-set analyses were performed in an independent exome-chip dataset from 1846 ADHD patients and 7519 controls (IMpACT). The gene-set from one family indeed showed a significant association with adult ADHD, suggesting that the variants in several genes might act together in increasing ADHD risk. The analysis strategy followed here might provide new knowledge for a better understanding of ADHD's etiology.

³Institute of Psychological Medicine and Clinical Neurosciences, MRC Centre for Neuropsychiatric Genetics and Genomics, Cardiff University School of Medicine, Cardiff, United Kingdom, ⁴Max Planck Institute for Psycholinguistics, Nijmegen, Netherlands.

Introduction: Prenatal smoking and alcohol consumption have been suggested as possible risk factors for ADHD. Inferring causality has not been possible because the mother provides both the prenatal environment and genetic risk factors for ADHD. We investigated if there are shared genetic effects between ADHD and possible risk factors for ADHD using polygenic risk score analysis in the general population.

Materials and Methods: ADHD polygenic risk scores were calculated for 8340 mothers from the Avon Longitudinal Study of Parents and Children (ALSPAC) based on the results of a genome-wide ADHD case-control study (Stergiakouli et al. 2012) and tested for association with smoking and alcohol consumption before and during pregnancy and with breastfeeding status.

Results: Higher genetic risk for ADHD was associated with higher odds of smoking before and during pregnancy and not breastfeeding (see Table). There was no evidence of association with alcohol consumption. Adjusting for ADHD polygenic score of the child did not change the association.

Conclusions: Our results show for the first time that there are shared genetic effects between ADHD and life style choices in mothers from the general population without the disorder. The mother can not only transmit genetic risk for ADHD to her offspring but also expose the child to risk factors through her life style choices that are in turn influenced by her genetic risk for ADHD.

Outcome	N	OR (95% CIs)	p value
Smoking before pregnancy	7530	1.05 (1.01 to 1.1)	0.03
Smoking at first trimester	7543	1.08 (1.03 to 1.15)	0.002
Alcohol consumption before pregnancy	7530	0.99 (0.91 to 1.08)	0.9
Alcohol consumption at first trimester	7543	0.98 (0.94 to 1.03)	0.5
Breastfeeding	6604	1.06 (1.01 to 1.11)	0.03

Sex-specific genome-wide common variant analyses of attention deficit hyperactivity disorder

J. Martin^{1,2,3}, R. Walters², D. Demontis⁴, M. Mattheisen⁴, S. Lee^{5,6}, M. C. O'Donovan², E. Robinson², Psychiatric Genomics Consortium: ADHD Subgroup, iPSYCH-SSI-Broad ADHD Workgroup, B. Franke⁷, A. Borglum⁸, S. V. Faraone⁹, A. Thapar³, B. M. Neale²;
¹Karolinska Institutet, Stockholm, Sweden, ²Broad Institute, Cambridge, MA, United States, ³Cardiff University, Cardiff, United Kingdom, ⁴Aarhus University, Aarhus, Denmark, ⁵University of New England, Armidale, Australia, ⁶Queensland Brain Institute, Brisbane, Australia, ⁷Radboud University Medical Center, Nijmegen, Netherlands, ⁸SUNY Upstate Medical University, Syracuse, NY, United States.

Attention deficit hyperactivity disorder (ADHD) shows substantial heritability as measured by twin/family studies and genome-wide association studies (GWAS). ADHD is about four times more common in males than females. What is unclear is the nature of the apparent female protective effect. One hypothesis is that female cases carry a higher burden of genetic risk. Alternatively, the sources of variation are different between the sexes. We examined these two hypotheses using genome-wide data from the Psychiatric Genomics Consortium and the iPSYCH Project in collaboration with the Danish Neonatal Screening Biobank.

Initial sex-specific GWAS meta-analysis of ~11,000 ADHD cases (24% female) and ~21,000 population controls/pseudo-controls (51% female) showed no genome-wide significant variants for either sex. Genetic correlation analyses of female and male ADHD using LD-score regression and GREML showed a strong bivariate heritability; $R_g(SE) \sim 1.0(0.2)$. Results examining the relative burden of common genetic risk variants, using a leave-one-sample-out polygenic risk score analysis approach, showed higher mean polygenic scores in cases than in controls but no association of ADHD genetic risk with sex in cases.

The high genetic correlation suggests that the vast majority of common variant risk is shared between females and males in ADHD and supports combining GWAS data from both sexes in meta-analyses. Further, these results suggest that common genetic variants do not appear to play a significant role in the sexual dimorphism of ADHD. Although no significant difference in polygenic risk has been detected, these analyses are still severely limited in power and will benefit from increasing sample sizes. (Wellcome-Trust:106047)

P09.009

The effect of parental age on the presence of de novo mutations - Lessons from neurofibromatosis type 1

S. Ben-Shachar¹, T. Dubov², H. Toledano-Alhadef³, F. Bokstein³, S. Constantini³;

¹The Genetic Institute, Tel-Aviv, Israel, ²Sackler Faculty of Medicine, Tel-Aviv, Israel, ³Tel-Aviv Medical Center, Tel-Aviv, Israel, ⁴Tel-Aviv Medical Center, Tel-Aviv, Israel.

Background: Neurofibromatosis type 1 (NF1) is the most common autosomal dominant neurocutaneous disease with a prevalence of 1:2,500. Approximately 50% of cases are sporadic. Advanced paternal age is associated with germline mutations and autosomal diseases. We aimed to use NF1 as a paradigm to study the effect of parental age on sporadic mutations rates for both advanced and younger parental ages.

Methods: The medical charts of 118 NF1 pediatric patients followed in a specialized Israeli NF1 clinic were evaluated. Thirty-one cases were diagnosed by genetic tests and 87 by NIH clinical criteria. Sixty-four cases (54%) had a negative family history of NF1 (sporadic cases). Data on parental ages at the time of the children's birth were compared to the national population database.

Results: Significantly fewer fathers had been 25-29 years old at their child's birth compared with fathers in the general population (7.8% versus 21%, respectively, $p=0.009$), and significantly more were ≥ 40 years old (29.7% versus 13.6%, respectively, $p=0.0002$). Differences in maternal age between these two groups were less prominent.

Conclusion: The risk for sporadic NF1 was lower when the fathers were younger at the time of the affected child's birth and gradually increased with paternal age.

Differential expression of inflammatory cytokines in peripheral blood mononuclear cells in early and late onset Alzheimer's disease

N. Unaltuna¹, G. Guven¹, E. Lohmann², H. Hanagasi², E. Ozer¹;

¹Department of Genetics, Institute for Experimental Medicine, Istanbul University, Istanbul, Turkey, ²Behavioural Neurology and Movement Disorders Unit, Department of Neurology, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Turkey.

Introduction: Neuroinflammation is involved in the Alzheimer's disease (AD) pathology. Our major focus was to clarify whether peripheral inflammation plays important roles in AD pathogenesis, particularly if there is a difference in expression of inflammatory cytokines in early vs late onset Alzheimer's patients (EOAD vs LOAD). For this, we analyzed the expression pattern of IL-1 β , IL-6, IL-10, IL-12, TGF- β and TNF- α in peripheral blood mononuclear cells of EOAD, LOAD and controls.

Materials-Methods: The study group consisted of 13 EOAD, 14 LOAD and 13 control patients. Quantitative Real Time PCR of each of the mRNA normalized with GAPDH was used to determine levels of cytokines. Parametric and non-parametric statistical tests were used for comparison of groups and correlations were analyzed using Pearson's linear correlation test.

Results: IL-1 β , IL-6 and TNF- α were found to be significantly down-regulated in EOAD when compared with the LOAD and the controls. Decrease of IL-12 expression was observed in EOAD when compared with LOAD. The correlation analyses revealed that IL-6 was inversely correlated with TGF- β for EOAD, for LOAD, however, IL-6 with IL-10 and IL-12 with TGF- β were positively correlated. Such differences are present in PSEN1 positive and negative patients as well.

Conclusions: This is the first study comparing expression levels of peripheral cytokines between EOAD and LOAD patients. Our results suggest that EOAD and LOAD have differences in immune response, which might be monitored in peripheral blood cells as biomarkers. Further studies with larger population are needed to explore the underlying mechanisms of our findings.

P09.011

Expression of inflammation-related miRNAs and their selected target genes in peripheral blood mononuclear cells of early and late onset Alzheimer disease patients

G. Guven¹, E. Lohmann², H. Hanagasi², C. Gulec³, E. Ozer¹, N. Unaltuna¹;

¹Department of Genetics, Institute for Experimental Medicine, Istanbul University, Istanbul, Turkey, ²Behavioural Neurology and Movement Disorders Unit, Department of Neurology, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Turkey, ³Department of Medical Genetics, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Turkey.

Introduction: Alzheimer Disease (AD) brains display a changed miRNA-expression-profile which is reflected also in peripheral blood mononuclear cells (PBMC). Therefore, we investigated the expression levels of inflammation-related miRNAs and their selected target genes in PBMC of early-onset AD (EOAD), late-onset AD (LOAD) patients and controls.

Materials-Methods: The study group consisted of 13 EOAD patients including 7 with [PSEN1(+)] and 6 without [PSEN1(-)] PSEN1 mutations, 14 patients with LOAD and 13 healthy, non-correlated controls. qRT-PCR determined levels of mir-146, mir-144, mir-34a and their target genes: TRAF6, TSPAN12, ADAM10, BECLIN1, TREM2. Statistical analyses were performed using SPSS software.

Results: mir-144 was significantly overexpressed whereas its target genes, ADAM10 and BECLIN1, were significantly down-regulated in PSEN1(-) EOAD group compared with the others.

In contrast, mir-34a was significantly down-regulated in PSEN1(+)EOAD compared with LOAD and its target gene TREM2 levels were found to be significantly decreased in PSEN1(+)EOAD when compared with controls, but not with LOAD.

mir-146a was significantly down-regulated in PSEN1(+)EOAD compared with LOAD. The levels of its target genes, TSPAN12 and TRAF6, were found to be significantly down-regulated in PSEN1(-)EOAD group compared with LOAD. Additionally, mir-146a expression was inversely correlated with TRAF6 in the LOAD group.

Conclusions: This is the first study comparing miRNAs and their target gene expression in PBMC of EOAD and LOAD patients. Our results suggest a different role of miRNAs in EOAD compared to LOAD. In addition, the presence/absence of PSEN1 mutation might also influence their regulation. However, studies including larger patient groups are requested to confirm our findings.

P09.012

Screening for preclinical Alzheimer's disease

D. Farouk¹, M. Shehab¹, M. Mekkawy¹, H. Afifi¹, M. Ragab², H. Awadallah², M. Afifi³, S. Temtamy¹;

¹The National research Center, Cairo, Egypt, ²Department of Environmental Medical Science, Institute of Environmental Research and Studies, Ain Shams University, Cairo, Egypt, ³Institute of psychiatry, Ain Shams University, Cairo, Egypt.

Introduction: The majority of Alzheimer's disease (AD) cases arise through interactions among genetic and environmental factors, the disease usually begins many years before clinical symptoms appear. Premature centromere separation (PCS) and micronuclei (MNi) are useful cytogenetic biomarkers for prediction and early diagnosis. Constricted life space and fewer years of education are two environmental risk factors for AD, avoiding the environmental factors in addition to early detection can significantly decrease the incidence of the disease.

Materials and Methods: This study was conducted on 26 patients diagnosed as AD and a group of 26 matched controls. All subjects performed life space measurement, Mini-Mental State Examination (MMSE), conventional cytogenetic analysis, Fluorescent In Situ Hybridization (FISH) analysis and Cytokinesis-block micronucleus assay (CBMN).

Results: The average years of education were significantly fewer in the patients group (P = 0.0466) and their average life space was constricted compared to controls (P = 0.0234). Significant positive correlation was found between score of MMSE and score of life space trajectories among the patients ($r_{s};^2 = 0.7886$) which demonstrates the effect of constricted life space on cognitive impairment. Cytogenetic results revealed a significant difference in percentage of PCS and score of MNi between AD patients and controls (P < 0.0001)

Conclusions: These results clarify that screening for AD by the environmental risk factors and the cytogenetic biomarkers can be valuable for early detection as chromosomal instability occurs many years before evidence of clinical symptoms, and treatment is beneficial at this stage.

Liver X Receptor genes variants modulate risk and phenotype of ALS

K. Mouzat^{1,2}, N. Molinari³, J. Kantar¹, A. Polge¹, P. Corcia⁴, P. Couratier⁵, P. Clavelou⁶, R. Juntas-Morales^{2,7}, N. Pageot^{2,7}, J. A. Lobaccaro⁸, C. Raouf⁹, S. Lumbroso^{1,2}, W. Camu^{2,7};

¹Laboratoire de Biochimie et Biologie Moléculaire, CHU Nîmes, Nîmes Cedex 9, France, ²INSERM UMR1051, Institut des Neurosciences de Montpellier, Hôpital Saint Eloi, Montpellier, France, ³IMAG, UMR 5149, DIM, CHRU de Montpellier, Montpellier, France, ⁴Centre SLA, Service de Neurologie et Neurophysiologie Clinique, CHRU de Tours, UMR INSERM U930, Tours, France, ⁵Centre SLA, Service de Neurologie, CHU Limoges, Limoges, France, ⁶Centre SLA, Service de Neurologie A, CHU Clermont-Ferrand, Clermont-Ferrand, France, ⁷ALS Center, Département de Neurologie, CHU Gui de Chaillac, Montpellier, France, ⁸Génétique Reproduction et Développement, Clermont Université, Clermont-Ferrand, France; CNRS, UMR 6293, GRéD, Aubière, France; INSERM, UMR 1103, GRéD, Aubière, France; Centre de Recherche en Nutrition Humaine d'Auvergne, Clermont-Ferrand, France.

Background: Amyotrophic lateral sclerosis (ALS) is one of the most severe neurodegenerative disorder, characterized by the loss of motor neurons. Phenotype of ALS patients is highly variable, and suffers from the lack of reliable molecular markers. Lipid metabolism has recently been suggested as a potent modulating factor of ALS progression. The two isoforms of nuclear receptors Liver X Receptors (LXRs), LXR alpha (LXR α) and LXR beta (LXR β) play a central role in lipid metabolism as cholesterol sensors. Several lines of evidence have also pointed LXRs as potential candidates to explain ALS phenotype variability. Subsequently, an association study using single nucleotide polymorphisms (SNPs) was conducted to explore LXRs as genetic makers for ALS.

Results: Associations between SNPs of LXR α (rs2279238 and rs7120118) and LXR β (rs35463555 and rs2695121) genes and ALS were assessed by genotyping using high-resolution melting analysis in a cohort of 438 ALS patients and 330 healthy controls. The two LXR α SNPs rs2279238 and rs7120118 were shown to be associated with ALS risk. Analysis of clinical parameters revealed that the two LXR α SNPs were associated with age at onset in ALS patients (p = 0.0027 and p = 0.0298 respectively). This association was also strengthened by the number of rare alleles carried by patients. Moreover, rs2695121 within LXR β gene was shown to be associated with disease duration (p = 0.0055).

Conclusions: These findings reveal a new genetic association between LXRs and both ALS risk and phenotype, opening new perspectives in the understanding of molecular mechanisms underlying the disease.

P09.014

Association of FTO gene variants with sporadic amyotrophic lateral sclerosis in Greek patients

K. Mitropoulos¹, C. Mizzi², E. Tsermpini³, E. Merkouri-Papadima³, A. Balasopoulou², V. Dellatola², V. Karathanasi³, T. Katsila³, G. P. Patrinos³;

¹University of Athens School of Medicine, Athens, Greece, ²University of Malta, Msida, Malta, ³University of Patras Faculty Health Sciences Department of Pharmacy, Patras, Greece.

Amyotrophic Lateral Sclerosis (ALS) is characterized by degeneration of upper and lower motor neurons in the motor cortex, brain stem and spinal cord. Patients develop progressive paralysis resulting in death, usually caused by respiratory failure. Until now, no effective therapeutic strategy exists. It is well documented that sporadic ALS is a multifactorial disease, in which a genetic component, such as SOD1, FTO, FUS, TARDP, C9orf72, has been evident.

We have analyzed 10 unrelated Greek sporadic ALS patients by whole genome sequencing. Our bioinformatics analysis revealed a strong correlation between several single nucleotide polymorphisms (SNPs) with the development of ALS. Subsequently, our analysis was expanded in 27 sporadic ALS patients of Greek origin and 50 ethnically matched healthy controls, which were genotyped by Sanger sequencing and allele-specific PCR.

Our data indicate a statistically significant outcome (p<0,001) for one of the studied SNPs when ALS patients are compared to healthy individuals.

As far as we know, this is the first study that reveals such an association between the FTO gene and the pathobiology of the disease. Nevertheless, due to small sample size, our study should only be considered a pilot study and replication in a larger population cohort is needed to confirm this finding.

P09.015

ANKK1 locus and Parkinson's disease risk

J. Hoernicka¹, D. Martínez-Rubio², E. Pérez-Santamarina², P. García-Ruiz², I. Pla⁴, M. Ezquerro⁵, M. Martí⁶, J. Puente⁶, F. Palau¹;

¹Institut de Recerca Pediàtrica, Hospital Sant Joan de Déu, Barcelona, Spain, ²Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), Valencia, Spain, ³Fundación Jimenez Díaz, Madrid, Spain, ⁴Centro de Investigación Príncipe Felipe, Valencia, Spain, ⁵Hospital Clínic of Barcelona, Barcelona, Spain, ⁶LabGenetics, Madrid, Spain.

Introduction: Single nucleotide variations (SNVs) of the ANKK1 gene have been reported to be associated with a wide spectrum of dopamine-related neuropsychiatric and cognitive traits. Given that cerebral dopamine depletion is a hallmark of Parkinson disease (PD) here we hypothesized that ANKK1 regulatory SNVs contribute to PD risk.

Materials and Methods: The study included a population sample of 200 PD patients (age 69.48±9.51 years) and 300 healthy controls (age 60.03±3.33) from the BancoADN, the DNA National Bank Carlos III in Spain, and 288 PD patients (age 53.40± 11.91) from the clinical series of Hospital Clínic of Barcelona (HCB). ANKK1 regulatory regions were studied using ENCODE data and Haploview and JASPAR software. Genotyping was performed by TfiI restriction digestion of PCR-amplified fragments. Functional validation was assessed by Luciferase Assay and Electrophoretic Mobility Shift Assay. Results: Our in silico analysis showed that rs7107223 could be a functional SNV that modulates transcription in the ANKK1 locus. It is located at the DNase I hypersensitive site (DHS) at the 5' ANKK1 gene. Genotyping of rs7107223 (Adenine [A] or Thymine [T]) SNV in the Spanish PD population showed the significant overrepresentation of A allele (P=0.0008) and genotypes following a dominant model (P=0.003; OR: 1.831). These findings were replicated in the HCB clinical sample. Functional validation studies indicated significant differences between A and T alleles in the binding, the promoter activity and the response to apomorphine.

Conclusion: rs7107223 is a regulatory variant of ANKK1 locus associated with PD risk.

Protective effects of ApoE ε2 on cognitive performance are gender-specific in healthy elderly from the AsIA-Neuropsychology Study

M. Via^{1,2}, L. Prades-Senovilla¹, N. Lamonja¹, J. López-Olóriz¹, E. López-Cancio², J. F. Arenillas⁴, M. T. Alzamora⁵, G. Pera⁵, P. Torán⁵, I. C. Clemente^{1,2}, A. Dávalos³, M. Mataró^{1,2};

¹Dept. Psychiatry and Clinical Psychobiology, University of Barcelona, Barcelona, Spain, ²Institute of Neurosciences, University of Barcelona, Barcelona, Spain, ³Department of Neurosciences, Hospital Universitari Germans Trias i Pujol, Universitat Autònoma de Barcelona, Badalona, Spain, ⁴Stroke Unit, Department of Neurology, Hospital Clínic Universitario, Valladolid, Spain, ⁵Primary Healthcare Research Support Unit Metropolitana Nord, IDIAP Jordi Gol, Santa Coloma de Gramenet, Spain.

Background: Age-associated cognitive decline and dementias have a substantial hereditary component but the effects of genetic risk variants may be mediated by individual characteristics. We analyzed potential associations of allelic variants in genes involved in neuronal growth and synaptic plasticity with cognitive performance in a large dementia-free elder population and explored potential interactions with age and gender.

Methods: The AsIA-Neuropsychology Study included 747 Spanish subjects older than 50 (mean age=66.1±7.6) with a moderate-high vascular risk (assessed by REGICOR score) and free of symptomatic vascular disease or dementia. Markers (SNPs) in 5 genes (APOE, BDNF, GCSF, VEGFA, and SDF1a) were genotyped. Neuropsychological assessment included tests in three cognitive domains: visuospatial skills and speed, verbal memory, and verbal fluency. Linear regression models were controlled for gender, age, years of schooling, and metabolic syndrome.

Results: ApoE ε2 allele was associated with a better performance in the memory and fluency domains (p=3•10⁻⁴ and p=0.01, respectively). A significant interaction with gender revealed that these associations were present only in women (p=2.87•10⁻⁵ and p=0.0023, respectively) and not in men, and were replicated for every individual neuropsychological test included in those domains. No other relevant associations or interactions were observed.

Conclusions: Our results show a strong effect of the ApoE ε2 allele in women in different neuropsychological assessments for both verbal memory and fluency, suggesting a high protective effect. The ApoE ε4 allele did not have a substantial effect on cognition in our cohort.

Grants: Spanish Ministry of Education and Science (SEJ2006-15399/PSIC).

P09.017

Contribution of chromosomal aberrations in mosaicism to Autism Spectrum Disorders

M. Lopez-Sanchez^{1,2,3}, I. Cuscó^{1,2,4}, A. Cáceres^{3,5}, J. R. Gonzalez^{2,2,5}, L. A. Pérez-Jurado^{1,2,4};

¹Genetics Unit, Universitat Pompeu Fabra, Barcelona, Spain, ²Hospital del Mar Research Institute (IMIM), Barcelona, Spain, ³Centre de Recerca en Epidemiologia Ambiental (CREAL), Barcelona, Spain, ⁴Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), Madrid, Spain, ⁵Centro de Investigación Biomédica en Red de Epidemiología y Salud Pública (CIBERESP), Madrid, Spain.

Introduction: Autism Spectrum Disorder (ASD) is one of the most frequent neurodevelopmental disorders. ASD has a strong genetic component in its etiology, including de novo germ-line mutations and copy number variants. Detectable mosaicism for chromosomal rearrangements in blood has been reported in >1% of the aging population (>65y), but is very rare in young people. Chromosomal mosaicism due to early developmental events could be causative of ASD.

Methods: We have studied molecular karyotypes (SNP array) of blood DNA of two large ASD datasets, the Autism Genome Project and the Simons Simplex Collection (4427 patients, 9268 parents, 2433 unaffected siblings) for mosaic chromosomal alterations >0.4Mb, using the MAD and Tripod softwares. As age-matched controls, we also used reported data of 5094 children with no developmental abnormalities. We independently analyzed data from cell-line DNA of 564 patients and 806 parents.

Results: Mosaic alterations (0.4-155Mb) were detected in blood DNA of 21 out of 4427 patients (0,47%). A total of 34 events were also detected in parental samples (0,37%) and 5/7517 unaffected children (0,07%). The frequency of detectable mosaicism is significantly higher in ASD patients. In cell-line DNA, the frequency was similar in cases and parents although 6 unbalanced chromosomal translocations were detected in patients and just 1 in parents.

Conclusion: Chromosomal aberrations present in mosaicism are detected in blood samples of a small but significant proportion of children with ASD (0,47%). This finding at early ages suggests that mosaicism may be present in other cell types affecting brain development and causing ASD.

P09.018

Genomic and genetic variation at complex segmental duplications in Autism Spectrum disorders

M. Codina-Solà^{1,2,3}, R. Flores^{1,2,3}, A. Homs^{1,2,3}, C. Aguado^{1,2,3}, L. Pérez-Jurado^{1,2,3}, I. Cuscó^{1,2,3};

¹Departament de Ciències Experimentals i de la Salut, Universitat Pompeu Fabra, Barcelona, Spain, ²Neurosciences Program, Institut Hospital del Mar d'Investigacions Mèdiques (IMIM), Barcelona, Spain, ³Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), ISCIII, Barcelona, Spain.

Introduction: Autism Spectrum Disorders (ASD) are among the most heritable neurodevelopmental conditions but the aetiology remains elusive in a high proportion of cases. Complex rearrangements and gene conversion events in segmental duplications (SDs) could contribute to the phenotype, but are largely unstudied. To determine their variation and role in ASD, we have studied two candidate hot-spot regions: the Williams-Beuren syndrome locus at 7q11.23 and the chr9 pericentromeric region.

Methods: We performed targeted sequencing of the multi-copy genes in SDs (*GTF2I*, *GTF2IRD2* and *CNTNAP3*) and single-copy genes in 279 ASD patients and 105 controls. To identify CNVs, SNVs and gene conversions, we mapped the sequences to a single paralogous copy and integrated read depth and relative paralogous sequence quantification. All results were experimentally validated by other methods in an extended case and control population.

Results: Copy-gains of a 7q11.23 block containing truncated *GTF2I* and functional *GTF2IRD2* genes were identified in 1.8% ASD cases vs 0.45% controls. We also identified a disruptive mutation (p.M1?) in a *GTF2IRD2* copy in two affected brothers, inherited from their father. In the chr9 pericentromeric region, a *de novo deletion* was identified in a patient but the global distribution of rearrangements and rare SNVs did not differ significantly between controls and patients.

Conclusions: Despite their complex genetic architecture, our method successfully identifies rearrangements and SNVs in SDs, such as copy-gains and mutations at *GTF2IRD2* or deletions of *CNTNAP3* that could represent susceptibility factors for ASD.

Grant support: FISPI1302481/PI1300823/FEDER, 2014SGR1468 and FI-DGR/2013.

The power of New Generation Sequencing in identifying mutations in non-specific ASD-ID phenotypes: the example of SHANK3

A. Mosca-Boidron^{1,2}, H. Poquet², M. Willems³, J. Thevenon^{4,2}, C. Redin⁵, C. Chauvin^{4,2}, Y. Duffourd², S. Lumbroso⁶, B. Gérard², J. Mandel², F. Amsellem⁷, A. Beggato⁷, R. Delorme⁷, N. Marle¹, P. Callier^{1,2}, J. Rivière², P. Kuentz², A. Piton⁵, L. Faivre^{4,2};

¹Cytogenetics, Dijon, France, ²Equipe Génétique et Anomalies du Développement, Dijon, France, ³Département de Génétique médicale, Montpellier, France, ⁴Département de Génétique médicale, Dijon, France, ⁵IGBMC, Strasbourg, France, ⁶Laboratoire de Biochimie, Nîmes, France, ⁷Psychiatrie de l'enfance et de l'adolescence, Hôpital Robert-Debré, Paris, France.

Introduction: Autism spectrum disorders (ASDs) are characterized by impairments in reciprocal social communication and stereotyped behaviors. Intellectual Disability (ID) frequently coexists with these two core symptoms. Monogenic causes are rare, among them, de novo or truncating mutations in *SHANK3* concern almost one in 50 children with autism and moderate to profound ID. *SHANK3* haploinsufficiency is frequently associated with neonatal hypotonia, moderate to severe ID, absent or severely delayed speech, ASD and moderate dysmorphic features (Phelan-McDermid syndrome). Thus, the question arises to look for the presence of distinctive signs to identify a subgroup of individuals who could benefit from the sequencing of this gene.

Materials and Methods: Here we report on 2 boys with ASD and ID and a girl with severe ID associated with a *SHANK3* mutation found by next generation sequencing (NGS) study (Illumina).

Results: Two of these mutations are truncated and de novo involving the exon 21 in the prolin-rich domain (NM_001080420.1:c.2955_2970dup (p.Pro992Arg*325) and NM_001080420.1:c.4381C>T (p.(Gln1461*)). The third is a 3 bases deletion variant NM_001080420.1:c.5090_5092delACC (p.(His1697del)) involving the exon 22 in the SAM (Sterile-Alpha-Motif) domain involved in multimerization of *SHANK3* protein.

Conclusion: The retrospective clinical examination of these patients did not permit to distinct specific signs, which highlights the phenotypic heterogeneity of these patients. Given the scarcity of variants involving *SHANK3*, the unsystematic presence of the distinctive clinical features of Phelan McDermid Syndrome, a NGS approach by panel or exome seems more justified than a targeted sequencing approach of *SHANK3* in this phenotype.

Autosomal dominant cerebellar ataxias (ADCA) are heterogeneous neurodegenerative diseases, associating a cerebellar syndrome to various other manifestations. They are frequently caused by polyglutamine expansions. Intronic repeat expansions, and conventional mutations, come next. Though 30 genes have been identified, the causative mutation is still unknown in 40% of patients.

We explored ADCA aetiologies, combining whole genome linkage analysis and exome sequencing in large families, to amplicon panel sequencing of known and candidate genes in 412 patients.

Sequencing a large cohort allowed us to obtain valuable information regarding the not much known nosology of conventional ADCA. We identified 17 patients with convincing single nucleotide variants in *CACNA1A* (4.12%). These are classically associated to episodic ataxia 2, while small nucleotide expansions are linked to progressive ataxia. We hereby confirm that these presentations are not genetically different. We also identified eight patients with biallelic mutations in *SPG7*; as well as eight carriers of p.Ala510Val alone, whose pathogenicity we discuss.

In this study, we also identified new candidate genes. *CACNA1G* encodes T-type Calcium channel Cav3.1. A variant of its voltage-sensing domain,

p.Arg1715His, recurrent in three pedigrees, has consequences on the electrophysiological characteristics of the channel, driving lowered excitability. This allows an interesting link with epilepsy, where *CACNA1G* gain-of-function variants are risk factors.

We hence report an epidemiological study of an unprecedentedly large ADCA cohort, which has direct clinical consequences; and a new causative gene, confirming the prominence of ion channels in ADCA pathophysiology. This work was funded by the European Union, F.R.S.-FRNS, ANR and VERUM.

Spinocerebellar ataxia type 37 (SCA37): first neuropathological findings and molecular characterisation of the critical region on 1p32

M. Corral-Juan¹, C. Serrano-Munuera², A. Rábano³, E. Gelpí⁴, L. Saiz², M. Del Pozo-Valero¹, L. Ispuerto⁵, R. Álvarez², V. Volpini⁶, I. Sánchez⁷, A. Matilla-Dueñas¹;

¹Health Research Institute Germans Trias-IGTP, Badalona, Spain, ²Hospital Sant Joan de Déu de Martorell, Martorell, Spain, ³CIEN Foundation, Madrid, Spain, ⁴Neurological Tissue Bank of the Biobanc-Hospital Clínic-IDIBAPS, Barcelona, Spain, ⁵Hospital Universitari Germans Trias, Badalona, Spain, ⁶IDIBELL, Hospitalet de Llobregat, Spain.

Introduction: We recently reported a new ataxia subtype, SCA37, characterised by slow progressing ataxia and altered vertical eye movements in 2 Spanish kindreds. Here we report the first neuropathological findings and the studies aimed at identifying the SCA37 molecular deficit on 1p32.

Material and Methods: Neuropathology, WGS, and custom-aCGH studies were performed. Cerebellum-specific RACE and Purkinje cells (PCs) RNAseq data from ENCODE were valuable to characterise putative cerebellar SCA37 transcripts. The SCA37 critical region was refined with WGS, SNPs, microsatellites, and long-PCR sequencing.

Results: Marked neuronal loss was present in the cerebellar cortex and inferior olives. Extensive Bergmann gliosis and loss of calbindin immunoreactivity, with aberrant dendrite arborisation, nuclear lobulation, irregularity and hyperchromatism, and multiple small perisomatic ubiquitinated inclusions were identified in cerebellar PCs. By WGS and genetic analyses, the SCA37 critical region was narrowed to 1.742 Mb on 1p32. Two non-recombinant SCA37-linked SNPs were useful to identify additional SCA37 index cases. Cerebellar RACE and PC RNAseq studies identified new putative regulatory exons within the SCA37 transcript selectively expressed in Purkinje cells. Long-PCR sequencing for SNP-allele discrimination identified putative structural regulatory candidate mutations in SCA37.

Conclusions: We report the first neuropathological findings showing diffuse cortical cerebellar degeneration in SCA37. Two linked-SNPs prove useful to identify additional SCA37 cases. RACE and RNAseq studies reveal expression of a specific SCA37 transcript in Purkinje cells. We propose that a regulatory structural mutation altering the proper temporal and/or spatial expression of the SCA37 gene underlies cerebellar neurodegeneration in SCA37. Project funded by Spanish ISCIII.

P09.022

Rare copy-number variations are associated with specific clinical manifestations in children with autism spectrum disorder

I. Shtein, I. Menashe;

Ben-Gurion University of the Negev, Beer Sheva, Israel.

Introduction: Autism spectrum disorder (ASD) is a complex heritable neurodevelopmental condition characterized by social, and communication disabilities. However, children with ASD manifest additional symptoms that further complicate the clinical picture of this disorder. Rare copy number variations (CNVs) play a significant role in ASD susceptibility. Here, we ask whether rare CNVs are associated with specific clinical manifestations among children with ASD.

Methods: We studied seventy clinical characteristics in 1115 children that are diagnosed with ASD and have CNV data from the Simons Simplex Collection (SSC). Associations between these characteristics and total burden of CNVs as well as specific CNVs, were determined at P<0.01.

Results: Rare CNVs were more prevalent among African-American females. Interestingly, core ASD traits (i.e. communication and social difficulties) were associated with genomic burden of duplications whereas severity of clinical comorbidities (e.g. IQ, irritability, and pregnancy optimality scores) were associated with genomic burden of deletions. Further, we found associations between several clinical characteristics and specific ASD-susceptibility CNV loci. Specifically, duplications in 15q11.2-q13.1, and in 16p11.2 were associated with a higher irritability, duplications in 22q11.21 were associated with a worse neonatal optimality score, and CNVs in 9p24.3 were associated with worse verbal ability.

Conclusions: Our results suggests that rare CNVs contributes to the severity of ASD across several clinical and behavioral aspects.

P09.023

Comparison of CRISPR-based methods for modeling loss-of-function in iPSC cells

C. M. Seabra^{1,2,3}, **P. Manavalan**¹, **D. J. C. Tai**^{1,2}, **M. Talkowski**^{1,3,4}, **J. F. Gusella**^{1,3,4};
¹Center for Human Genetic Research, Boston, MA, United States, ²GABBA Program - Institute of Biomedical Sciences Abel Salazar of the University of Porto, Porto, Portugal, ³Program in Medical and Population Genetics, Broad Institute of MIT and Harvard, Cambridge, MA, United States, ⁴Departments of Genetics and Neurology, Harvard Medical School, Boston, MA, United States.

Introduction: Given the rapid pace of discoveries that de novo loss-of-function (LoF) mutations in highly conserved genes represent penetrant sources of genetic risk in autism spectrum disorder (ASD), it is imperative to generate robust models that recreate the human cellular landscape, particularly for neurological disorders where brain tissue is not readily available, and to eliminate the confound of different genetic backgrounds.

Methods: We used an induced pluripotent stem cell (iPSC) line from a healthy male subject to perform dual-guide CRISPR/Cas9 gene editing of 9 independent genes for which LoF mutations represent strong risk factors for ASD. The efficiency of 30 dual guide-RNA combinations to generate deletions was then compared, using either FACS sorting or puromycin selection followed by serial dilutions to obtain single-cell derived colonies.

Results: Dual guide CRISPR successfully generated deletions in all genes, however the efficiency varied widely by guide-RNA and cellular protocol. The overall efficiency of the FACS method was 3.4% to generate predicted ablations, out of 1002 colonies screened (range = 0% - 10.6%). By contrast, the puromycin method had an average efficiency of 15.1% from 4437 colonies (range = 0% - 32%).

Conclusions: This systematic survey of genome editing approaches suggests that dual-guide deletion generation varies widely by guide-pair. We also find that the increased certainty of deriving a single cell from FACS sorting comes at a significant cost in terms of efficiency and cell viability compared to serial dilutions.

P09.024

Resilience formation against chronic stress: the Tsc2KO mouse model to study the involvement of the mTOR pathway

A. Arlt, **J. Winter**, **S. Schweiger**;
 Institute of Human Genetics, University Medical Center, Johannes Gutenberg University, Mainz, Germany.

Characteristic for autistic children is their reliability on well-structured days and predictable procedures. Deviations of these cause stress in them and result in behavioural abnormalities. We therefore hypothesize that autistic children have reduced resilience for chronic stress. In order to analyse mechanism of stress resilience in autism we are using a Tsc2KO mouse model for tuberous sclerosis. TSC2 (together with TSC1) is part of a complex that inhibits the mechanistic target of rapamycin (mTOR) kinase. Mutations in either of the two genes result in increased mTOR activity and upregulated downstream signalling. mTOR signalling plays an important role in memory formation. It also is supposed to be a key player in stress resilience.

According to these studies we have established a behaviour battery to analyse the consequences of chronic social defeat in Tsc2KO animals. After a 14-days' period of chronic stress exposure mice are being analysed in this battery, which consists of an object recognition test, an elevated plus-maze test, a test of nest building, an evaluation of social interaction, sucrose preference, spontaneous alternation in a Y-maze test, a tail suspension test and the analysis of prepulse inhibition of startle response.

First results show that non-stressed Tsc2KO animals have alterations in social behaviour and in nest building when compared to wildtype mice. Of note, they also show an altered response to stress and changes in stress resilience. These data will give us closer insight into specific problems in autism and will also gain our understanding of mechanisms underlying stress resilience.

P09.025

Association between copy-number variations and savant skills among people with autism spectrum disorder

H. Rosenthal, **I. Menashe**;
 Ben-Gurion University of the Negev, Beer Sheva, Israel.

Background: Savant skills, are reported in 10%-30% of people with autism spectrum disorder (ASD). The co-existence of these two traits suggests common underlying mechanisms that require further exploration. Copy-number

variations (CNVs) are excellent candidate to mutually underlie these two distinct conditions.

Methods: We studied the association between CNVs and savant skills among 1108 children diagnosed with ASD from the Simons Simplex Collection (SSC) database. Savant skills were determined based on five designated questions from the autism diagnostic interview revised (ADI-R) questionnaire. CNVs data were retrieved from a genome-wide analysis of CNVs in these children. **Results:** Savant skills were significantly more prevalent in our sample than in other children with ASD in the SSC cohort (42% vs. 29%; $P < 0.001$). Children with savant skills had, on average, a higher IQ (93.0 ± 24.2 vs. 79.1 ± 25.5 ; $P < 0.001$), and a larger head circumference (HC) (54.3 ± 2.55 vs. 53.8 ± 2.60 ; $P = 0.003$). Interestingly, savant skills were associated with a lower count of rare CNVs among children with ASD (14.0 ± 5.54 vs. 14.8 ± 6.2 for children with and without savant skills respectively; $P = 0.03$). In addition, children with exceptional computational ability had lower burden of rare deletions compared to other children (203.46 ± 164.25 vs. 333.67 ± 715.56 kb; $P = 6.8 \times 10^{-5}$) even after accounting for IQ and socioeconomic status. We also examined whether certain talents are predisposed by specific ASD susceptibility CNV loci, but no such associations were found.

Conclusions: Our findings suggest that CNVs contribute to the presentation of exceptional talents among children with ASD.

P09.026

Peculiar brain activity in autism spectrum disease due to 11p15.4-15.5 duplication

M. Szegedi¹, **G. Inczedy-Farkas**¹, **A. Szabó**², **I. Haltrich**³, **G. Fekete**³, **G. Rudas**², **L. R. Kozák**², **M. J. Molnár**¹;

¹Semmelweis University, Institute of Genomic Medicine and Rare Disorders, Budapest, Hungary, ²MR Research Centre - Szentágothai Knowledge Center, Semmelweis University, Budapest, Hungary, ³2nd Department of Paediatrics, Semmelweis University, Budapest, Hungary.

Introduction: ASD is a neurodevelopmental disorder with multiple genetic and non-genetic causes. The 11p15.4-15.5 duplication can be associated with intellectual disability and dysmorphic features. The aim was to assess the neural networks involved in visual and verbal memory encoding and retrieval in ASD due to 11p15.4-15.5 duplication.

Materials and methods: A woman with autistic features, macrocephaly and body asymmetry due to 11p15.4-15.5 duplication and 7 healthy controls were investigated. Six runs of BOLD fMRI data were collected to assess the networks of the visual and verbal memory encoding and retrieval; a single run of encoding task was followed by 10 minute-retention period, then 2 runs of the retrieval tasks both for visual and verbal domain respectively. During encoding participants were instructed to memorize the task stimuli, whilst during retrieval they were instructed to decide whether the given image or word was presented during the encoding period. Data analysis was performed using the SPM8 toolbox under Matlab, with standard processing steps.

Results: In patient fMRI for visual memory encoding/retrieval showed higher activation in the posterior insulae, and anterior and posterior cingulate cortices compared to the controls where visual areas were predominant in these tasks. Verbal memory activation was higher in the hippocampi, parahippocampal cortices, precuneus; and lower in the anterior insulae; higher visual areas in our patient compared to the controls.

Conclusion: The 11p15.4-15.5 duplication resulted in peculiar activity pattern of the brain responsible for visual and verbal memory in ASD. This observation may help to understand the pathogenesis of ASD.

P09.027

Association and functional significance of SNPs in the AVPR1A gene in autism spectrum disorder in Korean population

H. Yoo^{1,2}, **S. Kim**³, **S. Yang**³, **J. Park**⁴, **M. Park**²;
¹Seoul National University Bundang Hospital, Seongnam, Korea, Republic of, ²Seoul National University College of Medicine, Seoul, Korea, Republic of, ³Eulji University, Daejeon, Korea, Republic of, ⁴National Institute of Animal Science, Wanju, Korea, Republic of.

Objectives: The arginine vasopressin receptor 1A gene (AVPR1A) is related to social reciprocity in humans and animals. The objective of this study is to evaluate the association of AVPR1A with autism spectrum disorder (ASD) and the functional significance of the markers.

Methods: 1) The probands with ASD and their biological parents were recruited. Diagnosis was ascertained using ADI-R and ADOS. 2) Two microsatellites (RS3, RS1) in the 5' flanking region and 2 SNPs in the promoter region of AVPR1A were genotyped. Transmission disequilibrium test and quantitative association test with behavior measures were performed using the FBAT package (v.2.0.2c). 4) For evaluation of the functional significance of the associated marker, luciferase assay was performed.

Results: Total 212 family trios (9 multiplex families, 644 persons) participated. 1) One SNP (rs10877969) was strongly associated with ASD (additive p-value=1.62x10⁻⁶; dominant p-value=4.81x10⁻⁶). Haplotypes with rs10877969 and rs72945336 revealed statistical significances at the multiallelic mode (additive p-value=2.2x10⁻⁵; dominant p-value=1.43x10⁻⁵). 2) The rs10877969 was quantitatively associated with Social Responsiveness Scale and all subdomain scores of ADI-R (p<0.01). 3) In the luciferase assay with T98G cell line, the luciferase activity of rs7294536A promoter was higher than that of rs7294536G, while rs10877969 allelic variants didn't influence to promoter activity.

Conclusion: We observed significant association of an SNP of AVPR1A with affection status and social phenotypes of ASD, accompanied with functional activity of the marker.

Copy number variation in 19 Italian multiplex families with autism spectrum disorder: importance of synaptic and neurite elongation genes

C. Picinelli¹, C. Lintas², I. Piras¹, R. Sacco², C. Brogna², A. M. Persico^{1,2,3};

¹Mafalda Luce Center for Pervasive Developmental Disorders, Milan, Italy, ²Unit of Child and Adolescent Neuropsychiatry & Laboratory of Molecular Psychiatry and Neurogenetics, University „Campus Bio-Medico“, Rome, Italy, ³Unit of Child and Adolescent Neuropsychiatry, “Gaetano Martino” University Hospital, University of Messina, Messina, Italy.

Autism Spectrum Disorder is endowed with impressive heritability estimates and high recurrence rates. Its genetic underpinnings are very heterogeneous and include many common and rare variants located in hundreds of different loci, each characterized by variable levels of penetrance. Multiplex families from single ethnic groups represent a useful means to reduce heterogeneity and enhance genetic load. We screened 19 Italian ASD multiplex families (3 triplets and 16 duplets, total N=41 ASD subjects), using array-CGH (Agilent 180K). Certainly or probably causal CNVs, defined “clinically relevant CNVs”, were detected in 17/41 (41%) of ASD probands, corresponding to 9/19 (47%) multiplex families with at least one affected sibling genetically positive. However only in 3/9 (33%) of these families, siblings share the same causal or highly causal CNV. Additional potentially relevant CNVs not shared by affected sib pairs were detected also in these three families. 45 genes are located on the “clinically relevant” CNVs. Through an enrichment analysis, we found that 9/45 (20%) of these genes appear primarily involved in neurite outgrowth and synapse formation/management. Our results highlight the importance of synaptic and neurite elongation genes in the pathogenesis of autism, despite genetic heterogeneity in ASD even within multiplex families belonging to a single ethnic group. Differences in CNV burden may likely contribute to the substantial clinical heterogeneity observed between affected sibs. The genetic and epigenetic mechanisms underlying genomic instability in these families deserve further scrutiny.

P09.029

Increased frequency of the autism broader phenotype in mothers transmitting etiological CNVs to sons affected by Autism Spectrum Disorder (ASD)

M. Asif^{2,3}, I. Conceição^{3,2}, K. Kwiatkowska³, C. Rasga^{3,2}, C. Café⁴, L. Sousa⁵, G. Oliveira^{4,6}, F. M. Couto⁷, A. M. Vicente^{3,2,8};

¹Faculdade de Ciências da Universidade de Lisboa, Lisbon, Portugal, ²Biosystems and Integrative Sciences Institute, Lisbon, Portugal, ³Instituto Nacional de Saúde Doutor Ricardo Jorge, Lisbon, Portugal, ⁴Unidade de Neurodesenvolvimento e Autismo do Serviço do Centro de Desenvolvimento da Criança and Centro de Investigação e Formação Clínica, Pediatric Hospital, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal, ⁵University of Lisboa, Faculty of Sciences, DEIO and CEAUL, Lisbon, Portugal, ⁶University Clinic of Pediatrics and Institute for Biomedical Imaging and Life Science, Faculty of Medicine, University of Coimbra, Coimbra, Portugal, ⁷Department of Informatics, Faculty of Sciences, University of Lisbon, Lisbon, Portugal, ⁸Instituto Gulbenkian de Ciência, Oeiras, Lisbon, Portugal.

Autism Spectrum Disorder is a frequent neurodevelopmental disorder with a high male to female ratio. An increased prevalence of autism-like personality traits is found in unaffected relatives of ASD children, suggesting a genetic liability of a broader autism phenotype. We therefore hypothesized that the parents of ASD children who transmit etiological CNVs might exhibit ASD traits more frequently than non-transmitting parents. To test this hypothesis, we analysed CNV inheritance and parental behavioral traits in families from the Autism Genome Project, assessed using the Broad Autism Phenotype Questionnaire (BAPQ) (N=341) and the Social Responsiveness Scale (SRS) (N=456). We selected CNVs spanning well-established candidate

genes for ASD, and compared transmitting and non-transmitting parental test scores using a t-test corrected for multiple testing by the Group Benjamini-Hochberg Procedure.

Overall, CNV-transmitting parents did not differ significantly in BAPQ and SRS scores from non-transmitting parents. However, independent analyses of relative pairs revealed a significant difference in BAPQ global (t=-2.18; adjusted P=.032), BAPQ aloofness domain (t=-2.61; adjusted P=.032) and SRS scores (t=-2.03; adjusted P=.047) between mothers transmitting and mothers not transmitting etiological CNVs to their affected sons. Our findings indicate that mothers presenting personality traits in the broader autism phenotype are frequently carriers of pathogenic CNVs that they transmit to their ASD sons. The results from the analyses of maternal phenotype and CNV transmission patterns to sons support previous reports of maternal transmission bias to male offspring, and the prevalent hypothesis of a higher genetic risk tolerance in females due to putative protective factors. (FCT PD/BD/52485/2014)

P09.030

AUTS2 syndrome: Further delineation of the phenotype in a 68-years-old female

E. Sengun¹, K. Yarbarg^{2,3}, Y. Alanay¹;

¹Acibadem University School of Medicine, Istanbul, Turkey, ²Maltepe University School of Medicine, Istanbul, Turkey, ³Duzen Laboratories Group, Istanbul, Turkey.

Introduction: Genetic evaluation of individuals with neurodevelopmental disorders, with technical improvements in array based technologies and sequencing, has yielded an abundance of new candidate genes for intellectual disability (ID), autism spectrum disorders (ASDs), and developmental delay. We report a 68 year old female with mild-moderate intellectual disability, behavioral findings suggesting ASD, developmental delay and dysmorphic features. The SNP array analysis demonstrated a 257 kb deletion comprising exon 6 of AUTS2 gene.

Case Report: The patient was born at term as the first child of an unrelated couple following an uncomplicated pregnancy and delivery. Mild motor and significant speech delay were evident during childhood. On her physical examination at age 68, she had short stature, microcephaly and abdominal obesity. Mild facial findings and micrognathia were noted. She was followed for scoliosis since early adulthood. Orthopedic findings were present. Her intellectual disability was mild to moderate with behavioral problems. She was noted to be a very friendly, active and girly person. She had limited eye-contact, hyperverbal with limited vocabulary of 40-50 words. She had tics and obsessions, skin pricking, hyperorality and sound-sensitivity. She was not schooled but her family made sure that she was involved in daily activities.

Conclusions: This clinical report provides the natural history in the eldest patients yet to be reported and complements the existing evidence suggesting that disruption of the AUTS2 gene leads to a recently delineated neurodevelopmental phenotype with a wide spectrum, namely “AUTS2 Syndrome”.

P09.031

Targeted next-generation sequencing in search of monogenic causes of behavioural disturbance in children

K. Komlósi¹, S. Diederich¹, D. L. Fend-Guella¹, O. Bartsch¹, H. Hu², T. F. Wienker², H. H. Ropers^{1,2}, M. Huss³, J. Stewe³, U. Zechner¹, S. Schweiger¹;

¹Institute of Human Genetics, University Medical Center, Johannes Gutenberg University Mainz, Mainz, Germany, ²Max-Planck Institute for Molecular Genetics, Berlin, Berlin, Germany, ³Center for Pediatric Psychiatry, Psychotherapy and Psychosomatic at the Rheinhessen Clinic Mainz, Mainz, Germany.

Introduction: Behavioral disturbance can be the presenting symptom of genetically determined cognitive deficiency caused by de novo dominant, rare recessive and pathogenic copy number variations (CNV). NGS has accelerated diagnosis in genetically heterogeneous disorders with common clinical features.

Patients and methods: 28 children with unclear developmental delay and behavioral disturbance seen at a joint clinical genetic and psychiatric outpatient clinic underwent targeted NGS testing including over 1200 brain related genes (MPIMG-1). Following enrichment 2x300bp paired-end sequencing (Illumina Miseq Kit v3) was carried out on Illumina MiSeq and a modified Medical Resequencing Analysis Pipeline was used for variant calling. Results: In 3/28 cases pathogenic or likely pathogenic CNVs, in 8/28 a monogenic cause was identified. We found 6 cases with mutations in autosomal dominant neurodevelopmental genes, either reported and matching the patient's phenotype (PTPN11, SETBP1), or likely associated with the phenotype (DYRK1A, GRIN2B, ASXL1, ZEB2) but previously unreported.

In siblings with absent speech, intellectual disability, aggressive behavior and seizures a homozygous ALG1 mutation was associated with a mild form of CDG1k. In a further 4 patients, likely pathogenic unreported variants in known disease-causing genes (ASXL1, BRCA2, MBD5) were identified. Conclusions: Targeted NGS can be effective in delineating monogenic causes of a common clinical symptom associated with behavioural abnormalities. A definitive diagnosis helps the family come to terms with the condition and enables personalized treatment and care. Subsequent functional characterization of gene products via patient-specific iPSC models may lead to a better understanding of the mechanisms and open up future therapeutic possibilities.

Hyperkinetic movement disorders with pediatric-onset related to ADCY5 gene mutations: report of three Italian families

E. Mantuano¹, M. Carecchio^{2,3,4}, N. E. Mencacci⁵, G. Zorzi³, F. Zibordi³, A. Iodice⁶, C. Fusco⁶, L. Veneziano¹, C. Barzaghi², C. Panteghini², L. R'Bibo⁵, N. Wood⁵, B. Garavaglia², N. Nardocci²;

¹Institute of Translational Pharmacology, National Research Council, Rome, Italy, ²Molecular Neurogenetics Department, Movement Disorders Diagnostic Unit, IRCCS Foundation C. Besta Neurological Institute, Milan, Italy, ³Department of Child Neurology, IRCCS Foundation C. Besta Neurological Institute, Milan, Italy, ⁴Department of Translational Medicine, University of Milan Bicocca, Milan, Italy, ⁵Department of Molecular Neuroscience, Institute of Neurology, University College London, London, United Kingdom, ⁶Child Neuropsychiatry Unit, Santa Maria Nuova Hospital, Reggio Emilia, Italy.

Background: ADCY5 is a recently identified gene responsible for a wide spectrum of mixed hyperkinetic early-onset movement disorders including chorea, myoclonus and dystonia. Similarly to benign hereditary chorea due to TITF-1 mutations, the disease course seems to be non-progressive, but severe abrupt diurnal and nocturnal exacerbations of movement disorder are often present. To date, 7 mutations in 21 unrelated dominant families and sporadic cases have been reported.

Methods: 35 Italian unrelated cases with pediatric onset hyperkinetic movement disorder featuring a combination of chorea, myoclonus and dystonia who tested negative for TITF-1 mutations were recruited. ADCY5 exons 2 and 10, in which mutations have been identified in ~86% of families published to date, were sequenced.

Results: 3/35 cases (8.5%) showed mutations in exon 10. Two sporadic cases carried previously reported mutations (p.R418W, p.R418Q) and one familial case with autosomal dominant inheritance carried a novel mutation (p.R418G).

All patients presented between 1 and 4 years of age with delayed milestones and a movement disorders characterized by generalized dyskinesias, myoclonic jerks and mild dystonia. One patient showed prominent pyramidal signs in the lower limbs and perioral dyskinesia. In two cases exacerbations of hyperkinesias at night and during the day without specific triggers were described. In adolescence one patient switched from a choreic to a prominent myoclonic phenotype.

Conclusions: ADCY5 mutations are an important cause of early-onset, mixed hyperkinetic movement disorders. Paroxysmal worsening of movement disorders both during the day and at night seems to be a key diagnostic element in these cases.

P09.033

Bipolar Related Functional Variants in Calcium Channel Genes

N. L. O'Brien, A. Fiorentino, S. Sharpe, M. Way, M. Morgan, D. Curtis, N. Bass, A. McQuillin;

University College London, London, United Kingdom.

Bipolar Disorder (BD) is a highly heritable psychiatric illness. Members of the calcium channel gene family have been repeatedly implicated in BD through genome wide association studies, case-case meta-analysis and pathway analysis. This gene family includes the genes *CACNA1C*; encoding the α pore of L-type calcium channels, and *CACNG4*; encoding a transmembrane AMPA receptor regulator involved in trafficking AMPA receptors to the neuronal post synaptic density.

High resolution melting curve (HRM) analysis and whole genome sequencing (WGS) methods were used to identify functional variants in these genes in the UCL BD cohort. Variants predicted to impact gene regulation, transcription or to be damaging to protein structure were genotyped in a larger case/control cohort. For rare variants publicly available data, from healthy volunteers and individuals with psychiatric illnesses, was utilised for a more accurate determination of allele frequencies.

HRM identified two rare non-synonymous *CACNG4* variants associated with mental illness (rs371128228, $p=1.05 \times 10^{-4}$, OR=4.39 and

17:65026851(C/T), $p=5 \times 10^{-4}$, OR=9.52). Fluorescent activated cell sorting analysis demonstrated that the risk allele of rs371128228 decreased cell surface trafficking of AMPA-R1 ($p=0.026$).

WGS analysis of *CACNA1C* intron 3 identified two BD associated ($p=0.015$, OR=1.15) variants 105bp apart that were in complete LD. Both variants are predicted to create YY1 transcription factor binding sites. Luciferase reporter assays show a significant decrease in gene expression in the presence of both variants ($p=0.004$).

Using two different approaches this study identified four functional variants in two genes previously associated with BD that have a functional effect *in vitro*.

Introduction: Bipolar disorder (BD) is a heritable illness, contributed to by common variants of small effect and rare variants of higher penetrance. Pathogenic single nucleotide variants (SNV) of moderate effect are likely to be present in the encoded gene fraction (exome) and shared amongst individuals with BD in extended families.

Materials and methods: We selected 15 families (117 subjects), each containing 4 or more relatives with BD, to perform whole exome sequencing (WES) on the IonProton platform and copy number variant analysis (CNV) via CytoScanHD array (2 affected per family).

We selected SNVs and CNVs shared across multiple affected subjects, but also considered de novo variants. Linkage analysis using WES-derived genotypes refined family-specific linkage intervals. SNVs shared amongst affected and unaffected relatives were analysed combining all families for gene-set enrichment, gene ontology and KEGG pathways.

Results: The pool of SNVs shared amongst affected relatives was enriched in targets of the Fragile-X mental retardation 1 protein (FMRP) ($P=8E-09$) and post-synaptic density (PSD) genes ($P=8E-03$). The X-linked *IRS4* gene carried a truncating mutation in 5 affected siblings in one family. This candidate gene displays restricted expression in the amygdala, and *IRS4*^{-/-} female mice show compromised maternal behaviours. Our study also implicates the protocadherin genes, which act to mediate neuronal connectivity, with loss-of-function variants and deletions in several families.

Conclusions: Genetic approaches that combine WES, CNV and linkage analyses in extended families is effective in pinpointing genes and pathways that may contribute to the pathophysiology of the disorder.

Bipolar disorder genetic variation in the miR-708 gene and its binding targets

A. Fiorentino^{1,2}, N. L. O'Brien², D. Curtis^{3,4}, A. McQuillin²;

¹UCL Institute of Ophthalmology, London, United Kingdom, ²UCL Molecular Psychiatry Laboratory, London, United Kingdom, ³UCL Genetics Institute, London, United Kingdom, ⁴Centre for Psychiatry, Barts and the London School of Medicine and Dentistry, London, United Kingdom.

Introduction: rs12576775 has been found to be associated to bipolar disorder (BD) in GWAS. Downstream from the variant there is a genomic region with a high recombination rate that effectively restricts the size of associated region and implicates genes for miR-708, miR-5579 and the first exon of *ODZ4*. In this study the miR-708 gene, its surrounding region and its targets have been analysed for possible functional variants associated with BD. **Methods:** The surrounding areas of miR-708 were screened for variation using HRM analysis in 1,099 BD cases. Whole genome sequencing data from 99 BD subjects had been analysed for variation in potential miR-708 binding sites.

Results: A total of 3 variants were detected by HRM analysis across the region selected to be analysed. Only variants with a MAF lower than 0.01 in the general population were considered for genotyping in our case-control cohort. rs754333774 has been found in 3 bipolar cases, 2 schizophrenia (SCZ) cases and no controls. This variant is 260bp upstream miR-708 and could play a role in tuning the expression of the microRNA.

Four variants had been identified in miR-708 targets binding sites. None of

them had a markedly different allele frequencies in the BD compared to the general population.

Conclusion: We report a single recurrent BD and SCZ case only variant located in miR-708 gene that may have a role in the diseases susceptibility. These finding awaits replication in independent cohorts as does a functional analysis of the potential consequences of this variant. Grant references: MRC G1000708

Bipolar disorder (BD) is a highly heritable mood disorder with a lifetime prevalence of about 1%. Models of illness are most consistent with a polygenic contribution of common and rare variants to disease susceptibility. As the cumulative impact of common alleles may only explain around 38% of the phenotypic variance, rare variants of high penetrance have been suggested to contribute to BD susceptibility.

In the present study we investigated the role of rare variants in BD by conducting whole-exome sequencing of 81 individuals from 27 large multiply affected Spanish and German families. In each family 3 genetically distant affected individuals were selected for exome sequencing. For variant calling and data analysis, the VARBANK pipeline of the Cologne Center for Genomics was used. We focused on rare non-synonymous variants (minor allele frequency <0.1%) that were shared among all three affected individuals and predicted to be potentially/probably damaging by at least 3 of 5 applied bioinformatics tools. Segregating variants in genes affected in at least two independent families were validated using Sanger sequencing.

Among all families we identified 404 rare non-synonymous and potentially damaging variants spanning 393 genes. 8 genes harbored rare segregating variants in at least two independent families including RGS12 which is known to play an important role in promoting and maintaining neuronal differentiation. Pathway analysis of all genes with a Residual Variation Intolerance Score <10% revealed significant enrichment for 18 pathways after correction for multiple testing including synaptic membrane and axon guidance.

Bipolar disorder (BD) is a severe psychiatric disorder affecting about 1% of the world's population. The highly heritable disease is characterized by recurrent episodes of mania and depression.

As the cumulative impact of common alleles with small effect may only explain around 38% of the phenotypic variance for BD, rare variants of high penetrance have been suggested to contribute to BD susceptibility.

In the present study we investigated 226 individuals of 70 large multiplex BD families of German and Spanish origin by whole exome sequencing (Illumina HiSeq2500 platform). For data analysis the Varbank pipeline of the Cologne Center for Genomics was used. We filtered for rare (minor allele frequency <0.1%) and non-synonymous variants that are shared within each family and are predicted to be damaging by at least four of five different bioinformatics tools.

So far, we identified 955 rare, segregating and potentially damaging variants in 889 different genes. Pathway analysis of 269 genes with a Residual Variation Intolerance Score <25% showed a significant enrichment (p<0.001) for 37 pathways including neuron differentiation and axon development. In addition, 58 genes were implicated by rare variants in at least two unrelated families. These comprise NRXN2 which encodes a synaptic cell-adhesion molecule connecting pre- and postsynaptic neurons and mediating synaptic signaling.

Our preliminary results suggest that rare and highly-penetrant variants in genes involved in synaptic signaling and neuron development contribute to BD. Further investigation of the remaining families and follow up analyses are currently underway and will be presented at the upcoming conference.

CADASIL: Variants of unknown significance (VUS) may affect mRNA splicing of the NOTCH3 gene

H. Vlaskova¹, **M. Hrubá**², **H. Treslova**¹, **M. Hnizdova Bouckova**¹, **L. Dvorakova**¹, **R. Matej**³, **J. Sikora**¹, **H. Hulkova**¹, **V. Kozich**¹;

¹Institute of Inherited Metabolic Disorders, University Hospital and 1st Faculty of Medicine, Charles University, Prague 2, Czech Republic, ²Department of Genetics and Microbiology, Faculty of Science, Charles University, Prague, Czech Republic, ³Department of Pathology and Molecular Medicine, Thomayer Hospital, Prague 4, Czech Republic.

Background: Cerebral autosomal dominant arteriopathy with subcortical infarcts and leukoencephalopathy (CADASIL) is characterized by migraine, recurrent stroke, and dementia. CADASIL is caused by mutations in the NOTCH3 gene. Typical NOTCH3 mutations result in the the addition or the loss of a cysteine residue. Nonetheless, other types of NOTCH3 mutations were recently identified to also associate with CADASIL.

Patients and Methods: In a cohort of 220 patients suspected of having CADASIL, we detected by Sanger sequencing typical mutations in 70 individuals with 24 different alleles. In addition, we observed 7 variants of unknown significance (VUS) in the other 11 patients (p.G73V, p.R374=, p.S497L, p.T575=, p.R607H, p.V644D, c.2410+97A>T). In this study we examined the effects of 3 of these VUSs on mRNA splicing by analysing cDNA. Nucleid acids were isolated from peripheral blood leukocytes.

Results: The variants p.G73V and p.S497L did not exhibit any effect on structure alteration or mRNA stability. However, in-silico analyses predicted that a novel variant (c.1725G>A, p.Thr575=) generates a new donor splice site in exon 11 with subsequent missplicing. Indeed, the sequencing analyses revealed a deletion of 120 nucleotides (r.1607_1726del120) that putatively causes an inframe deletion of 40 amino acids including 6 cysteine residues. This abnormality is expected to lead to uneven disulfide pairing and consequently to abnormal folding of the Notch3 protein.

Conclusions: Our study demonstrates that non-typical NOTCH3 variants such as synonymous or missense mutations not affecting directly cysteine residues may be a potential molecular cause of CADASIL.

Copy number variations in psychiatric patients with intellectual disability and catatonia: an exploratory study

A. M. L. Vogels;

Centre for Human Genetics, Leuven, Belgium.

Introduction: Catatonia is a motor dysregulation syndrome co-occurring with a variety of psychiatric and somatic disorders. The good response to treatment with benzodiazepines and electroconvulsive therapy indicates a neurobiological background. Environmental factors as well as genetic factors play a role in the etiopathogenesis. Research on the genetic aetiology is limited. We hypothesize that copy number variations known to be risks factors for neurodevelopmental disorders may play a role in the aetiology of catatonia. The aim of this study is to describe the CNVs in a population of psychiatric patients with an intellectual disability and catatonia. Methods: Fifteen intellectually disabled adults admitted to a psychiatric inpatient unit and diagnosed with catatonia were selected for genetic examination. Medical files were analysed retrospectively to collect data on cognitive functioning and psychiatric diagnosis. A clinical genetic examination was performed. Blood samples were taken for molecular karyotyping (Comparative Genomic Hybridisation). Results: CNVs, including 5 duplications and 3 deletions, were detected in 8 of the 15 patients (53%). In 2 of these patients a microdeletion including SHANK3 was found. Psychiatric diagnoses in these patients are autism, psychotic and affective disorders. Intellectual disability ranged from borderline to severe disability. Conclusion: CNVs occurred in half of intellectually disabled psychiatric adults with catatonia. These findings suggest that SHANK3del may play a role in the aetiology of catatonia in intellectually disabled patients. Cognitive functioning ranged from borderline to severe intellectual disability. Genetic research in children as well as in adults with intellectual disabilities and psychiatric comorbidity is important and meaningful.

Our experience in Genetic testing of Cerebrous Cavernous Malformations: Revisiting indication criteria

M. Borregán, A. Esteve, A. Cueto, T. Vendrell, I. Valenzuela, J. Vilalta, A. Outerial, A. Tenes, E. Tizzano, O. Diez;

Department of Clinical and Molecular Genetics and Rare Disease Unit, Hospital Vall d'Hebron, Barcelona, Spain, Barcelona, Spain.

INTRODUCTION: Cerebral cavernous malformations (CCM) are vascular abnormalities that occur mostly sporadically and associated with a single lesion. CCM can also be inherited in an autosomal dominant pattern characterized by the presence of multiple lesions, but much less frequently. Three known genes KRIT1, MGC4607 and PDCD10 are usually studied when multiple cavernomas are found. When a single abnormality is found the yield of the molecular study is very low, but little is known when lesions are described as suggestive and/or not clearly quantified as multiple but as discrete. We aimed to analyse our casuistic to update recommendations for testing and counselling of families.

MATERIALS AND METHODS: We conducted a detailed clinical molecular analysis (sequencing and MLPA of KRIT1, MGC4607 and PDCD10) in 63 CCM patients referred from the Neurosurgery Department of our Hospital, in an effort to analyze the correlation of clinical and RMN findings with the molecular results.

RESULTS: We identified mutations in 35% of cases, which was increased up to 75% when only multiple lesions (n=28) were considered. No mutation was revealed in patients with a single cavernoma (n=9) neither in those with 2 lesions (n=18). Only one from 8 patients with more than two and up to four discrete number of lesions showed a mutation correlating with a positive family history.

CONCLUSIONS: Patients with a discrete number of malformations should be settle apart from the recognized familial multiple CCM to optimize GT yield and establish clear recommendations for clinical management and assessment of these families.

Autism-related gene expression is spatially restricted in mid-gestation human fetal cerebellum

I. A. Glass¹, K. Aldinger², A. Timms³, M. Deng⁴, T. Naluai-Cecchini⁴, D. O'Day⁴, M. Weaver⁵, M. O. Dorschner⁵, W. B. Dobyns¹, K. J. Millen¹;

¹Department of Pediatrics, University of Washington; Center for Integrative Brain Research, Seattle Children's Research Institute, Seattle, WA, United States, ²Center for Integrative Brain Research, Seattle Children's Research Institute, Seattle, WA, United States, ³Center for Developmental Biology and Regenerative Medicine, Seattle Children's Research Institute, Seattle, WA, United States, ⁴Department of Pediatrics,

University of Washington, Seattle, WA, United States, ⁵Department of Pathology, University of Washington, Seattle, WA, United States.

Introduction: Cerebellar dysfunction has a large impact on both cognitive and motor behavior and mounting evidence implicates the cerebellum in autism spectrum disorders (ASD). However, the impact of ASD genes on cerebellar development and function is largely unknown. Here, we defined the 15 post-conception week (pcw) human fetal cerebellar transcriptome and hypothesized that ASD genes have neuron-type specific expression.

Materials and Methods: Laser capture microdissection (LCM) of intact cerebella from two 15 pcw fetuses enabled isolation of Purkinje cell (PC) and granule cell (GC) progenitor neurons. High-quality RNA was isolated (RIN>8), sequencing libraries using TruSeq RNA Access kit were constructed, barcoded, and sequenced using the Illumina HiSeq 2000. Paired end reads were aligned to the human genome HG19 using Tophat2, genes and counts were summarized using HTSeq. Gene-level differential expression was analyzed using DESeq2.

Results: On average, RNA-seq generated 18 million high-quality reads per sample, 96% of which mapped uniquely. Hierarchical clustering using the most variable genes within the dataset distinguished LCM-isolated PC and GC samples, including several known PC- or GC-specific genes. ASD genes generated from exome sequencing studies were expressed either throughout the cerebellum or restricted to PC neurons.

Conclusions: LCM is an effective method to enrich for developing PC and GC neurons in human fetal cerebellum. ASD genes are expressed throughout mid-gestation cerebellum or restricted to PC neurons, further substantiating cerebellar neuroimaging and neuropathological findings in ASD, and providing a potential neuronal therapeutic target.

Neuronal ceroid lipofuscinoses (NCLs), a heterogeneous group of lysosomal storage disorders, include the rare autosomal recessive neurodegenerative disorder CLN2 disease (CLN2). CLN2 is due to mutations in *TPP1/CLN2* gene causing tripeptidyl-peptidase-1 (TPP1) enzyme deficiency. Classic late-infantile CLN2 has pediatric onset with initial symptoms of seizures and language delay followed by progressive dementia, motor and visual deterioration and early death. Variant phenotypes occur more rarely. CLN2 diagnosis is based on laboratory testing following clinical suspicion. Early diagnosis is key to optimizing clinical care and future therapies outcomes, yet delays in diagnosis are common due to low disease awareness, non-specific initial symptoms and limited diagnostic testing access in some regions.

In May 2015, international experts met to recommend best laboratory practices for early CLN2 diagnosis. When clinical signs suggest NCLs, TPP1 activity should be the first test performed (along with palmitoyl-protein-thioesterase-1 to exclude CLN1). However, since reaching initial suspicion of CLN2 and NCLs is challenging, where available, use of epilepsy gene panels to investigate unexplained seizures in childhood is endorsed. These panels should include *TPP1/CLN2* besides genes for other NCLs lacking biochemical tests.

Diagnostic TPP1 enzyme test in leukocytes is well established and robust and in DBS is considered diagnostic if followed by molecular testing. Future methods to measure TPP1 activity via MS/MS may improve DBS-based

TPP1 testing sensitivity allowing also future newborn screening. To confirm clinical suspicion of CLN2, the recommended gold standard for laboratory diagnosis is demonstrating deficient TPP1 activity and/or detecting causative mutations in each allele of *TPP1/CLN2* gene.

P09.044

Novel frameshift mutation in *CHD8* causes familial autism spectrum disorder with intrafamilial clinical variability

T. Reimand¹, K. Noormets², I. Talvik³, S. Pajusalu⁴;

¹Department of Genetics, Tartu University Hospital, Tartu, Estonia ²Department of Biomedicine, Institute of Biomedicine and Translational Medicine, University of Tartu, Tartu, Estonia ³Department of Pediatrics, Institute of Clinical Medicine, Tartu, Tartu, Estonia, ⁴Department of Neurology, Children's Clinic of Tartu University Hospital, Tartu, Estonia, Tartu, Estonia, ⁵Tallinn Children's Hospital, Tallinn, Estonia, ⁶Department of Genetics, Tartu University Hospital, Tartu, Estonia ⁷Department of Biomedicine, Institute of Biomedicine and Translational Medicine, University of Tartu, Tartu, Estonia.

Recently disruptive mutations in chromodomain helicase DNA-binding domain 8 (*CHD8*) gene were shown to cause neurocognitive syndrome involving autism spectrum disorder (ASD) and macrocephaly. We describe a familial case of *CHD8*-related syndrome showing variable clinical phenotype among three affected family members.

The proband was a girl, first referred to clinical geneticist at the age of 2y5m due to global developmental delay and facial dysmorphism. Her occipito-frontal circumference (OFC) was +2 SD. At the age of 6y she had mild intellectual disability, ASD, and epilepsy. Her communication skills improved with initiation of antiepileptic treatment. Novel heterozygous frameshift mutation in *CHD8* was detected by next generation sequencing panel (4800 genes): NM_001170629.1:c.2423_2424del, p.(Arg808Lysfs*12).

Her brother had congenital heart defect, bilateral inguinal hernias, and facial dysmorphism. He started to walk at the age of 2y. At 3y10m his OFC was +1.75 SD. He had no speech, and the developmental delay and ASD phenotype were more severe than in his sister. Their father had inguinal hernia, problems with making friends during childhood, and some learning difficulties. At the age of 29y he has facial dysmorphism, and poor eye contact but no remarkable communication problems. His OFC is 61 cm (> +2 SD). The same *CHD8* mutation was confirmed in both brother and father.

In conclusion, our study suggests that the clinical picture caused by *CHD8* mutations can vary significantly between family members. The most prevalent feature is ASD, but macrocephaly is not present in every individual.

P09.045

Case report: exome sequencing of a family with childhood disintegrative disorder.

F. Ceroni¹, M. Absoud², G. Baird², A. Velayos-Baeza¹, D. Newbury¹;

¹Wellcome Trust Centre for Human Genetics, Oxford, United Kingdom, ²Guy's & St Thomas' NHS Foundation Trust, London, United Kingdom.

Childhood disintegrative disorder (CDD) is a very rare but devastating neurodevelopmental condition characterised by rapid and severe decline in developmental skills (communication, play, self-care, cognition) in children with apparently normal previous development for the first 2 years of life. The regression results in significant long-term impairments in social communication skills, similar to features of Autism Spectrum Disorder (ASD) with severe intellectual disability. Extensive neurometabolic investigations usually do not reveal an underlying aetiology. We report an exome sequencing study of a family with two affected children and neurotypical parents. Pathway analyses of rare and potentially damaging variants highlighted two variants in genes involved in intracellular trafficking and recruitment of proteins to the centrosome: both children carry a maternal stop codon in *PCM1* (NP_006188, p.E1912X) and a paternal nonsynonymous change in *ALMS1* (NP_055935, p.S763N). *PCM1* is an essential component of the centriolar satellites and interacts with several proteins, including *DISC1* (disrupted in schizophrenia 1) and *BBS4* (Bardet-Biedl Syndrome 4). Mutations in *ALMS1* can cause Alström Syndrome, a rare recessive multi-system ciliopathy, closely related to the Bardet-Biedl Syndrome (BBS). The biological functions of *ALMS1* are still being elucidated, but roles in cilium function and maintenance, intracellular trafficking, signaling pathways and cell cycle regulation have been suggested. Although the functional interaction between *ALMS1* and *PCM1* needs to be further investigated, the participation of the two proteins to the same cellular network, which has been previously implicated in other neurodevelopmental disorders, led us to hypothesize a possible compound effect of the two identified variants.

P09.046

Structural chromosome 21-specific instability in the diseased brain

Y. B. Yurov^{1,2,3}, S. G. Vorsanova^{2,1,3}, T. Liehr⁴, A. D. Koloti^{2,1}, I. Y. Iourov^{1,2,5};

¹National Research Center of Mental Health, Moscow, Russian Federation, ²Research and Clinical Institute for Pediatrics named after YE Veltishev at the Pirogov Russian National Research Medical University, Ministry of Health, Moscow, Russian Federation, ³Moscow State University of Psychology and Education, Moscow, Russian Federation, ⁴Institute of Human Genetics, Jena, Germany, ⁵Department of Medical Genetics, Russian Medical Academy of Postgraduate Education, Ministry of Health, Moscow, Russian Federation.

Introduction. Chromosome 21 aneuploidy has been shown to affect the diseased brain especially in individuals with Alzheimer's disease (AD). However, structural chromosome 21-specific instability has never been a target for molecular (neuro)cytogenetic studies of the diseased brain. Here, we have addressed chromosome 21 structural variations in single cells of the AD, schizophrenia and autism brain as well as in the unaffected brain.

Materials and Methods. Ten AD, 18 schizophrenia, 12 autism and 20 age- and sex matched samples of the postmortem brain (frontal cortex, Brodmann area 10) were studied by interphase chromosome-specific multicolor banding (ICS-MCB) and NeuN- immunohistochemistry.

Results. We were able to show that rare recurrent rearrangements of chromosome 21 or structural chromosome 21-specific instabilities are found almost exclusively in the AD brain. These were isochromosomes 21q, 21q22->qter losses and chromosome 21 breaks at 21q21 and 21q22 affecting 0.6-3.7% of cells. NeuN immunohistochemistry has indicated that the instability randomly affects NeuN-positive and NeuN-negative cell nuclei in contrast to chromosome 21 breaks, which were more prevalent in NeuN-positive cell nuclei.

Conclusions. Our data suggests that chromosome 21-specific instability is able to contribute to the AD pathogenesis. One can hypothesize chromosome 21 breaks confined to NeuN-positive cells of the AD brain to result from the dysregulation of DNA replication/reparation or DNA damage response pathways. Supported by the Russian Science Foundation (Grant #14-35-00060) and ERA.Net RUS Plus Programme.

Population genetics of SNPs, associated with cognitive traits and Alzheimer's diseases, in populations of Russia

M. Swarovskaya, 634050¹, V. Stepanov^{1,2}, A. Bocharova¹, A. Marusin¹, K. Vagaitseva^{1,2};

¹Institute for Medical Genetics, Tomsk, Russian Federation, ²Tomsk State University, Tomsk, Russian Federation.

Introduction. Cognitive functions in normal population and in various forms of dementia, the main of which is Alzheimer's disease (AD), demonstrate a high level of heritability as well as considerable individual variability. Population background appears to be an important factor in personalized health care and predictive medicine directed to prevention of common diseases, including AD. The aim of this study was to estimate the variability of genetic markers strongly associated with cognitive performance (CP) and AD across the multiple Eurasian populations.

Methods. We selected 53 single nucleotide polymorphisms (SNPs) reported in recent GWAS as highly significantly associated with AD and CP, and investigated the population variability of these markers in 20 populations of Russia representing Eastern Europe, Caucasus, Central Asia, North Asia and Siberia.

Results. Considerable between-population variability in allele frequencies was found. Average genetic diversity ranged from 0.34 in Belorussians to 0.39 in Kazakhs. Population differentiation measured by *Fst* varied widely across the loci studied (from 0.005 to 0.144). Mean *Fst* for all SNPs was 0.048. Mean *Fst* for AD (0.033) proved to be substantially lower than population differentiation for CP (0.053). Allele frequencies tend to correlate between populations according their geographical locations.

Conclusion. Our data indicate wide inter-population variation in the frequency of alleles associated with cognitive functions in norm and pathology. This variability may contribute to variation in genetic predisposition to dementia in ethnically different populations and to population-specific patterns of associations.

Moroccan patient with *CCDC88C* related congenital hydrocephalus: A case report

W. Smaili^{1,2}, I. C. Jaouad^{1,2}, A. Baumer³, A. Rauch³, A. Sefiani^{1,2};

¹Centre de Génétique Humaine – Faculté de Médecine et de Pharmacie- Université Mohamed V, Rabat, Morocco, ²Département de Génétique Médicale, Institut National d'Hygiène, Rabat, Morocco, ³Institute for Medical Genetics, University of Zurich, Zurich, Switzerland.

Nonsyndromic congenital hydrocephalus is a rare condition characterized by abnormal accumulation of cerebrospinal fluid that leads to in utero onset of ventricles enlargement.

The disease etiology is poorly clarified and the most frequent monogenic form of congenital hydrocephalus is due to hemizygous mutations in the *L1CAM* gene. This form is X-linked and clinically characterised by a combination of hydrocephalus in association with adducted thumbs. Besides *L1CAM*, autozygosity mapping revealed that *CCDC88C* mutations seem to cause a distinct non-syndromic complex hydrocephalus inherited in autosomal recessive way, with apparently normal psychomotor development despite the impressive prenatal cerebral phenotype. This gene was identified as a further essential component of the Wnt signalling pathway in human brain development.

We hereby report the case of a Moroccan girl, born of consanguineous parents, with congenital nonsyndromic hydrocephalus. Fetal ultrasound at 27 weeks' gestation showed enlarged ventricles. Brain MRI at birth showed triventricular asymmetric hydrocephalus with devided appearance of the left lateral ventricle. The child had seizures with mild psychomotor delay. *CCDC88C* gene sequencing found a homozygous mutation in the exon 30: c.5265_5266delCA (p.Phe1755Leufs*4), parents were both heterozygous for this mutation.

Identification of *CCDC88C* autosomal recessive congenital hydrocephalus allowed us to offer adequate support to the patient and to provide genetic counseling to parents.

Severe neurodegenerative phenotype associated with progressive loss of myelination caused by a homozygous nonsense mutation in *CSTB*

A. O'Brien¹, C. R. Marshall^{2,3}, S. Blaser⁴, P. Ray^{2,5}, G. Yoon^{1,6};

¹Division of clinical and metabolic genetics, department of paediatrics, Hospital for Sick Children, Toronto, ON, Canada, ²Department of paediatric laboratory medicine, Hospital for Sick Children, Toronto, ON, Canada, ³The centre for applied genomics, Hospital for Sick Children, Toronto, ON, Canada, ⁴Division of paediatric neuroradiology, Hospital for Sick Children, Toronto, ON, Canada, ⁵Department of molecular genetics, University of Toronto, Toronto, ON, Canada, ⁶Division of neurology, Department of paediatrics, Hospital for Sick Children, Toronto, ON, Canada.

Introduction: Mutations of the cystatin B gene (*CSTB*; OMIM 601145) are known to cause Unverricht-Lundborg disease, or progressive myoclonic epilepsy-1A (EPM1A, MIM #254800). Most patients are homozygous for an expanded (>30) dodecamer repeat in the promoter region of *CSTB*. Some patients are compound heterozygotes for the dodecamer repeat and a point mutation, and these patients generally have an earlier age of onset and more severe phenotype. Case Report: Two sisters born to consanguineous parents of Sri-Lankan descent presented with profound global developmental delay, microcephaly, cortical blindness, and central hypotonia with peripheral hypertonia. Neither sibling ever developed head control, independent sitting or ambulation, and never developed speech. The elder sister had a seizure disorder while the younger one had multiple electroencephalograms which failed to detect seizures. Clinical examination of both sisters revealed profound microcephaly, beaked nose with overhanging columella, supernumerary teeth, and short neck. On serial brain imaging, they had progressive atrophy of the corpus callosum, and diffuse hypomyelination with progressive loss of myelination. Results: Exome sequencing revealed both siblings to be homozygous for a c.218dup (p.His75Serfs*) mutation in exon 3 of *CSTB*. Their mother was a confirmed carrier of the mutation; the father was unavailable for testing. Conclusion: The neuroimaging features of our patients are consistent with those observed in *Cstb*-knockout mice, which supports the hypothesis that disease severity is inversely correlated with the amount of residual functional cystatin B protein. To our knowledge, this is the first report of a homozygous nonsense mutation in *CSTB* in humans.

P09.050

Further case of the rare congenital neuronal ceroid lipofuscinosis form confirmed by targeted exome sequencing showing a novel cathepsin D mutation

K. Varvagiannis¹, J. Fluss¹, A. Poretti², M. H. Billieux¹, R. De Luca¹, P. Rimensberger¹, S. Hanquinet¹, M. Guipponi¹, E. Hammar¹, P. Makrythanasis^{1,3}, M. Lidgren^{1,2}, J. L. Blouin¹, R.

Steinfeld⁴, I. Kern¹, S. E. Antonarakis^{1,3}, S. Fokstuen¹;

¹University Hospitals of Geneva, Geneva, Switzerland, ²The Johns Hopkins School of Medicine, Baltimore, MD, United States, ³University of Geneva, Geneva, Switzerland, ⁴University of Göttingen, Göttingen, Germany.

Neuronal ceroid lipofuscinoses (NCLs) are a group of autosomal recessive neurodegenerative lysosomal storage disorders. Neuronal ceroid lipofuscinosis-10 (CLN10 – OMIM #610127) due to cathepsin D deficiency is the most severe form, characterized by prenatal onset, and presents at birth with congenital microcephaly, extensive neuronal loss, neonatal seizures and early death. Few cases have been reported to date.

We report on a female baby, born at 37 4/7 gestational weeks to consanguineous parents after an uneventful pregnancy. Apgar score was 2/2/3. At birth the neonate did not have sufficient spontaneous breathing and needed intubation. In addition, she developed neonatal seizures. Brain MRI revealed severe and diffuse atrophy on both the brain and the cerebellum. The signal on the thalami was decreased on T2 and increased on T1. The spectroscopy showed an important deficit of NAA and elevated lactate. Support was withdrawn 5 days after birth, given the poor prognosis. Based on the neuroimaging findings, a neurodegenerative disease with prenatal onset, like CLN10, was suspected.

We performed exome sequencing with targeted bioinformatic analysis of 225 genes responsible of prenatal/perinatal encephalopathy including the cathepsin D gene (*CTSD*). The results revealed homozygosity for a novel 3 base-pair deletion in *CTSD* presumed to lead to the deletion of a phenylalanine residue. Both parents were heterozygous carriers of the variant (NM_001909.4:c.686_688del). Functional studies were performed and demonstrated absence of cathepsin D enzyme activity as well as undetectable protein product in Western Blot, thus further suggesting pathogenicity of this variant. These results confirmed the diagnosis of CLN10.

P09.051

Mutations of the mTORC1-regulating complex GATOR1 in focal epilepsies

S. Baldassari¹, L. Licchetta², C. Marconi¹, C. T. Myers³, F. Palombo¹, P. Magini¹, H. C. Mefford³, M. Seri¹, LICE NFLE Study Group, P. Tinuper², F. Bisulli², T. Pippucci¹;

¹Medical Genetics Unit, Dept of Medical and Surgical Sciences, University of Bologna - Sant'Orsola-Malpighi Hospital, Bologna, Italy, ²IRCCS Istituto delle Scienze Neurologiche di Bologna - Dept of Biomedical and Neuromotor Sciences, University of Bologna, Bologna, Italy, ³Dept of Pediatrics, University of Washington, Seattle, WA, United States.

Focal epilepsies (FEs) account for nearly 60% of all epileptic syndromes and are characterized by epileptic discharges originating from a limited area of the brain with heterogeneous etiologies. The most genetically characterized forms of FEs are Nocturnal Frontal Lobe Epilepsy (NFLE), Epilepsy with Auditory Features (EAF) and Familial Focal Epilepsy with Variable Foci (FFEVF). The genes associated with these conditions cumulatively explain a low percentage of the cases. We performed Whole Exome Sequencing (WES) analysis on a cohort of patients with FE, including 60 NFLE probands and 25 EAF probands, together with their healthy parents in the case of sporadic patients (trios) or affected relatives when available. The genetic analysis revealed 7 variants in the known gene *DEPDC5* and 1 *NPRL2* variant, which encode two components of the GATOR1 complex, together with *NPRL3*, negatively regulating mTORC1 signaling cascade. Our findings contributed to the discovery of the involvement of all the GATOR1 complex genes in the pathogenesis of up to 9% of FEs, in contrast to the concept that specific seizure semiologies point to the main involvement of specific brain areas. We therefore screened for mutations in GATOR1 encoding genes in an additional cohort of 65 patients with FEs using Multiple Inversion Probe technology, finding a novel nonsense variant in *NPRL3* in one additional patient. The deregulation of GATOR1 in FEs have important implications for patients' diagnosis and treatment, suggesting GATOR1/mTOR signaling as a potential key target for effective anti-epileptic drugs.

P09.052

DHCR7 mutations causing Smith-Lemli-Opitz syndrome in a patient cohort from Balkan region

A. V. Kirov^{1,2}, T. Todorov², V. Plaiasu³, K. Kovacheva⁴, A. Todorova^{1,2};

¹Medical University Sofia, Sofia, Bulgaria, ²Genetic Medico-Diagnostic Laboratory Genica, Sofia, Bulgaria, ³Mother and Child's Care Institute IOMC "Prof.dr. Alfred Rusescu", Bucharest, Romania, ⁴UMBAL "Dr. G. Stranski", Pleven, Bulgaria.

Smith-Lemli-Opitz syndrome (SLOS) is a rare metabolic disorder inherited in an autosomal recessive pattern. Clinically it is characterized by developmental abnormalities, such as psychomotor retardation, craniofacial anomalies, limb malformations, pre- and postnatal failure to thrive, genital particularities and variable structural anomalies of internal organs. From biochemical point of view this condition is characterized by low plasma cho-

lesterol levels and high concentrations of the cholesterol precursor 7-dehydrocholesterol (7DHC) due to the deficient activity of 7DHC Δ 7-reductase encoded by the DHCR7 gene.

Here we report 8 unrelated patients from Romanian and Bulgarian origin with different mutations in the DHCR7 gene. We identified the following mutations: c.278C>T; p.(Thr93Met) - allele frequency 18,75%; c.293A>C, p.(Gln98Pro) - 6,25%; c.355delC, p.(Val126*) - 6,25%; c.452G>A; p.(Trp151*) - 37,5%; c.964-1G>C - 6,25%; c.976G>T; p.(Val326Leu) - 12,50%; c.1295A>G; p.(Tyr432Cys) - 6,25%; c.1315delC; p.(Leu439Cysfs*2) - 6,25%. The mutations were detected by Sanger sequencing (using BigDye terminator v3.1 Cycle Sequencing Kit). The DNA sequencing results were compared to NCBI Reference Sequence: NM_001360.2. The genetically confirmed diagnosis allowed genetic counseling and prenatal diagnosis in the affected families.

Generally the incidence of SLOS is not known accurately. The relative frequencies of SLOS mutations differ among populations. The estimate range may vary due to different criteria used in the selection of the patients. Although the absolute incidence in some countries is uncertain, it's clear that there are different incidences among various ethnic groups.

P09.054

Molecular profile of neurodevelopment in trisomy 21 using iPSC cells

M. Sobol¹, J. Klar¹, J. Nordlund², G. Annerén¹, A. Falk³, N. Dahl¹;

¹Uppsala University, Uppsala, Sweden, ²SNP&SEQ Technology Platform, Uppsala, Sweden, ³Karolinska Institute, Stockholm, Sweden.

We have created an in vitro system for the recreation of key events during early stages of neurodevelopment in Down syndrome (DS) using induced pluripotent stem (iPS) cells. Fibroblasts from two non-related DS patients with trisomy 21 and from two healthy control individuals were reprogrammed to iPS cells followed by differentiation to early neuronal progenitor cells (NPCs) and further into neurons.

Transcriptome profiles were obtained from total RNA of NPCs and neurons. We used the Illumina platform (SNP&Seq platform, SciLifeLab, Uppsala University) and the TopHat and Cufflinks workflow (reference GRCh37). Over 50000 mapped transcripts were identified for each RNA sample.

Data were analysed for differentially expressed transcripts in DS vs. control cells using Cuffdiff and FDR-adjusted p-value of the test statistic (q-values) with a significance cut-off $q < 0.05$. We detected 541 and 277 transcripts that were differentially expressed in NPCs and neurons, respectively. Moreover, 221 differentially expressed transcripts were "shared" between both cells types. To clarify pathways and molecular networks in neuronal cells associated with trisomy 21 we used PANTHER and GO analysis. Top GO molecular function clusters were extracellular matrix structural constituent (GO:0005201), receptor activity (GO:0004872) as well as transmembrane transporter activity (GO:0022857) in both NPCs and differentiated neuronal cells.

Our preliminary data suggest that both NPCs and neurons with trisomy 21 show similarities in their transcriptome aberrations when compared to controls. Data are being validated and integrated with genome-wide methylome as well as proteome data in search for markers suitable for rescue-screening.

Mutation in CEP63 co-segregating with developmental dyslexia in a Swedish family

E. Einarsdottir^{1,2}, I. Svensson³, F. Darki⁴, M. Peyrard-Janvid¹, J. M. Lindvall^{1,5,6}, A. Ameur⁷, C. Jacobsson⁸, T. Klingberg⁴, J. Kere^{1,2}, H. Matsson¹;

¹Department of Biosciences and Nutrition, Karolinska Institutet, Huddinge, Sweden, ²Folkhälsan Institute of Genetics, and Molecular Neurology Research Program, University of Helsinki, Helsinki, Finland, ³Department of Psychology, Linneaus University, Växjö, Sweden, ⁴Department of Neuroscience, Karolinska Institutet, Solna, Sweden, ⁵Bioinformatics Infrastructure for Life Sciences, Stockholm University, Stockholm, Sweden, ⁶Department of Biochemistry and Biophysics, Stockholm University, Stockholm, Sweden, ⁷Uppsala Genome Center, Uppsala University, Uppsala, Sweden, ⁸Department of Pedagogy, Linneaus University, Växjö, Sweden.

Genetic studies of developmental dyslexia (DD) have presented candidate genes based on mapping of chromosomal translocations, genome-wide linkage and association, and sequencing. Although genome-wide association studies have pinpointed new loci for DD, potential functional gene variants are missing. In contrast, family-based studies continue to be informative in DD, where the full set of variants from individuals can be ascertained in families with a dominant inheritance pattern.

Recently, we used whole exome sequencing (WES) on DNA from seven affected and three unaffected individuals from a Swedish pedigree segregating DD. High quality single nucleotide variants were filtered to retain rare non-synonymous variants segregating with DD but absent from an in-house da-

tabase of WES variants. We identified a predicted damaging mutation resulting in a p.R229L substitution in the centrosomal protein 63kDa (CEP63) required for normal centriole duplication and cell cycle progression. Further, a common CEP63 variant showed significant association with white matter volume partly overlapping with regions influenced by polymorphisms in the DD susceptibility genes *DYX1C1* and *KIAA0319*, consistent with previous reported roles in neuronal migration.

Preliminary confocal imaging showed localisation of both endogenous wild type CEP63 and exogenous p.R229L CEP63 to the centrosome in RPE1 cells suggesting a potential dominant negative effect of the mutant protein. Further studies may reveal the impact of p.R229L CEP63 on cellular function and brain development.

We acknowledge grants from the Karolinska Institutet, the Magnus Bergvall Foundation, the Swedish Research Council, Swedish Brain Foundation, the Knut and Alice Wallenberg Foundation and the Bank of Sweden Tercentenary Foundation.

P09.056

Mono-allelic and bi-allelic variants in EMC1, implicated in ER-mitochondria communication, are associated with neurodegeneration

Y. Bayram¹, T. Harel¹, G. Yesil², Z. Coban-Akdemir¹, W. L. Charnig¹, E. Karaca¹, A. A. Asmar³, M. K. Eldomery¹, J. V. Hunter⁴, S. N. Jhangiani^{1,5}, J. A. Rosenfeld^{1,6}, D. Pehlivan¹, A. W. El-Hattab⁷, M. A. Saleh³, C. A. LeDuc⁸, D. Muzny⁵, E. Boerwinkle^{9,9}, Baylor-Hopkins Center for Mendelian Genomics, R. A. Gibbs^{1,5}, W. K. Chung¹⁰, Y. Yang^{1,6}, J. W. Belmont¹, J. R. ¹Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX, United States, ²Department of Medical Genetics, Bezmialem University, Istanbul, Turkey, ³Section of Medical Genetics, Children's Specialist Hospital, King Fahad Medical City, Riyadh, Saudi Arabia, ⁴Department of Pediatric Radiology, Texas Children's Hospital, Houston, TX, United States, ⁵Human Genome Sequencing Center, Baylor College of Medicine, Houston, TX, United States, ⁶Baylor Miraca Genetics Laboratories, Baylor College of Medicine, Houston, TX, United States, ⁷Division of Clinical Genetics and Metabolic Disorders, Department of Pediatrics, Tawam Hospital, Al-Ain, United Arab Emirates, ⁸Departments of Pediatrics, Columbia University Medical Center, New York, NY, United States, ⁹Human Genetics Center, University of Texas Health Science Center, Houston, TX, United States, ¹⁰Departments of Pediatrics and Medicine, Columbia University Medical Center, New York, NY, United States, ¹¹Department of Pediatrics, Baylor College of Medicine, Houston, TX, United States.

Introduction: The paradigm of a single gene associated with one specific phenotype and mode of inheritance has been repeatedly challenged. Genotype-phenotype correlations can often be traced to different mutation types, localization of the variants in distinct protein domains, or the trigger of or escape from nonsense mediated decay.

Materials and Methods: Whole exome sequencing (WES) was applied to four affected individuals in two unrelated families with reported consanguinity, and two other families were sequenced with WES by a trio (proband and parents) approach.

Results: We identified homozygous variants in EMC1 that segregated with a phenotype of developmental delay, hypotonia, scoliosis and cerebellar atrophy in three families. In addition, a de novo heterozygous EMC1 variant was observed in an individual with a similar clinical and MRI imaging phenotype.

Conclusions: EMC1 encodes a member of the endoplasmic reticulum (ER)-membrane protein complex (EMC), an evolutionarily conserved complex which has been proposed to play multiple roles in ER-associated degradation (ERAD), ER-mitochondria tethering, and proper assembly of multi-pass transmembrane proteins. Perturbations of protein folding and organelle crosstalk have been implicated in neurodegenerative processes including cerebellar atrophy.

Monoallelic and biallelic inheritance have previously been associated with different genes in which either de novo mutations (i.e., GJB2, KIF1A, MAB21L2, and NALCN) or recessive mutations (i.e., AARS, CLCN1, COL6A1, DEAF1, EGR2, ENPP1, KRT14, and ROR2) may cause more severe phenotype. We propose EMC1 as a novel gene in which either biallelic or monoallelic variants may lead to a syndrome including intellectual disability and preferential degeneration of the cerebellum.

P09.057

Novel mutation in CACNA1A gene expressed as myoclonic epilepsy with drop attacks associated with mild cerebellar signs

G. Larom-Khan, A. Peleg, A. Harari-Shaham, L. Shamer-Meiri, N. Zelnik; Carmel medical center, Haifa, Israel.

Introduction: A toddler with global developmental delay and ataxia presented at two months of age with myoclonic jerks which later on evolved into drug-resistance myoclonic epilepsy with drop attack.

Methods: Whole exome sequencing was employed and revealed one hete-

rozygous mutation. This alternation was not present in the DNA samples of her parents.

Results: We detected a novel missense mutation (C.678G>T) in the CACNA1A gene. No single nucleotide polymorphisms were found in this region and its probability score was nearly 1.0. The CACNA1A gene encodes the α_1 -subunit A, a transmembrane pore-forming subunit of the P/Q or CaV2.1 voltage gated calcium channel which mediated entry of Ca(2+) ions into excitable cells and also involved in a Ca(2+) dependent processes, including muscle contraction, hormone or neurotransmitter release and gene expression.

Conclusion: CACNA1A mutations were previously reported in Episodic ataxia type2, Familial hemiplegic migraine type 1 and in Spinocerebellar ataxia 6. It was also recently associated with epileptic encephalopathy. The present report expands the clinical spectrum of CACNA1A-associated neurological and particular epileptic disorders, and suggests that early disturbance of the voltage-gated calcium channel activity may underlies neuronal insult which lead to ataxia to myoclonic epilepsy.

P09.058

Epileptic seizures associated with chromosomal abnormalities

M. Budisteanu^{1,2,3}, A. Tutulan-Cunita¹, S. Papuc¹, C. Iliescu², C. Burlouiu², I. Focsa¹, D. Craiu², I. Minciu², D. Barca², B. Budisteanu², M. Cristea¹, I. Borcan¹, A. Arghir¹; ¹Victor Babes National Institute of Pathology, Bucharest, Romania, ²"Prof. Dr. Alex. Obregia" Clinical Hospital of Psychiatry, Bucharest, Romania, ³Titu Maiorescu University, Bucharest, Romania.

Many chromosomal abnormalities are associated with different neurological conditions, including epilepsy. There are about 400 different chromosomal imbalances described with seizures or EEG abnormalities. In this paper we present our experience regarding epilepsy associated with chromosomal abnormalities.

Methods: 125 children with epileptic seizures, other neurological features, and/or dysmorphic features were evaluated by clinical, dysmorphological, neurological, psychiatric and psychological examinations, EEG, neuroimaging studies (CT, MRI), biological studies, genetic investigations (karyotype, FISH, array CGH).

Results: In 42 cases with epilepsy a chromosomal syndrome was identified, including Down syndrome (4 children), trisomy 18 (1 child), partial trisomy 13 (1 child), 1p36 deletion syndrome (3 children), Angelman syndrome (20 children), Miller-Dieker syndrome (2 children), Pallister-Killian syndrome (3 children), Williams-Beuren syndrome (1 child), Wolf-Hirschhorn syndrome (1 child). We identified, also, some very rare chromosomal rearrangements, with complex phenotypes associating epilepsy, which included 3p26 duplication; 8p21.2-p11.2 deletion; 3q26.31 duplication.

Discussion: Most of our patients presented chromosomal syndromes, either known to associate epilepsy in most patients (such as Angelman syndrome, Miller-Dieker syndrome, trisomy 13 and 18) or rarely presenting with seizures (such as Down syndrome, Williams-Beuren syndrome). Several rare chromosomal rearrangements were detected; the genotype-phenotype correlations were difficult to establish in some cases (no specific genes for epilepsy are known to be located in the affected regions - 3p26.3, 3q26.31). Further studies are needed to understand the mechanism of epilepsy associated with chromosomal abnormalities.

Acknowledgments: National Project PN 09.33.02.03.

P09.059

Targeted gene testing of 50 patients with epilepsy-related neurodevelopmental disorder.

M. Martinez-Garcia, M. Peña-Vilabelda, P. Maietta, J. Botet, S. Alvarez; NGS Laboratory. NIMGenetics, Madrid, Spain.

Background: Epilepsy is a common clinical and genetic heterogeneous neurological disorder, with a large number of cases caused by genetic factors. To understand the molecular basis of epilepsy, 141 genes associated to neuro-metabolic disorders, syndromic and non-syndromic epilepsy were routinely analysed on 50 cases.

Methods: Genomic libraries were generated using the Ion AmpliSeq™ Exome RDY as exome backbone, combined with an AmpliSeq panel design to improve gene coverage. Sequencing reads generated on the Ion Proton™ and Ion S5™ platform were analyzed using Torrent Suite software. Annotated variants using ION Reporter were prioritized with an in-house analytical pipeline to identify the causative variants. This approach assures an average depth of 100X and an average 98.3% coverage in the selected genes.

Results: Among the 50 probands analyzed, 22 (44%) were referred as Early Infantile Epileptic Encephalopathies (EEIE). This approach allowed us to identify potentially genetic causative variants on 40% of the cases. Among EEIE patients 64% (14/22) were genetically diagnosed. Out of the 63 iden-

tified variants, 26 were associated to a gene with an autosomal-dominant inheritance pattern, 5 of which were confirmed as "de novo". Furthermore, a combined analysis of genes related to other neurodevelopmental disorders as autism was performed on 8 cases.

Conclusions: Epilepsy panels based on WES provide a cost effective and comprehensive strategy, that accelerates the identification of a definitive clinical diagnosis, decreasing the familial anxiety, improving the prognosis accuracy and facilitating the therapy selection.

P09.060

Detection of genetic heterogeneity in Bulgarian patients with epilepsy

L. T. Balabanski¹, S. Ivanov¹, R. Vazharova¹, A. Savov², M. Malinov¹, D. Toncheva^{1,3}; ¹Malinov Clinic, Sofia, Bulgaria, ²National Genetic Laboratory, Sofia, Bulgaria, ³Department of Medical Genetics, Medical University of Sofia, Sofia, Bulgaria.

Background: Epilepsy encompasses a group of related neurological disorders characterised by recurrent seizures due to abnormal electric activity in the brain. The genetic basis of the disease is complex with defects in more than 200 genes predisposing to it. The aim of our study was to perform targeted next-generation sequencing and detect gene defects in 12 Bulgarian patients with either primary (6) or secondary epilepsy as part of another undetermined condition (6).

Methods: After DNA was extracted from blood, NGS libraries were prepared using either TruSight One or TruSight Inherited Disease gene panels. Sequencing was performed on an Illumina MiSeq system. Variant filtering and downstream analysis was done using Variant Studio and GenomeBrowse softwares.

Results: We detected pathogenic mutations in 6 of our patients (50%). Three of those with primary epilepsy carried missense mutations in SCN8A (p.Arg1872Gln), EFHC1 (p.Phe229Leu) and a deletion in CLCN1 (c.1436_1449delTACCCTGCGGAGGC). The genes affected in the patients with secondary epilepsy were RNASEH2B (p.Ala177Thr), IDS (p.Pro408Ser) and AP1S2 (p.Tyr86Ter), and their carriers were respectively diagnosed with Aicardi-Goutieres syndrome, mucopolysaccharidosis and X-linked syndromic mental retardation.

Discussion: The genetic heterogeneity in our cohort was expected bearing in mind the wide variability in severity and penetrance of the disorders from the epileptic spectrum. This underlines the need for using large gene panels in order to successfully detect defects in patients with epilepsy as a symptom. The identification of the causative mutation could deliver crucial insights into the aetiology of the disease and potentially pave the way for a personalised treatment.

P09.061

Dogs Reveal a Novel Candidate Gene for Human Myoclonic Epilepsies

R. Sarviaho^{1,2}, F. Wieländer³, F. James⁴, M. Cortez², G. Kluger^{5,7}, M. Kornberg⁸, A. Bathen-Noethen⁹, T. Flegel¹⁰, S. Bharti¹¹, M. Arumilli^{1,2}, M. Hytönen^{1,2}, A. Fischer³, H. Lohi^{1,2}; ¹Research Programs Unit, Molecular Neurology and Department of Veterinary Biosciences, University of Helsinki, Helsinki, Finland, ²Folkhälsan Research Center, Helsinki, Finland, ³Centre for Clinical Veterinary Medicine, LMU University of Munich, Munich, Germany, ⁴Department of Clinical Studies, Ontario Veterinary College, University of Guelph, Ontario, ON, Canada, ⁵Neurosciences & Mental Health Program, Peter Gilgan Centre for Research and Learning, SickKids Research Institute, Ontario, ON, Canada, ⁶Department of Neuropediatrics, Epilepsy Center, Vogtareuth, Germany, ⁷PMU Salzburg, Salzburg, Austria, ⁸Veterinary Hospital Trier, Trier, Germany, ⁹Veterinary Practice Bathen-Noethen, Cologne, Germany, ¹⁰Department of Small Animal Medicine, University of Leipzig, Leipzig, Germany, ¹¹Department of Medicine and Clinical Biology of Small Animals, Ghent University, Ghent, Belgium.

Introduction: Epilepsy is the most common chronic neurological disease in humans and dogs. Canine epilepsy resembles the human condition and provides opportunity for new gene discovery, functional characterization and establishment of a therapeutic model. We previously identified young dogs with myoclonic epileptic seizures in the Rhodesian Ridgeback (RR) breed (Wieländer et al., JVIM 2016; 30:444) and aimed here to further characterize the clinical and genetic background.

Materials and Methods: A study population of 17 RRs was established and the breed-specific myoclonic epilepsy was studied by a wide-scale medical examination and awake ambulatory wireless video-EEG. A GWAS was performed to map the gene in a cohort of 10 cases and 18 unaffected RRs followed by whole exome sequencing of two cases. Candidate mutation was validated in a larger cohort (n=40) of cases and controls by TaqMan qPCR assays. Epileptic cases across breeds (n= 965) were also tested for the mutation. The expression pattern of the candidate gene was established in 27 canine tissues including many brain regions by RT-PCR.

Results: Our clinical studies revealed a photosensitive myoclonic epilepsy with a characteristic EEG pattern and age of onset in juvenile dogs. Genetic

studies identified a fully penetrant recessive breed-specific truncating mutation in a novel neuronal RasGTPase gene.

Conclusions: Our study revealed a myoclonic epilepsy in juvenile dogs resembling partially human JME. Canine gene discovery represents a novel candidate gene for human myoclonic epilepsies and unravels a new disease mechanism while establishing a clinically relevant animal model for further functional and therapeutic approaches.

P09.062

Diagnostic targeted next generation sequencing in patients with epilepsy

P. Rump¹, Y. J. Vos¹, D. R. M. Vlaskamp^{1,2}, P. M. C. Callenbach², R. J. Sinke¹, C. M. A. van Ravenswaaij¹, O. F. Brouwer²;

¹University of Groningen, University Medical Centre Groningen, Department of Genetics, Groningen, Netherlands, ²University of Groningen, University Medical Centre Groningen, Department of Neurology, Groningen, Netherlands.

Introduction: Epilepsy has a heterogeneous aetiology with a substantial genetic component. We used a targeted next generation sequencing (NGS) gene panel for clinical genetic testing in a heterogeneous cohort of 125 patients with epilepsy.

Materials and Methods: A gene panel, based on Agilent Sure Select Target Enrichment®, including 144 genes was used. Within this panel, nine partly overlapping subpanels were designed based on different epilepsy phenotypes, namely: benign familial neonatal/infantile epilepsy (5 genes), epileptic encephalopathy (39 genes), focal epilepsy (12 genes), fever related epilepsy (12 genes), progressive myoclonic epilepsy (19 genes), metabolic disorders with epilepsy (43 genes), generalized epilepsies (14 genes), epilepsy in combination with other paroxysmal disorders (11 genes), and syndromes with epilepsy and intellectual disability (63 genes). Based on the phenotype of the patient one or more of these subpanels were analysed.

Results: A (likely) pathogenic variant was identified in 12.6% of the patients. All confirmed by Sanger sequencing. The yield was highest in patients with benign familial neonatal/infantile epilepsy (23%) or fever related epilepsy (22%). The genes involved were: CACNA1A, CDKL5, GRIN2A, KCNQ2, KCNQ3, MECP2, NHLRC1, PCDH19 (n=3), PRRT2, RANBP2 (n=2), SCN1A, and SYNGAP1. Using this approach we were also able to detect a mosaic pathogenic variant in the PCDH19 gene in a male patient. A variant of unknown significance was reported in 11.8% of the patients. In most instances clinical relevance could be excluded.

Conclusions: Our results demonstrate that targeted next generation sequencing offers a quick, comprehensive and efficient molecular screening in patients with epilepsy.

P09.063

Identification of a de novo mutation in a patient with idiopathic epilepsy by targeted exome sequencing

L. Raussell, M. Lazaro, L. Cabrera, M. Bermejo, M. Molero, A. Gomez, A. Arteché, P. Marín-García, C. Ruiz, J. García-Planells, M. García-Hoyos;
Instituto de Medicina Genómica (IMEGEN), Paterna, Spain.

Introduction: NGS (Next Generation Sequencing) approach is revolutionising our understanding in medical genetics and is increasingly allowing us to achieve genetic diagnosis of complex disorders. One example of such complex disorders is Epilepsy. Epilepsy is the most common neurological disorder in which nerve cell activity in the brain becomes disrupted, causing seizures or periods of unusual behaviour, sensations, and sometimes loss of consciousness. The genetic diagnosis of Epilepsy is usually very difficult because of the genetic heterogeneity and the high number of genes associated with the disease.

Objective: Genetic characterization of a patient with epilepsy by targeted exome sequencing.

Methods: The targeted exome sequencing for Epilepsy is encompassing all the coding regions of 116 genes associated with the disease. Library was prepared using TruSight One (Illumina) and samples were ultrasequenced using a NextSeq 500 sequencing system (Illumina).

Non-benign variants were confirmed and segregated in parental samples by Sanger sequencing.

Results: The use of this targeted exome in a patient with idiopathic epilepsy allowed us to identify a de novo probably disease-causing change in the SCNA8 gene.

Conclusion: Targeted exome is a diagnostic alternative to Sanger sequencing for genetic heterogeneous diseases such as Epilepsy. This new strategy gives us the possibility to simultaneously analyse several genes, reducing time and cost, and increasing the diagnostic yield.

Early and accurate diagnosis of patients with epilepsy is essential for suc-

cessful treatment and care, especially at the evolutionary phases of the disease.

P09.064

Exome sequencing for molecular analysis of early infantile epileptic encephalopathies (EIEE)

A. Marcé-Grau¹, E. Cuenca-León¹, A. Felipe-Rucián¹, F. Lopez-Pisón², M. Raspall-Chaure¹, A. Macaya¹;

¹Vall d'Hebron Institut de Recerca, Barcelona, Spain, ²Hospital Universitario Miguel Servet, Zaragoza, Spain.

Introduction: Genetic variants causing EIEE are currently identified in only a minority of cases. We explored the usefulness of Whole-Exome-Sequencing (WES) for both diagnosis and gene discovery in EIEE.

Methods: Peripheral blood DNA was extracted from forty unrelated trios (proband and unaffected parents). We used NimbleGen SeqCap EZ Exome v3.0 and Illumina TruSeq kits to generate libraries which were 30X sequenced in a HiSeq 2000 instrument. Exomes were aligned to NCBI build 37 reference sequence. Variants were called with SamTools, annotated using SnpEff and VarAnnot and classified according to predicted functional effect. Hard filters and IGV inspection were used to eliminate artifacts. Analysis was two-tiered and comprised evaluation of 169 epilepsy genes, followed by evaluation of remaining WES variants. Selected variants were Sanger-validated.

Results: A first-tier analysis revealed high-effect de novo mutations in EIEE-associated genes in 45% of the cases. STXBP1, KCNQ2, KCNT1 and SCN1A were the most commonly mutated genes in this cohort. In patients with neonatal presentation, WES displayed a higher diagnostic yield, 66% (12/18; p<.01). Second-tier analysis showed an excess of damaging mutations in several intolerant-to-variation genes, mainly related to synaptic function and neural transmission.

Conclusion: WES analysis led to the identification of de novo disease-causing mutations in genes previously related to EIEE in 45% of our cases, showing a better diagnostic yield in cases with neonatal onset. Among the remaining undiagnosed cases, several de novo variants emerged as plausible candidates to produce EIEE. Functional ongoing studies will help determining their causative role in the disease.

A novel mutation in PCDH19 enabled genetic diagnosis as Epilepsy and Mental Retardation Limited to Females

F. N. Tuncer¹, S. A. Ugur Iseri¹, B. Kara², H. Maras Genc², E. Uyur Yalcin², U. Ozbek¹;

¹Istanbul University, Institute of Experimental Medicine Department of Genetics, Istanbul, Turkey, ²Kocaeli University Faculty of Medicine, Department of Pediatrics, Division of Child Neurology, Kocaeli, Turkey.

Introduction: Epilepsy and Mental Retardation Limited to Females (EFMR) is a rare encephalopathy associated with PCDH19 mutations affecting heterozygous females, sparing hemizygous males. EFMR is characterized by intractable, fever sensitive generalized or focal seizures initiating within the first year of life, and clustered brief seizures occurring repeatedly during several days. This study includes a 4-year-old girl, whose genetic evaluation aided differential diagnosis between EFMR and Dravet syndrome (DS).

Materials and Methods: A 4-year-old girl with prominent intellectual disability was recruited for this study. Her physical, neurological, neuroimaging and electroencephalography (EEG) examinations were performed with information on family history. Her first seizure occurred at 8 months of age with fever, marking the beginning of neuromotor developmental delay. Atypical absence seizures emerged when she was 1.5 years old. She is the only affected person in the family among 2 brothers and 1 sister. Illumina HiSeq2000 was utilized in whole genome exome sequencing of the subject. Exome data was filtered to detect all genetic variants in DS related genes including PCDH19. Candidate genetic variants were subjected to familial segregation through PCR and direct sequencing.

Results: Genetic analyses revealed a novel nonsense mutation in PCDH19 apparently occurring de novo. In silico evaluations supported mutation's role in pathogenesis.

Conclusion: This study enabled genetic diagnosis of the case as EFMR, associating a novel PCDH19 mutation with the disease that provided the family with genetic consulting.

Progressive Cerebello-Cerebral Atrophy (PCCA) and Progressive encephalopathy with Edema, Hypsarrhythmia and Optic atrophy (PEHO) are allelic syndromes

D. Lev^{1,2}, R. Hady-Cohen¹, H. Ben-Pazi¹, E. Leshinsky-Silver¹, T. Lerman-Sagie¹; ¹Wolfson Medical Center, Holon, Israel, ²Sackler School of Medicine, Tel-Aviv University, Tel-Aviv, Israel, ³Shaare Zedek Medical Center, Jerusalem, Israel.

In 2003, a new syndrome was diagnosed in the Sephardic Jews population, it was named PCCA (Progressive Cerebello-Cerebral Atrophy) after its typical neuroradiological findings. There are two types: PCCA type 1 and PCCA type 2. Known causative genes are SEPSECS in type 1 and VPS53 in type 2. PEHO (Progressive encephalopathy with Edema, Hypsarrhythmia and Optic atrophy) is a syndrome prevalent in Finland. It includes progressive microcephaly, profound mental retardation, marked hypotonia and dysmorphic features. MRI shows progressive cerebellar and brainstem atrophy. Recently, mutations SEPSECS were found in patients with PEHO.

We diagnosed 2 siblings with PEHO. They have a developmental encephalopathy, limb and facial edema, infantile spasms and optic atrophy. MRI shows cerebellar and brainstem atrophy. Extensive workup did not reveal the causative gene. Whole exome sequencing was performed. The first analysis that was done 5 years ago did not reveal the causative mutations. Recently, a re-analysis of the data revealed the 2 common Moroccan mutations in VPS53 (exon 19 c.2084A>G p.(Gln695Arg) and c.1556+5G>A. The parents were found to be carriers of the mutations.

Comparing both syndromes reveals clinical and radiological similarities. Our revelation that VPS53 mutations, previously described to be the cause of PCCA1, and now are found as causative mutations is PEHO, actually put these two syndromes on the same spectrum. Likewise, SEPSECS gene that is the cause for PCCA1 was also found recently as the causative gene in PEHO. PCCA and PEHO share the same genetic and clinical spectrum and thus, are allelic syndromes.

P09.067

A polymorphism in CRAT is associated with HLA-DQB1*06:02 negative essential hypersomnia

T. Miyagawa¹, S. Khor², H. Toyoda², M. Yamasaki², M. Shimada², K. Mishima², Y. Honda², K. Tokunaga², M. Honda¹;

¹Tokyo Metropolitan Institute of Medical Science, Tokyo, Japan, ²The University of Tokyo, Tokyo, Japan, ³Neuropsychiatric Research Institute, Tokyo, Japan.

Essential hypersomnia (EHS) is a sleep disorder characterized by excessive daytime sleepiness but no cataplexy, can be divided into two broad classes based on the presence or absence of HLA (human leukocyte antigen)-DQB1*06:02 allele. HLA-DQB1*06:02 positive EHS and narcolepsy are associated with the same susceptibility genes. However, there are fewer studies of HLA-DQB1*06:02 negative EHS. Therefore, we performed a genome-wide association study in 119 Japanese patients with HLA-DQB1*06:02 negative EHS and 1,582 Japanese healthy individuals to identify susceptibility genes associated with HLA-DQB1*06:02 negative EHS. A replication study was conducted on 191 Japanese patients with HLA-DQB1*06:02 negative EHS and 433 Japanese healthy individuals. SNP rs10988217 located in CRAT (carnitine acetyltransferase) was found to be significantly associated with HLA-DQB1*06:02 negative EHS ($P < 5 \times 10^{-8}$, OR=2.8). An eQTL analysis showed that rs10988217 was significantly correlated with expression levels of CRAT in various tissue or cell types, including brain tissue ($P < 0.05$). CRAT gene encodes the carnitine acetyltransferase protein, which is a key enzyme for metabolic pathways involved with the control of the acyl-CoA/CoA ratio in mitochondria, peroxisomes and endoplasmic reticulum. In addition, The Metabolomics GWAS Server (doi: 10.1038/ng.2982.) revealed that rs10988217 affected succinylcarnitine levels in blood ($P < 10^{-17}$). Individual acylcarnitines levels were measured in 36 Japanese patients with HLA-DQB1*06:02 negative EHS and 68 Japanese healthy individuals. Levels of several acylcarnitines showed significant differences between the two groups. The results provide evidence that HLA-DQB1*06:02 negative EHS may have an underlying dysfunction in fatty acid oxidation pathway.

This study was supported by Grants-in-Aid for Scientific Research (B) (15H04709).

Are rare coding mutations in the genes related to genetic peripheral neuropathies risk factors in multiple sclerosis (MS)

A. Peterlin¹, A. Maver¹, A. Hodžič¹, S. Šega², J. Drulović³, I. Novaković⁴, T. Pekmezović⁵, S. Ristić⁶, M. Kapović⁶, B. Peterlin¹;

¹Clinical Institute of Medical Genetics, Ljubljana, Slovenia, ²Clinical Institute of Medical Genetic, UMC Ljubljana, Ljubljana, Slovenia, ³Neurology Clinic, CCS, Beograd, Belgrade, Serbia, ⁴Institute of Human Genetics, MF Beograd, Belgrade, Serbia, ⁵Department of

Biology and Medical Genetics, School of Medicine Rijeka, Rijeka, Croatia.

Introduction: MS is chronic inflammatory disease of the central nervous system with important genetic contribution. Although familial contribution to MS etiology is well established, much of genetic contribution still remains poorly defined. Several case reports reported comorbidity between different types of genetic peripheral neuropathies and MS. Therefore we hypothesized that there is an increased mutation burden in genes related to peripheral neuropathies among MS patients.

Materials and Methods: Whole exome sequencing using Nextera Coding Exome enrichment was performed in 48 patients with familial MS, 40 patients with sporadic MS and 92 population-matched controls. Genotypes were called using GATK toolkit in multisample mode and only sites with variant quality over 100.0 and genotyping rate of over 60% across all samples were kept in downstream analyses. The selection of variants among bioinformatically focused panel of 52 peripheral neuropathy related genes was narrowed in accordance of functional impact predicted by snpEff - all truncating variants and missense variants predicted as pathogenic by a majority of in-silico predictors, were considered in further burden analyses.

Results: We identified 8 candidate genetic variants (7 genes) that affect function in familial MS, and 11 candidate genetic variants (12 genes) in sporadic MS patients. Overall we detected a statistically significant 1.9-times enrichment of mutations ($p=0.004$) in the familial MS cases compared to the ExAC control samples.

Conclusions: Exome sequencing of peripheral neuropathy causing genes revealed an excess burden of deleterious coding variants in familial MS patients which supports previous evidence of comorbidity among peripheral neuropathies and MS.

Familiality of cognitive performance: analysis in patients with psychotic disorders and their first degree relatives

C. Prats¹, P. Ferentinos², J. Soler³, S. Miret⁴, S. Campanera⁵, M. Giralte⁶, M. Muñoz⁷, L. Fañanás¹, M. Fatjó-Vilas¹;

¹Faculty of Biology, University of Barcelona, Barcelona, Spain; ²Biomedicine Institute of the University of Barcelona (IBUB). Centre for Biomedical Research Network on Mental Health (CIBERSAM), Barcelona, Spain, ³2nd Department of Psychiatry, University of Athens, Greece, Spain, ⁴Facultat de Biologia, Universitat de Barcelona. Institut de Biomedicina de la Universitat de Barcelona (IBUB), Barcelona, Spain, ⁵Servei de Salut Mental, Psiquiatria i Addiccions, Hospital de Santa Maria. Institut de Recerca Biomèdica (IRB), Lleida, Spain, ⁶Centre de Salut Mental de Lleida, Servei de Salut Mental i Addiccions, Hospital Santa Maria, Lleida, Spain, ⁷Àrea d'Adolescents, Complex Assistencial en Salut Mental, Benito Menni. Sant Boi de Llobregat, Barcelona, Spain, ⁸Àrea d'Adolescents. Complex Assistencial en Salut Mental, Benito Menni. Sant Boi de Llobregat, Barcelona, Spain.

Background: Cognitive impairment can be observed not only in psychotic patients but also in their nonpsychotic relatives which highlight a familial component for the relationship between cognition and psychosis. However, not many studies have explored the degree of intrafamilial resemblance of cognitive deficits. Our aim was to examine the familial aggregation of several neurocognitive traits in a sample of patients with psychotic disorders and their first-degree relatives.

Methods: Familiality was explored in 71 patients and 153 healthy first-degree relatives. All underwent a neurocognitive-battery (IQ-WAIS, phonemic/semantic fluency, WCST). Family-level residual intraclass correlation coefficient (ICC) was calculated. Families were ranked according to the level of familiality (IRS) for each cognitive test. Analyses were implemented with Stata v.13.

Results: Significant familial aggregation was found for Intelligence quotient (IQ), phonemic and semantic fluency (executive function domain) ($p < 0.001$). Significant IRS was obtained for IQ and phonemic fluency ($p < 0.001$), classifying these families according to their familiality level. No correlation was found between IRS and their neurocognitive scores ($p > 0.05$), meaning that familial similarities among families are independent of the neurocognitive performance.

Discussion: Despite that different studies have found that patients and relatives display deficits on a variety of neuropsychological tasks, we detected that only IQ, phonemic and semantic fluency show a familial aggregation pattern. This is in line with the fact that even the cognitive heterogeneity of the illness, executive dysfunction is one of the most marked cognitive impairments in SZ (Snitz et al., 2006). In this sense, stratifying families according their familiality levels may reduce heterogeneity and facilitate the identification of shared genes/environmental factors involved.

P09.072

FOXG1 and NOVA1 haploinsufficiency in an infant with microcephaly, seizures and severe neurodevelopmental delay

H. Fryssira¹, S. Psoni², E. Tsoutsou¹, S. Amenta², E. Manolakos³, I. Papoulidis³, S. Kitsiou-Tzeli¹, N. Chaliasos⁴;

¹Medical Genetics, School of Medicine, National and Kapodistrian University of Athens, "Aghia Sophia" Children's Hospital, Athens, Greece, ²"Mitera" Maternity Hospital, Athens, Greece, Athens, Greece, ³"Access to Genome" Clinical Laboratory Genetics, Athens, Greece, ⁴Child Health Department, University Hospital of Ioannina (UHI), Ioannina, Greece.

Introduction: FOXG1 gene mutations have been associated with the congenital variant of Rett syndrome (RTT) since the initial description of two patients in 2008. The ongoing accumulation of clinical data suggests that the FOXG1-variant of RTT forms a distinguishable phenotype, consisting of mainly congenital microcephaly, seizures, hypotonia, developmental delay and corpus callosum agenesis.

Case Report: We report a 6-month-old female infant, born at 38 weeks of gestation after in vitro fertilization, who presented with feeding difficulties, irritability and developmental delay since birth. Microcephaly, a small forehead with bitemporal narrowing, dyspraxia, poor eye contact and strabismus were also noted. At 10 months the proband exhibited focal seizures and required valproic acid treatment. Sleep deprivation EEG showed signs of focal cerebral dysfunction. The MRI was normal.

The peripheral blood G-banding karyotype was normal (46, XX), as well as the DNA analysis of the MECP2 gene. Array-Comparative Genomic Hybridization was performed (AGILENT Technologies, resolution 200 Kb) and revealed a 4.09 Mb loss of the copy numbers in the spanning region 14q12, encompassing the FOXG1 and NOVA1 genes.

Conclusions: The proband presented similar features with patients with 14q12 deletions except for dysgenesis of corpus callosum. Disruption of the NOVA1 gene, which promotes the motor neurons apoptosis, has not been yet linked to any human phenotypes, but could act synergistically with the FOXG1 gene in our patient.

Since our patient is the first reported case with deletions of both the above genes, the thorough clinical follow-up could further delineate the Congenital Rett-Variant phenotypes.

Molecular diagnosis improvement in patients with frontotemporal dementia using Next-Generation Sequencing

A. B. de la Hoz^{1,2}, E. Blanco^{3,1}, N. Ibarluzea¹, R. Bereincua², A. Molano³, I. Ugarriza², S. del Mazo², M. A. López-Aríztegui³, M. Fernández^{3,1}, M. I. Tejada^{1,3,2};

¹BioCruces Health Research Institute, Barakaldo, Spain, ²CIBERER, Madrid, Spain, ³Cruces University Hospital, Barakaldo, Spain.

Introduction:

Frontotemporal dementia (FTD) is the second most common form of young-onset dementia after Alzheimer's disease and comprises about 10–20% of all dementias worldwide. It is inherited in 30–50% of patients. It includes a group of degenerative diseases characterized by the atrophy of frontal and temporal lobes. Mutations in three main genes are commonly associated with FTD: *MAPT*, *PGRN*, and *C9orf72*, but recent findings have identified rare and pathogenic variants in additional genes: *FUS*, *VCP*, *TARDBP* and *CHMP2B*. Next Generation Sequencing (NGS) is being used to identify new pathogenic variants.

Material and Methods:

A total of 48 FTD patients were assessed by means of a NGS panel. Target regions in the selected genes (*MAPT*, *PGRN*, *FUS*, *VCP*, *TARDBP* and *CHMP2B*) were amplified using an Ion AmpliSeq™ custom Panel. It consists of 93 amplicons (17.21Kb), with coverage close to 99.5% on targeted sequence. Libraries were sequenced on an Ion Torrent PGM platform. Data analysis was performed using Torrent Suite™ and Ion Reporter™ software. All variants were validated by Sanger.

Results: Two known pathogenic mutations (c.709-1G>A and c.359C>A) and a non-described missense variant (c.1604G>A) were found in *PGRN*. We also detected a polymorphic variant in *FUS* (3'-untranslated region [UTR], c.*41G>A), whose MAF is 0.005, in three of our patients.

Conclusion: This approach shows the utility of the NGS technology to identify both known pathogenic and low frequency variants likely associated with this disorder. It is a powerful and cost-effective tool to diagnose complex disorders with genetic heterogeneity such as FTD. Gobierno Vasco.

P09.075

Carriage of one or two FMR1 premutation alleles seems to have no effect on illness severity in a FXTAS female with an autozygous FMR1 premutation allele

L. Rodríguez-Reventa¹, J. Pagonabarraga², E. Granel², M. Alvarez-Mora¹, I. Madrigal¹, M. Milà¹;

¹Hospital Clinic, Barcelona, Spain, ²Hospital Sant Pau, Barcelona, Spain.

Introduction: Fragile X-associated tremor/ataxia syndrome (FXTAS) is a late-onset neurodegenerative disorder that occurs in FMR1 premutation carriers. The prevalence of FMR1 premutation carriers in the general population is relatively high, and although rare, a premutation in both X chromosomes may occur in females inheriting a premutation allele from each of both parent carriers. Here we report the first female with an autozygous (homozygous by descent) FMR1 premutation allele, who fulfills neurological and radiological FXTAS findings/criteria.

Material and Methods: Molecular characterization included CGG repeat length, AGG interruption pattern, FMR1 mRNA, FMRP levels quantification and SNP microarray. Neuroradiological assessment of 3T magnetic resonance imaging, neurological and cognitive/neuropsychological evaluations were performed.

Results: Neurological and neuroradiological examination of the female with the same FMR1 allele in the premutation range (77 CGGs) demonstrated FXTAS features. Further familial evaluation showed a similar neuropsychiatric profile, with impairments in cognitive flexibility and visuospatial function, mainly.

Conclusions: A unique family with an autozygous FMR1 premutation female is presented. Neurological/cognitive and neuroradiological examinations revealed FXTAS-specific findings in the female with the autozygous FMR1 premutation allele. The consistent molecular and cognitive/psychiatric phenotype in family members suggests that carrying one or two FMR1 premutation alleles has no effect on illness severity.

Acknowledgments: This work was supported by the Instituto de Salud Carlos III (ISCIII; PI12/00879), cofinanced by the Fondo Europeo de Desarrollo Regional 'una manera de hacer Europa' and AGAUR from the Autonomous Catalan Government (2014 SGR603). P09.076

Social anxiety and autism spectrum traits among adult FMR1 premutation carriers

M. Milà¹, O. Lopez-Mourel², E. Mur³, I. Madrigal¹, M. Alvarez-Mora¹, L. Rodríguez-Reventa¹;

¹Hospital Clinic, Barcelona, Spain, ²PIC, Parc de Recerca Universitat Autònoma de Barcelona, Barcelona, Spain, ³CSM Martí i Julià, Instituto de Neuropsiquiatria y Adicciones (INAD), Parc de Salut Mar, Barcelona, Spain.

Introduction: Behavioral symptoms and traits have been proposed as early markers in neurodegenerative diseases. The aim was of this study was to evaluate social anxiety and autism in FMR1 premutation carriers and controls using the Social Phobia Inventory and the Autism-Spectrum Quotient. **Material and Methods:** Fifty-nine premutation carriers (40 females; 19 males) (7 females and 9 males with FXTAS) were compared to 50 controls (32 females; 18 males).

Results: Our results show that FMR1 premutation carriers have higher social anxiety scores and autistic traits compared to controls. Indeed, the SPIN scores were higher increased in women FMR1 premutation carriers compared to men whereas the AQ scores were similar between the two genders. Finally, SPIN scores were correlated with the repeat size when the CGG number was greater than 100.

Conclusions: Overall, these results indicate that social anxiety is greater in FMR1 premutation carrier women than in controls but not in men. In addition, both men and women with the FMR1 premutation have an increased risk of autism traits. Our results suggest that a wide range of behavioral/psychiatric traits should be included within the Fragile X Spectrum disorder and that the penetrance of these traits depends on the genetic background (CGG repeat number, gene modifiers, epigenetic, among others) as well as on gender.

Acknowledgments: This work was supported by the Instituto de Salud Carlos III (ISCIII; PI12/00879), cofinanced by the Fondo Europeo de Desarrollo Regional 'una manera de hacer Europa' and AGAUR from the Autonomous Catalan Government (2014 SGR603).

P09.077

Skewed X inactivation in women carrying the FMR1 premutation and its relation with Fragile-X-Associated Tremor/Ataxia Syndrome

M. Alvarez-Mora, L. Rodriguez-Revenga, A. Feliu, C. Badenas, I. Madrigal, M. Mila; Hospital Clinic, Barcelona, Spain.

Introduction: Fragile-X-associated tremor/ataxia syndrome (FXTAS) is a late-onset multisystem neurological disorder characterized by intention tremor and cerebellar ataxia. We hypothesized that in FMR1 premutation females with FXTAS, a normal X chromosome might more frequently be inactivated; therefore, the aim of this study was to determine the relationship between skewed X chromosome inactivation (XCI) and FXTAS.

Material and Methods: We studied the XCI patterns of cases of FMR1 premutation in 10 women with FXTAS and 21 without FXTAS.

Results: The distribution of XCI patterns in the FXTAS and no-FXTAS groups showed differences regarding the allele presenting severe skewed XCI. In the FXTAS group, all cases preferentially inactivated the non-expanded X chromosome, whereas in the no-FXTAS group, all inactivated the expanded X chromosome. As expected, we found statistically significant differences in the skewed XCI on comparing FMR1 premutation women and controls.

Conclusion: Although the reduced sample size and blood XCI patterns are two limitations of this study, our results suggest that the skewed XCI of the normal FMR1 allele may be a risk factor for the development of FXTAS. Furthermore, our findings also support the protective effect of the expression of a normal FMR1 allele.

Acknowledgments: This work was supported by the Instituto de Salud Carlos III (ISCIII; PI12/00879), cofinanced by the Fondo Europeo de Desarrollo Regional 'una manera de hacer Europa' and AGAUR from the Autonomous Catalan Government (2014 SGR603). The CIBER de Enfermedades Raras is an initiative of the ISCIII.

P09.078

Neonatal onset epilepsy and polymicrogyria associated with GRIN1 mutation

E. Banne^{1,2}, L. Shemer-Meir³, N. Zelnik³, V. Meiner¹;

¹Center for Clinical Genetics, Hadassah-Hebrew University Hospital, Jerusalem, Israel, ²Genetic Institute, Kaplan Medical Center, Clalit Health Services, Rehovot, Israel, ³The Pediatric Neurology Unit, Carmel medical center, Haifa, Israel.

Introduction: Severe cases of polymicrogyria are linked with multiple neurological abnormalities, and considered an epileptogenic malformation. We present a child with severe psychomotor retardation, congenital progressive microcephaly, intractable epilepsy presenting as early-onset neonatal seizures, and generalized hypotonia. Brain MRI showed a migration and sulcation defect with bilateral fronto-parietal and temporal polymicrogyria. **Methods:** Chromosomal microarray and metabolic testing were normal. Whole exome sequencing followed by filtration of synonymous, dbSNP132 and in-house database variants identified a de-novo pathogenic mutation. **Result:** We detected a novel de-novo heterozygous mutation (c.2365G>A; p.D789N) in the GRIN1 gene. The gene encodes an NMDA receptor subtype of glutamate-gated ion channels with high calcium permeability and voltage-dependent sensitivity to magnesium which is mediated by glycine. NMDA receptors play an important role in the development of the central nervous system, processes of learning, memory and neuroplasticity and are crucial for neuronal communication.

Conclusions: The present report expands the clinical spectrum of GRIN1-associated neurological disorders, and supports human NMDA receptors have an in-vivo role in neuronal migration. GRIN1 mutations were previously reported in children with epilepsy, non-syndromic intellectual disabilities and recently with epileptic encephalopathy but not with malformations of cortical migration. Experimental models of NMDA receptor unit-specific knock-down/knock-out show a role for NMDA receptors in cortical neuron migration. Whether the described mutation serves as a dominant negative mutation, perhaps as a stereotactic disruption of the NMDA receptor heterodimerization, or as a toxic gain of function is yet to be investigated.

P09.079

Hereditary sensory and autonomic neuropathy type V: study of 2 cases

W. Manoubi¹, A. Mili¹, E. Achouri², A. Gdissa¹, J. Bouguila³, S. Haddad², N. Souayah³, S. Sassi¹, A. Msakni¹, R. Ben Sghaier¹, A. Saad¹, M. Gribba¹;

¹Laboratory of Human Cytogenetics, Molecular Genetics and Reproductive Biology Farhat Hached University, Sousse, Tunisia, ²Department of Pediatrics, CHU Fattouma Bourguiba University Hospital, Monastir, Tunisia, ³Department of Pediatrics, Farhat Hached University Hospital, Sousse, Tunisia.

Introduction: Hereditary sensory and autonomic neuropathy (HSAN)

type 4 is a rare inherited disease caused by a mutation in the neurotrophic tyrosine kinase receptor, type 1 gene located on chromosome 1. It is characterized by pain insensitivity, partial anhidrosis and pressure sensitivity. Self-mutilation injury involving the teeth, lips, ears, eyes, nose, and fingers are invariable feature of this disorder. **Objective:** In this context, we report a Tunisian family having two children affected by HSAN4. Indirect genetic analyzes showed a transmission profile for the HSAN by mutation of the *NTRK1* gene. **Patients and methods:** It is about a Tunisian consanguineous family. It shows two boys aged 6 and 4 years respectively with convulsive recurrent seizures and significant self-harm injuries. A total anhidrosis, insensitivity to pain and mental retardation were then highlighted. Genotyping by analysis of four microsatellite markers surrounding or inside the *NTRK1* gene, helped to establish the haplotype of each individual and to follow the transmission of haplotype associated with the disease. **Results:** the indirect study by genotyping revealed the presence of a homozygous haplotype associated with the disease in one of the affected brothers. The second brother died three months later because of septicemia and malignant hyperthermia. **Discussion and Conclusion:** The interest of the indirect diagnosis by genotyping is important to show the type of haplotype transmission among patients. This should be followed by sequencing the *NTRK1* gene looking for variations. This genetic study of this disease is important for prenatal diagnosis because there is no cure.

BACKGROUND: Hereditary spastic paraplegias (HSP) are genetically heterogeneous motor disorders, divided into pure (pyramidal syndrome) and complicated (additional manifestations). The prevalence and clinical spectrum of SPG31, one of the autosomal dominant HSPs, has not been studied in Spain.

AIM: To analyze frequency and phenotype of SPG31 in Spanish HSP patients. **METHODS:** Through an NGS panel of HSP genes complemented by Sanger sequencing, we analyzed REEP1 in 104 index patients with HSP (51 pure, 50 complicated, 3 unknown) in whom SPAST (SPG4) and ATL1 (SPG3) point mutations had been excluded. Neurological examination and pedigree data were obtained. In order to establish pathogenicity of the variants we checked the literature and variant databases, performed in silico predictions and evaluated intrafamilial co-segregation.

RESULTS: Probably pathogenic variants in REEP1 were observed in 6 patients (11.7% among pure HSP without point mutations in SPAST and ATL1). Two were missense variants, two splicing variants, one nonsense, and a 9bp deletion involving REEP1 first three codons. Only one of these variants had been previously reported. We also identified a rare, silent variant of uncertain significance. All index cases had pure HSP, however cognitive and psychiatric manifestations were present in affected relatives. Onset age was very variable.

CONCLUSIONS: SPG31 represents ~12% of pure HSP patients in whom SPG4 and SPG3 have been ruled out by sequencing. This frequency is similar to other countries, and slightly lower than that of SPG3. The variable onset age and clinical spectrum difficult genotype-phenotype correlation and genetic counseling.

Introduction: Mutations in the SPG4/SPAST gene are the major cause of hereditary spastic paraplegias (HSPs), a group of genetic disorders leading to

progressive spasticity and weakness of the lower limbs. This study includes the evaluation of a comprehensive spectrum of clinical features and the mutational screening of the SPG4/SPAST gene in patients with HSP worldwide. Patients and Methods: A large cohort of patients were recruited from Italian, Brazilian, and Japanese populations in a period from 2008 to 2016. Clinical and instrumental functional analyses consisted of neurological assessment and neuroimaging. Mutational screening was carried out by Sanger sequencing and MLPA analysis. Haplotype studies were also performed. Results: Our study highlights clinical and epidemiological differences among populations, showing unique genotype-phenotype correlations. Genetic analysis revealed a total of 52 different pathogenic changes in 284 patients: 21 sporadic cases and 263 from 96 families. Among them, six variants were novel and pathogenic. The analysis revealed a great portion of private mutations worldwide and confirmed the founder effect for one recurrent variant in the Italian population. Interestingly, mutations were detected in 21% of sporadic cases and in a range from 16% to 100% of families, depending on the number of affected in the family. Conclusion: This study represents the first worldwide SPG4/SPAST genetic screening on HSP patients. Epidemiological and clinical results broaden the spectrum of the clinical presentations associated with mutations in SPG4/SPAST. Finally, our findings provide evidence that the chance to detect SPG4/SPAST mutations varies proportionally to the number of affected in the family.

P09.082

Whole exome sequencing data analysis in recessive hereditary spastic paraplegia patients from Turkey

B. Ozes¹, A. Candayan¹, O. Ari¹, Y. Parman², E. Battaloglu¹,
¹Bogazici University, Istanbul, Turkey, ²Istanbul University, Istanbul, Turkey.

Hereditary Spastic Paraplegia (HSP) is a group of clinically and genetically heterogeneous neurodegenerative disorders. Lower limb spasticity and progressive weakness are observed in 'pure' HSP patients. In 'Complicated' HSP, additional neurological and non-neurological symptoms are observed. HSP can be inherited in autosomal dominant, autosomal recessive, or X-linked manner. 49 loci and 43 genes are associated with autosomal recessive form of HSP (ARHSP). One patient from each of twenty ARHSP families from Turkey is selected for whole exome sequencing (WES). After the determination of candidate variations, segregation analyses were performed in the families to confirm that the variation might be responsible for the HSP phenotype. In three of the families variations were identified in known HSP genes and segregation with the disease in the families are confirmed for these variations. Two of them are identified in SPG11 gene and they are c.1235C>G (p.Ser412Ter) variation in family P463 and c.6215_6219dupAGAT (p.Phe2074ArgfsTer15) variation in family H16. The other variation confirmed is c.825T>A (p.Y275X) in CYP7B1 gene in family H98. In eight of the families, various variations in HSP genes have been identified and in seven of the families, variations identified in the genes that are related to other neurological diseases. The segregation analyses are currently being performed for these families. For the remaining two families, WES data is still under analysis. With seven novel HSP gene candidates, our WES analysis gives promising preliminary data for identification of novel genes in families from Turkey and it suggests evidence for further genetic heterogeneity in ARHSP.

Rapid and highly sensitive screen for HTT CAG repeat expansions in Huntington disease using a one-step triplet-primed PCR and melt curve analysis strategy

M. Zhao¹, F. S. H. Cheah², M. Chen¹, C. G. Lee^{3,4,5}, H. Law⁶, S. S. Chong^{1,2,7},
¹Departments of Pediatrics, Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore, ²Kho Teck Puat – National University Children's Medical Institute, National University Health System, Singapore, Singapore, ³Departments of Biochemistry, Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore, ⁴Division of Medical Sciences, National Cancer Center, Singapore, Singapore, ⁵Duke-NUS Graduate Medical School, Singapore, Singapore, ⁶Department of Pediatric Medicine, KK Women's and Children's Hospital, Singapore, Singapore, ⁷Department of Laboratory Medicine, National University Hospital, National University Health System, Singapore, Singapore.

Introduction: Molecular diagnosis of HD can be performed confidently using triplet primed PCR (TP-PCR) which detects all expanded alleles regardless of size. However, rapid high-throughput HD screening strategies currently rely on PCR using primers that flank the repeat, which may fail to detect large expansions and lead to false negative results. We describe an improved one-step screen for HTT expansion mutations based on MCA of TP-PCR products.

Materials and Methods: The assay was optimized on 30 genotype-known

cell-line DNAs, and two plasmids pHTT(CAG)₂₆ and pHTT(CAG)₃₃ were used to establish the threshold temperatures (TTs) distinguishing normal from expanded alleles. A blinded analysis was performed on 69 genotype-known clinical samples. Potential effects of reagent variations and common PCR contaminants were also evaluated.

Results: All 30 cell-line DNAs generated distinct melt peaks and T_ms which correlated well with each sample's larger allele. The TTs accurately distinguished between samples that carried normal-only, intermediate and expanded alleles. A companion protocol allowed rapid sizing confirmation of screen-positive samples, including one carrying a ~175-repeat expansion. Blinded analysis demonstrated clear segregation between unaffected and affected clinical samples (100% analytical sensitivity and specificity). The assay worked well with 10ng to 1ug of input DNA from blood, saliva or buccal swab. Sodium acetate contamination increased T_m, whereas glycogen contamination had no effect.

Conclusions: Rapid, accurate, and high-throughput detection/exclusion of HD for differentiation from diseases with similar phenotypes can be achieved using this simple one-step screening assay, at one-third the cost of fluorescent PCR and capillary electrophoresis (€1.2/sample).

P09.084

Predictive testing on adult onset neurodegenerative diseases on social and personal life - a pilot study

P. E. Cohn-Hokke¹, J. C. van Swieten^{1,2}, A. Tibben³, E. J. Meijers-Heijboer¹, J. A. Kievit²,
¹VU University Medical Center, Amsterdam, Netherlands, ²Erasmus Medical Center, Rotterdam, Netherlands, ³Leiden University Medical Center, Leiden, Netherlands.

Background: Follow-up studies on predictive testing for neurodegenerative diseases mainly focussed on psychological outcome such as depression, anxiety and distress. Studies addressing the impact of predictive testing on employment, financial issues, lifestyle, relations and family life are scarce.

Objective: To investigate whether the course of life of mutation carriers of adult-onset neurodegenerative diseases differs negatively from non-carriers and untested at risk individuals.

Methods: Individuals, aged ≥35 years, tested while asymptomatic for Huntington's disease, frontotemporal dementia or Alzheimer's disease more than 2 years before the start of the study or at 50% risk for one of these diseases, were invited to complete a questionnaire of 70 items. Within a year, an additional questionnaire was completed, comprising 47 items with adjusted and additional questions. Of the 313 selected individuals, 17 carriers, 30 non-carriers and 27 untested persons responded, fulfilled the criteria and completed both questionnaires.

Results: We found no significant differences between carriers and non-carriers or untested individuals at risk in employment, financial situation and lifestyle or anxiety and depression. Carriers were more often single and childless, though these differences were not significant.

Conclusion: Although the low response rate requires caution when interpreting our observations, the findings of this pilot study suggest that the outcome of predictive testing on adult onset neurodegenerative diseases does not have a large negative effect on social and personal life.

P09.085

Mutations in the ABCC6 gene are associated with an increased risk for ischemic stroke

O. M. Vanakker¹, E. Y. G. De Vilder¹, S. Cardoen², M. J. Hosen³, D. Hemelsoet²,
¹Center for Medical Genetics, Ghent University Hospital, Ghent, Belgium, ²Department of Neurology, Ghent University Hospital, Ghent, Belgium, ³Department of Genetic Engineering and Biotechnology, Shahjalal University of Science and Technology, Sylhet, Bangladesh.

Background. Evidence is emerging that ischemic stroke (IS) results from a complex interplay between environmental and genetic risk factors. As heterozygous ABCC6 mutations were shown to be associated with increased cardiovascular risk, we evaluated the role of ABCC6 in cryptogenic IS.

Methodology. Direct sequencing of ABCC6 was performed in 424 consecutive cryptogenic IS patients and 250 healthy age- and sex-matched controls. Allelic frequency differences were analyzed using a two-tailed Fisher's Exact test. Logistic regression analysis assessed modification of mutation-stroke interaction by cardiovascular risk factors. In one familial case with an autosomal dominant inheritance pattern of IS, segregation of the identified ABCC6 mutation was studied.

Results. Eighteen carriers of one ABCC6 mutation were identified compared to 2 carriers in controls (Odds Ratio 5.4975 [p =0.023; 95% CI 1.2-23.8]). No interaction with other CV risk factors was confirmed. In one family, we established segregation of an ABCC6 mutation in 18 family members with repetitive ischemic stroke and/or cardiovascular disease at young age and

simultaneously identified two novel PXE patients.

Conclusion. The segregation of an ABCC6 mutation in affected members of a multi-generation family with cerebrovascular disease suggests ABCC6 mutations to be significant risk factors for IS. This was confirmed by a high incidence of ABCC6 mutations in a cohort of cryptogenic IS patients compared to controls. As also demonstrated by the diagnosis of two novel PXE patients, identification of ABCC6 mutation carriers can have important implications for genetic counseling and follow-up of these families.

P09.086

A new phenocopy of Kabuki syndrome

C. Lintas¹, I. S. Piras^{2,3}, M. Verdecchia^{4,1}, C. Picinelli³, R. Sacco¹, G. Merla⁵, M. Canali¹, A. M. Persico^{1,3,6},

¹University Campus Bio-Medico of Rome, Rome, Italy, ²The Translational Genomics Research Institute, Phoenix, AZ, United States, ³Mafalda Luce Center for Pervasive Developmental Disorders, Milan, Italy, ⁴Azienda socio sanitaria G Mancinelli, Montelparo (FM), Italy, ⁵IRCCS Casa Sollievo della Sofferenza Hospital, San Giovanni Rotondo, Italy, ⁶University of Messina, Messina, Italy.

We report on a 14 year old man who had received a clinical diagnosis of Kabuki syndrome when he was six. No mutations in the two associated Kabuki genes, KMT2D and KDM6A, were found by direct sequencing and Multiple Ligation Probe Amplification. Array CGH revealed a de novo 5 Mb deletion on chromosome 10p11.22-11.21 encompassing 15 genes. Enrichment analysis by Gene Ontology showed that some of the deleted genes (as ZEB1, NRP1, FZD8, PARD3 and ITGB1) play an important role in neurodevelopment whereas others are implicated in chromatin remodeling. Particularly, the histone modifier EPC1 gene falls within the same "epigenetic functional classes" of the two candidate Kabuki syndrome genes and it is functionally linked to these by means of H2A histone. Consistent with this finding we demonstrated a significant reduction in EPC1 transcript which should functionally equate the loss of function mutations associated with the two Kabuki candidate genes.

P09.087

Recurrent mutation in the KCNC3 gene causes strikingly different clinical picture of SCA13 in a single family

A. Todorova^{1,2}, T. Todorov², P. Palaima², E. De Vriendt³, V. Bojinova⁴, M. Koleva⁴, T. Chamova⁵, V. Mitev¹, A. Jordanova¹;

¹Medical University Sofia, Sofia, Bulgaria, ²Genetic Medico-Diagnostic Laboratory Genica, Sofia, Bulgaria, ³University of Antwerp, Antwerp, Belgium, ⁴MHATNP "St. Naum", Sofia, Bulgaria, ⁵Clinic of Neurology, University Hospital "Alexandrovska", Sofia, Bulgaria.

We report a family with autosomal dominant spinocerebellar ataxia affecting two sibs and their mother. The clinical onset of the mother was around the age of 18-19 years with scanning speech and gait ataxia. Brain MRI demonstrated cerebellar atrophy at the age of 23 and she has been clinically diagnosed as spinocerebellar ataxia (SCA). The clinical onset of the sons was much earlier at the age of 2 and 1 years respectively with gait instability. The motor development of the second boy was delayed and independent inassisted gait has not been achieved since the age of 2.5 years. Neuropsychological development in both children was normal. The neurological examination revealed ataxia of stance and gait, intention tremor, scanning speech. Convergent strabismus was present in the elder brother. Their brain MRI at the age of 2 showed cerebellar hypotrophy.

The following dominant spinocerebellar ataxias SCA1, SCA2, SCA3, SCA6, SCA7, SCA8, SCA10, SCA12, SCA17, DRPLA were excluded. The genes TTBK2 for SCA11 and PRKCG for SCA14 were tested negative by Sanger sequencing. The NGS (WES) revealed the mutation c.1268G>A, p.Arg423His in the KCNC3 gene for SCA13. The mutation was confirmed by Sanger sequencing, it segregated with the disease in the family.

SCA13 accounts for less than 1% of SCAs. This mutation has been previously published. Typically it is associated with early onset, but in our family the mother showed weaker and late onset manifestation in comparison to both sons. SCA13 shows wide spectrum of phenotypes even in the frame of a single family.

P09.088

De novo KCNH1 mutations in four patients with syndromic developmental delay, hypotonia and seizures

N. Matsumoto, R. Fukui, N. Miyake;

Yokohama City University Graduate School of Medicine, Yokohama, Japan.

The voltage-gated Kv10.1 potassium channel, also known as ether-a-go-go-related gene 1, encoded by KCNH1 (potassium voltage-gated channel, subfamily H [eag-related], member 1) is predominantly expressed in the central

nervous system. Recently, de novo missense KCNH1 mutations have been identified in six patients with Zimmermann-Laband syndrome and in four patients with Temple-Baraitser syndrome. These syndromes were historically considered distinct. Here, we report three de novo missense KCNH1 mutations in four patients with syndromic developmental delay and epilepsy. Two novel KCNH1 mutations (p.R357Q and p.R357P), found in three patients, were located at the evolutionally highly conserved arginine in the channel voltage sensor domain (S4). Another mutation (p.G496E) was found in the channel pore domain (S6) helix, which acts as a hinge in activation gating and mainly conducts non-inactivating outward potassium current. A previously reported p.G496R mutation was shown to produce no voltage-dependent outward current in CHO cells, suggesting that p.G496E may also disrupt the proper function of the Kv channel pore. Our report confirms that KCNH1 mutations are associated with syndromic neurodevelopmental disorder, and also support the functional importance of the S4 domain.

Phenotypic characterisation of a recurrent homozygous deleterious variant in the KCTD3 gene

E. A. Faqeih¹, A. A. Aljares², M. M. Saleh¹;

¹King Fahad Medical City, Riyadh, Saudi Arabia, ²Department of Pediatrics, College of Medicine, Qassim University, Riyadh, Saudi Arabia.

Introduction: An association between KCTD3 and multiple congenital anomalies has previously been published; here, we expand the phenotype associated with deleterious variants in KCTD3.

Case series: Six patients (one monozygotic twin) from three consanguineous families presented with early-onset severe psychomotor retardation (100%), epilepsy (100%), hypotonia (100%), spasticity (33%), and dysmorphic features (33%). Brain MRI revealed Dandy-Walker malformation (84%) and hydrocephalus (33%). Abdominal ultrasound revealed unilateral multicystic kidney disease (33%). Basic metabolic, biochemical, haematological work up and aCGH were unremarkable. Whole exome sequencing identified previously described homozygous likely pathogenic variant in KCTD3 c.166C>T (p. (Arg56*)) by the same research group in a one-year-old patient with a similar presentation.

Discussion: KCTD3 belongs to a family of accessory subunits that regulate the biophysical properties of ion channels. The disruption of this gene has been associated with autism and renal aging in mice. It is highly expressed in the kidney and brain. Complete loss of this gene in the six patients resulted in specific clinical phenotypes mainly affecting brain and kidney development.

Conclusion: We report on six patients with recurrent deleterious variants in KCTD3. To the best of our knowledge, this is the largest case series of a similar presentation and provides additional observations regarding the role of KCTD3 in brain and kidney development. The universal involvement of cerebellum in those patients with the KCTD3 homozygous mutation make it a new member to the expanding lists of cerebellar hypoplasia-associated genes. However, its exact neurocerebellar role, function and phenotypic effects need extensive functional study.

P09.090

A de novo KIF1A mutation in a patient having epileptic encephalopathy with PEHO-like features

A. Laari^{1,2,3}, M. Muona^{1,3,4}, C. Courage^{1,2,3}, M. Somer⁵, A. Lehesjoki^{1,2,3}, A. Anttonen^{1,6,7};

¹Folkhälsan Institute of Genetics, Helsinki, Finland, ²Neuroscience Center, University of Helsinki, Helsinki, Finland, ³Research Programs Unit, Molecular Neurology, University of Helsinki, Helsinki, Finland, ⁴Institute for Molecular Medicine Finland, University of Helsinki, Helsinki, Finland, ⁵Norio Centre, Rinnekoti Foundation, Helsinki, Helsinki, Finland, ⁶Department of Medical and Clinical Genetics, University of Helsinki, Helsinki, Finland, ⁷Laboratory of Genetics, Helsinki University Hospital, Helsinki, Finland.

PEHO syndrome (Progressive encephalopathy with Edema, Hypsarrhythmia and Optic atrophy; MIM 260565) is an autosomal recessively inherited progressive infantile encephalopathy. A significant number of patients presents with many of the clinical features of PEHO syndrome but do not show typical neuroradiological findings or progression of cerebellar atrophy and are classified as having PEHO-like syndrome. We recently identified the recessive founder mutation responsible for PEHO syndrome in Finnish patients (Anttonen et al., in revision). Langlois et al. (Eur J Hum Genet 2015) reported that PEHO syndrome is caused by de novo dominant variants in the motor domain of the KIF1A gene. In our exome study of 33 PEHO-like patients negative for the PEHO founder mutation we identified one patient with a de novo missense variant (c.757G>A;p.E253K) affecting the motor

domain of KIF1A. The variant has been published earlier (Lee et al., Human Mutation, 2014) in two patients with intellectual disability, cerebellar and optic atrophy and axonal neuropathy. Our patient presented with progressive cerebellar atrophy, optic atrophy and dysmorphic features quite similar to PEHO syndrome. In thorough evaluation of the imaging findings in different time points, the dysmyelination was more severe in this patient than in typical PEHO patients. Thus, the patient was concluded to have PEHO-like features.

Our findings, combined with analysis of data on patients reported in the literature to have likely pathogenic variants affecting the motor domain coding region of KIF1A imply that de novo mutations in KIF1A are associated with a PEHO-like phenotype rather than PEHO-syndrome.

P09.091

Kleefstra syndrome and infantile spasms: a rare association

S. Dimassi¹, N. Soyah², A. Labalme², D. Sanlaville², L. Boughammoura², A. Saad¹, S. Mougou-Zerelli¹;

¹Department of Cytogenetics and Reproductive Biology, Farhat Hached University Teaching Hospital, Sousse, Tunisia, ²Department of Pediatrics, Farhat Hached University Teaching Hospital, Sousse, Tunisia, ³Department of Genetics, Lyon University Hospital, Lyon, France.

Kleefstra syndrome is characterized by moderate to severe intellectual disability (ID), childhood hypotonia and distinct facial features. Additional findings can also be observed including heart defects, renal/urologic defects, genital defects in males, severe respiratory infections, autistic-like features in childhood, epilepsy,... The syndrome can be caused either by a submicroscopic 9q34.3 deletion or an intragenic haploinsufficiency mutation of the euchromatin histone methyltransferase 1 (EHMT1) gene.

We report here, the first 3-years old boy of non consanguineous parents, with severe ID, hypotonia, facial dysmorphism, cardiac defect, severe respiratory infection and infantile spasms (IS). Standard Karyotype was normal and array chromosome genomic hybridization (array CGH) showed a 826 kb 9q34.3 deletion ranging from 139,970,775 to 140,796,632 pb (hg19). The 9q de novo telomeric deletion was confirmed by FISH using 9q telomeric probe.

Epilepsy and Seizures of various types occur in 25 to 35% of patients. Only two cases of kleefstra syndrome associated to IS have been published to date. We described the third case of epileptic IS, an age related seizure type, occurring usually in clusters and characterized by a typical electrodecremental pattern and various interictal electroencephalographic abnormalities. EHMT1, encoding a histone H3 Lys 9 methyltransferase and involving in chromatin remodeling, accounts for the majority of features in Kleefstra syndrome and is probably responsible of the epilepsy phenotype.

P09.092

Novel mutation in POLR1C in RNA polymerase III-related leukodystrophy with myoclonus

A. Karkar¹, I. Kraoua², C. Driss², S. Samaan³, F. Renaldo³, M. Elmaleh³, I. Dorboz⁴, O. Boespflug-Tanguy³;

¹Genetics and Molecular Pathology Laboratory, Casablanca, Morocco, ²National Institute Mongi Ben Hamida of Neurology, Tunis, Tunisia, ³Robert Debré Hospital, Paris, France, ⁴INSERM, Paris, France.

RNA polymerase III (POLR3)-related leukodystrophy is an autosomal recessive neurodegenerative disorder characterized by childhood onset of progressive motor decline manifest as spasticity, ataxia, tremor, and cerebellar signs, as well as mild cognitive regression. Other features may include hypo/oligodontia and hypogonadotropic hypogonadism. This disorder is caused by mutations in *POLR3A* and *POLR3B* gene. Recently Thiffault et al. have identified a new gene *POLR1C* related to this disorder. This gene is also mutated in some Treacher Collins syndrome cases. Here we describe a novel mutation in a 23 year-old girl from a consanguineous Tunisian family. At the age of 5 years, she developed unsteady gait, hand tremor, dysarthria and movement disorders. The first examination at 13 years of age showed cerebellar syndrome, pyramidal signs in upper and lower limbs and generalized myoclonus. Brain MRI showed diffuse hyperintense signal of the supratentorial and cerebellar white matter, cerebellar atrophy and hypointensity on the T2-weighted images of the ventrolateral thalamus. The corpus callosum is slightly thinned. She was negative for NGS leukodystrophy-panel containing twenty six most frequently involved genes including the *POLR3A* and *POLR3B* genes used by the routine molecular diagnostic lab of Robert Debré Hospital. Sanger sequencing of the coding regions of *POLR1C* gene revealed a homozygous mutation (c.863T>C/ p.Phe288Ser). This mutation is a novel *POLR1C* mutation. This result confirms that the analysis of *POLR1C* gene is an additional way for POLR3-related leukodystrophy diagnosis in which severe non epileptic myoclonus and T2 hypointensity of the thalamus were not reported.

P09.093

Combined genetic and neuroradiological assessment of neuronal migration disorders

U. Hehr¹, S. Hinreiner¹, T. Geis², G. Schuierer³, S. M. Herbst¹;

¹Center for and Department of Human Genetics, University Regensburg, Regensburg, Germany, ²KUNO Children's University Hospital Regensburg, Regensburg, Germany, ³Division of Neuroradiology, University Hospital Regensburg, Regensburg, Germany.

Introduction: Neuronal migration disorders (NMD) are a clinically and genetically important cause of early developmental delay, cognitive impairment and seizures. A substantial proportion of practically all morphological forms has been associated with a wide variety of isolated or syndromal monogenic disorders.

Method: Conventional Sanger sequencing and CNV analysis by MLPA, more recently massive parallel NGS gene panel sequencing (MGPS), additional neuroradiological assessment of available cerebral MR (cMR) imaging.

Results: Conventional Sanger sequencing with MLPA in our laboratory allowed a genetic classification (mutation class VUS4 or VUS5) for 21.6% of our overall NMD patient cohort (981 independent patients with lissencephaly/pachygyria/polymicrogyria, double cortex, periventricular nodular heterotopia or complex NMD; 1.53 genes per patient). For a subgroup of 146 patients with cMR imaging available for pretest reevaluation causal mutations were identified in 30.8%.

Implementation of an individual combined diagnostic strategy including massive parallel NGS gene panel sequencing MGPS (45.8 genes per patient) and neuroradiological assessment of patients with NMD now allows not only a substantially faster and more cost-effective workup, but also further increases the diagnostic yield through detection of mutations in genes with small contribution (e.g. *DYNC1H1* or *TREX1*) and by screening for copy number variations (e.g. *LIS1*) for all tested genes within the known current technical limitations. Furthermore, sufficient MGPS coverage also increases the sensitivity to detect somatic mosaicism (e.g. *DCX*).

Summary: Our preliminary findings indicate a benefit of diagnostic MGPS for NMD, when combined with critical data assessment and interpretation in the context of individual clinical and neuroradiological findings.

P09.095

Genetic studies of multiple consanguineous families with primary microcephaly revealed pathogenic variants in ASPM and CDK6

M. A. Khan^{1,2}, M. Z. Ali², M. Kuster³, N. Ahmad⁴, V. Rupp³, H. Gul⁵, S. Abbas², V. Kumar¹, F. A. Mir¹, S. Khan¹, R. M. Mohammad¹, C. Windpassinger³, Z. Nawaz¹;

¹Hamad Medical Corporation, Doha, Qatar, ²Gomal University, D.I.Khan, Pakistan, ³Medical University of Graz, Graz, Austria, ⁴Hazara University, Mansehra, Pakistan.

Background: Primary microcephaly is a rare genetic disorder that is characterized by reduced head circumference and intellectual disability. Genetic studies have identified 15 (MCPH) causative genes which include *MCPH1*, *WDR62*, *CDK5RAP2*, *CASC5*, *ASPM*, *CENPJ*, *STIL*, *CEP135*, *CEP152*, *ZNF335*, *PHC1*, *CDK6*, *CENPE*, *SASS6* and *MFSD2A*. Physiologically, most of the protein products of these MCPH genes are involved in cell cycle and its regulation. Methods: The genomic analysis was performed through whole exome sequencing, while co-segregation of the identified pathogenic variants in the corresponding family members was carried out by sanger DNA sequencing. Results: In the present genetic study, we present three consanguineous Pakistani families segregating primary microcephaly that are ascertained from the rural area of Khyber-Pukhtunkhwa province of Pakistan. Sequence analysis of two families revealed one novel [NM_018136.4: c.10013delA (p.Asp3338Valfs*2)] and a previously reported [NM_018136.4: c.9730C>T (p.Arg3244*)] mutation in *ASPM* gene. The novel frame-shift mutation (p.Asp3338Valfs*2) in *ASPM* presumably truncate the protein synthesis that result in loss of armadillo type fold domain. The third family showed the same missense mutation [NM_001259.6: c.589G-A (p. Ala197Thr)] in *CDK6* gene as recently identified in a single Pakistani family.

Conclusion: *ASPM* is the most prevalent gene for MCPH in south Asian populations, and our study also expanded its mutational spectrum. The reported *CDK6* gene has previously been mapped in a consanguineous Pakistani family, and here we are reporting the second family. These results further extend the evidence of *CDK6* gene implication in MCPH and suggest its founder effect in the Pakistani population.

P09.096

2002-2016: What is known about reported MCPH patients?

P. Létard^{1,2,3}, P. Gressens^{1,4,5}, A. Verloes^{5,6}, S. Passemard^{1,5,6},

¹INSERM U1141 PROTECT, Paris, France, ²Service d'anatomie et cytologie pathologiques - CHU Jean Verdier, Bondy, France, ³Université Paris 13, Sorbonne Paris Cité, Bobigny, France, ⁴Center for developing brain, King's college, St. Thomas' Campus, London, United Kingdom, ⁵Université Paris Diderot, Sorbonne Paris Cité, Paris, France, ⁶Département de génétique, Hôpital Robert Debré, Paris, France.

Introduction: Microcephaly primary hereditary (MCPH) is a rare autosomal recessive neurodevelopmental disorder characterized by a reduction in brain growth, associated with an intellectual disability. MCPH is genetically heterogeneous with fifteen genes identified (MCPH1-15), coding proteins related to the centrosome. Here, we review clinical, molecular and radiological findings of reported MCPH patients and highlight prognostic factors. **Materials and methods:** We have performed an online literature research in PubMed database to identify any patient with mutations in MCPH genes. **Results:** 722 patients (326 families) have been reported, with a high rate of consanguinity. 44% are of Pakistani origin. In Europe, there are 41 families, often not-related. Mutations in ASPM represent the most frequent cause of MCPH (63% of families), followed by mutations in WDR62 (14%) and MCPH1 (6%) genes. 234 MCPH mutations have been reported, with a majority of nonsense and frameshift mutations. Intellectual disability is mild to moderate but neuropsychological assessment was almost never carried out (4% of reported patients). When performed, CDK5RAP2 patients have a better IQ than ASPM patients. A brain MRI was performed in 16% of patients: it was abnormal in 84%, and frequent abnormalities include: gyral simplification, corpus callosum abnormality and pachygyria. **Conclusion:** 722 patients have been reported with mutations in one of the 15 MCPH genes but clinical, neuropsychological and radiological data are often lacking, which makes genotype-phenotype correlations or genetic counseling still difficult. How these mutations alter brain structure and cognitive functions are major questions that we have now to solve in MCPH field.

Introduction: The MECP2 duplication syndrome (OMIM_300260) is a neurodevelopmental disorder X-linked characterized by severe to profound intellectual disability, early infantile hypotonia, autistic traits, seizures and recurrent respiratory infections. It usually affects boys, but also there are girls affected. Duplication could be de novo or inherited from asymptomatic carrier mother. It has been reported about 120 cases all over the world, without a known incidence.

The aim of the study is to characterize a Spanish cohort with MECP2 duplication syndrome to improve our knowledge of the disease and perform a genotype-phenotype correlation.

Material and Method: The cohort consists in 13 patients of both sexes diagnosed in different Spanish hospitals. The duplications were detected by MLPA and/or CGH-array. The clinical characterization was carried out using a checklist designed for the project. The molecular characterization is divided into several steps: 1) Checking the duplication by qPCR-doses, study XCI and FISH; 2) If FISH shows tandem duplication, we narrowed the breakpoints through qPCR, PCR-long and Sanger sequencing; 3) Analyze the expression of the two MeCP2 isoforms by RT-qPCR.

Results: In this collaborative study has been characterized a heterogeneous cohort, with both sexes, with different phenotypes (Rett-like and duplication patients) and inherited or de novo duplication located in different regions (tandem, other region of ChrX or ChrY). However, this information is not enough to create a clear genotype-phenotype correlation.

Conclusions: We suppose MECP2 duplication syndrome is an underdiagnosed disease that needs further characterization studies in order to give a better genetic and clinical diagnosis.

Introduction: Drug addiction is a neuropsychiatric disorder in which both environmental and genetic factors are involved. Work over the past decade has demonstrated a crucial role of epigenetic mechanisms in driving long-lasting changes in gene expression in several tissues, including the brain. **Material and methods:** Starting from a previously reported list of 2,878 SNPs that correlate with differential levels of methylation at CpG sites (allele-specific methylation), we obtained a sub-list of 88 SNPs using the following selection criteria: R²>0.5, only one SNP for each CpG site. Subsequently, we evaluated the possible contribution to drug dependence predisposition of these SNPs in a sample of 697 drug-dependent patients and 656 sex-matched controls from Spain and in a replication sample.

Results: A single SNP, rs3766612, was found associated with drug addiction (p-value=0.00071; OR-95%CI=1.41 (1.16-1.69)) and survived the Bonferroni correction for multiple testing. We then aimed at replicating this finding in a follow-up sample of 740 drug-dependent patients and 771 sex-matched controls, but rs3766612 was not found associated with drug addiction. Finally, we performed a pooled analysis including the discovery and replication samples where the SNP rs3766612 remained associated with drug addiction in the combined dataset (p-value=0.00655; OR-95%CI=1.19 (1.05-1.35)).

Conclusion: We detected a potential association between drug addiction and SNP rs3766612, which correlates with differential levels of methylation at the CpG island cg23166289. Interestingly, this CpG site is located in a genomic region that contains several genes belonging to families previously related to drug dependence, such as SYT14, LAMB3 or CAMK1G.

MSTO1 is a cytoplasmic protein involved in mitochondrial fusion dynamics and its human mutation is associated with mitochondrial myopathy

A. Gal^{1,2}, P. Balicza³, D. Weaver³, S. Naghdī², J. K. Suresh², G. Incedy-Farkas¹, V. Reményi¹, P. Várnai², T. Gyuris⁴, A. Farkas⁴, L. Nagy⁴, M. J. Molnar⁴, G. Hajnóczky²;

¹Institute of Genomic Medicine and Rare Disorders, Semmelweis University, Budapest, Hungary, ²MitoCare Center for Mitochondrial Imaging Research and Diagnostics, Department of Pathology, Anatomy and Cell Biology, Thomas Jefferson University, Philadelphia, PA, United States, ³Department of Physiology, Semmelweis University, Budapest, Hungary, ⁴Department of Biochemistry and Molecular Biology, University of Debrecen, Debrecen, Hungary.

Introduction: MSTO1 protein has been localized to mitochondria and linked to mitochondrial morphology but its specific role remained unclear. In this study, we investigated the role of MSTO1 on mitochondrial dynamics and bioenergetics in patient-derived fibroblasts and HeLa cells.

Methods: The whole exome-sequencing was performed a Hungarian family with mitochondrial disease resulting in myopathy, hypoacusis and psychiatric symptoms. The mitochondrial fusion-fission and bioenergetics in both patient-derived cells and cell lines using genetic rescue and gene silencing were investigated by live cell imaging, fluorometric measurements and immunoblotting.

Results: In this study, we identified a c.22 G>A, (p.Val8Met) mutation of MSTO1 in our patients. In the patient fibroblasts, the MSTO1 mRNA and protein abundance is decreased, mitochondria show fragmentation, aggregation, decreased network continuity and fusion activity. These can be reversed by genetic rescue. Short term silencing of MSTO1 in HeLa cells reproduced the impairment of mitochondrial morphology and dynamics observed in the patient fibroblasts without impairing bioenergetics. Contrary to a previous report, MSTO1 is mainly localized in the cytoplasmic area and shows only partial colocalization with the mitochondria. After plasma membrane permeabilization, MSTO1 is released to the cytoplasm.

Conclusions: Our findings indicate that MSTO1 has a role in mitochondrial morphogenesis and quality control by supporting mitochondrial fusion. MSTO1 likely interacts with the mitochondrial fusion machinery as a solub-

le factor at the cytoplasm-mitochondrial outer membrane interface. Loss-of-function mutation in MSTO1 is could be associated with mitochondrial disorders.

MLC1 mutational analysis in Korean patients with megalencephalic leukoencephalopathy with subcortical cysts

B. Lim, H. Cheong;

Seoul National University Children's Hospital, Seoul, Korea, Republic of

Megalencephalic leukoencephalopathy with subcortical cysts (MLC) is a rare inherited disorder characterized by macrocephaly, slow neurologic deterioration and seizures. Brain MRI shows extensive white matter signal abnormalities with subcortical cysts in the anterior temporal regions. The first causative gene, MLC1 is mutated in approximately 75% of patients and inherited as autosomal recessive trait. The defect in MLC1 has been known to hamper the ion and water homeostasis and osmotic balance in astrocytes, resulting chronic brain white matter edema. In this study, we present the clinical manifestation, neuroimaging and mutational analysis in the MLC patients first to be described from Korea. All of the four MLC patients had early onset macrocephaly, delay in the motor skills with a gradual onset of motor deterioration. Brain MRI showed typical MLC features. Two types of mutations were identified. p.A275D mutation was most commonly observed, six of eight (75%) alleles in Korean patients with MLC. Homozygous p.I113Gfs*4 frameshift mutation was identified in only one patient while patient's mother was heterozygous state. By MLPA and CGH + SNP microarray analysis, segmental loss of heterozygosity of chromosome 22 including MLC1 region was confirmed indicating maternal uniparental disomy.

P09.101

Sequencing in patients with familial and sporadic multiple sclerosis reveals the possible etiological role of rare and highly penetrant genetic variation

A. Maver¹, A. Hodzic¹, S. Šega², J. Druilović³, I. Novaković⁴, S. Ristić⁵, M. Kapović⁶, T. Pekmezović⁷, B. Peterlin¹;

¹Clinical Institute of Medical Genetics, Ljubljana, Slovenia, ²Department of Neurology, UMC Ljubljana, Ljubljana, Slovenia, ³Neurology Clinic, CCS, Belgrade, Serbia, ⁴Institute of Human Genetics, MF Beograd, Belgrade, Serbia, ⁵Department of Biology and Medical Genetics, School of Medicine Rijeka, Rijeka, Croatia.

Multiple sclerosis (MS) is a chronic autoimmune neurological disorder with complex genetic architecture. Despite efforts, even large genome-wide association studies (GWAS) failed to completely explain heritability of MS based on common genetic variation.

To characterize the possible role of rare, highly penetrant genetic variants in MS, we performed whole exome sequencing in 48 patients with familial MS, 40 patients with sporadic MS and 92 population-matched controls. We have focused the analysis to rare (<5%) and predicted pathogenic variants (truncating or predicted pathogenic missense variants) in 102 genes associated with MS in the most recent GWAS performed to date.

In the subset of patients with familial MS, we identified two novel truncating variants of high impact in MMEL1 and ALPK2 genes. Truncating variants in two further GWAS genes - IL7R and AHI1 were also identified in sporadic MS cases. Several predicted pathogenic missense variants were also identified in MS associated genes: 18 variants in familial MS cases and 27 in sporadic cases. Finally, we could also demonstrate an increased burden of rare predicted pathogenic variants in GWAS genes in both familial (OR=1.77, p=0.048) and sporadic MS cases (OR=2.5, p=0.0003), when comparing this load to the population of healthy controls.

Our results suggest the possible role of rare pathogenic variants in genes previously associated with MS in association studies. Furthermore, we report an increased overall burden of pathogenic variants within these genes in familial and sporadic cases with MS.

P09.102

Effect of genes in iron metabolism on multiple sclerosis development

N. Starčević Cizmarević¹, L. Lovrečić², B. Curko-Cofek³, V. Barac-Latas³, M. Kapović¹, B. Peterlin², S. Ristić¹;

¹Department of Biology and Medical Genetics, Faculty of Medicine, Rijeka, Croatia, ²Clinical Institute of Medical Genetics, University Medical Centre, Ljubljana, Slovenia, ³Department of Physiology, immunology and Pathophysiology, Faculty of Medicine, Rijeka, Croatia.

Introduction: Increased local iron concentration in brain parenchyma of multiple sclerosis (MS) patients is documented by magnetic resonance imaging, but role of iron in MS etiopathogenesis is still debated. Brain iron homeostasis is regulated by different factors, among which the transferrin and

hemochromatosis proteins seem to play a key role. The aim of study was to investigate whether HFE (C282Y, H63D), TF (P570S) and transferrin receptor (TFRC-S142G) gene variants contribute to MS development.

Materials and Methods: We genotyped 455 patients diagnosed with MS according to the revised McDonald criteria and 400 healthy controls from Croatia and Slovenia by PCR-RFLP or Real-time PCR method.

Results: A significantly higher frequency of the C282Y carrier mutation was observed in MS patients (6.3%) than in controls (3.1%) (P=0.033). Allele and genotypes frequencies for other polymorphisms did not differ significantly (P>0.05). A three year earlier onset was found in carriers of the C282Y mutation (P=0.106), and significantly earlier onset in TF-C2 homozygotes (P=0,016). Disease began eight year later in H63D homozygotes but statistical difference show borderline significance (P=0.056). Progression index of MS was higher in carrier of TFRC- S142G A allele also with borderline significance (P=0.051).

Conclusions: Our results indicate that HFE-C282Y mutation may be risk factor to MS susceptibility. Variants C282Y and TF-C2 are possible predictors for early onset of MS, while HFE-H63D prolong disease onset. Polymorphism TFRC-S142G might have influence on disease progression. Polymorphisms in HFE, TFRC and TF genes coding for iron binding and transporting proteins might contribute to pathogenesis of MS.

P09.103

Genetic basis of neurodegeneration with brain iron accumulation in Spanish population

C. Tello¹, V. Lupo¹, A. Darling², B. Pérez-Dueñas², C. Espinós¹;

¹Centro de Investigación Príncipe Felipe, Valencia, Spain, ²Hospital Sant Joan de Déu, Barcelona, Spain.

Neurodegeneration with brain iron accumulation (NBIA) is a heterogeneous group of inherited neurologic disorders characterized by progressive movement disorders and abnormal accumulation of iron in brain, specifically in the basal ganglia. Mostly affected are children in whom the progress of the disease is devastating and includes progressive slurred speech, dysphagia, dystonia, spasticity, parkinsonism, pure akinesia, oculomotor dysfunction, loss of vision and neuropsychiatric symptoms. There are 10 genes causing NBIA that resolve 80% of cases; the remaining patients are cataloged as idiopathic cases. The NBIA-causing genes play a role in multiple biological processes such as iron metabolism, mitochondrial dynamics, reactive oxygen species (ROS)-induced damage, lipid metabolism and autophagy. Our aim is the genetic characterization of patients with NBIA in Spanish population.

To establish the genetic basis of these patients we have analyzed the most common genes (*PANK2*, *PLA2G6*, *WDR45* and *C19orf12*) responsible for the disease by Sanger sequencing and Multiplex Ligation-dependent Probe Amplification (MLPA) in a clinical series of 57 patients diagnosed with NBIA.

To date we have achieved the molecular diagnosis for 40 NBIA patients: 31 patients carry mutations in *PANK2*, and 9 patients in *PLA2G6*. Eleven of these mutations are novel and functional studies are in progress with the aim to demonstrate its pathogenicity. No mutations were identified in the *C19orf12* or *WDR45* genes. We currently study the remaining six NBIA genes in the patients who remain undiagnosed by targeted next generation sequencing.

Copy number variants identification and clinical correlation in an adult population with intellectual disability and psychiatric/behavioural disorders

M. Viñas-Jornet¹, S. Esteba-Castillo², N. Baena¹, N. Ribas-VidaF, A. Ruiz¹, D. Torrents-Rodas³, E. Gabau³, C. Aguilera¹, R. Novell², M. Guitart¹;

¹Genetic Laboratory. Corporació Sanitària Parc Taulí, Sabadell, Spain, ²Specialized Service in Health Mental and Intellectual Disability, Parc Hospitalari Martí i Julià, Salt (Girona), Spain, ³Paediatric Service. Corporació Sanitària Parc Taulí, Sabadell, Spain.

Adults with unexplained intellectual disability (ID) have not been systematically addressed for genetic analysis. The goal of this study is to establish the genetic aetiology of 100 adult patients affected by dual diagnosis of mild (IQ=75-50) or moderate (IQ=50-35) ID and psychiatric/behavioural disorder. Different tests were used to evaluate cognitive and psychiatric profile. Patients were analyzed with a sequential genetic workflow, including molecular karyotype (array-CGH Agilent Technologies, 400K). Customized MLPA and FISH analyses were used to validate and determine the inheritance of pathogenic copy number variants (pCNV) and variants of unknown significance likely pathogenic (VOUSp).

We identified a genetic abnormality in 38 patients: 14 well known specific syndromes, 4 cases with chromosomal rearrangements and 20 cases with CNVs (8 pCNV and 12 VOUSp). A 2p16.2 deletion is the genetic basis in two

unrelated cases, describing a common cognitive, psychiatric and dysmorphic phenotype. Three unrelated patients present a 7q31 deletion as the putative genetic cause. A 15q14q15.1 duplication and an homozygous 3q29 duplication were identified in two independent siblings suggesting that both regions could be dosage sensitive.

Eleven genes included in pCNV or VOUSlp had been related to a wide range of psychiatric phenotypes: *NRXN1*, *IMMP2L*, *MSRA*, *SLC1A1*, *CTNNA3*, *SOX5*, *UBE3A*, *CHRNA7*, *SPRED1*, *PRKCA* and *SHANK3*. The CNVs contribute equally to both mild and moderate ID as well as to different psychiatric disorders even though the odds of having psychiatric co-morbidity was 4.22 times higher in patients with a causative CNV.

This work was supported by FIS(PI080778) and CIR(2010,2013,2014) grants.

Diagnosing Neuronal ceroid lipofuscinosis with Next-generation sequencing, an example

G. J. Braathen¹, S. Slinde², Ø. L. Busk¹, K. Tveten¹, Ø. L. Holla¹, H. T. Hilmarsen¹, J. R. Helle¹;

¹Section of Medical Genetics, Department of Laboratory Medicine, Skien, Norway,

²Department of Pediatrics, Telemark Hospital, Skien, Norway.

Introduction: The incidence of neuronal ceroid lipofuscinoses (NCL; CLN) in different countries vary between 0.5-3.9/100.000. NCLs are characterized by the intracellular accumulation of autofluorescent lipopigment storage material in different patterns ultrastructurally.

NCLs are clinically and genetically a heterogeneous group of neurodegenerative disorders. Originally, they were classified broadly according to age at onset. However with the identification of molecular defects, the NCLs are now classified numerically according to the underlying gene defect. NCL2 refers to NCL caused by mutation in the CLN2 gene (TPP1), regardless of the age at onset.

Next-Generation Sequencing (NGS) is fairly quick and to a low cost compared with old methods when sequencing many genes simultaneously. Exome sequencing is a technique for sequencing all the protein-coding genes in a genome. It is also possible to filter out and investigate for only the genes of interest.

Methods: A five year old girl developed early sleep problems that abated and during second year of life speech problems having only few words. From three years of age she had seizures, frequent falls, sleep problems and emotional stress. Her 14 months old brother had sleep problems and cries.

Results: Filtered NGS exome for CLN genes identified a compound heterozygous mutation in the TPP1 gene, i.e. NM_000391.3 c.509-1G>A and c.622C>T p.(Arg208*) consistent with the disorder NCL2.

Conclusion: These two variants have never been described together causing NCL2.

Filtered NGS exome is a powerful, cost- and time-effective tool to investigate all known genes causing NCLs.

Thus, MRI and eye investigation have been postponed.

P09.106

Genetic Contributions to Neuroticism-Related Brain Structures

H. Kim¹, H. Kang², S. Kim¹, Y. Chang³, S. Ryu³, H. Shin³, D. Lee³, H. Kim¹;

¹Ewha Womans University, Seoul, Korea, Republic of, ²Seoul National University, Seoul, Korea, Republic of, ³Sungkyunkwan University, Seoul, Korea, Republic of.

Introduction: Neuroticism is a moderately heritable personality trait considered to be a risk factor for stress and impaired health as well as psychiatric disorders. Our aim in this study is to test whether neuroticism is associated with brain volumes and to identify single nucleotide polymorphisms (SNPs) associated to the neuroticism-related brain volumes.

Materials and Methods: In this study, we combined genetics, imaging and personality data obtained from 123 women between the ages of 21-64 from Kangbuk Samsung Cohort Study. A total of 5,862,302 SNPs were tested for association with brain volume in a genome-wide association study. We also investigated if the identified SNPs are operating as a eQTL and in which brain region using Braineac web-based resource.

Results: High neurotic individuals showed increased volumes in precuneus, superior parietal lobule, middle frontal gyrus, and superior frontal gyrus. None of the genetic markers reached genome-wide significance. However, SNPs near *ADSS* for superior parietal lobule, within *RFXO1* for middle frontal gyrus, within *KCNH8* for superior frontal gyrus were showed suggestive p-values ($< 1 \times 10^{-5}$). The genes were previously reported to be associated with neurological phenotypes. Furthermore, allelic differences in the SNPs were associated with differential mRNA expression in the cis-acting region.

Conclusion: Our results could improve our conceptual framework of processes related to brain volume reduction and facilitate a better understanding

of neuroticism personality.

This research was supported by the National Research Foundation of Korea (NRF) funded by the Ministry of Education (NRF-2013R1A1A2062702) and Ministry of Science, ICT & Future Planning (NRF-2014R1A2A2A04006291).

P09.107

Exome sequencing identifies rare pathogenic NGLY1 mutations in a patient with developmental delay, seizures and hyperkinetic movement disorder

H. Daoud¹, J. Wagner², O. Jarinova¹, K. Boycott^{1,2}, H. McMillan³, D. A. Dymant^{1,2};

¹Department of Genetics, Children's Hospital of Eastern Ontario, Ottawa, ON, Canada,

²Children's Hospital of Eastern Ontario Research Institute, Ottawa, ON, Canada, ³Division of Neurology, Children's Hospital of Eastern Ontario, Ottawa, ON, Canada.

Background: N-glycanase 1 is a conserved cytosolic enzyme that catalyzes the deglycosylation of misfolded N-linked glycoproteins, an essential step in the endoplasmic reticulum-associated degradation pathway (ERAD). N-glycanase 1 deficiency, caused by loss-of-function mutations in the NGLY1 gene, is an extremely rare autosomal recessive disorder characterized by global developmental delay, movement disorder, hypotonia, liver dysfunction, and alacrima. To our knowledge, a total of 14 patients have been reported in the literature thus far.

Methods: We investigated a 23-month-old girl who presented with seizures, developmental delay, hypotonia, and hyperkinetic movement disorder. We performed whole Exome Sequencing (WES) in the patient and her parents using the Nextera Rapid Capture Exome kit (37 Mb) and the NextSeq 500 platform (Illumina).

Results: We identified compound heterozygous mutations in the NGLY1 gene: a nonsense mutation c.A1201A>T (p.Arg401*) inherited from the mother, and a splicing mutation c.1150-1G>C (p.?) inherited from the father. The nonsense mutation c.A1201A>T is the most common deleterious allele identified in patients with N-glycanase 1 deficiency. The splicing mutation c.1150-1G>C is novel and we show that it leads to an in-frame deletion (p.Asp335_Val384del) that removes part of the transglutaminase-like (catalytic) domain of the protein.

Conclusion: We report here an additional patient with compound heterozygous mutations in the NGLY1 gene detected by WES. The phenotype of our patient is consistent with the previously reported cases and further support that mutations in the NGLY1 gene lead to a recognizable disorder.

Serbia, ⁴Institute of Medical Genetics, CC Ljubljana, Ljubljana, Slovenia, ⁵Institute of

Neurogenetics, University of Luebeck, Luebeck, Germany.

Parkinson's disease (PD) is the most common movement disorder, clinically characterized by resting tremor, bradykinesia and muscle rigidity. Key neuropathological substrate of PD is loss of dopaminergic neurons in basal ganglia and presence of intraneuronal Lewy bodies. Vaste majority of PD cases have multifactor etiology but in 10-15% patients monogenic pattern of inheritance is noticeable, with familiar occurrence and/or early onset of disease. In the past decades at least 18 PARK disease causing and susceptibility loci have been identified, but genetic basis of PD is not fully clarified. Recent Next Generation Sequencing (NGS) methods have their application in this field also. We describe here results of NGS implementation in five PD families from Serbia. These patients have been previously screened for the most common mutations in PARK loci (LRRK2, PARKIN, PINK1, DJ1, GBA, VPS35) by direct sequencing of target regions and MLPA method. NGS was performed on Illumina MiSeq platform using TruSight One panel. After bioinformatic analysis of NGS data we detected novel TGM6 c.1076C>T (p.Pro359Leu) variant in early onset PD family with three affected members in two consecutive generations. Mutations in TGM6 usually cause spinocerebellar ataxia type SCA35, but it has previously been shown that mutations in other SCA genes are clinically present with PD. In another PD family NGS revealed previously detected susceptibility variant N370S in GBA gene. In the remaining PD families NGS did not reveal significant pathogenic variants. Our results support complexity of PD genetics, and illustrate power and challenges of NGS methods in this field.

¹Instituto de Investigación Sanitaria, Santiago de Compostela, Spain, ²Universidad de Santiago de Compostela, Santiago de Compostela, Spain, ³Fundación Pública Galega de Medicina Xenómica, Santiago de Compostela, Spain, ⁴Complejo Hospitalario Universitario, A Coruña, Spain, ⁵Complejo Hospitalario Universitario, Ourense, Spain, ⁶CIBBIM – Nanomedicina, Vall d'Hebron Institut de Recerca, Barcelona, Spain, ⁷Complejo Hospitalario Universitario, Vigo, Spain, ⁸Complejo Hospitalario, Pontevedra, Spain, ⁹Hospital Universitario Lucus Augusti, Lugo, Spain, ¹⁰Complejo Hospitalario Universitario, Santiago de Compostela, Spain.

Introduction: Niemann-Pick type C (NPC) is an autosomal recessive lysosomal disorder resulting from mutations in the NPC1 or NPC2 genes. Adult onset NPC has neuropsychiatric manifestations that can mimic several neurodegenerative diseases. Aim: Multicenter, transversal study to screen for NPC in adult patients with undiagnosed neurodegenerative disorders.

Materials and Methods: 1) Patient selection through retrospective revision of clinical records in neurology departments from Galicia (Spain). 2) Major inclusion criteria: progressive gait disorder, involuntary movements, supranuclear gaze palsy and cognitive decline. Secondary criteria: prolonged neonatal jaundice, visceral involvement, psychiatric symptoms, epilepsy, cataplexy and family history. 3) A Next Generation Sequencing panel was designed for Ion PGM® using AmpliSeq® Designer program with 99.8% coverage of NPC1 and NPC2. 4) Biochemical and cellular tests were performed in patients with suspected genetic variants.

Results: Eighteen patients (13 men, 5 women, ages 22-66) were included. Altogether, we identified five potentially pathogenic variants in NPC1 and one in NPC2. The diagnosis of NPC was confirmed in two cases with homozygous NPC1 mutations). One patient carrying only one splicing variant had a late disease onset and intermediate Filipin test result. Two patients had variants of as yet uncertain significance.

Conclusions: NPC should be considered in adults with neuropsychiatric disorders of unclear etiology. Analysis of gene panels via NGS provides an efficient diagnostic strategy. Genetic confirmation facilitates detection of additional family cases, allows early treatment and genetic counseling. The Filipin test aids in the interpretation of variants of uncertain significance. Funding: PI12/00742, Actelion Pharmaceuticals, Innopharma Project (MINECO-FEDER).

The evolving NRXN1 deletion syndrome; reduced penetrance, variable expressivity and complex counselling

M. M. Al Shehhi¹, J. E. Fitzgerald², V. McInerney³, S. Shen³, D. R. Betts¹, L. Mc Ardle¹, K. Gorman⁴, M. King⁴, A. Green¹, L. Gallagher², S. A. Lynch^{4,5};

¹Department of Clinical Genetics, OLCHC, Dublin, Ireland, ²Trinity Centre for Health Sciences, St. James's Hospital, Dublin, Ireland, ³Regenerative Medicine Institute, School of Medicine, NUI, Galway, Ireland, ⁴Children's University Hospital, Temple St., Dublin, Ireland, ⁵Academic Center on Rare Diseases, School of Medicine and Medical Science, University College Dublin, Dublin, Ireland.

Background: Deletions or mutations of neurexin-1 (NRXN1) remain a difficult counselling issue because of reduced penetrance and variable expressivity. We have reviewed 33 families known to our center to estimate penetrance and document the phenotype.

Method: Cases were identified by database review within our center or through collaboration with colleagues. Genomic data, clinical phenotype & family history information was extracted and analyzed. Penetrance was calculated using the method proposed by Kirov et al, 2014. The unaffected carriers were used as controls.

Results: We identified 53 NRXN1 deletion carriers and one individual with a point mutation of whom 37(69%) had a definite phenotype. 33 were probands and the rest were first degree relatives. 87% of probands were investigated because of unexplained developmental delay mostly speech and language or learning difficulties and 63% had Autism. 17/53 were intronic deletions. The overall penetrance was ~66% for any phenotype and 40% for Autism. Congenital anomalies were reported in 7 infants and seizures in 6. Conclusion: Our data suggest that neurexin-1 deletions present with a variable phenotype and are not fully penetrant. Intronic deletions are pathogenic. Whilst, a parent that carries the deletion has a 50% risk of passing it on, the risk of a child with the deletion developing Autism is approximately 40%.

Genetic counselling remains problematic as the additional factors that trigger the phenotype are unclear and impossible to predict. Larger studies will help remove ascertainment bias. Further biological studies may help us understand the variability observed.

P09.112

Deconstructing obsessive-compulsive disorder by whole exome sequencing and rare variant association study

L. Domenech¹, R. Rabionet¹, G. Escaramís¹, E. Real², D. Trujillano¹, H. Susak¹, M. Bosio¹, S. Ossowski¹, A. Carracedo³, P. Alonso², X. Estivill¹;

¹Centre for Genomic Regulation (CRG), The Barcelona Institute of Science and Technology, Barcelona, Spain, ²Hospital Universitari de Bellvitge, IDIBELL, L'Hospitalet de Llobregat, Spain, ³Santiago de Compostela University, Santiago de Compostela, Spain.

Obsessive-compulsive disorder (OCD) is a neuropsychiatric condition that affects 1-3% of the population worldwide. It is listed as the tenth most disabling illnesses of any kind. Family and twin studies demonstrated that OCD involves both environmental and polygenic risk factors. However, despite an abundance of candidate genes, linkage studies and GWAS, there has been very little progress towards elucidating the genetic causes of this disorder. This project represents a novel strategy that will contribute to explain the aetiology of OCD.

We performed whole exome sequencing of 306 unrelated OCD cases followed by a rare variant association study. Specifically, we aggregated exonic non-synonymous and splicing variants into genes and tested for association with OCD using a group of control exomes from our in-house database. We accounted for minor allele frequencies (prioritizing rare variants) and pathogenicity score. After implementing this study, we identified a list of genes harbouring a higher number of mutations in cases compared to controls. We then implemented a partial least square analysis to identify combinations of mutated genes that can distinguish between OCD cases and controls. We also performed a pathway enrichment analysis with the significant genes, finding enriched pathways related with brain neurodevelopment or function. Finally, we selected some of these genes for further analysis, including functional studies of the identified variants.

Stronger evidence of association for the significant genes identified will be obtained through replication in larger cohorts of OCD.

This work was supported by MINECO project SAF2013-49108-R. L.D. is supported by the Severo Ochoa program.

P09.113

Analysis of the role of copy number variation in Obsessive-compulsive disorder

D. Sanchez Chinchilla¹, L. Domenech¹, R. Rabionet¹, G. Escaramís¹, E. Real², D. Trujillano¹, H. Susak¹, M. Bosio¹, S. Ossowski¹, P. Alonso², X. Estivill¹;

Obsessive-compulsive disorder (OCD) is a neuropsychiatric disorder ranked by the World Health Organization among the 10 most debilitating disorders. The lifetime prevalence of OCD has been estimated to approximately 2% and, despite molecular studies have identified several relevant genes, much additional research is needed to establish definitive causes of the condition. In this study we tried to identify copy number variations (CNVs) conferring risk of OCD.

We have performed exome-sequencing on 306 OCD cases and more than 1000 non-OCD samples (control as well as other non-psychiatric disorders). Both NimbleGen and Agilent commercial exome capture kits were used for sequencing. In order to identify CNVs, we analyzed the data with ClinCNV (an in-house pipeline for CNV detection from exome data). Currently, we have performed the CNV calls in the OCD samples and are analyzing the remaining samples.

In the OCD cases, we identified an average of 33 CNV per individual, ranging in size from 1 kb to 3,5 Mb. Some of the detected variants were overlapping with known common CNVs. Some rare variants included relevant genes involved in psychiatric disorders. We will perform this analysis in the non-OCD samples and follow-up with association analysis and validation of relevant regions by direct typing in these and additional samples.

This work was supported by MINECO grant agreement SAF2013-49108-R.

Clinical and Genetic Features of PKAN Patients in a Tertiary Center in Turkey

N. H. Akcakaya¹, S. U. Iseri¹, E. Battaloglu², P. Tekturk³, H. Hanagasi⁴, M. Eraksoy³, U. Ozbek¹, Z. Yapici²;

¹Institute of Experimental Medicine (DETAE), Istanbul, Turkey, ²Bogazici University, Department of Genetics, Istanbul, Turkey, ³Istanbul University, Istanbul Medical Faculty, Department of Neurology, Division of Child Neurology, Istanbul, Turkey, ⁴Istanbul University, Istanbul Medical Faculty, Department of Neurology, Division of Movement Disorders and Behavioral Neurology, Istanbul, Turkey.

Introduction: Pantothenate kinase-associated neurodegeneration (PKAN), also known as neurodegeneration with brain iron accumulation 1 (NBIA1),

is caused by mutations of PANK2 gene. The major clinical types of PKAN's are early onset-rapid progressive form and late onset-slow progressive form.

Purpose: We aim to discuss clinical and genetic findings of 19 PKAN patients.

Method: Nineteen patients with prominent extrapyramidal symptoms and "eye-of-the-tiger" sign on the MRI, with clinically diagnosed PKAN included to the study. All patients were screened for PANK2 mutations. Medical history, neurological examination were documented. To predict the potential effects of novel variations on the PANK2 protein structure or function software in silico tools; Mutation Taster, SIFT and Polyphen and GeneSplicer were used.

Results: Twelve patients had early onset-rapid progressive form and seven patients had late onset-slowly progressive form. The presenting features were dystonia and gait disturbance in early onset patients whereas late onset presenting symptoms were varied. Mutation screening reveals five novel and six previously reported mutations. Beside exonic missense mutations and deletions; intronic mutations were also identified. Except one patient, all cases harbored the mutations in homozygous state.

Conclusion: The current report is first patient series of PKAN from Turkey associated with five novel inherited PANK2 mutations and shows a clear-cut genotype-phenotype correlation with a highest rate of homozygosity.

Funding: This work was supported by the grant of Scientific Research Projects Coordination Unit of Istanbul University, Project Number: 51985; Istanbul Development Agency, Project Number: TR10/15/YNK/0093.

P09.115 Parkinson's disease: identification of new variations in protein and antisense genes

M. Valente¹, R. Zangaglia², S. Gagliardi¹, I. Palmieri¹, I. Ricca¹, S. Zucca¹, C. Pacchetti², C. Cereda¹;

¹Center of Genomics and post-Genomics, C. Mondino National Institute of Neurology Foundation, Pavia, Italy, ²Parkinson's Disease and Movement Disorders Unit, C. Mondino National Institute of Neurology Foundation, Pavia, Italy.

Background. Deep sequencing technologies have revolutionized genetic studies, prompting innovative theories for Parkinson's Disease (PD). In addition to canonical protein genes associated with PD, potentially relevant antisense (AS) genes have been discovered as PINK1-AS. Variations in AS genes may interfere with protein gene regulation, affecting PD phenotype expression.

Objective. Identification of new genomic variants in both protein and AS genes in PD patients and expression of sense and AS genes in peripheral blood mononuclear cells (PBMCs).

Methods. Next Generation Sequencing analysis has been performed in a cohort of 80 Italian PD patients. True Seq Custom Amplicon Illumina platform was composed by PARK2, PINK1, DJ-1, LRRK2, SNCA, UCHL1, EIF4G1, ATP13A2, VPS35 and GBA genes. AS and protein coding gene expression was verified via RT-PCR.

Results. Data analysis showed the presence of new non-synonymous mutations in PARK2, LRRK2, PINK1 and ATP13A2. For mutations in PARK2 (p.W447G, p.R191Q), LRRK2 (p.L1784F, p.L2425V) and PINK1 (p.A124V) the in silico prediction (PolyPhen2 and Mutation Tester) supported its pathological implication, while the mutation in ATP13A2 (p.N1091S) resulted neutral. Regarding new AS genes, we found a not yet described SNCA-AS, aside from PINK1-AS and UCHL1-AS. An increase expression of AS versus sense genes was reported for SNCA-AS and UCHL1-AS in PD patients; a similar trend was observed in controls.

Discussion. NGS data indicated variations both in protein and AS genes, opening intriguing perspectives in PD genetics. In PBMCs, the expression of AS genes significantly increase respect to sense genes. Moreover, variation in AS genes are specific for antisense.

P09.116 Alteration of the splicing forms of the 5'-UTR of DJ-1 (PARK7) in SNPs related to Parkinson disease in Basque population

F. Cardona^{1,2}, V. Andreu-Fernández¹, J. Hernández-Baixauli¹, A. Baquero-Vaquero¹, I. Nebot¹, J. Martí-Massó^{3,2}, A. López de Munain^{3,2}, J. Pérez-Tur^{1,2,4};

¹Unitat de Genètica Molecular. Instituto de Biomedicina de Valencia. Consejo Superior de Investigaciones Científicas, Valencia, Spain, ²CIBERNED, Madrid, Spain, ³Instituto Biodonostia. Hospital Universitario Donostia, San Sebastián, Spain, ⁴Unidad Mixta de Investigación en Neurología y Genética Molecular. Instituto de Investigación Sanitaria La Fe (IIS La Fe), Valencia, Spain.

Introduction: DJ-1 (PARK7) codifies a chaperone with protease activity involved in stress response, particularly under oxidative conditions. This protein is also involved in mitochondria homeostasis, in collaboration with

Parkin and PINK1. Mutations in this gene have been associated to autosomal recessive Parkinson disease. In our group, genetic studies in a Basque population have shown a positive association of two single nucleotide polymorphisms (SNPs) near an area of alternative splicing in the 5'-UTR of DJ-1. Here we intend to determine how these SNPs affect the expression of the gene and if they affect the isoform ratio.

Material and methods: We used the exon trapping assay modified for exon 1, which does not contains naturally a splicing acceptor site. The quantification of the splicing forms was performed by RT-qPCR. To study the effect of the variants of the 5'-UTR in gene expression regulation, we used constructs with luciferase under the control of SV40 promoter and the different forms of the 5'-UTR of DJ-1. All the plasmids were transfected in SHSY-5Y cell line differentiated to dopaminergic neuronal phenotype, checking the differentiation by determination of the expression of tyrosine hydroxylase and by cell morphology.

Results: Preliminary studies show that the different alleles of these SNPs affect the ratio of the different splicing forms, and therefore the expression of the gene.

Conclusions: Two SNPs were found as associated to Parkinson disease in this population and the genotypes associated to the disease alter the correct expression of DJ-1.

P09.118 Search for genetic markers involved in Impulse Control Disorder in Parkinson's Disease: preliminary findings.

X. H. Castro Martínez¹, C. Martínez-García², P. J. García-Ruiz², J. C. Martínez Castrillo⁴, L. Vela⁵, M. Mata⁶, I. Martínez-Torres⁷, F. Palau¹, J. Hoenicka¹;

¹Institut de Recerca Pediàtrica Hospital Sant Joan de Déu, Barcelona, Spain, ²Centro de Investigación Príncipe Felipe, Valencia, Spain, ³Fundación Jiménez Díaz, Madrid, Spain, ⁴IRYCIS, Hospital Universitario Ramón y Cajal, Madrid, Spain, ⁵Hospital Universitario de Alorcón, Alorcón, Spain, ⁶Hospital Universitario Infanta Sofía, Madrid, Spain, ⁷Hospital Universitario La Fe, Valencia, Spain.

Introduction: Impulse control disorders (ICDs) comprise a wide spectrum of impulsive/compulsive behaviors frequently found in patients with Parkinson's disease (PD) receiving antiparkinsonian treatment. Here, we studied in PD patients three genes that code for proteins involved in meso-cortico-limbic circuit in the brain: i) ANKK1 for dopamine synthesis; ii) DRD3 for the dopaminergic receptor D3 and iii) SCL6A3 for the dopamine transporter.

Methods: Up to date, 33 early-onset PD patients (age below 45) have been recruited from the Spanish ICD Multicenter Study. ICD were assessed using the QUIP questionnaire. This test has been validated for each ICD with a potentially addictive reinforcement (ICDARs) as well as for punning.

Results: In the early-onset PD sample several tendencies were appreciated (Table): i) ANKK1, there is an overrepresentation of the A1+ genotype not only in the total sample (p=0.056) but also in ICD+, ICDAR and punning; ii) DRD3, the homozygous Ser9/Ser9 genotype seems to be protective factor; and iii) SCL6A3, the A9+ genotype seems to be a risk factor for ICD+ and punning. By contrast, in the classical PD sample, none of the genes were associated with the exception of SCL6A3 that showed the A9+ genotype overrepresented in the total sample (p=0.05).

Conclusion: Genetic factors associated with ICD in PD may be different depending on the age of onset.

Funding: Instituto de Salud Carlos III PI11/0731

LRKK2, GBA and SMPD1 founder mutations and Parkinson's disease in Ashkenazi Jews

E. Dagan¹, I. Schlesinger^{2,3}, A. Kurolop^{4,3}, M. Ayoub⁴, M. Nassar², J. Peretz-Aharon^{2,3}, R. Gershoni-Baruch^{4,3};

¹Department of Nursing, University of Haifa, Haifa, Israel, ²Department of Neurology and the Cognitive Neurology Institute, Rambam Health Care Campus, Haifa, Israel, ³The Ruth and Bruce Rappaport Faculty of Medicine, Technion - Israel Institute of Technology, Haifa, Israel, ⁴Institute of Human Genetics, Rambam Health Care Campus, Haifa, Israel.

Background: Parkinson's disease (PD) has been associated with mutations in leucine-rich repeat kinase 2 (LRRK2), glucosidase beta acid (GBA), and sphingomyelin phosphodiesterase 1 (SMPD1), more so in the Ashkenazi Jewish population. Here we describe the clinical characteristics of 271 PD patients and compare carriers of Ashkenazi founder mutations in the aforementioned genes to PD patients who are non-carriers of such mutations. **Methods:** The study cohort is composed of 271 Ashkenazi PD patients, previously reported by us (Dagan et al., 2015). Here we compare the clinical characteristics of PD patients stratified according to their carriage of founder mutations in the three causative genes (namely, SMPD1, GBA and LRRK2). PD patients, homozygotes for mutations in either GBA or LRRK2 and those who carried mutations in two causative genes were excluded. **Results:** Six (2.2%), 54 (19.9%), and 22 (8.1%) PD patients carried mutation in SMPD1, GBA or LRRK2, respectively. Post hoc analysis singled GBA carriers as having significantly earlier age at onset and two-sided clinical manifestation at diagnosis compared to all other PD groups - SMPD1 and LRRK2 carriers and non-carriers. Other clinical manifestations were comparable between studied groups. **Conclusion:** The overall clinical characteristics of PD patients carrying SMPD1, GBA, and LRRK2 mutations were similar to those of non-carriers. Although only GBA carriers demonstrate statistically significant earlier age of onset compared to non-carriers, it appears that LRRK2 and SMPD1 mutation carriers may reach significance with larger group numbers.

Conclusion: The overall clinical characteristics of PD patients carrying SMPD1, GBA, and LRRK2 mutations were similar to those of non-carriers. Although only GBA carriers demonstrate statistically significant earlier age of onset compared to non-carriers, it appears that LRRK2 and SMPD1 mutation carriers may reach significance with larger group numbers.

Association of functional RAGE gene polymorphisms in the pathogenesis of inflammatory with Parkinson's disease in Turkish population

H. Aslan¹, O. Cilingir¹, M. Ozdemir¹, B. Durak Aras¹, O. Kutlay¹, E. Erzurumluoglu¹, A. Afagh¹, M. Akinc², S. Ozkan², S. Artan²;

¹Eskisehir Osmangazi University, Faculty of Medicine, Department of Medical Genetics, Eskisehir, Turkey, ²Eskisehir Osmangazi University, Faculty of Medicine, Department of Neurology, Eskisehir, Turkey.

Parkinson Disease (PD) is a severe, progressive neurodegenerative disease. It is reported that genes responsible for the etiology of PD leads to the disease by the pathological mechanisms which cause neuron damages. A large number of polymorphic genetic changes are also known to pose a risk for Parkinson's disease.

Receptor for advanced glycation end-products (RAGE) gene encodes a protein which is expressed in microglial cells and this protein is also expressed in the central nervous system. Two distinct polymorphisms (374T>A, -429T>C and 63 bp Ins/Del polymorphisms) affect the RAGE expression. G82S polymorphism occurs as result of transition of serine in preference to glycine at the 82nd of the RAGE gene. The resulting polymorphic changes show an increase in ligand binding and downstream signaling.

The present study aims to investigate the relationship of -429T>C, -374T>A, 82G>S and 63 bp Ins/Del polymorphisms with PD. A total of 174 PD patients and 150 healthy-matched individuals in Turkish population were registered. Herewith, PCR-RFLP and ARMS methods were employed in order to be able to determine polymorphisms.

429T>C, -374T>A, and 82G>S polymorphisms showed significant differences between PD patients and controls ($p < 0.001$, $p < 0.05$, $P < 0.001$, respectively). However, no significant difference in the 63 bp Ins/Del polymorphisms could be seen between the groups. In conclusion 429T>C, -374T>A, and 82G>S polymorphisms may be related with inflammatory pathogenesis of PD. Since the analysis of these polymorphisms in PD is the first study in Caucasian population, the distribution of the alleles may shed light on future studies.

P09.121

Partial tandem duplication of the PDCD10 gene is a new mechanism of familial cerebral cavernous malformation

E. Borrás¹, I. Hernan¹, M. Gamundi¹, B. Mañé¹, B. Pascual¹, M. Font², D. Armengo³, M. Carballo¹;

¹Unitat de Genètica Molecular, Hospital de Terrassa, Terrassa, Spain, ²Servei de Neurologia, Hospital de Terrassa, Terrassa, Spain, ³Servei de Medicina Interna, Hospital de Terrassa, Terrassa, Spain.

Introduction: Familial cerebral cavernous malformation (CCM) is inheri-

ted as an autosomal dominant trait and it is caused by mutations in any of three genes involved in vascular morphogenesis and/or remodelling: KRIT1 (40%), CCM2 (20%) and PDCD10 (10-20%). Up to date PDCD10 mutations include partial or whole gene deletion, nonsense and splicing mutations. Here we report the first case of a partial tandem duplication of PDCD10 causing familial CCM.

Materials and methods: A 38-year-old male patient presented with paresthesias/dysesthesias in the left hemibody and referred pain with crural predominance. Cranial MRI revealed multiple CCM with probable complicated right frontal cavernoma. After discarding a common small deletion in CCM2, we performed MLPA analysis of the three CCM genes. Findings were confirmed by long-range PCR using primers designed to detect a tandem duplication of PDCD10 exons 6-7, followed by primer-walking sequencing and analysis of mRNA expression.

Results: The patient carried a tandem duplication of PDCD10 exons 6-7, probably in a mosaic state according to MLPA ratios. Primer-walking defined rearrangement junctions in introns 5 and 7, and identified the ends of the 7812-bp duplication. Consistently, an aberrant PDCD10 minor transcript with a 245-bp insertion, corresponding to duplicated exons 6-7, was identified by cDNA amplification.

Discussion: Duplication of PDCD10 exons 6-7 causes a frameshift and a premature stop codon (p.Asp133Leufs*14) that results in a loss-of-function allele. Therefore, this novel mechanism should be taken into account when performing mutation screening in CCM.

P09.122

Novel PIGN mutations in a patient with multiple congenital anomalies hypotonia seizures syndrome

K. Stouffs^{1,2}, S. Seneca^{1,2}, A. Jansen^{3,2}, A. Gheldof^{1,2}, M. Bonduelle¹, L. De Meirleir^{3,2};

¹Center for Medical Genetics, UZ Brussel, Brussels, Belgium, ²Neurogenetics Research Group, Reproduction Genetics and Regenerative Medicine Research Group, Vrije Universiteit Brussel, Brussels, Belgium, ³Paediatric Neurology Unit, Department of Paediatrics, UZ Brussel, Brussels, Belgium.

Introduction: Mutations in the phosphatidylinositol-glycan biosynthesis class N (PIGN) gene are causing defects in the glycosylphosphatidylinositol (GPI) anchor biosynthesis pathway. Problems in this pathway are associated with multiple autosomal recessive disorders, often involving the central nervous system. Mutations in PIGN are causing 'multiple congenital anomalies hypotonia seizures syndrome 1' (MACHS1).

Materials and Methods: Exome sequencing was performed in an 12-year old child from non-consanguineous parents from Belgian/Peruvian origin. The girl presented with early onset hypotonia and developmental delay. She had dysmorphic features including a flat nasal bridge and prominent nose. Over the years she remained severely delayed and hypotonic with choreo-athetotic movements and generalized epilepsy, responsive to treatment. ERG was abnormal. The MRI of the brain showed progressive cortical atrophy.

Results: Exome sequencing showed the presence of biallelic variants, c.1158delG, p.Leu386Phefs*17 and c.T956G, p.Val319Gly in the PIGN gene (RefSeq: NM_012327.5) as Sanger sequencing analysis of the parents showed the independent segregation of the two observed alterations.

Conclusions: Exome sequencing showed the presence of two novel changes in the PIGN gene causing MACHS1. The c.T956G alteration is predicted to be pathogenic (SIFT score 0 and PolyPhen score 0.986); while c.1158delG change is completely disrupting the protein. Consequently, MACHS1 in this patient has been confirmed.

P09.123

Primary microcephaly (PM) and primordial microcephalic dwarfism: screening for gene mutations in a large series of 450 patients

S. Drunat^{1,2}, S. Passemar^{3,2}, Y. Vial¹, N. Pourveau¹, H. Cavé^{1,4}, A. Verloes^{3,2};

¹Molecular Genetics-Robert Debré Hospital, Paris, France, ²U1141, Paris, France, ³Clinical Genetics-Robert Debré Hospital, Paris, France, ⁴U1131, Paris, France.

PMs are rare autosomal recessive disorders with a cumulate incidence from 1/10.000 to 1/100.000 births, depending on geographic origin. Five groups of PM are usually distinguished: MicroCephal, Primitive Hereditary, primary microcephaly with chorioretinopathy, and primary microcephalic dwarfisms: Seckel syndrome, microcephalic osteodysplastic dwarfism type 2, and Meier-Gorlin syndrome. PMs are characterized by an occipito-frontal head circumference more than 2 SD below the mean for sex, age, and ethnicity at birth, and at least below - 3 SD after six months. PMs result from mutations in more than 30 genes, considerably complicating molecular diagnostics. Therefore, due to the great clinical and genetic heterogeneity, two third to one half of PM patients have no identified gene mutation.

Mutation screening was performed in 450 patients with PM by targeted Sanger sequencing, panel gene NGS or exome sequencing. Causative mutations were found in 86 patients (19%). The majority of mutations were found in ASPM (34/86), followed by WDR62 (10/86) and MCPH1 (10/86). We also identified mutations in a further 19 genes (CDK5RAP2, CEP152, CEP135, PCNT, STIL, CENPJ, TUBGCP6, EFTUD2, TUBGCP4, RNU4ATAC, CIT, WDR81, DYRK1A, LIG4, RECQL3, MECP2, TUBA1A, KIF11 and PHGDH). Furthermore, by exome sequencing, we highlight some unexpected diagnoses, missed because the patient's phenotype lacks the typical clinical picture. With mutations found in more than 20 genes, this study illustrates the extreme genetic heterogeneity of PMs. Due to phenotypic heterogeneity and atypical clinical presentation in some cases, exome sequencing for targeted gene panel negative patients is an efficient strategy to improve the diagnosis yield.

P09.124

D178N-129Val genotype in a family with Creutzfeldt-Jakob Disease

Ö. Türedi¹, O. Çilingir², M. Aksu³, E. Gümüş², H. Aslan², S. Artan², H. Karabulut¹;

¹Ankara University, Ankara, Turkey, ²Osmangazi University, Eskişehir, Turkey, ³Acibadem Kayseri Hospital, Acibadem University, İstanbul, Turkey.

Introduction: Prion diseases are a heterogeneous group of fatal neurological disorders which leads to rapid progressive neurodegeneration. 10-15% of cases are caused by pathological mutations of the normal prion protein gene (PRNP) and D178N-129V haplotype determines Creutzfeldt-Jakob phenotype.

Materials and Methods: We present here a 53-year-old woman whose disease started with memory deficits, difficulty in instrumental activities, progressive cognitive impairment and ataxia. The clinical picture slowly worsened to a state of akinetic mutism in about 5 years. FLAIR and T2-weighted magnetic resonance imaging documented signal hyperintensity in the head of the caudate nucleus, inferior temporal lobe and insula. Testing for PRNP mutations was performed on genomic DNA sample. Since Huntington disease has similar symptoms, HTT gene CAG repeat size was also investigated. **Results:** The patient was found to be negative for HTT mutation. PRNP analysis revealed a GAC to AAC mutation at codon 178 resulting in aspartic acid to asparagine substitution, and homozygosity for valine at codon 129. The patient's father and mother were third degree cousins and her father, uncle and two aunts died a history of a neurological disorder very similar to that of the proband, and her paternal and maternal grandmother died after a rapidly progressive dementia. Molecular genetic data are not available for them. But the patient's brother and three cousins had the same mutation with the patient.

Conclusion: Clinical diagnosis of Creutzfeldt-Jakob disease is still challenging for most clinicians and therefore genetic testing should be performed where available for both diagnosis and genetic counselling.

P09.125

Mutations in RAB12 alter the TfR signaling pathway

E. Koschmidder¹, A. Rakovic¹, F. Borngräber¹, A. Schmidt^{1,2}, I. Brønne³, S. Schaake¹, D. Alvarez-Fischer¹, A. Weissbach¹, H. Jabusch^{4,5}, E. Altenmüller⁶, C. Klein¹, K. Lohmann¹;

¹Institute of Neurogenetics, Luebeck, Germany, ²Kurt Singer Institute for Music Physiology and Musicians' Health, Berlin, Germany, ³Institute for Integrative and Experimental Genomics, Luebeck, Germany, ⁴Institute of Musicians' Medicine, Dresden, Germany, ⁵Institute of Music Physiology and Musicians' Medicine, Hannover, Germany.

Introduction: We recently identified two missense mutations (p.I196V; p.G13D) in RAB12 in patients with musician's dystonia (MD) by exome and genome sequencing.

RAB12 encodes a small GTPase that has been linked to lysosomal degradation of the transferrin receptor (TfR). TfR regulates the mitochondrial network integrity via a signaling pathway involving Mitofusin 2 (Mfn2). We investigated the effect of RAB12 mutations on this pathway.

Materials and methods: For functional characterization of RAB12 mutants, we used three different cellular models: 1) fibroblasts of two MD patients carrying I196V, 2) fibroblasts of healthy subjects overexpressing RAB12 wildtype (WT), G13D, and I196V, and 3) SH-SY5Y cells also overexpressing RAB12 WT, G13D, and I196V. GTPase activity, subcellular RAB12 localization, TfR degradation, Mfn2 protein levels, and the mitochondrial network were investigated.

Results: Elevated GTPase activity was detected in both mutants. Immunofluorescent staining revealed colocalization of ectopically expressed RAB12 with lysosomes and an altered subcellular distribution of both RAB12 mutants. There was no significant effect on TfR degradation or Mfn2 levels under basal conditions. However, we detected a reduction of Mfn2 in the G13D mutant compared to WT upon induction of oxidative stress. Fi-

nally, increased branching of the mitochondrial network was observed in fibroblasts overexpressing mutated RAB12 (I196V>G13D) compared to WT. **Conclusion:** Mutations in RAB12 lead to an altered protein function as demonstrated by changes in GTPase activity, subcellular localization of RAB12, and mitochondrial network. The mitochondrial integrity may be disturbed in mutant cells independently of TfR degradation.

P09.126

The role of MEIS1 and SKOR1 in restless legs syndrome

F. Sarayloo^{1,2}, A. Grant², H. Catoire², D. Rochefort², A. Dangoumau², P. A. Dion^{2,3}, G. A. Rouleau^{2,3};

¹Department of Human Genetics, McGill University, Montreal, QC, Canada, ²Montreal Neurological Institute, McGill University, Montreal, QC, Canada, ³Department of Neurology and Neurosurgery, McGill University, Montreal, QC, Canada.

Restless legs syndrome (RLS), a sleep-related sensory-motor disorder, is characterized by an irresistible desire to move the legs because of abnormal sensations, induced in the evening by rest or inactivity and are partially relieved by movement. This common disorder has a prevalence of up to 15% in western populations. A successful GWAS on RLS patients identified common variants in intron 8 MEIS1 and intergenic region between MAP2K5/SKOR1 genes associated with RLS. These results were also replicated by other independent studies. Our group subsequently showed that MEIS1 risk haplotype is associated with decreased mRNA and protein expression of this gene. We examined the SKOR1 mRNA expression in patient cells with the MEIS1 risk haplotype using q-RT-PCR. A significant decrease in SKOR1 mRNA expression level was observed. A luciferase reporter assay using SKOR1 promoter region in HeLa cells with down regulated MEIS1 expression (using siRNA), followed by an EMSA using three fragments of SKOR1 promoter region was performed. The results suggest a direct interaction between MEIS1 and SKOR1. Given the transcriptional regulatory function of these genes, we are overexpressing or knocking out MEIS1 and SKOR1 genes, separately in human cell lines. Whole transcriptome of these sets of cells as well as control cells with normal endogenous expression of the genes will be extracted to perform RNA-Seq experiment. We believe that differential expression analysis of RNA-Seq data will lead to identify the genes that are in fact regulated by these transcription factors, some of which might have direct roles in RLS pathological pathways.

P09.127

Genetic diagnosis of patients with overlapping clinic Rett-like by targeted panel of genes

N. Brandi Tarrau¹, P. Pacheco Fernández¹, S. Vidal Falco², L. Blasco Pérez², A. García Cazorla¹, M. O'Callaghan¹, C. Ortez González¹, M. Poo Arguelles¹, E. Gean Molins¹, M. Pineda Marfa², J. García Peñas³, M. Guitart⁴, J. Armstrong Morón¹;

¹Hospital Universitario San Juan de Dios, Barcelona, Spain, ²Fundación San Juan de Dios, Barcelona, Spain, ³Hospital Infantil Universitario Niño Jesús, Madrid, Spain, ⁴Corporación Sanitaria Parc Taulí, Barcelona, Spain.

Introduction: It has been studied patients with clinical Rett (RTT) without genetic diagnosis using the Next Generation Sequencing (NGS). This type of diseases requires clinical diagnosis. The finding of a mutation confirms the diagnosis, but not necessarily established it.

NGS using targeted panel of genes facilitates the simultaneous study of causative genes of RTT and others whose mutation produces a similar or overlapping clinic, such Pitt Hopkins and Ohtahara syndromes.

Material and Methods: It has been designed a gene panel of 17 genes related to the clinical RTT-like presentation by HaloPlex Target technology. Enrichment System, for Illumina Sequencing.

Sanger sequencing was used in exons not well covered. If do not find any change, MLPA was done by causative RTT genes.

Results: We have detected mutations in genes that do not cause RTT pathology in 14 of 187 studied patients with clinical Rett-like. A total of 8 patients presented mutations in STBX1 gene, related with Ohtahara syndrome and 6 patients were redirected as a Pitt-Hopkins, finding mutations in causative TCF4 gene.

The database HGMD-professional, dbSNP, 1000 G and predictions pathology programs (Polyphen 2.0 and SIFT) were consulted.

NGS variants have been verified by Sanger sequencing and studied the origin of the mutation in the parents.

Conclusion: The genetic study by NGS allows to study a larger number of genes associated with RTT simultaneously, redirecting genetic diagnosis to other syndromes. Significantly reduce response time and the cost of the study.

P09.128

Discovery of new genes in Rett syndrome patients by WES

S. Vidal Falcó¹, M. Lucariello², E. Vidal Ocabo², N. Brandi Tarrau³, E. Gerotina Mora⁴, P. Jurado², M. Esteller Badosa^{4,2}, M. Pineda Marfa¹, J. Armstrong Morón²; ¹Fundació Sant Joan de Déu, Barcelona, Spain, ²Institut d'Investigació Biomèdica de Bellvitge (IDIBELL), Barcelona, Spain, ³Hospital Universitari Sant Joan de Déu, Barcelona, Spain, ⁴Cancer Epigenetics and Biology Program (PEBC), Barcelona, Spain.

Introduction: Rett syndrome (RTT) is a developmental disorder of early onset, genetic basis, dominant inheritance and X-linked. There are described three genes that cause RTT: MECP2, CDKL5 and FOXP1. However, the etiology of 15% of RTT patients still remains unknown. Thus, the aim of this project is to identify new candidate genes in a cohort of patients with RTT phenotype without genetic diagnosis by Whole Exome Sequencing (WES). **Material and Method:** The patient and healthy parents without genetic diagnosis and negative CGHarray Cytoarray Plus (180K) (Agilent Microarrays) were analyzed by WES with TruSeq Sample Preparation Kit (Illumina). The filtering criteria used were: search mutations with 1000g MAF below 0.05 in genes with dominant inheritance, de novo, X-linked, autosomal subject to imprinting and/or with functional impact in the CNS. For the validated mutations in genes related with gabaergic pathways (SLC6A1 and GABBR2), we performed RT-qPCR (TaqMan Gene Expression) and Western Blotting assay of RNA and protein extraction from peripheral blood. **Results:** Most of the validated mutations are genes expressed in the central nervous system: ion channels and GABA/glutamate/acetylcholine pathways. The preliminary studies of the SLC6A1 and GABBR2 expression were not conclusive.

Conclusions: We do not only identify 1 gene which causes RTT-like phenotype. Pathway of genes has to be address to understand overlapping phenotype, instead to one disease only. Although blood tissue has convenient extraction, we cannot detect RNA and protein of these genes. Our next studies are performing RT-qPCR and Western Blotting assays with RNA and protein extraction from fibroblasts.

Study the effect of Melilotus officinalis extract on expression of Daxx, Nfkb, Vegf, Syp, Psen1, Mapk3, Mtap2 and Tnf genes in the streptozotocin-rat model of sporadic Alzheimer's disease

N. - Bazazzadegan¹, P. Daneshmand¹, M. Dehghan Shasaltaneh², K. Saliminejad³, K. Kamali³, M. Banan¹, H. Khorram Khorshid¹; ¹Genetics Research Center, University of Social Welfare and Rehabilitation Sciences, Tehran, Iran, Islamic Republic of, ²Laboratory of Neuro-organic Chemistry, Institute of Biochemistry and Biophysics (IBB), University of Tehran, Tehran, Iran, Islamic Republic of, ³Reproductive Biotechnology Research Center, Avicenna Research Institute, ACECR, Tehran, Iran, Islamic Republic of.

Sporadic Alzheimer's disease (SAD) is a multi-factorial disease caused by genetic, epigenetic, environmental and metabolic factors. Current understandings of the possible mechanisms of AD such as inflammation and oxidative stresses in the brain have led us to investigation of potential AD therapeutics. Currently herbal medicines with few side effects are in the point of attention. *Melilotus officinalis* is a herbal extract with possible role as an anti-inflammatory and anti-oxidant agent that can improve the blood circulation. Among genes that have been implicated in SAD, eight genes including *Daxx*, *Nfkb*, *Vegf*, *Syp*, *Psen1*, *Mapk3*, *Mtap2* and *Tnf-α* have shown significant statistical diversity in Alzheimer human brain and STZ rat model. With this knowledge these genes have been chosen to be investigated for neuroprotective effect of *Melilotus officinalis* extract. This study was performed by comparing the expression level of genes in the hippocampus of SAD rat model using qPCR in treated and untreated groups. The therapeutic effect was studied at the behavioral, learning and memory level using Morris Water Maze (MWM) test as well. After determination of gene expression in the mentioned groups using qPCR technique, the higher expression in *Syp*, *Tnf*, *Mapk3* and lower expression in *Daxx*, *Nfkb*, *Vegf*, *Psen1*, *Mtap2* were identified in SAD rat's model treated with herbal extract. To determine the significance of changes, using statistical analyses is underway. In MWM, the significant changes in spatial learning that had been observed in rat's model group did not show any alteration in the herbal-treated group.

Autosomal recessive spinocerebellar ataxia-16 (SCAR16) is a rare progressive neurologic disorder characterized by truncal and limb ataxia resulting in gait instability. We studied a consanguineous family with three affected siblings presenting with cerebellar ataxia as the main and initial features plus variable other features. The age of onset was 57 years for the male and 31 and 37 for the females. All patients showed marked cerebellar atrophy on MRI. Further, clinical signs of pyramidal tract damage with increased lower limb tendon reflexes were observed, but no Babinski response, ankle clonus, lower limb spasticity or hypogonadism was evident. The females were unable to walk whereas the male had only moderate walking disability. One of the females had a relatively more progressive disease course and additionally cognitive impairment and nystagmus. Homozygosity mapping on three patients followed by exome sequencing on one patient revealed a novel homozygous c.*240T>C variant in the 3' UTR of STUB1 gene. The variant is absent in all public databases, is highly conserved among species and most likely disrupts the polyadenylation signal in the mRNA, as indicated by online tool DNA Poly(A) Signal Miner. In contrast to the previous reports, our findings show that STUB1-ataxia can start even after age 50, and neither hypogonadism nor spasticity is an obligatory feature. Also, the family is a rare example of a neurologic disease with more severe manifestation in females. Functional studies are ongoing to investigate the mechanism of pathogenicity resulting from the mutation. TÜBİTAK Grant 114Z829 and Boğaziçi Research Fund 15B01M5

P09.131

Neurodevelopmental copy number variants are enriched for novel schizophrenia risk factors

E. Rees, K. Kendall, V. Escott-Price, A. Pocklington, P. Holmans, M. O'Donovan, M. Owen, G. Kirov, J. Walters; Cardiff University, Cardiff, United Kingdom.

Introduction: At least 11 rare copy number variants (CNVs) have been shown to be major risk factors for schizophrenia. These CNVs also increase risk for other early onset neurodevelopmental disorders (NDs). We hypothesised that additional CNVs associated with NDs are likely to be hitherto undiscovered schizophrenia risk factors.

Methods: We analysed 50 ND CNVs that have not been associated with schizophrenia in a new sample of 6,934 schizophrenia cases and 8,751 controls, combined with previously published datasets, for a total of 20,403 schizophrenia cases and 26,628 controls.

Results: Collectively, these ND CNVs were significantly enriched for schizophrenia. (P=1.01 × 10⁻⁶, OR=1.90). 19 CNVs have increased ORs for schizophrenia, compared to only 4 with ORs < 1, and no observations were made among cases or controls at the remaining 27 loci. For individual loci, 16p12.1 deletions are significantly associated with schizophrenia risk after correction for multiple testing (case rate=0.16%, control rate=0.045%, q-value=0.017, OR=3.3). Two additional new loci reached nominal levels of statistical significance (deletions at 2q11.2 and duplications at 10q11.21q11.23). Our results suggest a large proportion of the 50 loci are likely to be novel risk factors for schizophrenia, but due to their rarity, the available sample size precludes statistical confirmation. Additionally, analysis of our new dataset alone provides independent support for the 11 known schizophrenia risk loci.

Conclusions: We provide evidence for the existence of additional schizophrenia CNV loci, identify deletions of 16p12.1 as a novel schizophrenia risk factor, and strengthen the support for an aetiological overlap between neurodevelopmental disorders.

P09.132

The neurodevelopmental mechanisms of schizophrenia: input of maternal genes

I. Halayenka¹, N. Danilenko¹, E. Aksyonova¹, A. Liaudanski¹, V. Objedkov², A. Kandratsenka¹, N. Drobot¹, M. G. Siniauskaya¹, O. Levdanskaya¹, O. Davydenko¹; ¹Institute of Genetics and Cytology, Minsk, Belarus, ²Belarusian Medical State University, Minsk, Belarus.

Introduction: According to the hypothesis of neurodevelopment of schizophrenia, the causes of the pathology are hidden in early stages of brain development, long before the disease manifestation. The idea that mother bears genetic predisposition to the development of different fetal anomalies due to various complications of pregnancy can explain the link between these unfavorable maternal situations and development of schizophrenia in progeny.

Materials and Methods: The aim of our research was to compare polymorphic allele rates of inflammation: TNF α (-308 G/A), IL-6 (-174G/C), detoxication: GSTM1 (del), GSTT1(del), CYP1A1 (6235 T/C), CYP2E1 (-1019C/T), methylation: (MTHFR (677C/T), COMT (Val158Met), DNMT3b (-149C/T) genes in mothers of healthy and suffering from schizophrenia persons. 158 mothers of patients and 82 mothers with healthy progeny were studied by PCR-RFLP.

Results: Significant differences in the distribution of COMT and IL-6 alleles were revealed between two groups. For the mothers of patients val/COMT (OR=3,82; rs4680) and gc/IL-6 (OR=3,13; CI: 1.5829 - 6.1825; rs1800795) were proved to be risk genotypes; val/COMT (OR=2,31; CI: 1.4275 to 3,7552) and w1/CYP1A1 (OR=2,27; CI: 1.1515 to 4.4586; rs 4646903) were elucidated as risk alleles.

Also the genotype combinations frequencies of functionally different genes varied significantly in examined maternal groups.

Conclusions: These results support the general hypothesis that connects the predisposition to schizophrenia with the anomalies during the prenatal development of nervous system. Possibly, processes of inflammation, detoxication and methylation, biochemically interconnected and determined in the maternal genome, can guide the peculiarities of fetal neurodevelopment that later enhance the risk of mental disorder .

P09.133

Analysis of exome sequence data provides further support for the involvement of histone pathways in the aetiology of schizophrenia

D. Curtis^{1,2};

¹UCL Genetics Institute, London, United Kingdom, ²Barts and the London School of Medicine and Dentistry, London, United Kingdom.

Weighted burden pathway analysis was applied to whole exome sequence data for 2045 schizophrenic subjects and 2045 controls. More weight was given to variants which were rare and/or to variants predicted to have a functional effect. The 1454 „all GO gene sets, gene symbols“ pathways were downloaded from the Molecular Signatures Database and were used to define gene sets. Overall, there was a statistically significant excess of pathways with more rare, functional variants in cases than controls. Among these were pathways involved in histone modification, as well neuron differentiation and membrane and vesicle function. This bolsters the evidence from other studies that histone modification pathways may be important in the aetiology of schizophrenia.

Schizophrenia (SCZ) is a common neuropsychiatric disorder with an estimated heritability of approximately 60-80%. So far, only a small proportion of its underlying genetic risk factors have been identified. In the search for new risk factors, the analysis of multiply affected families is a very promising approach. Here, we present the first exome sequencing study in multiply affected families with SCZ from Indonesia. In each of the nine families, three to five genetically distant individuals were exome sequenced on an Illumina HiSeq2500. For the data analyses the Varbank pipeline (<http://varbank.ccg.uni-koeln.de>), and the CLC Biomedical Genomics Workbench were used. For the downstream analyses only those variants were taken into account that were predicted to be deleterious, rare in publically available databases (minor allele frequency <0.1%), experimentally confirmed, and co-segregating within the respective family. On average, we have identified 30-50 mutations per family that fulfil these criteria. Indonesian samples are underrepresented in the publically available databases. Therefore the most promising variants are genotyped in 1,000 controls from Indonesia to exclude population stratification. All variants with a MAF >0.1% are excluded. Not all genes implicated in our study will be relevant for SCZ. In search for additional genetic evidence for the implicated genes, we check publically available SCZ exomes (>2,500 index patients and >1,000 parent-proband trios) and additional 150 in-house exomes of severely affected SCZ patients for the presence of mutations in the identified genes. The study is ongoing and more detailed data will be presented at the conference.

Background

Schizophrenia (SZ) patients and their first-degree relatives show more minor physical anomalies (MPAs)/abnormal craniofacial features (CFs) than the general population. Family studies found moderate heritability of MPAs/CFs, but no genetic markers have been consistently identified. This study aims to 1) examine the relationships between MPAs/CFs and clinical characteristics; and 2) identify MPAs/CFs-related genetic markers in schizophrenia.

Methods

A genome-wide association study was performed in 1,123 SZ patients to search for genetic variants of MPAs/CFs. Using a 6-item questionnaire to collect MPAs/CFs measurements and calculate a MPAs score. Genotyping was conducted using the PsychChip microarray co-developed by PGC and Illumina. Polygenic risk score analysis was applied to predict individual MPAs score.

Results

A total of 1,067 SZ patients and 330,000 SNPs entered final analysis. Patients with more hair whorls (p<0.03) or nostrils anteverted (p<0.01) showed higher positive symptoms scores. Micrognathia was associated with both positive (p<.0003) and negative (p<.0003) symptoms. A polygenic score was significantly associated with patients with higher MPAs score (p<.0001). No single nucleotide polymorphism reached genome-wide significance.

Conclusions

Our finding suggests that multiple variants with small effects influence MPAs/CFs in SZ. Further investigation into the pathways or biological functions of these variants would help us understand more about MPAs and its relationship to SZ.

Chan School of Public Health, Boston, MA, United States, ⁶Cologne Center for Genomics, University of Cologne, Cologne, Germany, ⁷Institute for Psychiatric Phenomic and Genomic (IPPG), Ludwig-Maximilians-University, Munich, Germany, ⁸Department of Psychiatry Psychosomatic Medicine and Psychotherapy, University of Frankfurt, Frankfurt, Germany.

Schizophrenia (SCZ) is a common disorder with a lifetime risk of ~1%. Only few of the patients are additionally diagnosed with cataphasia (speech disorder) or periodic catatonia (movement disorder). To the authors' knowledge, this is the first study performing exome sequencing in patients with these infrequent subphenotypes.

Four genetically distant individuals (from three multiply affected families) were exome sequenced. For the data analyses the Varbank pipeline (<http://varbank.ccg.uni-koeln.de>), and the CLC Biomedical Genomics Workbench were used. The analyses included only those variants that were: (i) predicted to be deleterious (Combined Annotation Dependent Depletion score ≥ 15 ; <http://cadd.gs.washington.edu/>), (ii) rare in publically available databases (minor allele frequency $\leq 0.1\%$), (iii) confirmed by Sanger sequencing,

and (iv) co-segregating within the respective family. The initial results of the analysis revealed 35 variants in 35 genes. We are currently genotyping all identified variants in 1,000 German population-based controls and will exclude variants with a minor allele frequency $\geq 0.1\%$. In addition, we performed gene-based tests (as implemented in VEGAS) in a genome-wide association study of SCZ (35,000 patients, 100,000 controls).

To validate the candidate genes identified, we will: (i) check publically available SCZ datasets ($>2,500$ exomes) and additional 50 in-house multiply affected SCZ families for the presence of mutations in the identified genes; (ii) re-sequence the most promising genes in independent patients with SCZ and controls. So far, our most promising candidate genes are ZNF426, NOS3, and MECP2. For these, at least one de novo mutation in a patient with SCZ was reported in the literature.

P09.138

Identification of six novel mutations in SCN1A gene in Hungarian patients with epilepsy

J. Bene^{1,2}, K. Hadzsiev^{1,2}, T. Szabo¹, E. Pöstyeni¹, E. Kovacs^{1,2}, R. Szalai^{1,2}, A. Till¹, A. Fekete-Locsei¹, B. Melegh^{1,2};

¹Department of Medical Genetics, University of Pécs, Pécs, Hungary, ²Szentagotai Research Centre, Pécs, Hungary.

Introduction: Epilepsies are a heterogeneous group of neurological disorders characterized by recurrent and unprovoked seizures. Family and twin studies revealed that 30-40 % of the epilepsy cases have a genetic component. Monogenic form of epilepsy represents 1 % of the idiopathic epilepsies and mutations of ion channel genes play a major role in the pathogenesis of this type of epilepsy. Among the ion channel genes mutations in *SCN1A* (sodium channel type 1 alpha subunit) gene are the most frequent and most clinically relevant. The aim of our study was to characterize the *SCN1A* mutation spectrum in Hungarian epilepsy patients.

Materials and methods: We performed the *SCN1A* gene mutation analysis of 106 Hungarian patients with epilepsy phenotype using Sanger sequencing. **Results:** A total of 12 different point mutations were identified. Half of the mutations were newly identified in 9 patients and involve 4 (67%) missense and 2 (33%) frameshift mutations. Moreover we detected 6 different known pathogenic *SCN1A* mutations in 10 patients, in which 3 (30.0%) of them were missense mutation, 2 (20.0%) of them were nonsense mutation, also 2 (20.0%) of them were splice region variant, and one (10.0%) of them was a frameshift-causing deletion.

Conclusions: The *SCN1A* gene mutation analysis of Hungarian patients with epilepsy resulted in the identification of 6 novel mutations, which could expand the spectrum of *SCN1A* mutations and supports the current understanding of genotype-phenotype correlations.

P09.139

Rare compound heterozygous variants in SCN3A in a patient with congenital hypotonia, micrognathia, trismus and developmental delay

I. L. Mero¹, A. M. Øye¹, Y. Sheng¹, S. C. Wallace², T. Stiris³, H. E. Høgevoid⁴, B. Paus⁵, M. D. Vigeland¹, K. K. Selmer¹;

¹Department of Medical Genetics, Oslo University Hospital, Oslo, Norway, ²Department of Pediatrics, Oslo University Hospital, Oslo, Norway, ³Neonatal Intensive Care Unit, Oslo University Hospital, Oslo, Norway, ⁴Craniofacial team and Department of Plastic and Reconstructive Surgery, Oslo University Hospital, Oslo, Norway, ⁵Department of Medical Genetics, Oslo University Hospital and Institute of Clinical Medicine University of Oslo, Oslo, Norway.

We report on a girl born to healthy non-consanguineous parents who previously experienced a stillbirth due to an umbilical cord knot. The patient was born at 38 weeks gestation, birth weight 2.7 kg. She presented with pronounced hypotonia, reduced suck-swallow reflex, micrognathia and trismus. At 24 months she has global developmental delay. She is only able to open her mouth 1cm, however during sedation full-range movement of her jaw is obtained. There is no history of seizures. Brain MRIs were initially reported normal, whereas a recent MRI shows volume loss of the cerebral peduncles, hypoplastic corpus callosum and increased T2/FLAIR signaling in the thalamic regions. The findings are suspicious of periventricular leukomalacia, but the clinical presentation does not support this diagnosis.

Trio exome sequencing identified two missense variants in NM_001081676 (*SCN3A*): c.5278G>A (p.E1760K) and c.A154A>C (p.N52H), each inherited from one parent. The former variant has a frequency of 5.77e-05 in ExAC and the latter has never been observed in ExAC, 1000GP, ESP6500, nor in our inhouse Norwegian database. Both variants are highly conserved (GERP 6.17 and 5.32 respectively), predicted pathogenic by SIFT and PolyPhen2 and CADD-scores are 16.74 and 23.2.

SCN3A is a sodium channel predominantly expressed in brain and muscle,

and not previously reported to cause autosomal recessive disease. Heterozygous mutations have been linked to focal epilepsy of childhood and in one case to encephalopathy with multiple congenital anomalies. Additional cases are needed to confirm whether mutations in *SCN3A* could cause an autosomal recessive neurodevelopmental syndrome.

Patients with Phelan McDermid Syndrome, (or 22q13.3 deletion syndrome) often have intellectual disability (ID), language impairment and autism. *SHANK3* is one of the genes that contribute to the phenotype. There is a high clinical heterogeneity and the genotype-phenotype correlation is still unclear. Our French collaborative study aims to precise it and look for potential modifying genetic factors.

We reported genetic and phenotypic data from 78 patients, 73 carried a 22q13.3 deletion and 5 had a duplication ranging in size from 45.8 kb to 9.10 Mb.

The neonatal period revealed mild motor developmental delay in deleted carriers. All patients exhibited language disorder and 50% had no verbal communication. Autistic traits were reported in 50% of cases, unfortunately, objective tests were available only for three patients. Most patients had intellectual deficiency and medical comorbidity were also noted. Long-term follow up of two patients showed motor regression and acute psychiatric disorder episode at adulthood. Patients with duplication had language disturbance and three presented with autistic traits.

We studied the correlation between the size of the deleted segments and the main clinical features. We also analyzed the presence of other CNVs affecting gene coding sequences to detect potential "second hit" implicated in the clinical heterogeneity of the syndrome.

Interestingly, 2 patients with deletion had also a CNV at 16p11.2 involved in ASD, ID and obesity.

Based on the results of this pilot study, we aim to extend this research to other European and International centers to identify factors that modulate the severity of the disorder.

P09.141

Heterozygous HTRA1 mutations are associated with autosomal dominant cerebral small vessel disease

Introduction: Cerebral Small Vessel Disease (SVD) represents a heterogeneous group of disorders leading to stroke and cognitive impairment. Various monogenic forms have been reported. However, they only account for a minority of familial SVD patients.

Material and methods: Pangenomic linkage analysis and whole exome sequencing were used to identify candidate genes in an autosomal dominant SVD family for which known SVD genes had been excluded. Candidate genes were then screened in 201 unrelated probands with a familial SVD of

unknown etiology.

Results: A heterozygous variant within HTRA1 (Arg166Leu), absent from public databases and predicted to be deleterious by in silico tools was identified in all affected members of the index family. Ten probands out of the 201 unrelated familial SVD probands (4.97 %) harbored a heterozygous HTRA1 mutation predicted to be damaging. There was a highly significant difference in the number of likely deleterious variants in cases compared to controls ($p=4.2 \times 10^{-6}$; OR=15.4; CI=4.9-45.5), strongly suggesting causality. In vitro activity analysis of HTRA1 mutants demonstrated a loss-of-function effect. Clinical and MRI features of this autosomal dominant SVD differed from those of CARASIL (a very rare, autosomal recessive SVD form, caused by biallelic HTRA1 mutations) by a later age of onset and the absence of extraneurological features.

Conclusions: Our data demonstrate that heterozygous HTRA1 mutations are an important cause of familial SVD. Screening of HTRA1 should be considered in hereditary SVD patients. Investigation of the pathogenicity of these heterozygous mutations in the trimeric HtrA1 enzyme is ongoing.

P09.142

Compound heterozygous SPATA5 mutations cause progressive neurodegenerative disorder with microcephaly, seizures and hearing loss

K. Õunap^{1,2}, S. Pajusalu^{1,3}, K. Reinson^{1,2}, A. Kaasik⁴, I. Talvik⁵, Ü. Murumets¹, T. Reimand^{1,2,3},

¹Department of Genetics, Tartu University Hospital, Tartu, Estonia, ²Department of Paediatrics, Institute of Clinical Medicine, University of Tartu, Tartu, Estonia, ³Department of Biomedicine, Institute of Biomedicine and Translational Medicine, University of Tartu, Tartu, Estonia, ⁴Department of Physiology, Institute of Biomedicine and Translational Medicine, University of Tartu, Tartu, Estonia, ⁵Tallinn Children's Hospital, Tallinn, Estonia.

Tanaka et al. (2015) recently identified 14 individuals with microcephaly, developmental delay, intellectual disability, hypotonia, spasticity, seizures, sensorineural hearing loss, cortical visual impairment, and biallelic presumably disease causing variants in spermatogenesis-associated protein 5 (SPATA5). SPATA5 encodes a ubiquitously expressed member of the ATPase protein family which is involved in mitochondrial morphogenesis during early spermatogenesis. Here we report two siblings with similar phenotype and compound heterozygous mutations in the SPATA5 gene.

Index patient had developmental delay since 2 months of age and remarkable regression since 7 months. At 1y she had microcephaly (-2 SD), spasticity, dystonic movements, strabismus, no eye contact, sensorineural hearing loss and tonic-clonic seizures. Brain MRI showed moderate cerebral atrophy, a slightly elevated signal intensity in white matter, and atrophic caudate nucleus suggesting a neurodegenerative disorder. Lysosomal disorders have been excluded by enzyme analyses. Elder brother had similar progressive disease and both died at 3 years of age.

Whole exome sequencing in index case identified two rare heterozygous mutations in SPATA5 gene: c.250C>T p.Arg84* and c.989_991del p.Thr330del (NM_145207.2). Compound heterozygosity of both affected siblings and heterozygosity of only c.250C>T in the mother was confirmed by Sanger sequencing.

The described family supports the conclusion by Tanaka et al. that mutations in SPATA5 might affect brain development and function, resulting in microcephaly, developmental delay, and intellectual disability. We are currently performing functional studies on patients' fibroblasts to further assess the role of the SPATA5 mutations.

Multidisciplinary investigation of backward-speech trait suggests a link between RIC3, RIPK1, ZBED5 and working memory

S. Preković¹, D. Filipović Đurđević^{2,3}, G. Csifcsák⁴, O. Sveljo^{5,6}, O. Stojković⁷, F. Ceroni⁸, D. F. Newbury⁹,

Introduction: Working memory is essential for the development of many language-related traits. It has been suggested that the rare trait of backward-speaking is linked to working memory. This trait is described as an ability to spontaneously and accurately reverse words. Here we describe individuals (the father and daughter) from a Serbian family who have the

ability to speak backward voluntarily.

Materials and Methods: We employed behavioral tests to describe the trait and neuroimaging (EEG and fMRI) to study the neural processing behind backward-speech. Moreover, we investigated coding sequence changes through exome sequencing and copy number variations using SNP array data in this family.

Results: Behavioral data suggests that backward-speech loads heavily upon working memory. Event-related potentials above the frontal lobe are affected by word reversal and the maintenance of backward-words in working memory. fMRI revealed that the left fusiform gyrus may facilitate backward-speech in the daughter. Exome sequencing identified three novel coding variants of potential significance in the RIC3, RIPK1 and ZBED5 genes.

Conclusions: Our data suggest that in the daughter, backward-speech is afforded by an extraordinary working memory capacity. We hypothesize that this is served by cholinergic projections from the basal forebrain to the frontal cortex and supported by visual semantic loops within the left fusiform gyrus and that these processes may be mediated by a genetic mutation in the RIC3 gene which encodes a chaperone for nicotinic acetylcholine receptors.

Spinal lipoma as a dysembryogenetic anomaly: 4 unusual cases of ectopic iliac rib within the spinal lipoma

A. Accogli¹, M. Pavanello¹, P. Accorsi², P. De Marco³, E. Merello¹, P. Nozza¹, C. Fiorillo¹, L. Pinell⁴, A. Cama¹, A. Rossi¹, M. Catala^{4,5,6}, V. Capra¹;

¹Istituto Giannina Gaslini, Genova, Italy, ²U.O. Neuropsichiatria dell'Infanzia e dell'Adolescenza, Spedali Civili, Brescia, Italy, ³U.O.C. Neuroradiologia, Spedali Civili, Brescia, Italy, ⁴Fédération de Neurologie, Groupe hospitalier Pitié-Salpêtrière APHP, Paris, France, ⁵Sorbonne Universités, UPMC Université Paris 06, Paris, France, ⁶CNRS, Institut de Biologie Paris Seine (IBPS) – Developmental Biology Laboratory, Paris, France.

Background: Congenital spinal lipomas are closed spinal dysraphisms belonging to the Neural Tube Defects (NTDs) group. They include a broad spectrum of lesions ranging from simple lipomas of the filum terminale to complex malformations. On histological evaluation, various tissue components of ectodermal, mesodermal or endodermal origin are found within the lipomas, with prevalence for nerves and striated muscle. Overall, rib malformations have been occasionally observed in patients with NTDs and in NTD mouse models. However, an ectopic rib arising within the spinal lipoma and articulating with the iliac crest has not been reported in neither of them.

Cases: We describe four patients affected by lipomyeloschisis or lipomyelomeningocele, with an unusual fibrocartilaginous protuberance arising within the lipoma and connecting to one iliac crest, resembling an ectopic rib. Histological evaluation confirmed the presence of cartilaginous tissue.

Discussion: This anatomical feature is reminiscent of the so-called caudal appendages that can arise elsewhere from the midline. In our cases, the presence of the extra-rib in the sacral region suggests a defect of the genetic pathway that controls the specification of the antero-posterior identity.

Conclusions: We expand the clinical spectrum of fibrocartilaginous anomalies associated with spinal lipoma, suggesting the presence of an ectopic rib as a new possible phenotype in NTDs. A careful analysis by neuroradiologists and pathologists should be performed in spinal lipomas to assess the presence of an ectopic rib or other uncommon developmental anomalies. Furthermore, molecular studies are required to detect the genetic cause of this unusual phenotype.

In-vitro characterization of STUB1 mutations in recessively inherited spinocerebellar ataxia-16

Y. Pakdaman^{1,2}, M. Sanchez-Guixé^{1,2}, R. Kleppe^{3,4}, K. Heimdal⁵, P. M. Knappskog^{1,2}, I. Aukrust⁶, S. Johansson^{1,2};

¹Department of Clinical Science, University of Bergen, Bergen, Norway, ²Center for Medical Genetics and Molecular Medicine, Haukeland University Hospital, Bergen, Norway, ³Department of Biomedicine, University of Bergen, Bergen, Norway, ⁴K.G. Jebsen Centre for Neuropsychiatric Disorders, University of Bergen, Bergen, Norway, ⁵Department of Medical Genetics, Oslo University Hospital, Oslo, Norway.

Introduction: Autosomal recessive spinocerebellar ataxia-16 is caused by mutations in *STUB1* encoding the ubiquitin E3 ligase and dimeric co-chaperone CHIP. There is limited knowledge about the mechanisms whereby these mutations cause the disease. This study aims to characterize the structure and function of six previously published pathogenic CHIP mutations.

Material and methods: Six mutations E28K, N65S, K145Q, M211I, S236T, and T246M were made by site-directed mutagenesis, and purified as recom-

binant proteins from *E. coli*. The mutants were analyzed and compared with wild-type CHIP by ubiquitination activity assay, limited proteolysis assay, oligomerization analysis by gel-filtration chromatography, and circular dichroism.

Results: Only N65S and T246M showed impaired ability to ubiquitinate the HSC70 chaperone. The limited proteolysis assay showed an increased stability against trypsin digestion for N65S, while T246M and E28K were more rapidly cleaved than wild-type, indicating a less compact protein structure. By gel-filtration chromatography analysis N65S showed a sharp dimeric peak compared to T246 and E28K that both generated broad oligomeric peaks. K145Q, M211I and S236T behaved overall similar to wild-type CHIP. Further characterization is currently being performed using circular dichroism to analyze protein structure/stability, and in cellular systems to analyze subcellular localization.

Conclusion: Our results illustrate that some mutations known to cause recessive spinocerebellar ataxia-16 can affect protein structure and ability of CHIP to dimerize *in vitro*. Hence, we speculate that *STUB1* mutations might not only affect CHIP's E3 ubiquitin ligase properties and interaction with its chaperones, but may also affect its protein structure and possibly stability *in vivo*.

Synaptotagmin-1 mutation is a recurrent disorder of neurotransmitter release

K. Baker¹, S. L. Gordon², UK10K Consortium, M. A. Cousin³, F. L. Raymond¹;
¹Department of Medical Genetics, University of Cambridge, Cambridge, United Kingdom,
²The Florey Institute, Melbourne, Australia, ³Centre for Integrative Physiology, University of Edinburgh, Edinburgh, United Kingdom.

Synaptotagmin-1 (*SYT1*) is a calcium-binding synaptic vesicle protein required for both exocytosis and endocytosis. We recently described the first human condition associated with a rare variant in *SYT1*. The individual harbouring this variant presented with an early onset dyskinetic movement disorder, severe motor delay, and profound cognitive impairment. Structural MRI was normal, but EEG showed extensive neurophysiological disturbances. Trio analysis of whole-exome sequence identified a de novo *SYT1* missense variant (I368T). Expression of rat *SYT1* containing the equivalent human variant in WT mouse primary hippocampal cultures revealed that the mutant form of *SYT1* correctly localizes to nerve terminals and is expressed at levels that are approximately equal to levels of endogenous WT protein. The presence of the mutant *SYT1* slowed synaptic vesicle fusion kinetics, a finding that agrees with the previously demonstrated role for I368 in calcium dependent membrane penetration. Expression of the I368T variant also altered the kinetics of synaptic vesicle endocytosis. Subsequently, three further cases of neurodevelopmental disorder associated with de novo mutation in *SYT1* have been identified. In common with the first case, structural brain development is normal whilst cortical electrophysiology is severely disturbed, though no case has experienced overt seizures. Motor development is consistently less severely disrupted than communication and social development. Unpredictable deteriorations in behavioural function are reported in all cases. Together, the clinical features, electrophysiological phenotype, and *in vitro* neuronal phenotype associated with *SYT1* mutation highlight presynaptic mechanisms of synchronous neurotransmitter release and short term plasticity that mediate human motor control and cognitive development.

Behavioral analysis of mouse model with combined deficiencies of β -Hexosaminidase A and sialidase Neu3 reveals motor coordination impairment and memory loss

S. Akyildiz Demir¹, E. Erdemli², B. Demir³, T. Dalkara³, T. Miyagi⁴, V. Seyrantep¹;
¹Izmir Institute of Technology, Izmir, Turkey, ²Ankara University, Faculty of Medicine, Ankara, Turkey, ³Hacettepe University, Ankara, Turkey, ⁴Tohoku Pharmaceutical University, Miyagi, Japan.

Tay-Sachs disease is a severe lysosomal storage disorder caused by mutations in the HEXA gene coding for α subunit of lysosomal β -Hexosaminidase A enzyme, which converts GM2 to GM3 ganglioside. Unexpectedly, the HexA^{-/-} mice have a normal lifespan and show no obvious neurological impairments until at least 1 year of age, owing to the ability of these mice to catabolise stored GM2 ganglioside via sialidase Neu3 removing sialic acid into glycolipid GA2 which further processed by β -Hexosaminidase B, thereby bypassing the HexA defect. To elucidate whether sialidase Neu3 can contribute to GM2 ganglioside degradation, we generated mice model with combined deficiencies of β -Hexosaminidase A and sialidase Neu3. HexA^{-/-}Neu3^{-/-} mice are

healthy at birth but died at 1.5-4.5 months of age. Slow movement, ataxia and tremor are among neurological abnormalities. TLC and IHC analysis showed massive accumulation of GM2 ganglioside in brain. Electron and light microscopy analysis of brain cortex showed lysosomal storage disease pathology similar to Tay-Sachs patient's. Behavioral analysis including passive-avoidance, rotarod and water maze revealed age-dependent motor coordination impairment and memory deficit which indicate progressive neurodegeneration in HexA^{-/-}Neu3^{-/-} mice compared to HexA^{-/-}. The unexpected severe phenotype of HexA^{-/-} mice appeared to be influenced by the status of sialidase Neu3 gene.

Genetic variants of TREM2 associated with neurodegenerative disorders

B. J. Peplonska, M. Berdyski, M. Kobrys, C. Zekanowski;
 Mossakowski Medical Research Centre Polish Academy of Sciences, Warszawa, Poland.

Introduction: TREM2 encodes triggering receptor expressed on myeloid cells 2 expressed on the cell membrane of many types of immune cells including macrophages, dendritic cells, osteoclasts and microglia. Activation of the TREM2 receptor on microglia stimulates phagocytosis activity and decreases microglial proinflammatory responses. The protein may play role in cleaning damaged or apoptotic cells and cellular debris and help resolve damage-induced inflammation. Given the reported antiinflammatory role of TREM2 in the brain, mutations and polymorphic variants may increase the risk of neurodegenerative conditions such as Alzheimer's disease (AD), amyotrophic lateral sclerosis (ALS), and frontotemporal dementia (FTD). Materials and Methods: The study group consisted of: 250 neurologically normal controls, 150 AD, 192 ALS, 144 FTD patients. TREM2 exon 2 with flanking intronic sequences was mined using Sanger fluorescent method (ABI 3130) in the whole studied group.

Results: Six rare variants located in exon 2 of TREM2 were identified, predominantly in heterozygous state. Three of them (R62H, R62C, D87N) are present in all groups. Variant D87N in homozygous state was identified in one FTD patient. R98W was found only in one AD patient, T66T and T66M were identified in FTD group only. The results suggest that variant T66M is in linkage disequilibrium with R62C one.

Conclusion: Due to modulatory action of TREM2 on inflammatory immune responses in microglia, we suggest that mutations and polymorphisms in TREM2 could contribute to disease pathogenesis in the Polish population.

Introduction: Williams-Beuren Syndrome is a rare neurodevelopmental disorder caused by a heterozygous deletion of 26-28 genes on chromosome band 7q11.23 manifesting a characteristic cognitive and behavioral profile including intellectual disability, increased general anxiety, overfriendly personality and visuospatial deficits. The complete deletion (CD) mouse model, which carries the same deletion found in WBS patients, recapitulates relevant features of WBS neurocognitive phenotype and shows a reduction in spine density in CA1 hippocampus. However, the mechanisms underlying these phenotypes are still unknown.

Materials and methods: We used some behavioral paradigms related to memory function to study cognitive dysfunction in CD mice. We also investigated synaptic transmission and plasticity by recording excitatory postsynaptic currents (EPSCs) at hippocampal CA3-CA1 glutamatergic synapses. Finally, the expression of molecules associated with synaptic plasticity was characterized by immunofluorescence techniques.

Results: Behavioral characterization of CD mice showed cognitive dysfunction, specifically in spatial working memory. In addition, some alterations in synaptic transmission and plasticity were present in CA1 hippocampus of CD mice, including a significantly reduced long-term potentiation. We also observed molecular dysregulation of some synaptic plasticity markers such as a reduction in BDNF expression in pyramidal layer of CA1 in CD mice.

Conclusions: Taken together, these data suggest that behavioral and cognitive deficits of CD mice could be linked to alterations in glutamatergic synaptic transmission and plasticity in hippocampus. In addition, our results

identify dysregulation of some synaptic plasticity markers that could be potential targets for a pharmacological therapy.

Effects of GTF2I-GTF2IRD2 interaction on the Williams-Beuren syndrome cognitive phenotype

G. Albericio¹, A. Antonell², C. Borralleras^{3,1,4}, D. Pérez^{1,3,4}, L. A. Pérez Jurado^{1,3,4}, V. Campuzano^{1,3,4},

¹Universitat Pompeu Fabra, Barcelona, Spain, ²Neurology Service, Hospital Clínic, Barcelona, Spain, ³Hospital del Mar Research Institute (IMIM), Barcelona, Spain, ⁴Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), Barcelona, Spain.

Introduction: Williams-Beuren syndrome (WBS) is a rare neurodevelopmental disorder caused by a heterozygous deletion at chromosome band 7q11.23. Haploinsufficiency for two General Transcription Factor genes (GTF2I coding for TFII-I and GTF2IRD1 coding for BEN-GTF3) has been associated with the WBS cognitive profile. A multi-copy and variably deleted gene of the family, GTF2IRD2, antagonizes TFII-I's activity and may modulate executive function and cognition in WBS. Depending on deletion breakpoints, WBS patients express different GTF2IRD2 copy-number and isoforms, including a chimeric form.

Methods: We analyzed by immunofluorescence assays the subcellular localization of TFII-I in neuronal cultures of mice with the complete WBS-deletion (CD). The subcellular localization and interaction between different GTF2IRD2 isoforms and TFII-I was also studied by immunofluorescence and pull-down assays in COS7 cells.

Results: We observed a clear reduction of nuclear TFII-I in neurons of CD mice, consistent with gene dosage. GTF2IRD2 isoforms were differentially localized in the cells but all interacted with TFII-I. Transient expression of patient-derived chimeric GTF2IRD2 in neurons of CD mice resulted in an increased amount of nuclear TFII-I.

Conclusions: Our data show that interactions between GTF2IRD2 isoforms and TFII-I could affect the nuclear bioavailability of TFII-I and may explain part of the phenotypic variability in WBS. Considering the capital role of TFII-I dosage on WBS sociability and cognition, understanding these mechanisms might provide novel therapeutic targets for these features.

Association of serotonin transporter gene polymorphisms (5-HTTLPR and rs 25531) and life-histories with psychopathology vulnerability profiles: a study performed with healthy young adults

M. Alvarez^{1,2}, P. Pereira², L. Manco^{1,2}, S. Cherpe³, M. Cunha³, J. Pinto Gouveia^{4,3}, P. G. Mota¹;

¹Department of Life Sciences, University of Coimbra, Coimbra, Portugal, ²Research Center for Anthropology and Health, University of Coimbra, Coimbra, Portugal, ³CINEICC, University of Coimbra, Coimbra, Portugal, ⁴Faculty of Psychology and Education Sciences, University of Coimbra, Coimbra, Portugal.

Introduction: Variation in both 5-HTTLPR and rs25531 polymorphisms, at the serotonin transporter gene SLC6A4, is hypothesized to moderate the response to stress on depression by serotonin transporter levels and/or by amygdala structure. The aim of this study was to look for statistical interactions between genotypes, defined by both polymorphisms, and phenotypes, defined by levels of anxiety, depression and stress, under specific environmental risk factors in young adults.

Materials and Methods: A total of 300 Portuguese healthy young adults were assessed for: i) genotype at both 5HTTLPR and rs25531 segregation sites; ii) levels of anxiety, depression and stress estimated by EADS-21 scale; and iii) psychosocial environment stressors, including parents mental illness, childhood abuse and general well-being, using the CTQ and MHC scales, respectively. Statistical interactions between genotype, phenotype and the environmental variables were screened using Generalized Linear Models test (GLM), implemented in IBM SPSS 22.

Results: The allele's frequency spectrum found in Portuguese young adults is similar to those observed in other European population samples, and match the values predicted by Hardy-Weinberg equilibrium. Highly significant statistical interactions were found between SLC6A4 low transcriptional genotypes and levels of anxiety, depression and stress scored by EADS-21. Parents depression was the strongest environmental stressor for the development of mood symptoms ($p < 0.001$). Gender had not a significant effect ($p = 0.077$).

Conclusions: Our results confirmed the association of 5HTTLPR S and rs25531g alleles to mood symptoms and the usefulness of the interaction gene x environment experimental design in the interpretation of psychopathology vulnerability profiles.

Psychological consequences of pathway alterations as a target for genomic psychology

M. A. Zelenova^{1,2,3}, S. G. Vorsanova^{2,1,3}, Y. B. Yurov^{1,2,3}, A. M. Kazmin², I. Y. Iourov^{1,2,4};

¹Mental Health Research Center, Moscow, Russian Federation, ²Research and Clinical Institute for Pediatrics named after Y.E Veltishev at the Pirogov Russian National Research Medical University, Ministry of Health, Moscow, Russian Federation, ³Moscow State University of Psychology and Education, Moscow, Russian Federation, ⁴Department of Medical Genetics, Russian Medical Academy of Postgraduate Education, Ministry of Health, Moscow, Russian Federation.

Introduction. Genomic alterations to molecular pathways influence intellectual functioning. However, psychological consequences of genomic changes remain largely obscure. To get further insights into the emerging field of genomic psychology, new tools for correlating genomic and psychological data appear to be required. Here we propose an approach combining psychological evaluation using International Classification of Functioning (ICF-CY), chromosomal microarray and original bioinformatic approach for network based-classification.

Materials and methods. To test the approach, we studied 7 children (16 years) with varying degrees of intellectual disability, autism and congenital malformations. From the ICF-CY, we focused on general mental functions, communication and involvement.

Results. Three cases demonstrated copy number variations and losses of heterozygosity spanning genes involved in metabolic pathways (KEGG: hsa01100): PON1, PON2, PON3, UROC1, UGT1A8, UGT1A10. Bioinformatic analysis showed these genomic and epigenomic variations to underlie phenotypic features. Application of ICF-CY showed that all children had little to no phrasal speech (d1331), troubles maintaining cyclic interaction with a person (d3503) and about 50% success in responding to complex requests (more than 3 parameters) (d3102). All children were engaging in symbolic play and shared activities with adults.

Conclusions. The correlation between psychological and genomic data can shed light on molecular pathways to brain malfunctioning. Here, we demonstrated that an opportunity to obtain such correlation combining genomic, bioinformatic and psychological methodology does exist. In order to confirm the found typical features and the effectiveness of the approach it should be applied towards a larger cohort. Supported by the Russian Science Foundation (grant:14-15-00411).

A novel mutation in SLC16A2 gene in a Turkish boy with Allan-Herndon-Dudley Syndrome

E. Tasdelen¹, V. Bas², H. Aslan¹, O. Cilingir¹, E. Erzurumluoglu¹, M. Ozdemir¹, B. Durak

Aras¹, O. Kirkbyik², Y. Kutbay³, S. Artan¹;

¹Eskisehir Osmangazi University, Faculty of Medicine, Departments of Medical Genetic, Eskisehir, Turkey, ²Eskisehir State Hospital, Departments of Pediatrics Endocrinology, Eskisehir, Turkey, ³Tepecik Training and Research Hospital Department of Medical Genetics, Izmir, Turkey.

Allan-Herndon-Dudley syndrome (AHDS, MIM 300523) is an X-linked recessive neurodegenerative disorder, with severe mental retardation, an impaired speech ability, truncal hypotonia, poor head control, generalized muscle weakness, spastic quadriplegia, joint contractures, movement abnormalities and feeding difficulties in combination with changed thyroid hormone (TH) levels. The cases, have increased serum levels of fT_3 , while TSH concentrations are normal and low-normal fT_4 . Seizures, poor weight gain, hyperactive deep tendon reflexes observed in some patients. MCT8 is transporter triiodothyronine (T_3) hormone, and plays an important role to uptake into neuronal cells. Mutations in the MCT8, also known as SLC16A2, have been related with AHDS.

We here identified a five years old boy with developmental delay, truncal hypotonia, spastic paraplegia, psychomotor retardation, mild dysmorphic facial features and pathognomonic thyroid function tests, such as elevated fT_3 and low fT_4 levels. Elongated face, poor feeding, pectus carinatum, inability to walk and independently sit, myoclonic movements, hyperreflexia were noted. Thyroid profile and clinical findings of patient that were consistent with AHDS. Sanger sequencing of the SLC16A2 gene revealed a hemizygous mutation in exon 1 (p.E9X; c.25G>T). The proband's mother and grandmother have heterozygous c.25G>T mutation, but the proband's uncle with psychomotor retardation, could not be analysed, since he had passed away nine months ago. To our knowledge, this mutation has not been previously reported in the etiology of AHDS. Due to generated premature stop codon, the mutation is evaluated disease causing mutation.

P10.02

Application of Next Generation Sequencing (NGS) in the ALS research: a study in Swedish families

R. Rofogaran¹, L. Köhn², A. Birve¹, A. Nilsson¹, M. Berdyski¹, P. Andersen¹;
¹Department of Pharmacology and Clinical Neuroscience, Umeå University, Umeå, Sweden, Umeå, Sweden, ²Department of Radiation Sciences, Oncology, Umeå University, Umeå, Sweden, Umeå, Sweden.

Amyotrophic lateral sclerosis (ALS) is a progressive neurodegenerative disorder that eventually leads to the death of motor neurons and fatal paralysis. Approximately, mutations in 26 genes have been associated with pathogenesis of ALS and several of them are also linked with fronto-temporal dementia (FTD). However, mutations in these genes explain less than one-third of ALS cases. NGS technologies can be used to generate deep sequencing of target genome regions, such as the exome or known disease loci. Generally, the specificity and accuracy of the results from panels are more reliable compared to whole-exome sequencing data since panels have better and more efficient data coverage than whole-exome sequencing. The aim of the current project is to analyze 26 genes that are associated with ALS disease using NGS panel. After library and indexed-enriched library preparations and validations of samples who had previously tested negative for C9orf72 mutations, the samples were sequenced on Miseq. Analyzing the data showed the sufficient sequencing with mean coverage of more than 150X. Then, bioinformatics analyzes were done and the coding and splicing variants were selected and filtered against MAF below 1% which have been described in HGMD. Our results showed mutations in SOD1 and other ALS-linked genes as well. The results will be discussed in more detailed. To conclude, the combination of DNA capture enrichment systems and high-throughput sequencing techniques can be used to have deep insight for the diagnosis of ALS.

*The project has been funded by grants for Peter Andersen, Umeå University, Sweden

P10.03

Study of the role of epigenetic regulators in the pathogenesis of ALS

C. Bernardini, M. Bernardinelli, M. Branzini, L. Di Pietro, F. Michetti, E. Ricci, M.

Sabatelli;

Università Cattolica del Sacro Cuore, Rome, Italy.

ALS is characterized by the progressive loss of neuromuscular junction (NMJ) and muscle mass, followed by muscle weakness, paralysis and death. Most of the studies on ALS focused primarily on motor neurons (MN) to understand the etiology of the disease. However, there are evidences suggesting that muscle dysfunction and NMJ degeneration occur long before symptom onset and may contribute to MN death. Recently, HDAC4 was identified as the critical linker connecting neural activity to muscle transcription; indeed induction of HDAC4 leads to increased levels of myogenin. Moreover the regulation of RNA metabolism in the NMJ is an emerging mechanism involved in ALS pathogenesis, and microRNAs (miRNAs) could be the mediators of this process. The aim of this study is to unravel the molecular pathway that exists between nerve and muscle in order to control the mechanisms that exacerbate the disease. In particular selected genes and miRNAs involved in the innervation pathway have been analyzed in human skeletal muscle derived from ALS patients. 12 ALS patients with 7 relative controls have been collected for this aim. Selected genes and miRNAs were then analyzed through qPCR and differential expression of HDAC4, MYOG, mir-23a, mir-155 and mir-206 was found. Collectively these data suggest that the innervation pathway is modulated in skeletal muscle in ALS patients and identify specific miRNAs potentially acting in HDAC4 inhibition. The inhibition of HDAC4 could represent a promising therapeutic approach to enhance motor performance and slow disease progression in patients with ALS.

This study has been funded by Arisla

P10.04

Confirming FIG4 as a risk gene for amyotrophic lateral sclerosis (ALS) in a central European cohort by whole exome and targeted sequencing

I. Ranganau^{1,2}, A. Osmanovic^{1,2}, A. Kosfeld¹, S. Abdulla², C. Janssen², S. Petri², R. G. Weber¹;

¹Department of Human Genetics, Hannover Medical School, Hannover, Germany,

²Department of Neurology, Hannover Medical School, Hannover, Germany.

Amyotrophic lateral sclerosis (ALS) is the most common adult-onset motor neuron disease characterized by progressive degeneration of upper and lower motor neurons. It leads to increasing weakness of voluntary muscles until death occurs from respiratory failure within an average of three years. While important progress has been made in understanding the genetic etiology of ALS, the majority of genetic variation involved in ALS is still undefined. In this study, we performed whole exome sequencing (WES) in an ALS

family showing an autosomal dominant inheritance pattern with incomplete penetrance, comprising an index patient and his affected paternal great-aunt. By using an overlapping strategy to identify variants shared by the patient and his father, we detected a rare heterozygous frameshift mutation in *FIG4* predicted to truncate the *FIG4* protein in its active site. *FIG4* encodes a phosphoinositide 5-phosphatase with a key role in vesicle trafficking in eukaryotic cells. Bi-allelic *FIG4* mutations have previously been described to cause Charcot-Marie-Tooth disease, type 4J (CMT4J) and Yunis-Varon syndrome. Recent studies showed an association between heterozygous *FIG4* mutations and ALS. Therefore, we performed WES or targeted sequencing of *FIG4* in 200 ALS patients of mainly central European origin revealing five additional known or novel rare heterozygous missense mutations predicted to be deleterious. Disease duration was relatively long in four of six *FIG4* mutation carriers, and three of six displayed a predominant upper motor neuron phenotype. Here, we confirm *FIG4* as an ALS risk gene identifying novel or known rare heterozygous variants in 3% of European patients.
