We examine the clinical utility of current screening criteria and UCPCR testing in the Emirati population. Paediatric and adult cases are recruited and 2 hour post-prandial UCPCR is determined. Next generation sequencing of known monogenic diabetes genes is performed to confirm a diagnosis of MODY and to help identify patients for the investigation of novel genetic aetiologies in the Emirati population, by performing whole exome sequencing. Recruited patients were 126 type 1 diabetes and 16 type 2 diabetes paediatric patients and 67 type 1 diabetes and 64 type 2 diabetes adult patients. 2 Tailed Spearman correlation test showed that in type 1 diabetes patients, UCPCR was negatively correlated with duration of diabetes (r=-0.6, p < 0.001); there was a weak correlation between UCPCR and duration of diabetes in patients with type 2 diabetes (r=-0.23, p= 0.044). UCPCR was significantly lower in paediatric patients with type 1 diabetes with duration of less than 1 year (median 0.583) compared to more than 1 year (median 0.015) (p< 0.001).

We suggest that UCPCR test could be valuable for discrimination between type 1 and type 2 diabetes and/or MODY in paediatric and adult Emirati patients and can lead to an earlier clinical diagnosis and adequate management.

E-P03.29

Exome analysis establishes the diagnosis of microvillus inclusion disease (MVID) in a family with cholestatic liver disorder as the predominant clinical feature

D. Bartholdi¹, C. Courage², C. Margini³, F. Dallèves¹, J. Dufour³, S. Gallati¹;

¹Division of Human Genetics, University Children's Hospital, Bern, Switzerland,

²Folkhälsan Institute of Genetics, Helsinki, Finland, ³Department of Visceral Surgery and Medicine, University Hospital, Bern, Switzerland.

Microvillus inclusion disease (MVID) is a severe congenital enteropathy characterized by intracytoplasmatic microvillus inclusions and brush border atrophy in intestinal epithelial cells. It is an autosomal recessive disorder caused by mutations in the MYO5B gene (MIM#606540) encoding the myosin Vb protein. The disorder is characterized by intractable secretory diarrhoea in infancy. Intestinal failure secondary to diarrhea is frequent and children with MVID are dependent on parenteral nutrition. Long-term outcome is generally poor.

We report a patient who is now 30 years of age and who presented with unclassified cholestatic liver disorder and recurrent diarrhoea four weeks after birth. His two older brothers had died of an unclassified liver disorder in infancy. The clinical course in the patient reported here stabilized in the second year of life after which he suffered from occasional episodes of diarrhoea only, but presented with severe cholestatic liver disorder as the predominant clinical feature. The putative diagnosis of progressive familial intrahepatic cholestasis (PFIC1/2) was established. However, molecular analysis of the ATP8B1 and ABCB11 genes did not reveal any pathogenic mutations, excluding PFIC1/2 as the likely diagnosis. In order to establish the correct diagnosis we performed exome sequencing. This analysis revealed two heterozygous disease-causing mutations in the MYO5B gene

(c.242A>G, p.His81Arg and c.4798C>T, p.Gln1600*) establishing microvillus inclusion disease (MVID) as the diagnosis in the patient. In summary, we present further evidence for the broad clinical variability in MVID and confirm that this disorder can manifest predominantly as cholestatic liver disorder.

E-P03.30

A panel of five gene polymorphisms investigated in childhood nephrotic syndrome in Romania

C. Duicu¹, C. O. Marginean¹, F. Tripon², A. Crauciuc², C. Banescu²;

¹Pediatric Department No 1, University of Medicine and Pharmacy Tg. Mures, Romania, Tg. Mures, Romania, ²Genetic Department, University of Medicine and Pharmacy Tg. Mures, Romania, Tg. Mures, Romania.

Background: Nephrotic syndrome (NS) is a common renal problems encountered in children.

Nephrotic syndrome (NS) is caused by different disorders that damage the kidneys. Recent studies have described that certain genetic mutations are involved in the NS pathway, prognostic and response to therapy.

Aim: This study was performed to investigate if there is any association of some polymorphisms (ACE angiotensin converting enzyme I/D gene polymorphism, VEGF I/D (vascular endothelial growth factor), NPHS2, Tumor Necrosis Factor α (TNF α) G308A and IL-6 174G>C gene polymorphism and nephrotic syndrome.

Materials and methods: The study protocol was approved by the Ethics Committee of the University of Medicine and Pharmacy Tg.Mures. Our study included a number of 57 patients with NS and a control group which included 123 healthy persons. The gene polymorphisms were determined by the PCR and PCR-RFLP techniques using specific primers.

Results: Mutations (NPHS2) were detected in 100% of congenital-onset NS. Patients with NS had a higher percentage of II and ID genotype than the control group (especially in girls).

Conclusions: We were unable to show a relationship between VEGF I/D, TNF α G308A, IL-6 174G>C gene polymorphism and NS. There is an association between NS and ACE I/D polymorphism, the deletion might be a protective factor and insertion a risk factor. Mutation in NPHS2 gene represent a risk factor for congenital NS.

Further investigations with a larger scale, multicenter studies are necessary to confirm/clarify these findings and to elucidate the role of these genes polymorphisms in NS development and course of treatment.

E-P03.31

Molecular screening of the human Melanocortin 4 Receptor (MC4R) gene in obese Maltese Type 2 Diabetic patients

S. Eljali, N. P. Pace, J. Vassallo, A. E. Felice;

University of Malta, Msida, Malta.

Obesity is a complex trait arising from complex gene-lifestyle interactions. It is a risk factor for cardio-metabolic diseases, including type 2 diabetes (T2DM). Investigations on early onset/severe obesity have identified variants in genes acting on the central regulation of appetite. Of particular interest is the melanocortin 4 receptor (MC4R). Mutations in this gene represent the most frequent cause of early-onset non-syndromic obesity.

The aim of this investigation was to perform mutational screening of the MC4R exon in obese Maltese T2DM patients.

Methods

We sequenced the MC4R exon in 192 obese T2DM patients of Maltese ethnicity. PCR amplification was followed by Sanger sequencing at GATC Biotech, Germany.

Results

MC4R sequence variants are uncommon in obese T2DM patients. Sequence electropherograms were screened for homozygous SNPs and insertion-deletion variants (InDels). No homozygous SNPs or indels were detected in the study

cohort. Sequence electropherograms were inspected to identify heterozygous variants in the MC4R exon. Five cases (3 Males, 2 Females) were identified carrying the missense rs2229616 variant in the heterozygous state. rs2229616 C/T polymorphism results in a Valine to Isoleucine substitution at codon 103. Our data shows that MC4R mutations are rare, and do not contribute to adult obesity associated with insulin resistance in T2DM. These findings are in keeping with studies that showed that obesity causing mutations in MC4R have a very low prevalence in an obese cohort from Southern Italy.

Conclusion

This is the first investigation into the prevalence and spectrum of MC4R variants in obese Maltese adults.

E-P03.32

PRSS1, SPINK1, CFTR, and CTRC mutations in Korean patients with idiopathic pancreatitis

S. Cho, S. Shin, K. Lee;

Yonsei university, Seoul, Korea, Republic of.

AIM: This study aimed to identify mutations in PRSS1, SPINK1, CFTR and CTRC genes with idiopathic pancreatitis in Korean patients.

METHODS: The population under study consisted of 116 Korean subjects (65 males, 51 females, mean age 30.4 yrs, range 1-88 yrs), diagnosed with idiopathic pancreatitis. Genomic DNA was extracted from whole blood samples, amplified by PCR and sequenced using the Sanger method. Multiplex ligation-dependent probe amplification (MLPA) was performed to assess copy number variations (CNVs) using an MLPA kit. Students t-test (unpaired), χ^2 test or Fisher's exact test was used for analyzing data as appropriate.

RESULTS: We identified three types of PRSS1 mutations in 11 patients, including N29I (n=1), R122H (n=1), and G208A (n=9). 16 patients exhibited heterozygous mutations in SPINK1, including c.194+2T>C (n=12) and N34S (n=3). A novel splicing mutation in the SPINK1 gene, c.194+1G>A, was found in a 41 yr old man diagnosed with pancreatic duct stone and chronic pancreatitis. A heterozygous CFTR Q1352H mutation was detected in 8 patients. One patient had a heterozygous CTRC P249L mutation that has been reported to be a high risk variant for pancreatitis. PRSS1 and SPINK1 gene copy numbers were normal in all patients. Weight loss occurred more frequently in patients carrying the G208A mutation, while pancreatic duct stones occurred more frequently in patients with the c.194+2T>C mutation.

CONCLUSION: Mutations in PRSS1, SPINK1, and CFTR were associated with idiopathic pancreatitis in contrast to mutations in CTRC. CNVs of PRSS1 and SPINK1 were not detected.

E-P03.33

A novel compound heterozygous mutation in the URAT1/SLC22A12 in a Japanese patient with renal hypouricemia

K. Ichida^{1,2};

¹Department of Pathophysiology, Tokyo University of Pharmacy and Life Sciences, Tokyo, Japan, ²Division of Kidney and Hypertension, Jikei University School of Medicine, Tokyo, Japan.

Renal hypouricemia is an inherited and heterogeneous disorder characterized by impaired tubular uric acid transport. Exercise-induced acute renal failure and urolithiasis are frequent complications of renal hypouricemia. Urate transporter 1 gene (URAT1/SLC22A12) and glucose transporter 9 gene (GLUT9/SLC2A9) are causative genes for renal hypouricemia (MIM: 220150, 612076). URAT1/SLC22A12 is the main transporter for uric acid reabsorption at the apical membrane of the renal tubules, while GLUT9/SLC2A9 at the basolateral membrane. In Japanese, over ninety percentages of renal hypouricemic patients have URAT1/SLC22A12 mutations and c.774G>A (p.W258X) accounts for about eighty percentages of URAT1/SLC22A12 mutation. We have investigated a middle-aged male patient with renal hypouricemia who had frequent exercise-induced acute renal failures by moderate level exercise. A compound heterozygous mutation in the URAT1/SLC22A12 was found, a c.774G>A and a novel mutation c.935_997delinsTGG. Further consideration is required, as the mutations cannot account for the frequent exercise-induced acute renal failures.

E-P03.34

The association between the PTPN22 1858C>T variant and T1D Saudi children.

I. Alabdulkareem¹, I. Altawayjri², A. Alrumaih², A. Al-Mohrej², M. Almkalki², A. Nasr², M. AlDubayee²;

¹King Abdullah International Medical Research Center, Riyadh, Saudi Arabia, ²King Saud bin Abdulaziz University for Health Sciences, Riyadh, Saudi Arabia, ³King Abdullah Specialized Children's Hospital, King Abdulaziz Medical City, Riyadh, Saudi Arabia.

Type 1 diabetes (T1D) is a chronic disease in which the pancreas cannot produce insulin because of the destruction of β -cells mostly mediated by cytotoxic CD8+ T-cells with help from CD4+ T-cells Protein tyrosine. Recently, the phosphatase non-receptor type 22 (PTPN22) has been reported to be one of the major genes that may involve in the incidence of T1D in children. A single nucleotide polymorphism (SNP) at nucleotide 1858 in codon 620 (C>T; Arg620Trp; **rs2476601**) in PTPN22 has been reported to be associated with T1DM in North American studies.

PTPN22 gene maps on chromosome 1p13.3-p13.1, encodes lymphoid protein tyrosine kinase (LYP) acts as negative control of T-cell activation and T-cell development. The other high influence genetic markers reported to have linked with T1D incidence in the children, are the human leucocyte

antigen (HLA-DR/DQ) and insulin gene (INS).

This study is aimed to investigate the presence of the rs2476601 SNP among children diagnosed with T1D at King Abdullah children hospital. A total of 24 patients were subjected to PTPN22 gene sequence for the presence rs2476601 SNP.

Our sequencing data showed that the rs2476601 SNP is present in all of the subjects. This pilot study may show some strong association between the T1D and the presence of the rs2476601 SNP in Saudi population.

Our future plan is to expand the number of patients (aiming 1000 subjects) and do high throughput sequencing (gene panels) for PTPN22 and other genes (HLA-DR/DQ and INS).

Characterization of novel mutations in FLG gene in Mexican patients with ichthyosis vulgaris

M. Rivera-Vega¹, E. Alarcon-Perez², F. Zuñiga³, J. Cazarin-Barrientos³, L. Gonzalez-Huerta¹, M. Martinez-Saucedo¹, J. Toral-Lopez⁴, S. Cuevas-Covarrubias⁵;

¹Genetica, Hospital General de Mexico, Mexico DF, Mexico, ²Genetica, Hospital Regional de Chiapas, San Cristobal de las Casas, Mexico, ³Dermatologia, Hospital General de Mexico, Mexico DF, Mexico, ⁴Centro Médico Ecatepec, ISSEMYM, Edomex, Mexico, ⁵Genetica, Facultad de Medicina, Hospital General de Mexico, Universidad Nacional Autonoma de Mexico, Mexico DF, Mexico.

Ichthyosis vulgaris (IV, OMIM: 146700) is a genodermatosis that represents one of the most frequent single-gene disorder in humans beings. With an incidence of 1 in 250 newborns, IV presents a semi dominant inheritance pattern caused by homozygous, compound heterozygous, or heterozygous mutations in the FLG gene that is located on chromosome 1q21. The loss-of-function mutations in the FLG gene are the cause of IV and sometimes are associated with atopic diseases in 37-50% of the cases. The phenotypic characteristics of IV include palmar hyperlinearity, keratosis pilaris, and a fine scale that is most prominent over the lower abdomen, arms, and legs. The aim of the present study is to describe three novel mutations in the FLG gene in patients with IV. Genomic DNA was analyzed through whole exome sequencing, PCR and DNA sequencing analysis in IV patients, non-affected members of the families and in 100 normal controls. STS protein activity was conducted to completely discard X-linked ichthyosis. We detected three novel mutations (p.P487S, p.S1482Y and p.S3962L) in the FLG gene of the subjects with IV. These results add more diversity of the type of mutations in the FLG gene in IV patients.

E-P04.06

Occurrence of the most frequent type of mutation in FLG gene in Mexican patients with vulgar ichthyosis

L. Gonzalez-Huerta¹, F. Zuñiga², J. Cazarin-Barrientos³, H. Urueta-Cuellar¹, M. Martinez-Saucedo¹, S. Cuevas-Covarrubias⁴;

¹Genetica, Hospital General de Mexico, Mexico DF, Mexico, ²Genetica, Hospital Regional de Chiapas, San Cristobal de las Casas, Mexico, ³Dermatologia, Hospital General de Mexico, Mexico DF, Mexico, ⁴Genetica, Facultad de Medicina, Hospital General de Mexico, Universidad Nacional Autonoma de Mexico, Mexico DF, Mexico.

Ichthyosis vulgaris (IV, OMIM: 146700), a semidominant condition, is caused by homozygous, compound heterozygous, or heterozygous mutation in the filaggrin gene (FLG; 135940). FLG gene is located on chromosome 1q21, which defects seem to also be associated with atopic diseases. IV is one of the most frequent single-gene disorder in human beings. It incidence is 1 in 250 based on a survey of 6,051 healthy English school-children. The phenotypic characteristics include palmar hyperlinearity, keratosis pilaris, and a fine scale that is most prominent over the lower abdomen, arms, and legs. In the present study, we determined in 15 Mexican patients the presence of the most frequent mutations reported in IV (p.R501* and c.2282del4) in the FLG gene. IV diagnosis was performed clinically and molecularly. To discard the X-linked diagnosis, we determined the steroid sulfatase activity in leucocytes, PCR and DNA sequencing of the STS gene. DNA sequencing of the FLG gene were conducted through Sanger method. We found the mutation change p.R501* in four patients; one of them was a compound heterozygous with the mutation p.R501*/p.P487S (a novel mutation). The mutation c.2282del4 was not present. These mutations represent 26.6% of the analysed sample what denotes a different occurrence that those reported in other populations.

E-P04.08

Association of GSTM1, GSTT1 and GSTP1 gene polymorphisms of Lichen Planus in Turkish population

S. Artan¹, I. Bulur², H. Aslan¹, B. Durak Aras¹, M. Ozdemir¹, O. Kutlay¹, E. Erzurumluoglu¹, K. Haziyeve¹, Z. N. Saracoglu², O. Cilingir¹;

¹Eskisehir Osmangazi University, Faculty of Medicine, Department of Medical Genetics, Eskisehir, Turkey, ²Eskisehir Osmangazi University, Faculty of Medicine, Department of Dermatology, Eskisehir, Turkey.

Lichen planus (LP) is an inflammatory and chronic immune-mediated skin disease. The oxidative stress and antioxidant defense mechanisms have been identified in the inflammatory and chronic dermatological diseases. *GSTM1*, *GSTT1* and *GSTP1* are important enzymes to utilize many products of oxidative stress as a substrate. Aim of this study is to determine the effects of these antioxidant genes polymorphisms on the molecular etiology of the LP. The study group consisted of 56 patients with LP and 98 age- and sex- matched healthy unrelated controls. *GSTM1* and *GSTT1* genotypes were determined by multiplex PCR, but *GSTP1* polymorphisms were analyzed by using PCR-RFLP technique. Genotype frequencies of the *GSTM1*, *GSTT1* and *GSTP1* polymorphisms showed significant differences between Lichen Planus patients and control populations as are shown in table. The *GSTP1*- Val/Val genotype, *GSTM1*-null and *GSTT1*-null polymorphisms may be connected with LP. Since the analysis of these polymorphisms in LP is the first data published in the world.

Comparison of GSTM1, GSTT1 and GSTP1 frequencies between patients and controls			
Genotype	LP (n=56) n(%)	Control (n=98) n(%)	P value
<i>GSTM1</i>			
Null (-)	5(3,2)	0(0)	<0,01
Present (+)	51(96,8)	98(63,6)	
<i>GSTT1</i>			
Null (-)	13(8,4)	0(0)	<0,001
Present (+)	43(91,6)	98(63,6)	
<i>GSTM1/GSTT1</i>			
+ / +	38(24,7)	98(100)	<0,001
<i>GSTP1</i>			
Ile/Ile	2(1,3)	15(9,7)	<0,05

Report of two novel mutations in FBN1 gene and one novel mutation in TGFBR2 gene in five Iranian families suspicious to Marfan and Marfanoid syndrome

E. Esmaeilzadeh-Gharehdaghi¹, S. Yazdanipour², M. Garshashi¹;

¹Tarbiat modares university, Tehran, Iran, Islamic Republic of, ²Islamic Azad university dentistry, Tehran, Iran, Islamic Republic of.

Marfan syndrome is an autosomal dominant disorder that affects the body's connective tissues with a relative highly prevalence. Cardinal manifestations involve the ocular, skeletal, and cardiovascular systems. This study was performed to investigate mutation spectrum and responsible gene in a cohort of 4 Iranian families with Marfan syndrome and 1 family with possible diagnosis of Marfan syndrome and Aneurysm respectively. All the coding regions of FBN1 gene in the first four patients were screened by target-enriched next generation sequencing. One patient from the remaining family was subjected to NGS panel for total 14 genes (ACTA2, CBS, FBN1, FBN2, MYH11, COL3A1, SMAD3, TGFBR1, TGFBR2, MYLK, MSTN, COL5A2, TGFBR2, SLC2A10). This study revealed two novel mutations c.6288C>A (p.Cys2096Ter) and c.6793T>G (p.Cys2265Gly) in FBN1 gene in two of the families and one novel mutation c.1333G>A (p.Gly445Arg) in TGFBR2 gene which is related to autosomal dominant Loey's-Dietz syndrome in the family with Marfan syndrome and Aneurysm. The confirmation study by sanger sequencing showed that all of these three mutations co segregate with the disease in the three families. In two families no mutation in FBN1 gene was observed. This result indicates the allele heterogeneity of FBN1 and TGFBR2 genes by introducing three novel mutations in five Iranian families.

E-P04.10

Frequency of deletions in the NF1 gene analyzed through MLPA in a sample of Mexican patients with neurofibromatosis 1

J. Valdes-Miranda¹, L. M. Gonzalez-Huerta¹, J. Cazarin-Barrientos², S. Cuevas-Covarrubias³;

¹Genetica, Hospital General de Mexico, Mexico DF, Mexico, ²Dermatologia, Hospital General de Mexico, Mexico DF, Mexico, ³Genetica, Facultad de Medicina, Hospital General de Mexico, Universidad Nacional Autonoma de Mexico, Mexico DF, Mexico.

Neurofibromatosis type I (NF1) (OMIM #162200) presents an occurrence of 1 in 2500-3500 newborns. Clinically, NF1 is characterized by cutaneous café-au-lait spots, skin-fold freckling, Lisch nodules in eyes and neurofibromas. NF1 has an autosomal dominant inheritance with complete penetrance age-dependent. NF1 is caused by molecular defects in the NF1 gene located

on chromosome 17q11.2, a gene with 60 exons, alternative splicing and expression in most tissues. NF1 encodes neurofibromin 1, a tumor suppressor protein that participates in the regulation of cell growth and proliferation. A large number of mutations are observed in NF1 patients (point mutations, indels and complete gene deletions including flanking regions). The aim of the present study was to determine the frequency of deletions in the NF1 gene through MLPA in a sample of 38 Mexican patients with NF1. MLPA technique was performed in genomic DNA in all patients. Four deletions that include a complete deletion of the NF1 gene and three intragenic deletions were observed. We detected a frequency of gene deletions in the NF1 gene in Mexican population similar to those reported for other populations (5-10%). We observed a higher prevalence of intragenic deletions than complete deletions of the NF1 gene. This type of studies is necessary in most populations to identify the frequency and type of this molecular defect in NF1.

E-P04.11

NF type 1: a single center's experience in the Aegean region of Turkey

A. Ece Solmaz¹, H. Onay¹, E. Isik², T. Atik², F. Ozkinay¹;

¹Ege University Medical Faculty Medical Genetics Department, İzmir, Turkey, ²Ege University Medical Faculty Pediatric Genetics Department, İzmir, Turkey.

Introduction: Neurofibromatosis 1 (NF1) is an autosomal dominant condition caused by mutations in the NF1 gene. It is also a multisystem disease that shows high penetrance with a wide variability in the phenotype. The most common features are multiple café-au-lait spots, axillary and inguinal freckling, multiple cutaneous neurofibromas, and iris Lisch nodules.

Materials and Methods: A total of 8 unrelated Turkish NF1 patients, 2 females and 6 males, were included in this study. All patients met the diagnostic criteria proposed by the NIH. We screened the whole coding and splice site regions of the NF1 gene using next generation sequencing.

Results: We identified 8 different NF1 mutations, including 1 missense, 3 nonsense and 4 small deletion mutations. Among these pathogenic variants 5 were novel.

Age of the patients at the time of NF1 molecular diagnosis was 18.4 years. Six patients (75%) had not a family history of NF1. Among 8 patients, Café-au-lait spots were shown in 8 (100%), neurofibroma in 6 (75%), freckling in 4 (50%), and Lisch nodules in 3 (37.5%).

Conclusion: It has been shown that NF1 is an extremely heterogenous disease at both clinical and molecular levels in Turkish population as it is in the other populations. Mutation distribution indicate no mutational hot spots within the NF1 gene in our population. This is the first study from Western Turkey investigating mutation spectrum of the NF1 gene.

E-P04.12

Report of novel mutation of COL1A1 gene in Osteogenesis imperfecta

M. Ebrahimi Nasab¹, S. Asadollahi¹, M. Seyedhassani¹;

Dr. Seyedhassani Medical Genetic Center, Yazd, Iran, Islamic Republic of.

Introduction: Osteogenesis Imperfecta (OI) is a heritable disorder characterized by increased bone fragility. Previous studies suggested that the majority of the inheritance of familial OI may be autosomal dominant. COL1A1/2 genes related OI are characterized by fractures with minimal or absent trauma, variable dentinogenesis imperfecta, and in adult years, hearing loss. The clinical features of COL1A1/2-related OI represent a continuum ranging from perinatal lethality to individuals with severe skeletal deformities, mobility impairments, and very short stature to nearly asymptomatic individuals with a mild predisposition to fractures, normal dentition, normal stature, and normal life span. Fractures can occur in any bone, but are most common in the extremities. The Aim of this study was to molecular assessment of the mother and daughter of family with OI.

Materials and Methods: We have evaluated mother (Proband) with panel DX0195 by Next Generation Sequencing (NGS) test that included 13 genes related to OI. NGS detected a mutation (c.2613+6 T>C) that occurred in intron 37 of COL1A1 gene. Her husband and daughter were assessed for this mutation by PCR-Sequencing method.

Result: Our data shown her daughter had the same mutation and is very likely suffering from osteogenesis imperfect.

Conclusion: Novel variant c.2613+6T>C (Het) on gene COL1A1 has not been reported for its pathogenicity. So according to our study this mutation can be considered as a pathogenic mutation. Bioinformatics analysis confirmed this pathogenicity.

E-P04.17

Novel RECQL4 mutation causing Rothmund-Thomson syndrome

D. Halperin¹, M. Drabkin¹, Y. Yogev¹, Y. Perez¹, O. Birk^{1,2};

¹The Morris Kahn Laboratory of Human Genetics, National Institute for Biotechnology in the Negev, Faculty of Health Sciences, Ben-Gurion University of the Negev, Beer sheva, Israel, ²Genetics Institute, Soroka University Medical Center, Ben-Gurion University, Beer sheva, Israel.

Three siblings of a consanguineous Bedouin Israeli kindred presented with a syndrome of premature aging with poikiloderma and skin atrophy, thin hair and unique dysmorphism – with frontal bossing, small sunken eyes, saddle nose and a small mouth. Severe intrauterine growth retardation (IUGR) was evident in all cases, culminating in severe failure to thrive (FTT). Osteoporosis – leading to multiple fractures, was evident in all 3 affected individuals and absence of thumbs was evident in one. Two of the affected individuals died by the age of 2 years.

Whole exome sequencing of the affected individuals identified 8 homozygous mutations shared by all 3. Filtering of the whole exome sequencing data for known benign variants using open access databases (HapMap, EVS and 1000 genomes) and our in-house data of over 100 ethnically matched exomes, identified a single deleterious homozygous mutation relevant to the phenotype: c.1038_1039delCC in RECQL4 resulting in a frameshift and premature stop codon of the mature protein: p.R347fs*2. RECQL4 mutations have been previously associated with several syndromes, namely: Rothmund-Thomson (omim#268400), Baller-Gerold (OMIM#218600) and Rapadilino (OMIM#266280). RECQL4 encodes a DNA helicase protein and the novel mutation identified in this study is of the few described to date that cause Rothmund-Thomson syndrome. The molecular developmental mechanisms through which different syndromes evolve due to mutations affecting this protein are yet to be elucidated.

E-P04.18

Association between transforming growth factor beta 1 gene and idiopathic scoliosis

S. Nikolova¹, V. Yablanski², E. Vlaev², A. Savov¹, I. Kremenski³;

¹National Genetic Laboratory, Medical University-Sofia, Sofia, Bulgaria, ²Department of Orthopedics and Traumatology, Tokuda Hospital Sofia, Sofia, Bulgaria, ³Molecular Medicine Center, Medical University-Sofia, Sofia, Bulgaria.

Introduction. The transforming growth factor-beta (TGF-β1) functional polymorphism rs1800469 (C-509T) corresponding with a higher transcriptional activity than the wild-type variant and with higher levels of the gene product was previously described to be associated with the etiology and progression of idiopathic scoliosis in Russian population. The purpose of our case-control study was to investigate the association between TGF-β1 (rs1800469 C/T) and idiopathic scoliosis in Bulgarian population.

Materials and Methods. The association study was performed on 105 patients and 210 controls. The mean Cobb angle was 54.6° ± 22.70 and the mean age of the patients was 11.2 ± 3.1 years. After obtaining written informed consent peripheral blood samples were collected and genomic DNA was extracted automatically. The genotyping was carried out by TaqMan Real-Time PCR method. The statistical analysis was performed by Pearson Chi-squared test with p-value less than 0.05 as statistically significant.

Results. The frequencies of the polymorphic T allele and TT genotype in the total group of patients and in the subgroup of patients with Cobb angle above 40° were significantly higher than that in the controls (p < 0.05). In addition, this case-control study revealed statistically significant association between TGF-β1 (rs1800469) and idiopathic scoliosis in females, early and late onset idiopathic scoliosis, familial and sporadic forms.

Conclusions. The results confirmed a previously reported association between the TGF-β1 gene and idiopathic scoliosis in Russian population and suggested that the molecular marker TGF-β1 (rs1800469 C/T) is independent predisposing and modifying factor of idiopathic scoliosis in Bulgarian patients.

Polymorphisms in autophagy genes are associated to Acute Coronary Syndrome

R. Usategui-Martin¹, A. Medina Herrera¹, B. Crego-Vicente¹, O. Cortes-Fernández¹, E. Bueno-Martínez¹, I. Cruz-González², J. Rama-Merchán², P. Sánchez-Fernández², R. González-Sarmiento¹;

¹Molecular Medicine Unit. Department of Medicine. University of Salamanca- Institute of Biomedical Research of Salamanca (IBSAL), Salamanca, Spain, ²Department of Cardiology. University Hospital of Salamanca- Institute of Biomedical Research of Salamanca (IBSAL), Salamanca, Spain.

Acute coronary syndrome (ACS) is the main cause of death in the European Union. ACS includes a series of acute myocardial ischemic states as unstable angina, non-ST-segment elevation myocardial infarction (NSTEMI) and ST-segment elevation myocardial infarction (STEMI). ACS is the result of the formation of occlusive thrombi (STEMI) or no occlusive thrombi (NSTEMI) in the coronary arteries resulting to rupture of vulnerable atherosclerotic plaques. As a result of energy depletion due to the ischemic process an activation of the autophagy occurs to replenish metabolic substrates and to remove damaged organelles. So the aim of our study was to characterize whether polymorphisms in genes involved in autophagy would modify the risk of developing ACS. We have studied ATG2B rs3759601, ATG16L1 rs2241880, ATG10 rs1864183 and ATG5 rs2245214 polymorphisms to evaluate their role in the susceptibility of suffering ACS in a cohort of 323 Spanish patients.

Our results showed that being a carrier of the allele G of ATG2B rs3759601 polymorphism and being a carrier of the allele C of the ATG16L1 rs2241880 polymorphism were associated with increased risk of developing ACS. The analysis of the NSTEMI patients versus STEMI patients showed us that being a carrier of the variant allele G of the ATG2B rs3759601 polymorphism increased the risk of developing STEMI.

The variant alleles of the ATG16L1 rs2241880 and the ATG2B rs3759601 polymorphisms are related with decreased autophagy process therefore our study suggests that a defective autophagy could be involved in an increased risk to suffer ACS.

Paternal lineage I as a risk factor of coronary artery disease in Slovak men

E. Petrejčíková¹, M. Fecenková¹, J. Hubcejová¹, I. Boroňová¹, I. Klobošová¹, J. Kmeč²; ¹Prešov University, Faculty of Humanities and Natural Sciences, Department of Biology, Prešov, Slovakia, ²Kardiocentrum, FNŠP J.A.Reimana, Prešov, Slovakia.

Introduction: Coronary artery disease (CAD) is a major cause of high mortality in Slovakia. Generally, men have a higher risk than women of developing coronary heart disease in middle age. We assumed that genetic variability in the Y chromosome (especially haplogroup I) could be a risk factor for a higher incidence of coronary artery disease in the Slovak male population independently of traditional cardiovascular risk factors.

Materials and Methods: Genomic DNA was extracted from peripheral blood and buccal swabs of 133 Slovak patients with CAD and 127 control samples. Males were genotyped for Y-SNPs on 7500 Fast Real Time PCR instrument (Life Technologies) using TaqMan assays. We compared traditional cardiovascular risk factors in carriers of the haplogroup I and in men with other paternal lineages.

Results: Based on analysis, haplogroup I was no significantly more common in men with coronary artery disease than in controls (24.81% [n=33] vs. 25.2% [n=32]). There were no significant differences in biochemical and clinical parameters between patients with paternal lineages I and patients with other Y-haplogroup. We did not confirm the association between haplogroup I and increased risk of coronary artery disease in this study (OR 0.9797, 95% CI 0.5578 to 1.7177, p=0.942).

Conclusion: In Slovak population, our results showed the carriers of haplogroup I are not more likely to suffer from coronary artery disease than men with other paternal lineage. None of the traditional cardiovascular risk factors associated with Y-chromosomal haplogroup I.

This study is the result of the project implementation VEGA 1/0563/14.

E-P05.10

Next-generation sequencing to determine a genetic cause of familial intracranial aneurysms

E. Hitchcock^{1,2}, J. Diamond², P. Eydoux^{1,3}, K. Townsend^{1,2}, G. Redekop^{1,4}, W. Gibson^{1,2}; ¹University of British Columbia, Vancouver, BC, Canada, ²Child and Family Research Institute, Vancouver, BC, Canada, ³Children's and Women's Health Centre of British Columbia, Vancouver, BC, Canada, ⁴Vancouver General Hospital, Vancouver, BC, Canada.

Introduction: Intracranial berry aneurysms (IBA) are a common disease that occur in 1-3% of the general population, and in 3.6-6.5% of adults over 30 years of age. Approximately 12-15% of patients have affected first-degree relatives, and are considered to have familial intracranial aneurysms (FIA). No specific genetic variants causing isolated IBA or FIA have been identified thus far. The aim of this study is to identify rare DNA variants that are major risk factors for FIA.

Methods and Results: This study currently has enrolled three families with FIA, and recruitment of additional families is ongoing. We analyzed family one using whole-genome SNP microarrays to map genomic regions shared only among affected family members, in combination with whole-exome sequencing (WES) to identify rare genetic variants in a single proband. Over-

lap of these data produced a list of 112 candidate variants. Whole-genome sequencing will be performed on the proband of family two. WES will be performed on family three and on the probands of newly-enrolled families. We describe a detailed workflow of the analysis of sequencing data obtained from these families. Candidate variants were selected for being rare and potentially damaging, then subsequently prioritized by the gene's involvement in an associated syndrome, vascular function, or inflammation. Genes containing candidate variants in multiple independent families will be modeled in zebrafish.

Discussion: A validated FIA gene would be expected to identify a key protein in the molecular pathogenesis of intracranial aneurysms in both its familial and sporadic forms.

Supported by the Brain Aneurysm Foundation.

Hereditary haemorrhagic telangiectasia (Rendu-Osler-Weber syndrome): molecular genetic testing in the Czech Republic - update

J. Necasova¹, Z. Svestkova¹, J. Nemeckova¹, M. Penka^{2,3}, R. Gaillyova^{1,3}, I. Valaskova^{1,3}; ¹The University Hospital Brno, Department of Medical Genetics, Brno, Czech Republic, ²The University Hospital Brno, Department of Clinical Hematology, Brno, Czech Republic, ³Masaryk University, Faculty of Medicine, Brno, Czech Republic.

Hereditary Hemorrhagic Telangiectasia (HHT) is an autosomal dominant vascular disorder caused by mutations in endoglin (ENG) or activin receptor-like kinase-1 (ALK1, ACVRL1) genes. Clinical diagnosis is based on the presence of two (suspected) or more (definite) Curaçao's diagnostic criteria. The majority of mutations reported on the International HHT Mutation Database (hhtmmutation.org) are predicted to lead to stop codons, either due to frameshifts or direct nonsense substitutions. We reported our first results with genetic testing in the Czech Republic previously. We used classical sequencing approaches to perform molecular characterization in 12 new clinically affected individuals. Coding regions and exon/intron boundaries of both genes were sequenced and we detected a total of 8 different mutations in the two genes. Three known missense mutations were identified in the ACVRL1 gene, in exons 7 and 8. Three of five mutations identified in the ENG gene were novel with frameshift effect in exons 5 and 7, and two were known mutations - one missense in exon 5 and splice site mutation in intron 8. No mutations were found in ENG/ACVRL1 in 4 probands. Our laboratory has performed genetics testing for HHT on 28 probands since 2012. Approximately 54% of affected patients have at least one mutation in either endoglin or ACVRL1 gene. We plan to perform deletion/duplication analysis using MLPA (Multiplex ligation-dependent probe amplification analysis) in all patients with HHT retrospectively.

Genetics Contribution in Blood pressure and Hypertension

S. Zoroufchin Tamiz, M. S. Fallah, M. S. Daneshpour; Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran, Islamic Republic of.

Introduction: Hypertension is an emerging public health problem and one of the most frequent risk factor for cardiovascular disease. Genetic of hypertension varies from monogenic to polygenic-multifactorial forms which the latter is developed by interaction of various genes and environmental factors. Here we present a narrative review to further elucidating the genetics of elevated blood pressure (BP).

Material and Methods: Literature was searched through PubMed, dbGap and HuGE navigator and Google Scholar using a combination of following terms: hypertension or BP, genetic, genome wide association study (GWAS). Those manuscripts having data regarding the genes involving in monogenic hypertension or essential hypertension was included. After shortlisting related papers, most significant related genes and SNPs with monogenic and polygenic hypertension was included including most relevant studies such as WTCCC, CHARGE study, BRIGHT study, ICBP-GWAS, The Global BPgen consortium.

Results: BP heritability is estimated to be 30% to 50%, but GWAS results failed to unravel it. Large amount of this proposed heritability remained to be discovered which could be explained by primary overestimation of this measure. Limitation of GWAS to uncover underlying genetic cause might be due to not covering all common SNPs and the role of rare variants and lack of GWAS efficiency to detect them.

Conclusions: Polygenic characteristic of BP which is manifested by smaller effect of large number of variant needs further studied and the result could alter the focus of disease management from treatment toward prevention, also personalized therapy by using different drug to remedy individuals with specific genotypes.

E-P05.14

The development of a novel hypoxia inducible system to treat cardiovascular diseases caused by ischemia

M. Gunduz, S. Cigdem, A. Celik, T. Kaya, B. Eryonucu, M. Acar, E. Gunduz; Turgut Ozal University, Ankara, Turkey.

Tissue hypoxia, or ischemia, is the condition that describes the poor conveyance of oxygen and other vital products to tissues and organs. Up to now, the number one cause of death worldwide is caused by ischemia and related conditions such as heart attack or stroke. HIF-1 α is a transcription activator that functions as a master regulator of oxygen homeostasis. HIF-1 α protein levels increase under hypoxic conditions as a result of decreased O₂-dependent prolyl-hydroxylation, ubiquitination and degradation.

We aimed to break up clots in blood vessels and to prevent damage caused by reperfusion by producing antioxidant enzymes using hypoxia inducible systems. We added oxygen dependent degradation (ODD) domain of HIF1 α between and in front of TetR DNA binding domain and VP16 transactivation domain, so that TetR-ODD-VP16 or ODD-TetR-VP16 could activate transcription of therapeutic genes controlled by tetracycline response element (TRE), in a HIF1 α independent manner. In addition, we also designed therapeutic genes under control of hypoxia response element (HRE) of HIF1 α target genes. Western blotting and immunofluorescence assay results showed the expression and nuclear localization of TetR-ODD-VP16 and ODD-TetR-VP16 constructs under hypoxic conditions, but not normoxic. In addition, using fluorometric reporter systems we proved functionality of these constructs under hypoxic conditions.

In conclusion, we developed hypoxia responsible systems that can be engineered into endothelial cells to prevent ischemia related cardiovascular diseases.

Jervell-Lange Nielsen Syndrome: you can (not) miss it!

S. J. R. Joosten¹, M. Voorendt², S. Saleminck¹, R. B. Tanke¹, A. van den Wijngaard², C. L. M. Marcelis¹;

¹Radboudumc, Nijmegen, Netherlands, ²Academic Medical Center Maastricht, Maastricht, Netherlands.

Introduction ~ Jervell-Lange Nielsen Syndrome (JLNS) is an autosomal recessive variant of familial long QT syndrome (LQTS). JLNS is caused by homozygous or compound heterozygous mutations in the KCNQ1- or KCNE1-gene. JLNS is characterized by congenital profound bilateral hearing loss, a long QT interval and ventricular tachyarrhythmias.

Case ~ The index patient presented with a cardiac arrest at the age of 15 years. The electrocardiogram (ECG) showed typical signs of LQTS. The boy was already known by a paediatric neurologist, because of delayed development with a seizure disorder (normal EEG) and an ENT specialist, because of congenital deafness.

Two of his brothers were also diagnosed with deafness at birth and seizures at young age. One of them died suddenly at the age of 4. ECG tracing of the other brother showed also signs of LQTS.

Genetic testing of both the index patient and his brother showed a compound heterozygous mutation (c.644dupT and c.1343dupC) in the KCNQ1-gene, which confirm the diagnosis of JLNS.

Conclusion ~ The index patient and his brother were deaf since birth and diagnosed at a young age with seizures. One brother died suddenly at an age of 4 and was also deaf since birth. This family was diagnosed with JLNS just after the cardiac arrest of the index patient. The diagnosis JLNS could have been recognised much earlier in this family, because of the typical combination of deafness, recurrent collaps and sudden death in this family.

E-P05.16

A novel mutation in KCNQ1 gene in a Moroccan family with Jervell and Lange-Nielsen syndrome

N. Adadi^{1,2}, N. Lahrouchi³, I. Ratbi¹, R. Bouhouch⁴, I. Fellat⁴, R. Amri⁴, C. Bezzina³, A. Sefiani^{1,4};

¹Centre de génomique humaine, Faculté de médecine et pharmacie, Mohammed V University in Rabat, Morocco, Rabat, Morocco, ²Institut National d'hygiène, Rabat, Morocco, ³Department of Experimental Cardiology, Meibergdreef 9, Amsterdam, The Netherlands, Amsterdam, Netherlands, ⁴Electrophysiologie et Stimulation cardiaque, Clinique Belvédère, Rabat Morocco, Rabat, Morocco.

Jervell and Lange-Nielsen syndrome (JLNS; MIM 220400) is a rare autosomal recessive cardioauditory ion channel disorder that affects 1/200000 to 1/1000000 children. It is characterized by congenital profound bilateral sensorineural hearing loss (SNHL), a long QT interval, ventricular tachyarrhythmias, and episodes of torsade de pointes on the electrocardiogram. Cardiac symptoms arise mostly in the early childhood and consist of syncope episodes during periods of stress, exercise, or fright and are associated

with a high risk of sudden cardiac death. JLNS is caused by homozygous or compound heterozygous mutations in KCNQ1 on 11p15.5 or KCNE1 on 1q22.1-q22.2. We report on a 10 year-old boy with congenital hearing loss, a severely prolonged QT interval who presented with multiple episodes of syncope. His parents are first-degree cousins. We performed Sanger sequencing and identified a novel homozygous variant in KCNQ1 (c.1343dupC, p.Glu449Argfs*14). Both parents were heterozygous carriers of this mutation. The identification of the genetic substrate in this patient confirmed the clinical diagnosis of JLNS and allowed us to provide appropriate management to the patient and genetic counseling to his family. In addition, this finding contributes to our understanding of genetic disease in the Moroccan population.

The impact of Prothrombin G20210A mutation on young-onset stroke in Lithuanian population

V. Tatarunas¹, R. Vainoriene¹, D. Cereskevicius¹, I. Valanciute¹, V. Asmoniene¹, V. Lesauskaite²;

¹The Hospital of Lithuanian University of Health Sciences Kauno klinikos, Kaunas, Lithuania, ²The Institute of Cardiology of Lithuanian University of Health Sciences, Kaunas, Lithuania.

Introduction: The aim of this study was to analyze carriers of the Prothrombin G20210A mutation having thrombotic complications, to identify patients with young-onset stroke and to find the distribution of this mutation in a random sample of the population.

Materials and methods: four cases of patients, who had been hospitalized due to thrombotic complications at the Hospital of Lithuanian University of Health Sciences Kauno Klinikos from 2014 until 2016, were analyzed. A random sample of 475 subjects was studied in the laboratory of Molecular Cardiology of the Institute of Cardiology of Lithuanian University of Health Sciences by using commercial Taqman probes (Applied Biosystems, UK).

Results: The 4 patients were carriers of a G20210A heterozygous G/A genotype. None of them carried the FV:Leiden p.R506Q mutation. Three of the represented patients had thromboembolic complications. These three patients were males aged 20.4, 36.4 and 45.3 years. One female patient aged 1.4 years had an ischemic stroke. Thus, one of four patients with a prothrombotic state and a G/A genotype had an ischemic stroke. Population analysis revealed that only (n=4) 0.8 % of G/A prothrombin G20210A heterozygotes and (n=1) 0.2 % of A/A homozygotes were present in a random sample of Lithuanians population.

Conclusions: Our results show that the Prothrombin G20210A is a very rare mutation in the Lithuanian population. However, results of this study also show that the Prothrombin G20210A mutation might significantly increase the risk of young-onset stroke.

BCAP31 associated global developmental delay, sensorineural hearing loss and movement disorder mimicking mitochondrial encephalopathy in a male

S. Albanyan, A. Altenaiji, N. Monfared, S. Mahmutoglu; The Hospital for Sick Children, Toronto, ON, Canada.

Introduction: BAP31, encoded by *BCAP31* located on Xq28, is involved in the export of transmembrane proteins from the endoplasmic reticulum. Pathogenic variants in this gene have been reported in patients with global developmental delay (GDD), dystonia, deafness and dysmorphic features. We report a new patient with *BCAP31* associated GDD, bilateral sensorineural hearing loss, generalized dystonia and choreoathetosis. **Case Report and Results:** This 3.5-year-old boy presented with microcephaly and failure to thrive within the first 3 months of life. His brain MRI showed bilateral increased signal intensity in globus pallidus at age 3 months raising the suspicion of mitochondrial encephalopathy. His muscle biopsy showed pleomorphic subsarcolemmal collection of mitochondria in electron microscopy. His respiratory chain enzyme activities were normal. Various targeted next generation sequencing panels for mitochondrial disorders were negative. He was enrolled to a whole genome sequencing research study (Genome Clinic, Center for Genomic Medicine, The Centre for Applied Genomics) for mitochondrial disorders. He had a hemizygous pathogenic variant, c.533_536dup (p.Ser180AlafsX6), in *BCAP31*. His family history was positive for sensorineural hearing loss in his mother who had normal cognitive functions. She was heterozygous for same variant. **Conclusions:** We report

a new patient with *BCAP31* associated GDD, microcephaly, failure to thrive, dystonia and choreoathetosis. We also report for the first time a symptomatic heterozygous mother. Clinical features, muscle histopathology, brain MRI features as well as family history were suggestive of mitochondrial encephalopathy. Whole genome sequencing confirmed the diagnosis of *BCAP31* in our patient.

E-P06.02

The association between chronic periodontitis, type 2 diabetes mellitus and polymorphisms in IL6 and VDR gene

C. Cristescu¹, A. Craciun², S. Spandole-Dinu³, I. Radu³, A. Alexiu³, C. Sinca³, M. Toma³, C. Serafinceanu², L. Berca⁴, D. Cimponeriu³;

¹Titu Maiorescu University, Bucharest, Romania, ²Nicolae Paulescu NIDNMD, Bucharest, Romania, ³University of Bucharest, Bucharest, Romania, ⁴National Institute of Research and Development for Food Bioresources, Bucharest, Romania.

Complex interactions between periodontal pocket microbiota, host immune response and other risk factors (e.g. smoking, metabolic diseases) have been described. Thus, there are potential contribution of vitamin D receptor and IL6 polymorphisms to predisposition for chronic periodontitis (CP) or type 2 diabetes mellitus (T2DM). Torque teno virus (TTV) produces chronic infections and can interfere with IL-6 production and secretion.

Aim: The aim of this study was to evaluate the association between four genetic polymorphisms and CP or T2DM in Romanian population.

Material and methods: Patients with CP without T2DM (n=150), T2DM with CP (D-CP=150) and matched clinically healthy subjects (n=300) were recruited for this study. The rs2228570 C>T, rs7975232 G>T, rs731236 T>C from VDR locus and rs1800795 from IL6 locus were genotyped by PCR based methods polymorphisms. In addition, the presence of Torque Teno viruses in all samples was detected by nested-PCR.

Results: Torque Teno viruses were detected with similar frequency in all groups. The distribution of genotypes in all lots is not different from the Hardy-Weinberg equilibrium. Evidence of association between D-CP were obtained for rs1800795 in combination with TTV (p<0.05). The VDR genotypes or the haplotype are similar distributed in patients and control lots. No significant association was detected between investigated polymorphisms and age at diagnosis of CP or T2DM.

Conclusions: We found that association between rs1800795 and TTV can change the risk for chronic periodontitis in diabetic patients from Romania.

E-P06.06

Fabry Disease: Report of a mexican family with a previously unreported mutation in exón 6 of the GLA gene (c.968C>G p.P323R)

I. P. Dávalos Rodríguez¹, M. A. Aceves-Aceves¹, S. A. Alonso-Barragán¹, I. M. Salazar-Dávalos¹, L. E. Wong-Ley Madero², C. A. Ramírez-Aréchiga³, E. Cervantes-Pérez⁴, J. J. Magallanes-Ordoñez^{4,5}, D. García-Cruz¹, N. O. Dávalos-Rodríguez^{1,6,7};

¹Instituto de Genética Humana Dr. Enrique Corona, CUCS, Universidad de Guadalajara, Guadalajara, Mexico, ²Hospital Civil de Tepic, Tepic, Mexico, ³Departamento de Bienestar y Desarrollo Sustentable, Centro Universitario del Norte, U de G, Colotlán, Mexico, ⁴Doctorado en Farmacología, CUCS, Universidad de Guadalajara, Guadalajara, Mexico, ⁵Hospital Regional "Dr. Valentín Gómez Farías" Cirugía Plástica, Zapopan, Mexico, ⁶Hospital General de Occidente SSJ, Zapopan, Mexico, ⁷Hospital Regional "Dr. Valentín Gómez Farías" Genética, ISSSTE, Zapopan, Mexico.

Introduction: Fabry Disease (FD) is a lysosomal storage disorder caused by a deficiency of the enzyme α -galactosidase A. It is an X-linked trait caused by a mutation in the GLA gene on Xq22.1. The phenotype/genotype in FD is heterogeneous. FD causes glycolipids to accumulate in the vascular and endothelium.

Objective: We present the case of a 3 generation family where five individuals are identified as carriers of a previously unreported heterozygous variant of FD in exón 6 of the GLA gene.

Case report: The probanda is a 9 month-old female, product of non-consanguineous parents. At 24 hours of birth, bilateral subconjunctival hemorrhage and jaundice appear, remaining in intensive care for breathing difficulties, heart murmur and hypertension. Renal ultrasound: ectasia in left kidney, small right renal artery and right renal hypoplasia. FD Testing: Gene Sequencing GLA heterozygous variant in exon 6 of the GLA gene (c.968C>Gp.P323R). HPLC/Tandem MS lyso Gb3 0.8ng/ml (reference<0,8/ml). Family sequencing studies: 4 members (mother, maternal: aunt, cousin and grandfather), with same mutation. Normal Gb3. None of them had F.D. symptomatology.

Discussion: In this case only the probanda presents clinical manifestations of FD at birth. There are no reports of infants with these findings. In this variety the genotype/phenotype association appear to be independent findings.

Conclusions: FD has a high genetic heterogeneity. Molecular studies and

genotype-phenotype correlation are required to clarify the variability. Family clinical and molecular studies are required to prevent complications and implement enzyme replacement therapy to improve the quality of life if necessary.

E-P06.07

A novel GLA mutation in a Maltese patient with early-onset Fabry disease

I. Borg^{1,2}, C. Apap³, S. Aquilina³, S. Pirotta⁴, G. Sciriha⁴, M. Vella⁴, S. Eichler⁵, A. Rolfs^{6,5};

¹Department of Pathology, University of Malta, Msida, Malta, ²Medical Genetics Unit, Mater Dei Hospital, Msida, Malta, ³Dermatology Department, Sir Paul Boffa Hospital, Floriana, Malta, ⁴Ophthalmology Department, Mater Dei Hospital, Msida, Malta, ⁵Centogene AG, Rostock, Germany, ⁶Albrecht Kossel Institute for Neuroregeneration, University of Rostock, Medical Faculty, Rostock, Germany.

Fabry disease is an X-linked lysosomal storage disorder. Mutations in the GLA gene result in deficient alpha galactosidase A enzyme activity and subsequent progressive accumulation of globotriaosylceramide (GL-3) in the vascular endothelium and various body organs.

Here we report a novel hemizygous mutation p.Lys240ArgfsX29 in exon 5 of the GLA gene in a 15 year old male who presented with angiokeratomas in the trunk region, pain in the body extremities, gastrointestinal pain and cornea verticillata. Alpha galactosidase A activity was 0.0078mU/mg (normal range 0.36-0.84 mU/mg). This mutation was subsequently found in his asymptomatic 45 year old mother. No other family members were found to carry this mutation. Concentration of the biomarker Lyso-Gb3 was markedly increased at 195ng/ml (normal reference <0.9 ng/ml).

In view of the clinical phenotype and the very low alpha galactosidase A activity we conclude that this novel mutation is the cause of Fabry disease in this patient.

Isabella Borg received a research grant from Shire plc. Arndt Rolfs is supported by Shire Int with several travelling grants and unrestricted educational grants for scientific projects and workshops.

E-P06.08

Primary familial hypercholesterolemia (FH) in children might be caused by different genes

I. M. Abramova¹, E. Hramtsova¹, A. Y. Vasina², I. Y. Melnikova¹, V. Larionova^{3,1};

¹North-Western State Medical University named after I.I. Mechnikov, St. Petersburg, Russian Federation, ²St. Petersburg State University, St. Petersburg, Russian Federation, ³Center For Rare Diseases and Molecular medicine „IEM“ RAS, St. Petersburg, Russian Federation.

The role of the molecular testing is the most important in the early diagnostics of autosomal recessive FH, since lipid level in parents may be normal. Diagnostics of autosomal dominant form of FH (ADH) is possible by both routine laboratory tests and family history evaluation.

Material and Methods: Analysis of mutation in a gene of a receptor of LDLP DeltaG197 exon 4 in two patients with FH. Results: Patient M., 6 years old, with skin xanthomas in palms, elbow and knee joints, inguinal and popliteal folds. The first elements of xantoma appeared at the age of 4 years old. The patient's lipidogram showed cholesterol 16mmol/l, triglycerides (TG) 4.5 mmol/l, low-density lipoprotein (LDLP) 8.52 mmol/l. The family pedigree revealed early heart attacks in relatives of the 2nd and 3rd degree on the maternal line. His mother had tendinous xanthomas at the age of 29 years old and his father has normal lipid analysis. Mutation in LDLP DeltaG197 4 exon was detected in the child, his mother, and the mother's side relatives. Patient A., 14 years old. Lipidogram showed cholesterol-10.8 mmol/l, TG-2.0 mmol/l, HDL-C-1.8 mmol/l, LDLP-8.1 mmol/L. Mutation in LDLP gene DeltaG197 exon 4 was not detected. Parents' lipid analyses were normal. Family history was not available.

Conclusions: In the patient M., ADH might be caused by mutation in LDLR gene. In the patient A., normal lipidogram in the parents and relatives did not allow excluding the autosomal recessive FH (ARH1), which can be confirmed by the further analysis of LDLRAP1 gene.

E-P06.09

Revealing a novel mutation in GALC gene with Krabbe disease

I. Suer¹, A. Koparır¹, R. Celik², A. Onul^{2,3}, A. Yüksel⁴, M. Ozen^{3,5,6},

¹Istanbul University, Istanbul Medical Faculty, Department of Internal Medicine, Division of Medical Genetics., Istanbul, Turkey, ²Biruni University, Reyhan Genome Center., Istanbul, Turkey, ³Biruni University, Department of Medical Genetics/Molecular Biology and Genetics., Istanbul, Turkey, ⁴Biruni University., Istanbul, Turkey, ⁵Department of Medical Genetics, Cerrahpasa Medical School, Istanbul University., Istanbul, Turkey, ⁶Department of Pathology and Immunology, Baylor College of Medicine., Houston, TX, United States.

Introduction: Krabbe disease (KD) is a rare autosomal recessive inherited neurometabolic disorder associated with the mutations in GALC gene. This gene is located in the 14q31 and comprises of 17 exons. 138 mutations have been reported in the GALC gene and the mutations change galactocerebrosidase activity. The clinical findings can be seen in various spectrums depending on galactocerebrosidase activity.

Material and Method: In the current study, we present a Turkish male with KD having neurodevelopmental delay, increased spasticity, homocystinuria, seizures, and optic atrophy. Galactocerebrosidase deficiency was demonstrated by biochemical analysis. We utilized next generation sequencing (NGS) as a diagnostic tool to identify the molecular basis of KD and we confirmed suspected variants by Sanger sequencing.

Result: We found a novel homozygous c.825C>G p.Asp275Glu missense mutation in exon 7 of GALC and confirmed it by Sanger sequencing. Parents were demonstrated to be heterozygous for this mutation.

Conclusion: Finding novel mutations in the related gene of Krabbe disease is beneficial for establishing certain diagnosis and estimating the prognosis of the disease. It is also important for deciding proper treatment alternatives for the physicians.

E-P06.12

Case report: Novel IVD gene mutation induces Isovaleric acidemia (IVA)

S. Mohammadi, M. Ebrahimi Nasab, S. Seyedhassani;

Dr. Seyedhassani Medical Genetic Center, yazd, Iran, Islamic Republic of.

Introduction: Isovaleric acidemia (IVA) is an autosomal recessive inborn error of the leucine metabolism that is caused by a deficiency of isovaleryl-CoA dehydrogenase (IVD). Isovaleryl-CoA dehydrogenase (IVD) is a mitochondrial matrix enzyme that catalyzes the third step in leucine catabolism. The genetic deficiency of IVD results in an accumulation of isovaleric acid, which is toxic to the central nervous system and leads to isovaleric acidemia. **Materials and Methods:** In this study, the proband with symptoms of IVA referred us. We used the newborn screening for metabolic diseases with GC/MS method that shown an increased significant of C5 organic acid, the result of screening and symptoms of newborn confirmed the Isovaleric acidemia (IVA). Then we evaluated all of the exons and exon-intron boundaries of IVD gene with PCR-Sequencing method.

Results: We identified a novel homozygous mutation (c.326 T>C p.L109P) in exon 4 of IVD gene. The heterozygosity of his parents for the mentioned mutation was confirmed by PCR-Sequencing method. There was no report of this mutation in the literature; because this mutation was present in the parents, in heterozygous state, it is very likely to be pathogen. Bioinformatics analysis (with UMD-Predictor, ExPasy, UCL-CS, Polyphen and CADD Score) confirmed our studies.

Conclusion: Our study showed a novel mutation for IVD. This result can be used for genetic counseling and prenatal diagnosis.

E-P06.13

L-2-Hydroxyglutaric aciduria: Identification of a novel mutation in the L2HGDH gene at Turkish Family

H. Bagis¹, M. Ö. Çevik¹, I. Güneş¹, B. Ekmekçi², Ö. F. Karaçorlu¹;

¹University of Adiyaman and Medical Faculty, Department of Medical Genetic, Adiyaman, Turkey, ²University of Adiyaman and Medical Faculty, Department of Neurology, Adiyaman, Turkey.

Background: L-2-Hydroxyglutaric aciduria (L-2-HGA) is a rare inborn error of metabolism caused by mutations in the L-2-hydroxyglutarate dehydrogenase (L2HGDH) gene which is mapped at chromosome 14q22.1, consists of 10 exons. We have identified a novel L2HGDH gene mutation and three L-2-HGA patients at a family.

Case Presentation: A 29-year-old man admitted to our clinic with complain of epilepsy and mild intellectual disability. His brain MRI revealed a symmetrical, extensive subcortical white matter lesion and also a cystic lesion at deep white matter. Urine test for organic acids showed a significantly increased level of 2-hydroxyglutaric acid and simultaneous plasma lysine

amino acid level also was very high. These findings suggest us diagnosis of L-2-HGA. After L2HGDH gene sequence analysis, a homozygous variation, c.738G>A (p.Lys246Lys), in exon 6 reported. The variation has no effect on amino acid residue but its location at the last codon of sixth exon and may alter splicing. After further evaluation; his brother and his sister also have similar signs and their molecular analysis showed same c.738G>A change at L2HGDH gene. Parents have third cousin marriage and have no symptoms. Parents' gene analysis confirmed heterozygous single base change at same nucleotide and so diagnosis of siblings' L-2-HGA disease at molecular level.

Conclusion: For the understanding associated clinic symptoms and identification of exact mechanisms of this rare disease we have an ongoing project for high consanguinity rates and diseases burden at South-East of Turkey especially at Adiyaman province and at the village of this family. Possible genotype-phenotype correlation will be declared after study.

E-P06.14

The Leigh syndrome caused by novel SURF1 mutation detected in Slovakia

D. Danis¹, M. Skopkova¹, K. Brennerova², M. Kolnikova³, T. Kurdiava¹, B. Ukropcova¹, J. Ukropec¹, J. Stanik^{1,2,4}, I. Klimes¹, D. Gasperikova¹;

¹Institute of Experimental Endocrinology, Biomedical Research Centre, Slovak Academy of Sciences, Bratislava, Slovakia, ²First Department of Pediatrics, Medical Faculty of Comenius University and Children Faculty Hospital, Bratislava, Slovakia, ³Department of Pediatric Neurology, Medical Faculty of Comenius University and Children Faculty Hospital, Bratislava, Slovakia, ⁴Center for Pediatric Research, Hospital for Children & Adolescents, University of Leipzig, Leipzig, Germany.

Leigh syndrome (LS) is a genetically heterogeneous disease caused by insufficient function of the mitochondrial respiratory chain. Typical presentation starts in infancy with psychomotor regression, ataxia, dystonia, lactic acidosis and characteristic MRI findings. Nuclear gene SURF1 encodes an assembly factor for cytochrome c-oxidase complex and is vital for its function. Autosomal recessive mutations in SURF1 cause approximately one third of COX-related LS cases.

Patients and Methods: Psychomotor delay, severe hypotonia, hypotrophy, hypoglycemia and elevated blood and CSF lactate were noted in 6 month-old boy. Decreased activities of Complex II and IV were witnessed. Nevertheless, MRI was not pointing to LS at the time. Demyelination of pons, mesencephalon and basal ganglia were observed later at 11 months and rapid progressive deterioration lead to death at the age of 1 year. Blood sample was collected for whole exome sequencing (WES) at the age of 6 months. WES was performed on Complete Genomic's platform. Called variants were loaded into Gemini SQLite database and all nuclear genes encoding mitochondrial proteins were inspected.

Results: Two heterozygous deletions c.845_846del(p.S282Cfs*9) and c.823_833+7del(p.I275Vfs*13) were found in SURF1 (biallelic presence confirmed by allele-specific PCR followed by Sanger sequencing). The c.845_846del variant is the most common pathogenic variant in SURF1. Previously unreported c.823_833+7del variant is not present in population databases (dbSNP142, ESP, ExAC, LOVD) and resulting protein would lack functional C-transmembrane domain therefore we consider it pathogenic. **Conclusions:** We have identified two variants (one novel) in SURF1 which resulted in LS with ambiguous onset but with rapid progression.

Support: APVV-107-12

Identification and characterization of the novel point mutation m.3634A>G in the mitochondrial MT-ND1 gene associated with LHON syndrome

L. Carreño Gago^{1,2}, J. Gamez³, Y. Cámara^{1,2}, E. Alvarez de la Campa⁴, J. Aller-Alvarez³, D. Moncho⁵, M. Salvado³, A. Galan⁶, X. de la Cruz⁴, T. Pinos^{1,2}, E. García-Arum^{1,7,2};

¹Departament de Patologia Mitochondrial i Neuromuscular/Hospital Universitari Vall d'Hebron Institut de Recerca (VHIR), Barcelona, Spain, ²Centro de Investigaciones Biomédicas en Red de Enfermedades Raras (CIBERER)/ISCIII, Barcelona, Spain, ³Departament de Neurologia/Hospital Universitari Vall d'Hebron, Barcelona, Spain, ⁴Translational Bioinformatics/Hospital Universitari Vall d'Hebron Institut de Recerca (VHIR), Barcelona, Spain, ⁵Departament de Neurofisiologia/Hospital Universitari Vall d'Hebron, Barcelona, Spain, ⁶Departament d'Oftalmologia/Hospital Universitari Vall d'Hebron, Barcelona, Spain, ⁷Department of Clinical and Molecular Genetics and Rare Disease Unit/Hospital Universitari Vall d'Hebron, Barcelona, Spain.

Leber's hereditary optic neuropathy (LHON) is a mitochondrial genetic disease characterized by acute or subacute, progressive, and bilateral central visual loss. The most cases of LHON syndrome are caused by point mutations in MT-ND1, MT-ND4 and MT-ND6 genes.

We report a homoplasmic novel mutation m.3634A>G in MT-ND1 gene (p.Ser110Gly), in a patient with a classic clinical features of LHON syndrome.

Several observations support the idea that mutation is pathogenic and involved in the clinical phenotype of the patient: 1) the mutation affected a conserved nucleotide and amino acid; 2) in the same amino acid was previously reported a pathogenic mutation (m.3635G>A,p.Ser110Asn) in a patient with LHON syndrome; 3) the mutation was not observed in databases like Mitomap and Human Mitochondrial Genome Database; 4) in silico predictors programs classified the mutation as “probably damaging”; 5) cybrids carrying the mutation presented decreased enzyme activity of complex I and lower cell proliferation and mitochondrial membrane potential respect to control cybrids.

E-P06.16

Late-onset Tay-Sachs disease (LOTS) with common Ashkenazi mutation in a patient of Russian-Tatar ethnicity

G. E. Rudenskaya, A. M. Bukina, T. M. Bukina, E. Y. Zakharova, D. Pyankov; Medical Genetics Research Centre, Moscow, Russian Federation.

Introduction: Two variants of GM2 gangliosidosis, Tay-Sachs disease common in Ashkenazi Jews (gene HEXA) and less frequent but occurring globally Sandhoff disease (HEXB), have rare late-onset forms differing from common infantile phenotype and poorly detected clinically.

Materials and Methods: We diagnosed LOTS in 27-year-old female of mixed ethnicity (Russian mother and Tatar father). Enzyme and DNA tests were used.

Results: The patient coming from Bashkiria (south-east of European Russia adjoining Ural) had typical presentation of adolescence-onset, slow-progressing proximal spinal amyotrophy, spinocerebellar ataxia with cerebellar atrophy on MRI, subclinical polyneuropathy and normal intelligence. We suspected late-onset GM2 gangliosidosis by correspondence 14 years after disease onset. Minding patient's origin, Sandhoff disease seemed probable, but laboratory findings were those of LOTS: decreased hexosaminidase A level with residual activity 4% and HEXA mutation c.805G>A (p.Gly269Ser). Mutation looked like homozygous, but heterozygosity was found only in father and not in mother which may have several explanations: patient's false homozygosity due to maternal HEXA large deletion (though HEXA large deletions are rare), p.Gly269Ser de novo or germinal mosaicism in mother. The origin of mutation in upper generations of family could not be traced. The mutation in homozygous or compound-heterozygous state is common for Ashkenazi LOTS and was also found in few non-Ashkenazi LOTS families, mostly with roots matching regions of historical Ashkenazi settlement (Navon et al, 1990; Neudorfer et al, 2005), but not in Turkic populations as in our case.

Conclusion: The case points to wider spread of HEXA p.Gly269Ser mutation than was thought.

E-P06.17

The face of treated Wolman syndrome

C. Breen^{1,2}, S. A. Jones^{1,2}, S. Douzgou^{1,2};

¹Manchester Centre for Genomic Medicine, Manchester, United Kingdom, ²Institute of Human Development Faculty of Medical & Human Sciences, University of Manchester, Manchester, United Kingdom.

The natural history of classic early onset lysosomal acid lipase deficiency (also known as Wolman disease) is characterised by hepatosplenomegaly and severe failure to thrive followed by death within 6 months of life. The presence of vacuolated lymphocytes and adrenal calcification may also aid diagnosis although this is confirmed with enzymatic and molecular tests. Treatment with the licensed enzyme replacement therapy sebelipase alfa (Kanuma, Alexion) has led to patients surviving longer than the previously reported life expectancy. As the children have become older, we noted that they share similar craniofacial features. We propose a facial gestalt in early onset lysosomal acid lipase deficiency including down-slanting palpebral fissures, a depressed nasal bridge and mid face hypoplasia.

E-P06.19

Association of FTO Gene Variants with Metabolic Syndrome (MetS) risk factors in Tehran cardio-metabolic Study (TCGS)

S. Masjoodi¹, S. Zoroufchin¹, B. Sedaghatikhayat¹, M. S. Fallah¹, K. Guity¹, F. Aziz², M. S. Daneshpour¹;

¹Cellular and Molecular Endocrine Research Center, Research Institute for Endocrine Sciences, Shahid, Tehran, Iran, Islamic Republic of, ²Endocrine Research Center, Research Institute for endocrine sciences, Shahid Beheshti University of Medical Sciences, Tehran, I.R. Iran, Tehran, Iran, Islamic Republic of.

Background: Metabolic Syndrome (MetS) has many components like waist circumferences and hypertension. Fat mass and obesity-associated gene

(FTO) could play important role in their metabolism. The present study tries to examine the relationship between FTO and CETP gene variants and 2 metabolic syndrome risk factors in affected subjects.

Materials and Methods: This association study was conducted in affected MetS 1120 participants in TCGS. Nine different single-nucleotide polymorphisms (SNPs) of FTO and CETP genes (rs1121980, rs1421085, rs1558902, rs8050136, rs7202116, rs6499640, rs1864163, rs3764261, rs1800775) were genotyped using Tetra ARMs-PCR. All data adjusted by age and smoking status. The association of each SNP with Mets parameters was analyzed by Plink software.

Results: Four FTO variants (rs1121980, rs8050136, rs1558902 and rs1421085) were associated with waist circumferences and hypertension. Risk-alleles of three first SNPs were significantly associated with diastolic and systolic blood pressure and waist circumferences in the both gender. Strong association were observed in presence of minor allele A at rs8050136 with diastolic and systolic blood pressure and waist circumferences (P dbp = 0.007, p sbp = 0.005, p waist = 0.0008). In rs1421085 the C minor allele showed a significant result males (P dbp = 0.005, p sbp = 0.019, p waist = 0.005).

Conclusions: A significant interaction between rs8050136 and diastolic and systolic blood pressure as well as waist circumferences was seen. In conclusion, the presence of A allele could be a predictor of high waist circumferences and increase blood pressure.

Implementing the survey of disease natural history as a tool to collect complex information on mitochondrial patients in Lithuania and Latvia

B. Burnyte¹, I. Inashkina², B. Lace², D. Pelne², A. Molyte¹, K. Grigalioniene¹, V. Kucinskas¹, A. Utkus¹;

¹Department of Human and Medical Genetics, Faculty of Medicine, Vilnius University, Vilnius, Lithuania, ²Latvian Biomedical Research and Study Centre, Riga, Latvia.

Mitochondrial disorders (MD) result from impaired cellular energy metabolism and encompass a broad range of conditions with variable manifestations including neuromuscular, cardiac, ophthalmic, auditory, endocrine, and renal involvement. These patients are referred to clinical geneticists by any doctor, mainly pediatrician, neurologist or general practitioner, who suspects a MD diagnosis based on clinical grounds. The objective of this work is to standardize the collection of clinical and research data across Lithuania and Latvia.

Hence, we developed the survey of disease natural history to help us select a group of patients with clinical mitochondrial syndromes and with suspected MD, including respiratory chain deficiency, for a molecular and functional study which is a part of the collaborative project. The survey in use was adapted for both countries in 2015 and includes demographics, genealogy, clinical data, results of biochemical, histochemical and genetic investigations. Nijmegen mitochondrial disease criteria were also added to this survey (Morava E et al, 2006). The tool will serve as a baseline for data to be obtained in 2015-2017. 64 patients were enrolled in 2015. 12.50% of them make up a definite MD group, 73.44% make up a probable MD group and 14.06% are in a possible MD group. Data and biosamples will be accessible to study collaborators and, on request, to other researchers to assist relevant studies. Adopting the survey will improve patient selection and allow us to validate and interpret data from this collaborative project. We will report all preliminary data received during the first year of this study.

TYMP Gene IVS9+1G>A mutation is Related with Hypergonadotropic Hypogonadism in Patients with Mitochondrial DNA Depletion Syndrome Type 1

B. Çavdarlı¹, C. Çavdarlı¹, Ö. Ünal², S. Seylaner³;

¹Ankara Numune ETH, Ankara, Turkey, ²Dişkapı Pediatrics ETH, Ankara, Turkey, ³Intergene Genetics Center, Ankara, Turkey.

Introduction: Mitochondrial DNA depletion syndrome 1 (MIM #603041), also named MNGIE (Mitochondrial Neurogastrointestinal Encephalomyopathy) is an autosomally recessive inherited multisystemic disorder caused by mutations in TYMP gene which encodes Thymidine phosphorilase, the enzyme of mitochondrial nucleotide synthesis (1). MNGIE is characterised with gastrointestinal dysmotility, peripheral neuropathy, sensorineural hearing loss, ophthalmoplegia, ptosis and mitochondrial energy metabolism defects.

Material-methods: A 24 years old male with chronic diarrhea, cachexia and ptosis was evaluated. He was the second child of healthy parents who had third degree consanguineous marriage. Auditory assessment was normal

and external ophthalmoplegia and ptosis were noted by ophthalmologic examination. Myopathic alterations were indicated on electromyography and diffuse patchy intensity increment was seen in subcortical white matter on the cranial MR images. Hormone analyses of the patient revealed elevated FSH and LH levels in relation to his hypoplastic gonads and external genitalia. **Result:** DNA sequence analyses revealed a homozygote IVS9+1G>A mutation in TYMP gene.

Conclusion: We report the second patient with hypergonadotropic hypogonadism and a homozygote IVS9+1G>A mutation in TYMP gene (2). Gonadal dysfunction might be the result of mitochondrial defects. MINGIE syndrome patients with a IVS9+1G>A mutation in TYMP gene should be investigated for hypergonadotropic hypogonadism.

E-P06.22

Case Report: A novel mutation in Classic Maple Syrup Urine Disease

M. Yavari^{1,2}, M. Mirjalili¹, S. Seyedhassani¹;

¹Dr. Seyedhassani Medical Genetic Center, Yazd, Iran, Islamic Republic of; ²Department of Biology, Faculty of Science, Yazd University, Yazd, Iran, Islamic Republic of.

Introduction: Maple syrup urine disease (MSUD) is an autosomal recessive metabolic disease caused by mutations in the *BCKDHA*, *BCKDHB*, *DBT* and *DLG* genes, which encode the E1 α , E1 β , E2 and E3 subunits of the branched-chain α -keto acid dehydrogenase (BCKD) complex, respectively. This complex is involved in the metabolism of branched-chain amino acids. MSUD can be divided into 4 types, depending on the amount of BCKD enzyme activity present in the affected individuals. The most common type of MSUD is the classic form.

Materials and Methods: In this study, we analyzed the DNA sequences of *BCKDHA* gene in an infant who suffered from MSUD and died at the age of 17 days. Quantitative tandem mass spectrometric analysis was used to assess the levels of branched-chain amino acids in plasma. All of the exons and exon-intron boundaries of *BCKDHA* genes were amplified under standard PCR conditions. PCR products were subjected to Sanger sequencing and output files were aligned to the human genome reference and analyzed by Finch TV 1.4 software.

Results: Screening of all exons and adjacent introns revealed a homozygous deletion (GTTTTC(A⁴⁷)TCTCtGGATGA) as in exon 2 of the *BCKDHA* gene resulting in protein alteration. The heterozygosity of his parents for the mentioned deletion was confirmed by direct sequence analysis of the corresponding segment. This deletion causes a frame shift alteration.

Conclusions: We have identified a novel *BCKDHA* mutation. This finding can be useful in genetic counseling. Prenatal diagnosis is suggested to investigate of the fetus in the next pregnancy.

E-P06.25

Investigation of The Genetic Factors Which Effect Obesity,Physical Activity Level and Eating Behavior

D. Kirac¹, T. Avçilar², O. Kasımay Cakır³, O. Deyneli⁴, D. Yazıcı⁴, H. Kurte⁵, E. C. Kaspar⁵, A. I. Güneş²;

¹Yeditepe University, Faculty of Medicine, Department of Medical Biology, Istanbul, Turkey, ²Marmara University, Faculty of Medicine, Department of Medical Genetics, Istanbul, Turkey, ³Marmara University, Faculty of Medicine, Department of Physiology, Istanbul, Turkey, ⁴Marmara University, Faculty of Medicine, Department of Endocrinology and Metabolism, Istanbul, Turkey, ⁵Yeditepe University, Faculty of Medicine, Department of Biostatistics, Istanbul, Turkey.

Obesity is a major contributory factor of morbidity and mortality. Besides environment factors, genetic factors may also contribute to the level of physical activity and eating behaviours thus effect obesity. Therefore the aim of this study is to investigate the effect of various gene mutations on obesity, physical activity levels and eating behaviours. 100 patients and 100 healthy individuals were enrolled to the study. Physical activity levels were measured with an accelerometer. Eating behaviours were evaluated using Three-Factor Eating questionnaire. The information about other risk factors were also collected. DNA was isolated from peripheral blood. Mutations of MC4R and the region located 2696 to 3275 bp upstream of the MC4R start codon were investigated with PCR and direct sequencing. 6 mutations in FTO, 1 mutation near MC4R and 1 mutation in NMB were investigated with real-time PCR. Results were evaluated statistically. rs1051168 and rs8050146 mutations were found statistically significant in patients, rs1121980 was found statistically significant in controls. 16 mutations were found in MC4R of

which 14 of them are novel and 8 of them cause amino acid change. 5 mutations were found near MC4R in which 4 of them are novel. Also it was found that, some obesity related factors and questions of TFEQ are associated with various gene mutations. Any relation between gene mutations and physical activity levels were not detected. Due to the genotype data, physical activity demands and eating behaviours, it may be possible to recommend patients for proper exercise and eating patterns to prevent obesity.

E-P06.26

Isovaleric acidemia : a case report with a new mutation

H. Onder Yılmaz, S. Seyhan, M. Çakır, A. H. Çebi, M. İkbal; Karadeniz Technical University Medicine Faculty, Trabzon, Turkey.

Isovaleric acidemia is a rare, autosomal recessive, isovaleryl coenzyme A dehydrogenase enzyme deficiency disorder associated with an organic acid metabolism. There are two forms of the disease 1-)Acute form (approximately 50% of cases) appear in two weeks of life with lethargy, vomiting and dehydration.2-)Chronic intermittent form occurs after stress or a high protein intake during later childhood.It is seen in 1/250,000 live births. Mutations in the IVD gene causes isovaleric acidemia.Up to now there is 25 defined mutation in IVD gene.In this study, we present a 8-years-old-male who was brought to our emergency clinic with vomiting,fever and abdominal pain. The patient was hospitalized with acute pancreatitis. Two years ago he has been determined with same diagnosis.Cystic fibrosis whole gene sequence analysis was negative. Newborn screening of metabolic disorders was performed due to existing of refractory vomiting and abdominal pain, the absence of drugs or toxic agents ingestion,history of brother death. Due to diagnosis of isovaleric acidemia on tandem mass metabolic screening panel we made IVD gene whole exom sequence analysis. As a result we determine the patient p.E117K(c.349G>A)(Homozygous). The analysis of known mutations that are sent from the patient's parent and his healthy siblings were determined as p.e117k (c.349G>A)(heterozygous). We present this case because it is a new mutation in the IVD gene.

E-P06.27

The PAH mutations in different ethnic groups from Rostov region (Russia)

M. A. Amelina¹, S. S. Amelina², A. A. Stepanova³, A. V. Polyakov A.V.³, S. I. Kutsev^{3,4}, R. A. Zinchenko^{3,4};

¹Academy of Biology and Biotechnology of Southern Federal University, Rostov-on-Don, Russian Federation, ²The Rostov State Medical University 29, Nakhichevansky Street, Rostov-on-Don, 344022, Russia, Rostov-on-Don, Russian Federation, ³Research Centre for Medical Genetics, 115478, Russia, Moscow, Moskvorechye st.1, Moscow, Russian Federation, ⁴Pirogov Russian National Research Medical University, 117997, Russia, Moscow, Ostrovityanova st. 1., Moscow, Russian Federation.

Introduction: The PAH mutations in PKU patients of different ethnic groups from Rostov region were studied.

Materials and methods: Epidemiological, PCR, sequencing, MLPA. DNA analysis of PAH gene was conducted in 130 PKU patients (72.2% Russian, 3.95% Armenian, 3.95% Turks, 1.59% Dargin, 0.79% Jews).

Results: Diagnostic efficiency was 100%, 40 different PAH mutations were revealed. Among Russian PKU patients (190 chromosomes) the major mutation is R408W (50,77%). The second frequent mutation is IVS12+1G>A (3,46%). Less common mutations were R261Q(2,69%), P281L (1,54%), R158Q (2,31%), R252W(1,15%), L48S (1,15%), 21 mutations (A300S, EX-5del, IVS4+5G>T, IVS10-3C>T, R297H, A342T, A403V, E280K, F39del, F299C, IVS2+13T>G, IVS7+1G>A, IVS9+5G>A, IVS10-11G>A, K363fsdelG, R176X, R408Q, Y268C, p.N133_Q134>Rfs, c.47_48delCT, p.V245A) were detected only once.

The Armenians PKU patients (10 chromosomes) had genotypes: R252W/IVS10-11G>A (2 patients), F39del/IVS10-11G>A (1 patient), K363>Nfs/IVS10-11G>A (1 patient), P281L/R261Q (1 patient). The most frequent mutation was IVS10-11G>A and R252W.

The Meskhetian Turks PKU patients carried genotypes R408W/R408W (2 patients), IVS10-11G>A/IVS10-11G>A (2 patients) and E390G/IVS11+1G>C (1 patient).

In two Dargin PKU patients the major mutation was R261X, 3 of 4 chromosomes (genotype patients R261X/R261X, R261X/R261Q). The Jewish patient is a carrier of the genotype R408W/R408W.

Conclusions: The results of the study can be used for optimizing Medical Genetic Counselling in PKU families in the Rostov region.

This work was partially funded by RFFI grants 14-04-00525 and 15-04-01859.

E-P06.29

Novel pathogenic variant in the PEX3 gene with unusual biochemical findings and a mild clinical presentation in the Zellweger syndrome spectrum

K. Bjørge¹, H. H. Mørk¹, R. Fjær¹, S. Ferdinandusse², S. S. Amundsen¹, M. A. Kulseth¹, K. Selmer¹;

¹Oslo University Hospital, Oslo, Norway, ²Academic Medical Center, Amsterdam, Netherlands.

Zellweger spectrum disorders (ZSDs) are caused by a defect in peroxisome biogenesis due to mutations in one of 13 PEX genes. Clinical findings are heterogeneous, with the most important features being liver dysfunction, developmental delay and other neurological abnormalities, adrenocortical dysfunction and impairment of hearing and vision. Typically, ZSD patients accumulate very long-chain fatty acids, phytanic acid and bile acid intermediates, and have a deficiency of plasmalogens in erythrocytes. Most patients with a PEX3 defect present with a severe form of Zellweger syndrome with death in the first year of life.

We present a brother and sister from a consanguineous marriage who are homozygous for a novel pathogenic variant c.206-1G>T in intron 2 of PEX3. The patients are in their twenties and have spastic tetraparesis, nystagmus, visual impairment, leukodystrophy and mental retardation.

mRNA studies in patient fibroblasts revealed that the c.206-1G>T substitution abolishes the normal splice site. This leads to activation of a cryptic acceptor splice site and production of an in-frame transcript with a 27bp (9aa) deletion.

Biochemical studies revealed normal peroxisomal parameters in blood and fibroblasts, but catalase immunofluorescence microscopy analysis showed that peroxisomes were enlarged in most cells and in some cells the number of peroxisomes was reduced.

Our patients exemplify how a splice site variant predicted to give a severe phenotype can be less severe than expected due to activation of a cryptic splice site. Based on the mRNA studies we propose that the in-frame product has residual activity explaining the milder phenotype in our patients.

E-P06.32

Lack of association between rs1326634 polymorphism and T2D: Tehran Lipid and Glucose Study (TLGS)

A. Zadeh-Vakili¹, H. Karimi², M. Zarkeshi¹, M. S. Daneshpour¹;

¹Cellular and Molecular Endocrine Research Center, Obesity Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran, Islamic Republic of, ²Department of biology, East Tehran branch, Islamic Azad University, Tehran, Iran, Islamic Republic of.

Introduction: Type 2 diabetes (T2D) is a multifactorial disease. One of the most important genes involving in this disease is SLC30A8. This study was conducted to investigate the relation between rs1326634 C>T polymorphism and T2D in a Tehranian population.

Materials and methods: Subjects were 603 T2DM and 1100 healthy, chosen from among participants of the Tehran Lipid and Glucose Study. Polymorphism from SLC30A8 gene was genotyped using the Tetra-Arms-PCR and results were confirmed by direct sequencing.

Results: Distributions of genotypes did not differ between cases and controls. The frequency of CC, CT, and TT genotypes was 29.4, 41.4, and 29.2% respectively, in controls. In the case group, the frequency of CC, CT, and TT was 24.6, 46.2, and 29.2%, respectively. Means of BMI, waist, and hip circumference were higher in TT control subjects ($P < 0.05$). After adjustment for age, sex, and BMI in cases, the probability of high TG decreased by 54% among heterozygote (CT) vs. the homozygote combined group (CC+TT) (95% CI: 0.34-0.85, $P = 0.009$). After splitting by sex and adjustment for age and BMI, in male cases, the probability of high TG was significantly decreased by 47%, among heterozygotes (95% CI: 0.25-0.87, $P = 0.016$).

Conclusion: Although we found no association between the rs1326634 polymorphism and T2D, obesity-related indices, as risk factors for T2D, showed a significant relationship with TT genotype in controls. Based on these results, heterozygosity for T allele predisposes individuals to obesity, the effect that may be masked by other factors in diabetic patients.

E-P06.36

Identification of a new point mutation in MOCOS gene that is responsible for Xanthinuria Type II in a compound heterozygous case

E. Perez, A. Lafuente, M. Ortiz, J. Orts, S. Ferrando, A. Zúñiga; Hospital de la Ribera, Alzira (Valencia), Spain.

Hereditary xanthinuria (HX) is a rare autosomal recessive disorder caused by a deficiency of xanthine dehydrogenase/oxidase (XDH/XO), affecting purine metabolism. Symptoms are related with extreme insolubility of xanthi-

ne, and include urolithiasis, crystalluria, hematuria, recurrent urinary tract infections and renal colic. Two clinically indistinguishable types of classical HX have been described. Type I (XDHD; OMIM#278300) is a simple XDH deficiency due to mutations in XDH gene, whereas Type II (XDH/AO CD; OMIM603592) results from a combined deficiency of XDH and aldehyde oxidase (AO) caused by mutations in molybdenum cofactor sulfurase (MOCOS) gene, located on chromosome 18q12.2. Only about 150 cases of HX have been reported currently, being the prevalence higher in the Mediterranean and Middle East. Type I appears to predominate. We report a rare case of Type II HX in a female infant from non-consanguineous parents.

The patient presented hypouricemia and hypouricosuria, as well as higher concentrations of hypoxanthine and xanthine in urine. Xanthine calculi were confirmed by infrared spectroscopy. The genetic study was performed by PCR amplification of the XDH and MOCOS genes with specifically designed primers and subsequently Sanger sequencing. Results were negative for XDH, but two different mutations were found in MOCOS: c.1104_1105delCT (p.Leu363ProfsTer16; NM_017947) maternally inherited; and the novel mutation c.1387G>A (p.G463R; NM_017947) paternally inherited. Pathogenicity was determined by in silico analysis with PolyPhen-2 and Mutation Taster softwares.

In our case, final diagnosis and typing of HX has been achieved by molecular genetics, avoiding more invasive tests like allopurinol loading test and intestinal or liver biopsy.

E-P06.37

Novel compound heterozygout mutation in zellweger syndrome

S. Seyedhassani^{1,2}, N. Tabibnejad^{1,3}, M. Ebrahimi¹;

¹Dr. Seyedhassani Medical Genetic Center, Yazd, Iran, Islamic Republic of, ²Genomic Research Center, Shahid Beheshti Medical Science University, Tehran, Iran, Islamic Republic of, ³Research and Clinical Center for Infertility, Shahid Sadoughi Medical Science University, Yazd, Iran, Islamic Republic of.

Introduction: A couple with two neonates suffering from multiple congenital anomalies was referred to genetic counseling center. They had non-familial marriage without any evidence of genetic disorder in familial pedigree. The first neonate malformations were prominent forehead, low set ear, short neck, short nose, corneal clouding, micrognathia, high arch palate, pectus carinatum, ventricular septal defect, abnormal palmar crease, limbs deformities and club foot. Karyotype and CGH array were reported normal. He was died in third month. The second neonate had similar manifestations and was died in sixth month. The first case was assumed as Larsen syndrome before NGS. But the molecular analysis for FLNB gene was normal.

Materials and methods: Whole Exome Sequencing were used to enrich all exons of protein-coding genes as well as some important other genomic regions. Next generation sequencing was performed to sequence close to 100 million read on Illumina sequencer. In general, test platform examined >95% of the targeted regions with sensitivity of above 99%. Bioinformatics analysis of the sequencing results was performed using international databases and standard bioinformatics software. We performed Sanger sequencing on proband and parent in order to confirm the mutations.

Results: Two deleterious missense mutations in PEX1 gene were found. There were heterozygous condition NM_001282677: exon21:c.3274dupC:p.Q1092fs and NM_000466:exon7:c.G1407A:p.W469X in mother and father respectively.

Conclusions: There was no report of these mutations in the literature. Mutation in this gene is shown to cause Peroxisome biogenesis disorder 1A (Zellweger). This data can be used for genetic counseling and prenatal diagnosis.

Detection of Alpha Thalassemia by Using Multiplex Ligation Dependent Probe Amplification as an Additional Method for Rare Mutations in Southern Turkey

O. Ozalp Yuregir¹, A. Ayaz¹, S. Yalcintepe¹, S. Canbek¹, D. Y. Acik¹, B. T. Yilmaz², T. B. Balci³;

¹Numune Training and Education Hospital, Genetics Diagnosis Center, Adana, Turkey, ²Numune Training and Education Hospital, Department of Hematology, Adana, Turkey, ³Numune Training and Education Hospital, Department of Pediatric Hematology, Adana, Turkey, ⁴Children's Hospital of Eastern Ontario, Department of Genetics, Ottawa, ON, Canada.

Alpha thalassemia is the most common single gene disorder in the Cukurova Region in Turkey. It is therefore routinely screened, including premaritally, in our region. The heterogeneous molecular basis of the disease makes al-

pha thalassemia mutation detection difficult and complex. Besides well established methods, multiplex ligation dependent probe amplification (MLPA) is known as an effective, simple and specific method for the detection and characterization of deletions and duplications. We employed MLPA testing to 30 patients with hematological parameters suggestive of alpha thalassemia carrier status but was negative for alpha thalassemia with conventional reverse dot blot hybridization (RDB). We found alpha globin gene deletions in 3 out of 30 (10 %) patients with MLPA. We propose that MLPA can be used as a second tier test in addition to other techniques such as RDB to identify alpha thalassemia carriers in high prevalence regions such as ours, thereby allowing clinicians to provide accurate genetic counselling.

E-P07.02

Role of the C1858T polymorphism of protein tyrosine phosphatase non-receptor type 22 (PTPN22) in children and adolescents with type 1 diabetes

M. Provenzano, A. Blasetti, C. Di Giulio, S. Tumini, L. Comegna, G. Prezioso, R. Chiuri, F. Chiarelli, L. Stuppia;
G d'Annunzio University, Chieti, Italy.

Type 1 diabetes (T1D) is an immune-mediated disease causing the destruction of insulin-producing β -cells. The degree of β -cell destruction and the consequent amount of residual β -cell function are heterogeneous and can lead to variations in C-peptide secretion. In recent years, interest has been expressed on the susceptibility polymorphisms of T1D. The aim of this study was to define the frequency of the C1858T polymorphisms in the PTPN22 gene, which codes for a protein (Lyp) that may negatively regulate the proximal signaling pathway after T cell receptor activation, in a cohort of 113 Caucasian patients (58 male and 55 female) with T1D, and to assess a possible link to a group of clinically relevant variables: age at onset, gender, diabetes-related autoantibodies, residual β -cell function, and daily insulin requirement six months after diagnosis. The C1858T variant (rs2476601) was investigated through PCR-RFLP and we found that the frequency of the PTPN22 C1858T polymorphism in the analyzed diabetic patients is 17.7%. A statistically significant correlation between the polymorphism and higher levels of C-peptide at diagnosis and lower insulin requirement at six months from diagnosis was seen ($p=0.001$ and $p=0.04$). Moreover 1858T variant carriers were more frequently positive for glutamic acid decarboxylase autoantibodies than wild type subjects ($p=0.19$) at diagnosis. In conclusion, these findings if extended to a larger cohort of samples may characterize a subset of T1D patients with a defined genetic pattern, who may be eligible for trials aimed at preserving the residual β -cell function.

A novel missense MVK mutation in a family with familial Mediterranean fever-like disease

I. Karacan¹, S. Uğurlu², **A. Tolun**³, E. Tahir Turanlı^{1,4}, H. Özdoğan²;
¹Department of Molecular Biology and Genetics, Istanbul Technical University, Istanbul, Turkey, ²Department of Internal Medicine, Division of Rheumatology, Cerrahpaşa Faculty of Medicine, Istanbul University, Istanbul, Turkey, ³Department of Molecular Biology and Genetics, Boğaziçi University, Istanbul, Turkey, ⁴Dr. Orhan Ocaltıray Molecular Biology-Biotechnology and Genetics Research Center, Istanbul Technical University, Istanbul, Turkey.

Introduction: Monogenic autoinflammatory diseases are mainly disorders of innate immunity and characterized by unprovoked inflammatory attacks. We studied a consanguineous family with two affected children, with an initial diagnosis of Familial Mediterranean Fever (FMF). While recurrent febrile attacks with serositis, high acute response and parental origin were consistent with FMF, disease onset before age one year, delay in growth, no mutation in MEFV and poor response to colchicine were not typical features of this disease.

Methods: SNP genotype data for all family members were used for multi-point linkage analysis. Targeted sequencing was performed for MVK residing in one of the linked regions and seven other autoinflammation related genes, IL1RN, LPIN2, MEFV, NLRP12, NLRP3, TNFRSF1A and PSTPIP1. After the identification of the causative mutation, serum IgD and urinary mevalonic acid levels were measured.

Results: Linkage analysis detected seven candidate regions. The largest candidate region, at 12q24.11-q24.31 (LOD=1.92), contained 191 genes. Novel homozygous c.481T>C (p.Cys161Arg) mutation in MVK, the gene responsible for Hyper IgD Syndrome (HIDS) was identified. At the protein level, cysteine at position 161 is totally conserved in mammals. Urinary mevalonic acid was not detected for either patient, and serum IgD level was slightly elevated for only one patient.

Conclusions: We identified a novel homozygous MVK mutation in patients with a FMF-like disease but without a typical HIDS phenotype. We hypoth-

size that this novel mutation underlies the atypical clinical presentation. Phenotypic variability of HIDS is well known, and our findings further expand the MVK mutation phenotype.

Supported by TÜBİTAK Grant-114Z829.

EKLf mutation co-related with HPFH phenotype in β -thalassemia patients in Iran

M. Hamid¹, S. Ershadi Oskoue², G. Shariati³, E. Babaei², H. Galehdar³, A. Saberi²;
¹Pasteur Institute of Iran, Tehran, Iran, Islamic Republic of, ²University of Tabriz, Tabriz, Iran, Islamic Republic of, ³Ahvaz Jundishapur University of Medical Sciences, Ahvaz, Iran, Islamic Republic of.

Introduction: KLF1 gene is an essential transcription factor for primitive and definitive erythropoiesis, any mutation in KLF1 gene may interfere with its proper related function in erythropoiesis process in red blood cell maturation and lead to alter proper activation of its downstream protein through globin switching, which results an increase in fetal globin blood level (HbF). This study aims to investigate whether KLF1 mutation can associate with high HbF level in β -thalassemia patients in southwest of Iran, the region that has high frequency of hemoglobinopathy disorders. Materials and Methods: At first the human KLF1 gene was amplified via PCR procedure, and sequencing was used to determine any mutation in these patients. Also XmnI polymorphism in the position of -158 of γ -globin gene promoter were analyzed in all patients. Results: Analysis of sequencing revealed a missense mutation in KLF1 gene, S102P, which was detectable in 10 out of 23 cases with HPFH phenotype. Among studied population only in individuals with HbF level between 3.1%_25.6% the mutation was identified. Statistical analysis showed that allele frequency of the mutation S102P among studied group is significant (P-Value=0.3383). Allele frequency for positive and negative results of XmnI digestion in patient with increased HbF level 0.565, and 0.434 were determined respectively, which showed a positive association with increased HbF level (P-Value= 0.3508). Conclusions: According to statistical results of S102P mutation, and Xmn1 Polymorphism strongly suggest that both polymorphisms have association with HPFH phenotype in southwest of Iran.

E-P07.07

Combined immunodeficiency in 11q terminal deletion (Jacobsen syndrome)

T. Hovnik¹, A. Ihan², L. Lovrečić³, Š. Blazina⁴;
¹Unit of Special Laboratory Diagnostics, Children's Hospital Ljubljana, University Medical Centre Ljubljana, Slovenia, Ljubljana, Slovenia, ²Institute of Microbiology and Clinical Immunology, Faculty of Medicine, University of Ljubljana, Slovenia, Ljubljana, Slovenia, ³Clinical Institute of Medical Genetics, Division of Obstetrics and Gynecology, University Medical Centre Ljubljana, Slovenia, Ljubljana, Slovenia, ⁴Department of Allergy, Rheumatology and Clinical Immunology, Children's Hospital Ljubljana, University Medical Centre Ljubljana, Slovenia, Ljubljana, Slovenia.

Background: Terminal 11q deletion syndrome also known as Jacobsen syndrome (JS; OMIM#147791) is a rare genetic disorder that affects different body systems. Antibody deficiency is common in patients with JS but there has been only a few reports on additional T-cell defects.

Methods and results: Standard and molecular cytogenetics studies on peripheral blood lymphocytes from patient and her parents showed 46,XX,del(11)(q23.3).ish del(11)(q23.3)(D11S1037)-dn.Using array CGH, deletion breakpoint was shown to be at the band 11q24.1 encompassing most of the crucial genes responsible for typical phenotype of JS. Immunologic workup was consistent with antibody deficiency. In addition to low IgM, IgG4 and B-cells, low recent thymic emigrants, helper and naïve T-cells were also found.

Conclusion: We present a patient with confirmed JS in whom T-cell deficiency was observed in addition to antibody deficiency and other features of the syndrome. T-cell deficiency was not present during the initial evaluation, which highlights the importance of performing a thorough immunological follow up in patients with 11q terminal deletion syndrome. The prevalence of combined immunodeficiency in patients with JS is not known, as most patients have not yet been evaluated for T-cell defect.

E-P07.10

Vitamin D genes CYP27B1 and VDR regulated by the MS functional variant rs1087713 under inflammatory and autocrine-like stimuli

M. Fedetz¹, M. Karaky¹, C. Barrionuevo¹, C. Delgado², G. Izquierdo³, A. Alcina¹, F. Matesanz¹;

¹Instituto de Parasitología y Biomedicina López Neyra, CSIC, Granada, Spain, ²Centro Regional de Transfusión Sanguínea Granada-Almería (CRTS), Granada, Spain, ³Unidad

de Esclerosis Múltiple, Hospital Universitario Virgen Macarena, Sevilla, Spain.

Introduction: Vitamin D deficit is considered an important risk factor for many inflammatory and autoimmune diseases. In this study we present the influence of multiple sclerosis-associated regulatory variant rs10877013 on the expression of genes involved in vitamin D activation (CYP27B1), vitamin D receptor (VDR) and vitamin D degradation (CYP24A1) under inflammatory environment.

Materials and Methods: We used lipopolysaccharide and interferon gamma activated monocytes from 119 individuals and vitamin D-stimulated lymphoblastoid cell lines (LCLs, n=109) of 1000 Genomes to quantify the mRNA expression of vitamin D genes by RTqPCR.

Results: The expression level of CYP27B1 was associated with the rs10877013 genotypes ($P=5.0E-6$) in activated monocytes. This association between gene expression and variant genotypes was not observed in LCLs. Inversely, rs10877013 genotypes were associated with VDR expression in LCLs ($P=6.0E-4$) but it was not in monocytes. Finally, CYP24A1 was highly and specifically induced by active vitamin D (1,25-(OH)₂D₃) and its expression correlated with the expression of VDR in LCLs but no polymorphism was found to be associated with its expression in a search of variants in 1 Mb around its position.

Conclusions: The MS-associated variant rs10877013 is a genetic determinant that affects the functioning of vitamin D system linking environmental and genetic risk factors.

A Case of Novel Translocation

M. N. Somuncu, A. G. Zamani, M. S. Yildirim;

Department of Medical Genetics, Meram Medical Faculty, Necmettin Erbakan University, KONYA, Turkey.

Translocations are the rearrangement when a segment from one chromosome is becomes a nonhomologous chromosome or to a new site on the same chromosome. Genetic changes especially structural chromosomal aberrations as translocations have been usually observed in hematologic malignancy. Pure red cell aplasia (PRCA) is an hematologic disorder that maturation of erythrocytes are arrested and erythroblasts are mostly absent in bone marrow however white blood cell (WBC) and platelet production is normal. Ethio-pathogenesis of PRCA is clinic heterogeneity but the anemia usually can cause to PRCA and red blood cell (RBC) is ceased to produce in bone marrow. So that the maturation and differentiation of the blood cells can be hinder in hematologic pathway and can even lead to childhood lymphoma. Structural rearrangement of chromosome 1q31 between chromosome 2q37 has been reported with PRCA ten years old patient. Proband were referred to our clinic for bone marrow karyotype analyse had thrombocytopenia and anemia phenotype from pediatric hematology. We analysed the patient karyotype as 46,XX t(1;2)(q31;q37).

We have reported this novel rearrangements that has not been observed in any disorder contributing to the literature.

E-P07.12

Thrombomodulin gen analysis in a case of atypical haemolytic-uremic syndrome

I. Tirado¹, N. Vilalta², J. Mateo¹, I. Coll¹, B. Cuevas¹, J. López-Pardo¹, G. Fraga², S. Brió², E. Martínez-Sánchez¹, J. Fontcuberta¹;

¹Thrombosis and Haemostasis Unit, Hematology Department Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, ²Pediatrics Department Hospital de la Santa Creu i Sant Pau, Barcelona, Spain.

Introduction: Atypical haemolytic-uremic syndrome (HUS) is a condition presenting with the classic triad (microangiopathic haemolytic anaemia, thrombocytopenia and renal failure). Half of the patients have mutations in genes that regulate the complement system. Recently, mutations in the thrombomodulin (THBD) gene (an endothelial protein with anti-inflammatory and anticoagulant properties) have been reported in 5% cases. Our laboratory investigated the thrombomodulin gene in a patient diagnosed with atypical HUS.

Materials and Methods: A 21 month- old female was admitted to our emergency room with 5 days evolution fever. Physical examination revealed micropetechiae at lower limbs and hepatomegalia. Laboratory parameters showed microangiopathic haemolytic anaemia, acute renal failure, thrombocytopenia, hyperferritinemia, hypofibrinogenemia, elevated D-dimer concentration and 9% of ADAMTS-13 activity. With all these criteria the patient was diagnosed of atypical HUS and macrophagic activation syndrome.

We investigated the exon 1 of thrombomodulin gene associated with the atypical HUS. ABI3500 (Applied Biosystems®) was used to Sanger sequence the regions of the gene in different fragments delimited by primers that included all exon region of thrombomodulin gene.

Results: No mutations were found in the fragments sequenced of the patient. In our patient, DNA fragments from thrombomodulin gene analysed by direct sequencing do not show any variation. We performed the same analysis in a control group without findings.

Conclusion: The patient here discussed was diagnosed with atypical HUS and did not present THBD mutations. Next step will be study another genes implicate in this syndrome.

Association between CARD15/NOD2 gene polymorphisms and Ulcerative colitis (UC) and Crohn's disease in Turkish population

S. Budak Diler¹, E. Derici Eker², F. Polat³, S. Yaras²;

¹Niğde University, Niğde, Turkey, ²Mersin University, Mersin, Turkey, ³Kocaeli University, Kocaeli, Turkey.

Introduction: Ulcerative colitis (UC) and Crohn's disease (CD) are chronic inflammatory bowel diseases which are similar to each other for their clinical features and epidemiology. R702W, G908R and 1007fsInsC polymorphisms in CARD15/NOD2 genes are found to be related to this disease. We aimed to determine P268S and M863V polymorphisms in CARD15/NOD2 genes associated with an increased risk of developing UC and CD and to establish correlations between P268S and M863V genotypes in Turkish population.

Materials and Methods: This study included 153 healthy controls and 107 patients (42 CD and 65 UC) with CD and UC. The P268S and M863V gene regions were amplified using polymerase chain reaction (PCR), detected by restriction fragment length polymorphism (RFLP). The results of patient and control group were evaluated statistically.

Results: According our results, the P268S CC genotype was prevalent on patients and controls (55% vs 67%), followed by genotypes CT (38% vs 27%) and TT (7% vs 6%) in CD. The prevalence of genotypes of CC (wild-type), CT (heterozygous mutant) and TT (homozygous mutant) profiles for the P268S polymorphism were 69%, 25% and 6% respectively in UC patients, and 67%, 27% and 6% respectively in healthy control groups. Just two bands of 212 bp and 160 bp were found in wild-type M863V in all subjects and no other mutant band (372 bp) of M863V was detected using PCR-RFLP fragment electrophoresis.

Conclusions: There are no association P268S and M863V polymorphisms between patients with CD and UC and control groups in Turkish population.

Global developmental delay in a girl with Int22h1/int22h2-mediated Xq28 deletion.

E. Lloveras, L. Barranco, V. Cirigliano, A. Canellas, M. Costa, C. de la Iglesia, D.

Fernandez, M. Herrero, B. Méndez, N. Palau, M. Piqué, D. Yeste, E. Ordóñez, L. Rueda, A. Plaja;

Departaments de Genètica i Genètica Molecular. LABCO Iberia. Barcelona, Esplugues de Llobregat, Spain.

Introduction: A new deletion/duplication syndrome within Xq28 chromosomal band has recently been described caused by nonallelic homologous recombination between low-copy repeats (LCRs)intron 22 homologous region 1 (int22h1) and 2 (int22h2), in addition to int22h3, within the F8 gene. The duplication has been identified in males with cognitive impairment and females with mild or normal phenotype. The reciprocal deletion is rare. Only few cases have been described in the literature of normal females with skewed inactivation and at higher risk of miscarriages. We report a case of a girl with global developmental delay and Int22h1/int22h2-mediated Xq28 deletion.

Material and methods: ArrayCGH (Cytochip ISCA 8X60K, Bluegenome, Illumina) was performed in peripheral blood from a 4 years old girl with global developmental delay. Her mother had clinical history of miscarriages. Chromosome X inactivation studies were performed in peripheral blood using methylation-specific PCR of the polymorphic CGG repeat in the promoter region of the FMR1 gene.

Results: The proband was found to have a 450kb Xq28 deletion spanning from 154.1 to 154.5 Mb. The deletion included the F8 [MIM 300841], RAB39B [MIM 300774], CLIC2 [MIM 300138] and VBP1 [MIM 300133] genes. Complete skewed X chromosome inactivation pattern was observed.

The history of recurrent miscarriage reported in the mother strongly suggests her being an asymptomatic carrier of the same deletion. ArrayCGH is in progress.

Conclusions: Our patient shows global developmental delay and Int22h1/int22h2-mediated Xq28 deletion suggesting, but not demonstrating, the possibility that female carriers may occasionally show global developmental delay.

E-P08.03

Microdeletion of 10q21.3-q22.1 including CTNNA3 in a boy with intellectual disability, mucocutaneous pigmentation, and juvenile colon polyposis

C. Venegas-Vega^{1,2}, M. Guardado¹, J. Berumen^{1,2};

¹Hospital General de México, Mexico DF, Mexico, ²Facultad de Medicina, Universidad Nacional Autónoma de México, UNAM, Cdmx, Mexico.

Introduction: We described the case of a 9-year-old boy with a de novo 10q21.3-q22.1 microdeletion, intellectual disability (ID), attention-deficit hyperactivity disorder, mucocutaneous pigmentation, and juvenile colon polyposis (JCP). Methods and Results: Cytogenetic analyses in the proband and her parents was normal; Chromosomal Microarray Analysis (CMA) by CytoScan Optima in the patient revealed a deletion of about 4.41 Mb ([hg19] chr10:68,299,927-72,715,960), while CMA of parental DNA was normal. Although no similar size deletions were reported in DECIPHER database, there are several patients with much smaller pure deletions (86.05 to 378.77 Kb) that clustered at CTNNA3 gene (chr10:68,165,545-69,222,108). The most remarkable common feature of these cases was intellectual disability, global developmental delay and autism spectrum disorder. Moreover, the analysis of the gene content of the deleted region showed 40 MIM genes; of which only four have been implicated in autosomal dominant diseases. Our patient does not exhibit any clinical data of those conditions. In order to identify that genes could be involved in the phenotype, we analyzed physiologic roles, functional interactions, and also which those are dosage-sensitive. The results pointed to CTNNA3 (607667), LRRTM3 (610869) and SIRT1 (604479); all located in 10q21.3, as best candidates. Thus, these three genes may either individually or in combination be responsible for ID with JCP seen in our patient. Conclusions: To the best knowledge, this is the first report of a de novo 10q21.3-q22.1 deletion. This case suggests a novel genomic disorder at 10q21.3 region associated to ID with JCP.

E-P08.04

Different terminal chromosome 12q microdeletions are associated with defined clinical features

S. Genovese¹, V. Alesi¹, C. Surace¹, M. Bertol², M. Digilio³, A. Novelli¹;

¹Laboratory of Medical Genetics, "Bambino Gesù" Children's Hospital, Rome, Italy, ²Institute of Genetic Medicine, Newcastle University - Central Parkway, Newcastle upon Tyne, United Kingdom, ³Medical Genetics Unit, "Bambino Gesù" Children's Hospital, Rome, Italy.

Introduction: Deletion of 12q telomere is rare and few cases with different breakpoints and clinical features have been described in literature so far. Materials and methods: We have studied by means of oligo array CGH (Comparative Genomic Hybridization) two cases with this rearrangement: a 12 years old female patient and a 13 years old male patient both with intellectual disability, behavioral disorder, and obesity. Results: We have detected two microdeletions in the 12q24.33 chromosome region, 3.4 Mb and 1.4 Mb in size respectively, involving many common genes that may contribute to the clinical picture of the patients. These microdeletions partially overlap with deletions of other patients described in DECIPHER (Database of genomic variation and Phenotype in Humans using Ensembl Resources; <https://decipher.sanger.ac.uk/>) and previously published in literature with intellectual disability, kidney disease and problem of development of genitals. We have observed the presence of a minimum deleted region (660 Kb), located in the 12q subtelomeric segment including the P2RX2 gene, which has been previously proposed as a candidate gene for intellectual disability. In fact, behavioral disorder and mild mental retardation were common to all the patients. Larger deletions extended up to the proximal regions (3-9 Mb) containing the STX2 and NCOR2 genes, seem to be involved in urinary-genital apparatus and connective tissue anomalies. Conclusion: The comparison between our patients and the other ones already described has allowed us to link the size of deleted region to the clinical features.

E-P08.05

17p13.1 microdeletion: genetic findings on microcephaly

E. A. Rolo, A. Sousa, S. Serafim, R. Rodrigues, S. Custódio, R. Silveira-Santos, J. Dupont, A. B. Sousa;

Serviço de Genética Médica, Departamento de Pediatria, Centro Hospitalar Lisboa Norte-Hospital Santa Maria, EPE; Centro Académico de Medicina de Lisboa, Lisboa, Portugal.

Introduction: 17p13.1 microdeletion syndrome has a wide spectrum of clinical features, including intellectual disability, absent/very poor speech, dysmorphism and microcephaly. This clinical diversity is partly a consequence of deletion size, which ranges from 245kb to 4.4Mb. Thus, it is suggested that two or more microdeletion syndromes may exist within this region and a genotype-phenotype correlation has yet to emerge. Here we discuss the genetic and clinical features observed in a patient with a small 17p13.1 deletion. We focus on microcephaly, a prominent feature of this syndrome. Material and Methods: We report a 4-year-old boy referred to aCGH testing presenting with global psychomotor delay, facial dysmorphisms and microcephaly. Family history was unremarkable. Samples were studied by aCGH (NimbleGen CGX 135K, Perkin Elmer). Genomic analysis was performed with Genoglyphix v3.0 software (Signature Genomics). Results: aCGH revealed a de novo microdeletion of 287.53kb in the 17p13.1 region (hg19; chr17:7,119,830-7,407,357) containing 23 OMIM genes. Overlapping our deletion with the previously reported 17p13.1 microdeletions, we identified a new minimal region of 92kb for microcephaly. Conclusions: The phenotype observed in our patient is consistent with the 17p13.1 microdeletion syndrome. Previously reported patients with 17p13.1 deletions pointed to an overlapping region associated with microcephaly, including four genes, ASGR1, ACADVL, DVL2 and GABARAP. Considering the presence of microcephaly in our patient and the lack of ASGR1 gene in the deleted segment, we propose to exclude this gene as a candidate for this feature. These findings contribute to narrow the 17p13.1 critical genomic region associated with microcephaly.

E-P08.06

1q44 microdeletion syndrome: a de novo 314 kb CNV involving HNRNPU and FAM36A genes in a girl with psychomotor delay, epilepsy and corpus callosum hypoplasia

A. Sousa, S. Custódio, R. Silveira-Santos, P. Dias, A. B. Sousa;

Serviço de Genética Médica, Departamento de Pediatria, Centro Hospitalar Lisboa Norte-Hospital de Santa Maria, Centro Académico de Medicina de Lisboa, Lisboa, Portugal.

Introduction: 1q44 terminal microdeletion has emerged as a clinically recognizable syndrome. Phenotypic presentation, although heterogeneous, includes moderate to severe developmental delay (DD)/intellectual disability (ID), microcephaly and seizures. Corpus callosum abnormalities are also commonly observed, but attempts at defining its critical region have yielded inconsistent results to date. Small size interstitial deletions within 1q44 locus are rare and help to appoint candidate genes for this particular trait. Materials and Methods: We describe a 12-year-old girl referred for array-CGH testing due to moderate DD/ID. At physical examination, she presented short stature, craniofacial dysmorphisms including bifid uvula, convergent strabismus, bilateral ankle valgus deformity and pes planus; head circumference was normal. Brain-MRI revealed corpus callosum hypoplasia. She had been diagnosed with absence epilepsy at 11. Results: A de novo 314 Kb deletion in 1q44 terminal region was detected by arrayCGH (CGX-HD 180K, Signature Genomics/Perkin Elmer), including the FAM36A, HNRNP and EFCAB2 genes (HG19 Chr1:244,961,796-245,276,463). Discussion/Conclusions: Except for the absence of microcephaly, this patient has a full 1q44 microdeletion phenotype. Selmer KK et al. reported a boy with a 163 kb deletion in 1q44 involving the FAM36A and HNRNPU genes, who also had moderate DD/ID, absence seizures, thin corpus callosum and normal head circumference. This case reinforces FAM36A and HNRNPU as good candidate genes for 1q44 microdeletion features, namely corpus callosum abnormalities. Functional studies are needed to clarify the role of these genes in brain development.

E-P08.07

Case report compilation of submicroscopic chromosomal gains and losses at Xp22 region in individuals with intellectual disability detected by Microarray based comparative genomic hybridization (array-CGH)

S. Franco¹, C. Benito¹, V. A. Penacho², I. Manchón², D. Amorós², I. Gómez-Milanés², L. A. Alcaraz²;

¹Hospital Regional Málaga, Málaga, Spain, ²Bioarray, S.L., Elche, Spain.

Context: Submicroscopic chromosomal gains and losses are responsible for intellectual disability (ID) and dysmorphic features that affects about 3% of the population. The distal portion of the short arm of the human X chromosome (Xp22) is a region that undergoes frequent genomic rearrangements. **Objective:** Our goal is to compile case reports of submicroscopic gains and losses located at Xp22 region that were undetectable by routine cytogenetic analysis while reliable detection was feasible by array-CGH. **Methods:** Samples from 14 subjects anonymized (5 unrelated), collected at Hospital Carlos Haya, were ascertained in Bioarray as having Xp22 gains/losses. Five unrelated patients presented ID and dysmorphism suspicious of an underlying chromosome abnormality not confirmed by karyotyping. Agilent 60K Oligonucleotide array-CGH platform based on the construction of the hg19 genome sequence was used in order to detect such gains/losses. **Results:** Five unrelated cases carried copy number variations ranging in size from ~0.126 to ~1.6 Mb. Two subjects showed duplications of maternal origin (microduplication at Xp22.31) and three had submicroscopic changes of unknown origin, as parental testing of origin was not performed (microdeletions at Xp22.33 and Xp22.32, and microduplication at Xp22.33). DLRS value that calculates the probe-to-probe log ratio noise of arrays was <0.2 in all the cases, which means a precise detection of very small aberrations. **Conclusions:** Our data confirm that Agilent 60K array-CGH can accurately detect microduplications and microdeletions at Xp22 region. It contains over 60,000 probes designed especially to detect small gains/losses in regions associated with mental retardation and/or developmental syndromes, among others.

E-P08.08
Implementation of aCGH assessment in genetic diagnostic of patient with global development delay/intellectual disability or multiple congenital anomalies - Romanian experience

I. Streata, S. Sosoï, A. L. Riza, F. Burada, F. Mixich, M. Ioana; University of Medicine and Pharmacy of Craiova, Human Genomics Laboratory, Craiova, Romania.

Introduction: Assessment of DNA copy number through array-CGH represent a powerful diagnostic tool for clinicians. Genomic microarrays are used as first-tier genetic tests in postnatal assessment of subjects diagnosed with unexplained global development delay (GDD)/ intellectual disability (ID), autism spectrum disorders (ASD) or multiple congenital anomalies (MCA) in almost all West European countries. Two years ago, we started to implement in South-West Romania the postnatal aCGH assessment of individuals with unexplained GDD/ID or CMA.

Materials and methods: We assessed 30 patients diagnosed with unexplained GDD/ID or CMA. Conventional cytogenetic evaluation did not detect any chromosomal imbalance that could be associated with the clinical phenotype of the patients. DNA isolated and purified from peripheral blood was examined for copy number variations (CNVs) using Roche NimbleGen 3x720K/12x135K or Agilent 4x180K/ 8x60K ISCA design oligonucleotide microarray. Copy number data was analyzed with Nexus 6.1 software (Nexus BioDiscovery, El Segundo, CA).

Results: aCGH assessment identified in several patients submicroscopic changes (microdeletions or microduplications) that could partially explain the clinical phenotype.

Conclusion: This study demonstrated the utility and importance of genetic testing through aCGH in the management and counseling of patients with unexplained GDD/ID or CMA and their families.

E-P08.10
Complete genetics study of a Bardet-Biedl Syndrome: from 60K oligonucleotide array-CGH to whole-exome sequencing

C. Benito¹, S. Franco¹, V. Penacho², D. Amorós², I. Manchón², I. Gómez-Milanés², L. A. Alcaraz²;

¹Hospital Regional Málaga, Málaga, Spain, ²Bioarray, S.L., Elche, Spain.

Context: The Bardet-Biedl syndrome (BBS) is an autosomal recessive disorder characterized by retinitis pigmentosa (RP), obesity, polydactyly, hypogonadism, kidney dysfunction and cognitive impairment. Its diagnosis is established by clinical findings and pathogenic variants found in at least 19 genes. **Case Report:** Four-year-old boy had development delay, hypogonadism, obesity and poor visual acuity. He was born with polydactyly for which he had surgery at 10-month-old. He also presented polycystic kidney disease, RP and hypospadias. No family history was reported. A Bardet-Biedl syndrome was suggested at Hospital Carlos Haya. **Objective:** Genetics study by CGH+SNP microarrays and whole-exome sequencing to identify pathogenic BBS-related variants. **Methods:** Blood samples from boy and both parents were ascertained in Bioarray. Firstly, 129 BBS-related mutations were studied by Agilent Custom CGH+SNP microarray. Both Agilent 60K and 400K

array-CGH were performed to detect microduplications/microdeletions. Finally, a whole-exome sequencing (Illumina HiSeq 2000) was carried out. **Results:** A total of 115/129 BBS-related mutations analyzed were excluded; 14 of them, in BBS1 gene, got no signal. Array-CGH 60K detected a microdeletion that affects one probe in BBS1 so size cannot be determined due to its low-density. No loss of heterozygosity was shown by CGH+SNP Microarray. **Results from array-CGH (400K)** determined a 11q13.2 homozygous microdeletion in the boy that affects BBS1 (0.011 Mb). Also, heterozygous deletions in both of the asymptomatic parents were found. Whole-exome sequencing confirmed BBS1 deletion and its size. **Conclusion:** Our data confirm that combination of Agilent 400K array-CGH and whole-exome sequencing can accurately detect pathogenic BBS-related variants.

Microarray analysis for novel copy number variations in Saudi family with intellectual disability and epilepsy

M. I. Naseer¹, A. G. Chaudhary¹, M. Rasool¹, F. Talal Ashgan¹, H. Schulten¹, F. Bibi², M. M. Jan³, M. H. Al-Qahtani¹;

¹CEGMR, King Abdulaziz University, Jeddah, Saudi Arabia, ²KFMRC, King Abdulaziz University, Jeddah, Saudi Arabia, ³Department of Pediatrics, Faculty of Medicine, King Abdulaziz University, Jeddah, Saudi Arabia.

Background

Epilepsy is genetically complex but common brain disorder affecting millions of people of the world with almost of all age groups. Novel Copy number variations (CNVs) are considered as important reason for the numerous neurodevelopmental disorders along with intellectual disability and epilepsy.

Material and Methods

In order to study novel CNVs and related genes in Saudi family in six affected and two normal individuals with epileptic seizures, intellectual disability (ID), and minor dysmorphism, we performed the high density whole genome Agilent sure print G3 Hmn CGH 2x 400K array-CGH chips analysis results were also validated by using quantitative real time PCR.

Results

Our results showed novel deletions, duplications and deletion plus duplication on differential chromosomal regions in the affected individuals that were not shown in the normal and parents. Amplifications were observed in the chromosome 1, 16 and 22 with LCE3C, HPR, GSTT2 and GSTTP2 genes respectively whereas the deletions were observed in the chromosomal regions 8p23-p21, the potential gene in this region is CSMD1 (OMIM: 612279) and chromosome 11 with potential genes OR4C6 and OR4P4 respectively.

Conclusions

We found some of the novel deletions and duplication in our study. Our results suggest that array-CGH should be used as a first line of genetic test for epilepsy except there is a strong indication for a monogenic syndrome. The aim of this study was to identify novel mechanisms underlying epileptic disorder, may help to recover the clinical management of individual cases in decreasing the burden of epilepsy in Saudi Arabia.

E-P08.12
Complex chromosomal rearrangement - terminal deletion 21q22.13, duplication 4p16.2, and putative mosaic trisomy 8 - in a child with developmental delay, mild facial dysmorphic signs, and muscle hypertonia

U. Heinrich¹, D. Wahl², M. Heinrich³, I. Rost¹;

¹Centre for Human Genetics and Laboratory Diagnostics, Martinsried, Germany,

²Medical Practice for Genetic Counseling and Psychotherapy, Augsburg, Germany, ³IL. Children's Hospital of the Central Hospital, Augsburg, Germany.

Case report: Here we present a 7 months old female with facial dysmorphic signs, high palate, hypotonia, pes supinatus, short stature, and borderline microcephaly. She is the first child of healthy nonconsanguineous parents.

Materials and Methods: Conventional karyotyping was performed using standard GTG banding technique. For array CGH analysis the CytoChip Oligo 180K microarray was used. Segregation analyses were performed by quantitative PCR. For the validation of the putative mosaic trisomy 8, FISH analysis was carried out on peripheral blood cell nuclei using a centromere 8 probe. **Results:** Karyotyping of peripheral blood lymphocytes revealed a terminally deleted chromosome 21. The characterization using array CGH showed a 9,22 Mb deletion with the proximal breakpoint lying in the DYRK1A gene in band 21q22.13. In addition, a 355 kb duplication in band 4p16.2 including the genes EVC and EVC2 as well as a putative mosaic trisomy 8 was revealed. Parental karyotyping was inconspicuous proving the deletion 21q to be de novo, and qPCR analyses could demonstrate the maternal origin of the duplication 4p16.2. FISH analysis of peripheral blood cells could not confirm

the putative mosaic trisomy 8.

Discussion: Pure partial monosomy 21q is a rare event and is associated with highly variable phenotype including variable dysmorphic signs, heart defects, seizures, motor developmental delay as well as intellectual disability. The influence of the maternally inherited duplication 4p16.2 on the phenotype remains unclear. As the putative mosaic trisomy 8 could not be confirmed in blood cells, the examination of a second tissue should be considered.

E-P08.13

Interstitial deletion of 5q35.1-q35.2 detected by array-CGH in a boy presenting with heart defect and intellectual disability

A. Röpke, C. Müller-Hofstede, S. Ledig, P. Wieacker, F. Tüttelmann; Institut für Humangenetik, Münster, Germany.

We report on a 15 years old boy, first child of healthy, non-consanguineous parents. During pregnancy, a ventricular septal defect (VSD), atrial septal defect (ASD) and an omphalocele were diagnosed. At the time of presentation, he demonstrated global developmental delay and unspecific facial dysmorphism. Conventional cytogenetic analysis revealed an apparently normal male karyotype (46,XY; GTG banding at 550 band level). Array-CGH analysis (Agilent 400k microarray set) uncovered a de novo deletion of 1.6 Mb in the chromosomal region 5q35.1-q35.2. This deletion was confirmed by FISH analysis.

The deletion comprises 11 genes including the NKX2-5 gene (OMIM 600584). Mutations in the NKX2-5 gene were identified in patients with ASD, VSD, tetralogy of Fallot, and other congenital cardiac defects. The deletion does not overlap with the minimal Sotos syndrome deletion region.

To the best of our knowledge, there are only two reports on patients with small deletions in 5q35.1-q35.2 including the NKX2-5 gene. One patient was described with severe heart defect, microcephaly, minor facial dysmorphic features, scoliosis, cryptorchidism, learning difficulties associated with ADHD and an IQ of 83. He carried a 2.2 Mb deletion in 5q35.1-q35.2 (Baekvad-Hansen et al., 2006). The other patient (Decipher database, patient 257414) with ASD, cryptorchidism, hypothyroidism and intellectual disability showed a 2.1 Mb deletion in 5q35.1-q35.2.

E-P08.14

Down syndrome and obstructive sleep apnea in children

T. Marcovici^{1,2}, M. Puiu^{1,2}, G. Brad^{1,2}, D. Nicoara², T. Bizerea¹, O. Marginean^{1,2}; ¹University of Medicine and Pharmacy „Victor Babes”, Timisoara, Romania, ²„Louis Turcanu” Children’s Emergency Hospital, Timisoara, Romania.

Introduction. In children with Down syndrome obstructive sleep apnea (OSA) is common. Predisposition to OSA is dependent on oropharyngeal anatomical peculiarities of Down syndrome and obesity is an aggravating factor. Sleep fragmentation, episodic nocturnal hypoxemia and hypercapnia result in reduced release of GH (growth hormone) during sleep and onset of the short stature. The association of hypothyroidism emphasizes the cognitive deficit due to trisomy 21 and obstructive sleep apnea. Compromising somatic growth in height is a powerful long-term consequence in children with OSA.

Material and method. We present the case of a 10 year and 5 months old boy with Down syndrome in which the periodic clinical and laboratory assessment identified the presence of hypertrophic adenoids and tonsils, sleep apnea, thyroid hypofunction and dyslipidemia.

Results. The patient is obese (BMI = 23kg / m² at the 95th percentile for gender and age), with residual SAO after tonsils and adenoids ablation, hypercholesterolaemia and mild subclinical hypothyroidism (TSH = 5.71 uIU/mL, FT3 = 6.82 pmol/L, FT4 = 14.27 pmol/L). Sleep polygraphy revealed mixed apnea, predominantly obstructive, with apnea-hypopnea index = 18.3/hour, average SaO₂ = 95%, desaturation index = 20.5/hour. It was recommended hypocaloric diet, lateral decubitus posture during sleep, substitution with potassium iodide and reevaluation in order to initiate CPAP.

Conclusions. Evaluation of sleep apnea and thyroid function in patients with Down’s disease is mandatory. Obstructive sleep apnea, obesity and hypothyroidism require interdisciplinary and individualized management in these patients.

Molecular and phenotypic characterization of intronic SNP rs2239809 of faciogenital dysplasia 1 (FGD1) gene

Y. M. Khimsuriya¹, N. M. Kharod², G. U. Padmani³, J. B. Chauhan¹, N. Roy¹; ¹Ashok & Rita Patel Institute of Integrated Study & Research in Biotechnology and Allied Sciences (ARIBAS), Anand, India, ²H.M. Patel Center for Medical Care and Education, Karamsad, India, ³Bachpan Children Hospital and Neonatal Care, Surat, India.

Introduction: Faciogenital dysplasia gene (Xp11.22) mutations are associated with genetically heterozygous Aarskog-Scott syndrome (ASS) as well as Non-syndromic X-linked intellectual disability. FGD1 protein is an important regulator of events that control extracellular matrix remodeling, bone development, cell migration and also involved in the regulation of few secretory proteins. Recent studies suggest that non-coding variants are equally important for disease progression. Current study tests manifestations of intronic variant SNP rs2239809 of FGD1 in intellectually disabled children.

Materials and Methods: The prediction of associated intronic variants of FGD1 gene was performed using GWAS (Genome Wide Association Study) central database and GWAS 3D web server. PCR-RFLP was performed for screening of selected intronic variants. Sanger sequencing was used to validate single nucleotide change in FGD1 gene. Clinical features were studied and compared; partial pedigree was recorded for selected patients.

Results: The significant alteration was found in two affected children from different family harboring intronic variant c.659+27T>C (rs2239809) at intron 3 of FGD1 gene. Surprisingly, female and male showed different phenotypic appearance for same variation. Atypical X-linked inheritance pattern was observed in case of female patient.

Conclusion: Present study provides significant insight that intronic variant also affects gene functions. Our data do not support that X linked inheritance favoring FGD1 gene mutations in the affected male and female patients. Further study needed for confirmation of inheritance pattern, several pathophysiological manifestations and variability of X inactivation in case of female patients.

Patient with language impairment, intellectual disability, autism and de novo truncating FOXP1 variant helps to define emerging somatic phenotype associated with FOXP1 defects

D. Prchalová¹, M. Havlicová¹, M. Hančárová¹, V. Stránecký², Z. Sedláček¹; ¹Department of Biology and Medical Genetics, Charles University 2nd Faculty of Medicine and University Hospital Motol, Prague, Czech Republic, ²Institute of Inherited Metabolic Disorders, Charles University 1st Faculty of Medicine and General University Hospital, Prague, Czech Republic.

FOXP1 (forkhead box protein P1) is a transcription factor important in neurodevelopment. Thirteen patients with *de novo* protein-disrupting intragenic FOXP1 variants have been reported. They have language impairment, developmental delay/intellectual disability (ID) and autistic features. We report an 8-year-old boy with severe language impairment, moderate ID and atypical autism. His speech regressed at 18 months of age and started to improve again since 5 years of age. However, expressive speech is severely affected and shows no progress. The boy is hyperactive and anxious. Other features include hypotonia, mild facial dysmorphism, hypermetropia and strabismus.

Karyotyping and microarray analysis yielded no findings. Targeted next-generation sequencing using the TruSight Autism panel (Illumina) identified a private heterozygous nonsense FOXP1 mutation (NM_032682.5:c.1319C>G, p.S440*), which was confirmed using Sanger sequencing in the patient but in neither of his parents indicating its *de novo* nature. The aberrant transcript is likely removed by nonsense mediated decay (NMD), and FOXP1 haploinsufficiency was proposed as the main pathogenic mechanism. If the transcript escaped NMD, the p.S440* mutation would truncate FOXP1 between the leucine zipper dimerization domain and the FOX DNA-binding domain. A recently functionally characterized neighbouring FOXP1 variant p.Y439* showed aberrant protein localization.

Our patient supports the role of FOXP1 in language, cognition and behaviour, and helps to define the emerging characteristic somatic phenotype of FOXP1 mutation carriers which may include prominent forehead, frontal hair upsweep, arched eyebrows, hypertelorism, downslanting palpebral fissures, ptosis, low-set ears, short nose with a broad tip and smooth philtrum.

Supported by NT/14200, 00064203, CZ.2.16/3.1.00/24022 and NF-CZ11-PDP-3-003-2014.

Deletion 21q22.3 and duplication 7q35q36.3 in a Colombian patient

F. Ruiz-Botero, H. Pachajoa; Universidad Icesi, Cali, Colombia.

Introduction: Genetic disorders are a major cause in the etiology of intellectual disability cases; however, the analysis by conventional techniques such as cytogenetic karyotyping only allows the detection of chromosomal alterations in approximately 9.5% of them. The inclusion of new technologies such as high resolution microarray analysis have allowed the study of alte-

rations in chromosomal segments that are less than 5Mb in length; this has led to an increase in the diagnosis of these patients up to 25%.

Case report: We report the first case of an eight-year-old Colombian girl of mixed race ancestry, with clinical features that include: delayed psychomotor and language development, intellectual disability, upward slanting palpebral fissures, divergent strabismus, low-set and rotated ears, tall and broad nasal bridge, flat philtrum, bifid uvula, posterior cleft palate, increased anteroposterior diameter of the chest, congenital heart defect type interauricular communication, scoliosis and umbilical hernia. Genetic analysis was performed using comparative genomic hybridization array, which evidenced the deletion of a region of approximately 3,608Mb on chromosome 21q22.3, and a duplication of 12,326Mb on chromosome 7q35q36.3, these alterations affect approximately 112 and 186 genes, respectively.

Conclusions: To this date, this is the first report of an associated terminal deletion of 21q and 7q duplication in a patient with delayed psychomotor development and intellectual disability. It is considered that future implementation of exome and RNA sequencing techniques, and analysis of their proteomic expression in a clinical context could lead to better analysis and interpretation of the genotype-phenotype correlation in cases similar to that described.

E-P08.19

Microdeletions/ microduplications among patients with intellectual disability in the Republic of Macedonia

G. Bozhinovski¹, E. Sukarova Stefanovska¹, Z. Gucev², E. Sukarova Angelovska², N. Angelovska², O. Jotovska², D. Plaseska-Karanfilska¹; ¹Research Center for Genetic Engineering and Biotechnology "Georgi D. Efremov", Skopje, Macedonia, The Former Yugoslav Republic of, ²Pediatric Clinic, Medical Faculty, Skopje, Macedonia, The Former Yugoslav Republic of, ³Institute for Mental Health of Children and Youth "Mladost", Skopje, Macedonia, The Former Yugoslav Republic of.

Gains or losses of genomic regions less than 5Mb, are delineated as a cause of many genetic disorders and are frequently associated with intellectual disability (ID), multiple congenital anomalies, various dysmorphic features or autism. The use of array comparative genomic hybridization (aCGH) technology in clinical practice increases the detection rate of causative genetic imbalances in approximately 15% of patients with ID of unknown cause. Due to the simplicity and flexibility of the performance multiplex ligation probe amplification (MLPA) is a method of choice for detection of known microdeletions/ microduplications in less developed countries.

We aimed to evaluate the diagnostic yield of MLPA technique for identification of microdeletion/microduplication syndromes among patients with ID. A total of 120 patients with various degrees of ID, autism and/or different dysmorphic features were included in the study. MLPA kit P245 was used in all patients, while P371-4 were used in patients with specific aberrations. MLPA revealed chromosomal imbalances in 15 out of 120 patients (12.5%). Some imbalances were associated with well-described syndromes: Wolf-Hirschhorn Syndrome or 4p16.3del. (n=2), and Prader Willi/Angelman or 15q11.2-q13.1del. (n=3). Other patients harbored uncommon chromosomal imbalances: 1p36.3 deletion, 3q29 deletion, 9q22 deletion, 15q13.2-13.3 duplication, 15q24.1 deletion, 17p11.2 deletion, 17p11.2 duplication, 17q21.31 deletion and 22q11.21 duplication. Xp deletion was also detected in one patient. Four of the rare chromosomal imbalances were confirmed and more precisely determined by array CGH analysis.

In conclusion, MLPA is rapid, low-cost technique that revealed the cause of intellectual disability in 12.5% of the patients in our setting.

E-P08.20

Primary immunodeficiency disorder associated with severe intellectual disability and abnormal brain MRI findings in a patient with 3q29 microduplication syndrome - A case report

I. Streata¹, S. Soso¹, A. L. Riza¹, F. Burada¹, M. G. Netea², F. Mixich¹, M. Ioana¹; ¹University of Medicine and Pharmacy of Craiova, Human Genomics Laboratory, Craiova, Romania, ²Department of Medicine and Nijmegen Institute for Infection, Inflammation and Immunity (N4i), Radboud University Nijmegen Medical Center, Nijmegen, Netherlands.

Introduction: Chromosome interstitial 3q29 microduplication syndrome (OMIM 611936) has been associated with a recognizable pattern of abnormalities such as mild to moderate cognitive impairment, cerebral palsy, speech delay, autistic traits, seizures, obesity, musculoskeletal anomalies (chest-wall and fingers deformities) and common craniofacial dysmorphic features.

Materials and method: We have investigated a 34-year old woman with severe intellectual disability, abnormal brain MRI findings suggestive for fronto-temporal dementia and primary immunodeficiency characterized through persistent mucosal infections with *Candida albicans*. Results of

EEG, karyotype, cerebral fluid analyses, abdominal ultrasound and urine/plasma metabolic screens were normal.

DNA isolated and purified from peripheral venous blood was further assessed by array-CGH platform (Roche NimbleGen, Madison, WI, USA) using an Array-CHX 3x720k slide. Copy number data was analyzed with Nexus 6.1 software (Nexus BioDiscovery, El Segundo, CA).

Results: - Assessment through Array-CGH identified 1.65 Mb duplication at 3q29. The duplicated region encompasses 29 genes including several protein coding genes such as RNF168, WDR53, TFRC, PIGX, PAK2, NCBP2, PIGZ, MF12, BDH1, FBXO45 or DLG1 and a non-coding mRNA: mir4797

Conclusions: We described a case with typical 3q29 microduplication syndrome with severe phenotype. To our knowledge, this is the first case with primary immunodeficiency features and expands the heterogeneous clinical spectrum of this syndrome. Consideration should be given to the above mentioned locus (3q29) in patients with recurrent fungal infections, intellectual disability and/or abnormal brain MRI findings.

Acknowledgement: This study was supported within the frame of European Social Fund, Human Resources Development Operational Program 2007-2013, project no. POSDRU/159/1.5/S/136893

E-P08.21

Screening for copy number variations on the X chromosome in patients with unexplained intellectual disability

P. P. Henrique^{1,2}, C. R. Lincoln-de-Carvalho^{1,2}, M. P. de Mello¹, A. P. Marques-de-Faria²; ¹Laboratory of Human Molecular Genetics, Center of Molecular Biology and Genetic Engineering, University of Campinas (UNICAMP), Campinas, São Paulo, Brazil, ²Department of Medical Genetics, School of Medical Sciences, University of Campinas (UNICAMP), Campinas, São Paulo, Brazil.

X-linked intellectual disability (XLID) is one of the most frequent genetic causes of intellectual disability (ID) occurring in 10-12% of all affected male individuals. Around 100 genes have been considered as determinant of XLID, however the role for many of them remains to be elucidated despite the knowledge on the great majority. Therefore, the aim of this study was to investigate copy number variations in XLID genes using Multiplex Ligation-dependent Probe Amplification technique in males with global developmental delay or ID of undetermined origin. A hundred and seven individuals were investigated using SALSA MLPA P106 MRX kit (MRC-Holland), which covers about 16 of the XLID genes, and alterations were confirmed by Real Time Polymerase Chain Reaction (qPCR). A normal invariant pattern was observed in 104 out of 107 individuals, and three showed variations that have been interpreted as duplications. One patient presented increased signal for HUWE1 gene, which plays a role in the control of neural differentiation. The second showed increased signals corresponding to regions of SCL6A8 and GDI1 genes; the former is included among genes involved in the creatine deficiency syndrome and the latter is involved with non-syndromic XLID. Conversely, the variation in ARX gene observed in MLPA analysis for the third patient was not confirmed in the qPCR assay. The first two individuals showed manifestations that support duplications as a cause of clinical phenotypes. These results reinforce the importance of including XLID gene analysis in the investigation of individuals with ID of undetermined origin.

E-P08.23

MECP2 duplication syndrome in a female patient with characteristic and novel clinical symptoms

K. Hadzsiev^{1,2}, M. Czako^{1,2}, A. Lőcsei-Fekete¹, A. Szabó^{1,2}, B. Meleg^{1,2}; ¹Department of Medical Genetics University of Pécs, Pécs, Hungary, ²Szentágotthai Research Centre, Pécs, Hungary.

Background: MECP2 duplication syndrome is a rare disorder, occurs almost exclusively in males and is characterized by moderate to severe intellectual disability, weak muscle tone in infancy, feeding difficulties, poor or absent speech, refractor seizures and muscle spasticity, developmental delay or regression. Affected females have been described only in rare cases

Patient: Here we present a female patient who was born after uneventful first pregnancy at 34 week of gestation with a birth weight of 2120 g. At the first day of life the cardiologic examination revealed pulmonary valvular stenosis. At that time in her dysmorphic status brachycephaly, deep set ears with a preauricular fistula on the left side, short limbs and hepatomegaly were to be detected.

Later on severe feeding difficulties developed which improved around the 18th month of age, but she administered anti-reflux formula because of GERD. Her somatomental development was severely delayed and extreme shyness, muscle spasticity and an excessive sweating developed. During the first year of life she required some hospitalization because of recurrent airway infection

Result: We performed an aCGH and detected an Xq28 duplication with a size of 293-kb. The duplication contained the MECP2 and IRAK1 gene.

Discussion: The most observations on patient with Xq28 microduplication syndrome indicate that the minimal duplication region, including MECP2 and IRAK1 was sufficient to cause the typical clinical phenotype of MECP2 duplication syndrome.

Conclusion: In our patient with MECP2 microduplication syndrome beside the known clinical symptoms novel features were described.

E-P08.25

Autosomal recessive primary microcephaly caused by deletion 8p23.1 in MCPH1 gene

M. Hejtmankova, V. Becvarova, L. Hnykova, J. Horacek, M. Trkova, D. Stejskal; GENNET, Praha 7, Czech Republic.

Case report: We present a case where a mentally retarded female, whose previous diagnosis was referred to as autistic spectrum disorder, has primary microcephaly inherited as an autosomal recessive. Her birth weight was 2500g at 38 week of gestation. Diagnosis of microcephaly was confirmed early after birth. Head circumference was on 3rd percentile. She has not suffered epilepsy, but she has had mild dysmorphic features and moderate cognitive impairment. She was referred to geneticist to specify the diagnosis at the age of 8.

Methods: We have used SNP array (Illumina) analysis. The homozygous deletion of approximately 46 kb, encompassing the first three exons of the MCPH1 gene (microcephalin 1), was found in child. The phenotype in the heterozygous carrier mother was normal. The phenotype and genotype of her biological father was unknown.

Conclusion: Microcephaly may be part of many genetic malformation syndromes or may result from a variety of intrauterine factors. More specific and accurate diagnosis with molecular confirmation may provide a possibility of more focused health supervision, which could be essential for patient and genetic counselling in prenatal diagnosis of parents.

E-P08.27

Copy number variants in a cohort of Romanian patients with neurodevelopmental disorders

A. Arghir¹, S. Papuc¹, C. Iliescu², D. Craiu², D. Barca², B. Budisteanu², I. Focsa¹, M. Cristea¹, I. Borcan¹, M. Budisteanu^{1,2}, A. Tutulan-Cunita¹; ¹Victor Babes National Institute of Pathology, Bucharest, Romania, ²"Prof. Dr. Alex. Obregia" Clinical Hospital of Psychiatry, Bucharest, Romania.

Neurodevelopmental disorders (NDDs) are life-long impairing conditions, with high impact on the patient and family. Genetic and environmental factors are known contributors to human development and behavior. Thus, revealing the underlying genetic causes of these conditions is of great importance both in clinical practice and research.

We report on our experience with array-CGH (Agilent Technologies platform) in NDDs investigation. 140 patients, aged 2 months to 18 years were referred to our laboratory for genetic testing with intellectual disability and other clinical features (dysmorphism, congenital malformations, autism or other behavior problems, speech delay). Array-CGH findings were confirmed by FISH and qPCR tests, and parental studies were performed when necessary.

Pathological CNVs were detected in 30 patients, preferentially involving the following chromosomes: 4 (5 patients), 22 (5 patients), X (3 boys and one girl with XY karyotype and sex reversal due to DAX duplication), 9 and 3 (each, 3 patients).

Besides well-described syndromic regions (e.g. Wolf-Hirschhorn, Cri-du-chat, Mowat-Wilson, Smith-Magenis, 22q11.2 deletion, Phelan-McDermid, MECP2 duplication syndromes), other genomic regions, rarely reported in patients with NDDs, were either deleted or duplicated in our cohort. Among these regions, 1q21.3-q22, 3p26.3, 9p24.3-24.1, 9q34.1 harbour candidate genes for NDDs and have the potential to define new clinical entities.

Our data illustrates the utility of array-CGH in the investigation of patients with intellectual disabilities and other neurodevelopmental disorders. Well-described CNVs, both molecularly and clinically, contribute to better defining new genomic regions involved in the pathogenesis of NDDs.

Acknowledgments: National Project PN 92.033.02.03.

E-P08.28

Clinical and molecular aspects and genotype-phenotype correlation in Rett syndrome

P. Zengin Akkus, **G. E. Utine**, O. Akgun Dogan, P. O. Simsek Kiper, E. Z. Taskiran, G. Haliloglu, K. Boduroglu; Hacettepe University, Ankara, Turkey.

Introduction: Rett syndrome is a neurodevelopmental disorder characterized by early neurological regression following a seemingly normal early

development, and is seen almost exclusively in females. Acquired fine and gross motor functions, language and communication skills are lost, with coexisting autonomic dysfunction and seizures. Rett syndrome is seen due to mutations in MECP2 gene and is a clinical diagnosis. However, molecular testing may reveal potential genotype-phenotype correlations.

Materials and Methods: Twenty-four patients with documented MECP2 mutations were evaluated for possible genotype-phenotype correlations. Median age of the patients was 6.5 years (2-24 years). Clinical severity was assessed using Pineda scoring system. Mutations of patients were grouped into methyl-CpG binding domain (MBD), interdomain (ID), transcriptional repression domain (TRD) and C-terminal (CT) mutations.

Results: Pineda scores were 5-23 (median 10.5) in whole group. Median scores were as follows in subgroups: 9 in MBD (n=7, range 5-15), 12 in ID (n=3, range 10-17), 11 in TRD (n=9, range 6-23) and 7 in CT (n=4, range 6-11). No statistically significant difference among median scores was found (p>0.05). One 2-year-old patient had deletion encompassing exons 1-2, and had a Pineda score of 15.

Conclusion: In theory, phenotype-genotype correlations could be drawn for Rett syndrome, based on the observations that the encoded protein has distinct domains with specific functions and that various missense or nonsense mutations can affect all domains. Groups with larger numbers of patients may reveal presence of such correlations, which was statistically not possible in the present sample.

E-P08.29

Detection of small SHANK3 deletions in patients with delayed speech and developmental delay using Array-CGH

F. Martínez-Granero¹, M. Calvente¹, J. C. Cigudosa^{1,2}, J. Suela¹;

¹NIMGenetics, Madrid, Spain, ²Centro Nacional de Investigaciones Oncológicas, Madrid, Spain.

Introduction

The 22q13.3 deletion syndrome, also known as Phelan-McDermid syndrome (PMS), is a neurodevelopmental disorder with a wide range of deletion sizes (100 Kb to 9 Mb), and a great phenotypic variability. Most neurological features are thought to be caused by haploinsufficiency of SHANK3 gene, which encodes for a core scaffolding protein at the postsynaptic density of glutamatergic synapses. The present study aimed to detect deletions affecting only to the SHANK3 gene (<100 Kb) so that a better genotype-phenotype correlation can be achieved in patients with PMS.

Materials and Methods

Array-CGH including 15kb resolution for SHANK3 gene (KaryoNIM® Autism 180K array-CGH, designed by NIMGenetics®) has been used for analyzing patients suspected to bear PMS. Data analysis was done using hg19 genomic build and ADM-2 statistic (set as 6).

Results

We identified 8 individuals with 22q13.33 deletions, but only three of them were selected since they harboured pure SHANK3 deletions. Specifically, patient 1 and 2 showed a 50-60 Kb deletion affecting exons 10 to 23 and 4 to 23, respectively. On the other hand, patient 3 showed the smallest deletion, being 23 Kb sized and affecting exons 8 to 17. The three patients were diagnosed with developmental delay and/or intellectual disability. In addition, patient 1 and 3 also showed autism spectrum disorder.

Conclusions

These results supports haploinsufficiency of the SHANK3 gene, which encodes for a structural protein of the postsynaptic density, as a major causative factor in the neurological symptoms observed in Phelan-McDermid syndrome.

E-P08.30

Syndrome of unknown etiology: female patient with severe growth and mental retardation, macrocephaly, pubertas tarda and dysgerminoma

M. Stampfer, S. Beck-Woedl, O. Riess, A. Riess;

Institute of Medical Genetics and Applied Genomics, University of Tuebingen, Tuebingen, Germany.

We report on a 19-year old female; the second child of non-consanguineous German parents. She was born at term with normal height and weight but macrocephaly. Furthermore a meconium ileus, malrotation and an umbilical hernia were present at birth. A small atrial septal defect closed spontaneously. She developed epileptic spasms at 4 months of age, but was without further spasms under treatment. At the age of 8 years she developed atonic seizures with no reoccurrence under therapy. cMRI showed myelination disorder. Metabolic tests were normal. She learned to walk at the age of 6 years. A dysgerminoma was detected at age 14 and was treated with salpingo-ovarectomy and chemotherapy. The patient has hypothyroidism and is treated with L-Thyroxin. Her menstruation started with 18 years, she got

no pubic hair yet.

At age of 19 years, she is very small (17 cm < 3. centile), has a disproportionate stature and mild muscular hypotonia. Dysmorphic features include coarse face, macrocephaly, macroglossia, hypertelorism, smooth philtrum, thin upper lip vermillion, wide nasal base and ridge and downslanting palpebral fissures. She has short, broad thumbs, brachydactyly V and flat feet. She has severe mental retardation with minimal understanding and developed no expressive speech. She has a cheerful temper most of the time. The karyotype is 46,XX. There were no CNVs in Array-CGH (180k-chip Agilent). Next generation sequencing was performed for 525 genes associated with mental retardation (TruSight One Panel, Illumina). There was no causative mutation detected. The etiology of the syndrome remains unsolved.

E-P08.31

One novel mutation in ALDH3A2 segregated with Sjögren-Larsson syndrome in an Iran-based family; a case report

M. Taghdiri¹, A. Kashef², M. Fardaei², M. Miryounesi³;

¹Genetics center of welfare organization, Shiraz, Iran, Islamic Republic of, ²Department of medical Genetics, Shiraz University of Medical Sciences, Shiraz, Iran, Islamic Republic of, ³Genomics Research Center, Shahid Beheshti University of Medical Sciences, Tehran, Iran, Islamic Republic of.

Sjögren-Larsson syndrome (SLS) is a rare type of congenital ichthyosis with neurologic signs and intellectual disability. Homozygous mutations in one gene ALDH3A2 are known to be responsible for this syndrome. This is a condition in which the specific membrane-bound fatty aldehyde dehydrogenase (FALDH) is deficient due to lack of normal alleles of ALDH3A2. In the absence of FALDH, toxic metabolites cause problem in various tissues, and mainly in brain and skin.

Here we report an interesting case of SLS from Iranian population which represents a novel two-base deletion in ALDH3A2 gene sequence accompanying major phenotypic signs of SLS including generalized ichthyosis, hyperkeratosis, pruritus, and intellectual disability.

Using standard DNA sequencing and targeted mutation analysis on the patient's DNA sample, we found a novel 2-bp homozygous deletion, c.1241_1242delAT, resulting in a frame shift and protein truncation (p.His414Gln*fs3).

Our findings would be of paramount importance in both diagnostic approach and molecular studies of SLS.

E-P08.32

SOX5-associated intellectual disability: an underdiagnosed syndrome?

K. Writzl¹, A. Maver¹, L. Kovacic², B. Peterlin¹;

¹Clinical Institute of Medical Genetics, Ljubljana, Slovenia, ²Novartis Ireland Ltd, Novartis, Vista Building, Elm Business Park, Dublin, Ireland.

Haploinsufficiency of SOX5, encoding a member of the SOX (SRY-related HMG-box) family of transcription factors, involved in the regulation of chondrogenesis and the development of the nervous system, was recently identified as the underlying cause of the 12p12.1 microdeletion syndrome. The syndrome is characterized by global developmental delay, intellectual disability, poor expressive speech, mild dysmorphic facial features, hypotonia, skeletal abnormalities, strabismus, behaviour abnormalities, and variable other anomalies. While eleven patients with likely causal deletions involving only SOX5 gene have already been reported in the literature, the causal role of SOX5 sequence variants is unclear with only one such variant being described in detail (Nesbitt et al., 2015).

We describe two patients with de novo variants in SOX5 identified by whole exome sequencing: one consensus splice-site variant and the other predicted pathogenic missense variant with evaluation of structural consequences by in silico protein modelling in progress. The patient with a splice-site variant presented with global developmental delay, hypotonia, strabismus, and scoliosis, which correlates well with the previously-described SOX5-associated phenotype. The patient with a missense variant had a more severe clinical course and presented with microcephaly, failure to thrive, seizures, and severe global developmental delay. No aggressive behaviour was noted in either patient. Both patients had hypoplastic corpus callosum.

In summary, these cases highlight the utility of exome sequencing in patients with genetically heterogeneous and non-specific disorders such as hypotonia, developmental delay and intellectual disability (ID) and suggest that patients with SOX5-related ID might be underdiagnosed.

E-P08.34

Clinical features and follow-up findings of Williams-Beuren Syndrome patients

B. G. Nur¹, S. B. Karauzum², E. Mihci¹;

¹Akdeniz University Medical School, Pediatric Genetic Department, Antalya, Turkey, ²Akdeniz University Medical School, Department of Medical Biology, Antalya, Turkey.

Introduction: Williams-Beuren syndrome (WBS) is characterized by distinctive facial features, growth delay, mental retardation with typical neurobehavioral profile, cardiovascular anomalies, endocrine anomalies, autoimmune pathologies, and infantile hypercalcemia. The aim of this study was to evaluate our WBS patients with clinical and follow-up findings in a Turkish cohort.

Materials and Methods: Twenty-four patients (12 girls, 12 boys) (24 months-39 years) who diagnosed as WBS between 2000 and 2013. All patients had FISH analysis, after clinical assessment.

For obtaining uniform clinical data, a questionnaire was designed according to AAP guidelines and growth parameters were plotted on WBS growth charts. Follow-up findings and medical problems recorded and they underwent the following evaluations;

-Physical and neurologic examination

-Developmental assessment.

-Cardiologic evaluation (electrocardiogram, echocardiogram), blood pressure

-Genitourinary evaluation (ultrasonography, renal function)

-Ophthalmologic evaluation

-Hearing assessment

-Dental evaluation

Statistical Analysis

Demographic variables and clinical features analyzed using descriptive statistics.

Results: The facial features of the patients, associated diseases were seen in table 1, 2.

The gastrointestinal system pathologies and symptoms were seen in table 3. Discussion: Diagnosis of this syndrome relies mainly on recognition of the characteristic facial features. The variability of the findings often makes clinical delineation difficult. In this study we performed a multisystem assessment with multidisciplinary approach and we describe the clinical features and medical complications in this cohort of patients. We must be careful for complications in the follow-up of WBS patients. Early diagnosis of pathologies and adequate management of these abnormalities are essential to improve the quality of life of the patients and to prevent other chronic diseases, and its complications.

E-P08.35

Hemophilia B in a Female with Intellectual Disability caused by a Deletion of Xq26.3q28 encompassing the F9 gene

R. Kersseboom^{1,2}, A. Kattentidt², F. de Vries³, A. Kievit²;

¹Tragel Zorg, Clinge, Netherlands, ²Zuidwester, Middelharnis, Netherlands, ³Erasmus medical centre, Rotterdam, Netherlands.

Hemophilia B is an X-linked recessive disorder caused by mutations in the F9-gene on Xq27.1. Mainly males are affected but about 20% of female carriers have clotting factor IX activity below 0.40 IU/mL and bleeding problems. Fragile-X syndrome (FMR1-gene) and FRAXE syndrome (AFF2-gene) are well known causes of X-linked recessive intellectual disability. Simultaneous deletion of both the FMR1- and AFF2-gene in males results in severe intellectual disability. In females the phenotype is more variable. We report on a 19-year-old female with severe intellectual disability and a longstanding bleeding history that was diagnosed with mild hemophilia B after finding an 11 Mb deletion in Xq26.3q28 that included the IDS-, SOX3-, FMR1-, AFF2- and F9-genes. To the best of our knowledge, this is the first patient with an Xq26.3q28 deletion encompassing the FMR1-, AFF2- and F9-genes, thereby causing both intellectual disability and mild hemophilia B.

E-P08.02

10q11.21q11.22 microdeletion in a boy with intellectual delay and multiple congenital anomalies

S. Abbaspour¹, P. Keshavarz¹, S. Afzal², Z. Nadem², A. Kahnmoee², F. Falahabadi², A. Davoudi^{1,2};

¹Guilan University of Medical Science, Rasht, Iran, Islamic Republic of, ²Medical Genetic Laboratory of Dr. Keshavarz, Rasht, Iran, Islamic Republic of.

Background: 10q deletion syndrome is an uncommon chromosomal disorder. Features that often occur in people with 10q deletion include developmental delay, intellectual disability and distinctive facial features.

Case report: We report a case of microdeletion 10q in a boy with 11-year-old

from northern Iran. The patient was born full-term, with a natural child-birth, after a pregnancy without interurrences. After birth, he had tend to grow more slowly than their peers. During childhood, raising the head end of the bed for sleeping and snore noisily when asleep. The patient, pronounced her first words at the age of 22 months. The patient speech was severely affected. So that the patient was unable to stating the obvious words. Because of his low IQ, unable to accompany normal school. During the physical exam at the age of 11, patient weight (20.8 kg) and height (124 cm) was somewhat lower than normal. Other facial features in patient included; position of hairline that placed lower than normal. Chin and lower jaw was small and slightly receding. Hand-eye coordination and fine motor skills in patient was slower than his peers. Her gross motor skills were delayed by 8 months. Investigation of patient teeth's showed that was much irregular dentition. Check the status of skeletal patient showed that has a curvature and deformation of the sole of the foot and heel.

Conclusion: It is strongly recommended, parents should have the opportunity to meet a genetic counsellor to discuss the specific recurrence risks to be undertaken in children.

-759C/T polymorphism in HTR2C gene and atypical antipsychotic-induced weight gain among Romanian psychotic patients

N. Andreescu¹, R. Gradinaru¹, L. Nussbaum¹, S. Farcas¹, V. Dumitrascu¹, M. Puiu¹, A. Emandi Chirita²;

¹University of Medicine & Pharmacy Victor Babes, Timisoara, Romania, ²University of Medicine & Pharmacy, Timisoara, Roumania, Timisoara, Romania.

Metabolic and endocrine side effects of atypical antipsychotics have become an increasing concern for clinicians and scientific researchers due to the fact that atypical antipsychotics are more and more prescribed to children and adolescents.

We aim to investigate whether the 5-HT2C -759C/T polymorphism was associated with weight change and hyperinsulinemia in Romanian pediatric patients.

81 schizophrenic and bipolar patients, aged between 9 to 20 years (median age 15.74±4) were enrolled from University Hospital for Child and Adolescent Psychiatry and Neurology of Timisoara. All the patients were under treatment with atypical antipsychotics (Risperidone, Aripiprazole, Olanzapine). Body Mass Index was recorded for different time points and fasting blood samples were taken to measure insulinemia. 5-HTR2C -759C/T polymorphism identification was carried out.

From the study group, 22 patients presented the -759C/T polymorphism in 5-HT2C gene and we identified 2 lots based on their specific genotype: the first lot included patients with C/CC genotype and the second lot included patients with T/CT genotype. No significant statistical difference in changes of BMI from baseline to different endpoints was found between the 2 lots. A significant statistic difference (p=0.035) between the lots identified based on genotype was found for insulinemia after 18 months of treatment.

Taking into consideration that weight gain is a trait in which multiple genes involved interact with environmental influences, the development of a more complex algorithm should have better chance to be implemented as a clinical tool and maybe -759C/T polymorphism would find a definite role in this algorithm.

E-P09.02

A new case with atypical 22q11.22q11.23 duplication in a boy with developmental delay and hyperactivity

L. Otaola¹, I. Marti², J. S. Crettaz¹, R. Muguerza¹, Y. Ramirez¹, R. Sáez¹, O. Martínez-Mugica²;

¹Genetics Department - Donostia University Hospital, San Sebastián, Spain,

²Neuropediatrics Department - Donostia University Hospital, San Sebastián, Spain.

The chromosomal region 22q11.22q11.23 has long been recognized to be susceptible to genomic rearrangement. The great majority of these recurrent CNVs are mediated by recombination between nonallelic homologous segmental duplication. The incidence is not estimated precisely because many individuals are without symptom. The phenotypic expressions are variable and there are some contradictory features. More recently, this genomic instability has been shown to extend distally to the commonly deleted/duplicated region, involving low copy repeats LCR22E-H. Despite the small number of reported cases, many of these shared clinical characteristics, including developmental delay, psychomotor retardation, hypotonia and epi-

lepsy.

To better dissect the genotype-phenotype correlations, we report a 10 year old boy with cognitive disorder, hyperactivity and developmental delay. In the presence of a normal 46XY karyotype, CGHa is requested.

Analysis was performed on a GeneChip (Affymetrix®) platform with a Cytoscan array 750K. Data have been analyzed with the Chromosome Analysis Suite 2.0 software.

CGHa identified an interstitial inherited microduplication in the 22q11.22q11.23 region, flanked by LCR22E-H, of 2.1-Mb size. The carrier's father shows normal phenotypic features. Unlike the cases reported so far, our patient doesn't show epilepsy and muscle hypotonia.

The varied phenotypic expression, the incomplete penetrance and the number of familial cases observed, makes it exceedingly difficult to ascribe pathogenicity to these duplications.

Further accumulation of the patients as well as careful clinical assessment of both the diagnosed individuals and their carrier parents is required for full characterization of the condition to provide better diagnosis and counseling of the patients' families.

E-P09.05

The TREM2 p.R47H variant has a smaller effect than APOE ε4 allele on Alzheimer's risk in Hungarian patient

R. Bencsik¹, V. Reményi¹, D. Csaban¹, B. Szatmari², Z. Grosz¹, M. Molnar¹;

¹Institute of Genomic Medicine and Rare Disorders, Semmelweis University, Budapest, Hungary, ²Richter Gedeon Ltd., Budapest, Hungary.

Most of the dementias are complex multifactorial disorders. Apolipoprotein-E (APOE) ε4 allele is a well-known risk factor of late-onset sporadic Alzheimer disease (AD). Low frequency coding variants in TREM2 are associated with increased Alzheimer disease (AD) risk, while loss of functions mutations of this gene result in autosomal recessive early-onset dementia. In this study we tested the role of TREM2 p.R47H and APOE-ε4 genotypes in early and late-onset AD and FTD in a Hungarian cohort.

The APOE ε4/ε4 genotype and TREM2 p.R47H were investigated in 140 Hungarian patients with dementia (53 male 87 female mean age 65±13) and 71 controls without cognitive decline (40 male 31 female mean age 65±11) with PCR-RFPL methodology.

The TREM2 p.R47H mutation was found in heterozygous form in 3 patient, while it was absent in controls. The mutation allelic frequency in the AD cohort is: 1%. (p=0,01 CI95% (0,002-0,018)). The APOE investigation detected the following genotypes: ε3/4 in 43, ε4/4 in 10 cases respectively. The frequency of the APOE ε4 allele is 45% (p=0,45 CI95% (0,408-0,492)) in the demented population.

Our results confirm the association between TREM2 p.R47H and risk of AD, the observed effect on risk was substantially smaller than the effect of APOE ε4 allele in the Hungarian patients.

This work was supported by the project KTIA_13_NAP-A-III/6

An epilepsy syndrome: 16p13.11 microdeletion syndrome

M. Balasar¹, P. Taşdemir¹, H. Yavuz²;

¹Necmettin Erbakan University Medical Faculty, Department of Medical Genetics, KONYA, Turkey, ²Necmettin Erbakan University Medical Faculty, Department of Pediatric Neurology, KONYA, Turkey.

Introduction: Microdeletions in 16p13.11 region can cause neuropsychiatric disorders such as schizophrenia, autism, mental retardation and epilepsy. In recent years it has been shown that 16p13.11 microdeletion syndrome is a rare epilepsy syndrome. The estimated prevalence of the disease is about 1/14000. Our case was referred to the hospital with afebrile seizures when he was 7 months old. He had been suffering afebrile seizure 3-4 times a day for a month. He had no history of other diseases. Physical examination was normal. His parents were not related. His mother had a history of abortion. It has been learned that, his mother and grandfather had hearing loss and his other grandfather had schizophrenia. The case's ocular fundus examination, hearing test, heart examination and echocardiography, abdominal ultrasonography, brain magnetic resonance examination was normal. Materials and Methods: EEG, conventional cytogenetics analysis and array-CGH analysis were performed. Results: The patient was diagnosed with infantile spasm considering EEG findings and he was treated. Chromosome analysis was performed on peripheral blood and the karyotype was 46,XY. Array-CGH analysis result was arr[hg19]16p13.11p12.3(15,404,452-18,669,725)x1. 3.265 kb deletion was determined in the p arm of chromosome 16. Genetic counseling was given to family. Array-CGH analysis was also planned for his parents. Conclusions: Some deletions and/or duplications are known to cause some sporadic epilepsy syndromes in the human genome. An

16p13.11 microdeletion case have been presented here in order to emphasize the importance of the Array-CGH analysis in such cases.

E-P09.07

Autism and seizure in a patient with maternal derived 15q11.2-q13.1 duplication - Case report

M. Martínez Atienza^{1,2}, S. García Linares^{1,2}, A. Rubio Lopez de la Oliva^{1,2}, A. González Ramírez^{3,4}, A. Mora Guijosa^{1,2}, M. Pérez Sánchez^{1,2};

¹Complejo Hospitalario de Granada. SAS, Granada, Spain, ²Instituto biosanitario de Granada, Granada, Spain, ³FIBAO. Complejo Hospitalario de Granada. SAS, Granada, Spain.

Proximal 15q duplications that include the critical region for Prader-Willi syndrome (PWS) and Angelman syndrome (AS) have been reported in patients with autism. Of the cases of autism reported to have duplications of the PWS/AS critical region, all have been maternal in origin.

We describe here a female patient in which autism segregates with maternal inheritance of a proximal 15q duplication. The patient was born at 37 gestation weeks with a weight of 3150 gr. and no incidences in neonatal period. In posterior pediatric revision was detected language and cognitive delay, suspected due to autistic disorder (AD), at 3 years age presented epilepsy episodes. The familiar history include father and maternal grandmother with epilepsy, maternal uncle with autism and a sister healthy.

Comparative Genomic Hybridization (CGH-Array) with the Nimblegen CGX Cytogenetic Microarrays platform, supplied by PerkinElmer, was performed for the patient and parents

The CGH-Array was normal in the father and both mother and patient presented a duplication of 5,56 Mb in 15q11.2-q13.1 PWS/AS region (arr(hg19)15q11.2-q13.1(22,822,019-28,379,369)x3).

The Array-CGH from grandmother, maternal uncle and sister were not done. This result is according with previous studies that show the correlation between this duplication and autistic disorder when have been maternal in origin. The family history with the maternal uncle diagnosed of autistic disorder also agree this possibility. The epilepsy, presented in some members of both families, can be originated for another unknown genetic alteration, without any correlation with the PWS/AS region.

E-P09.08

Novel single base pair deletion in ATM cause ataxia telangiectasia in an Iranian proband

A. Salehi Chaleshtori¹, M. Ahmadvand², O. Bashti¹, M. Noruzinia^{1,3};

¹Department of Medical Genetics, Faculty of Medical Sciences, Tarbiat Modares University, Tehran, Iran, Islamic Republic of, ²Department of Hematology and Blood Banking, Faculty of Medical Sciences, Tarbiat Modares University, Tehran, Iran, Islamic Republic of, ³Sarem Cell Research Center (SCRC), Sarem Women's Hospital, Tehran, Iran, Islamic Republic of.

Introduction: Ataxia-telangiectasia is a rare disorder caused by mutations in ATM gene. This gene produces a serine/threonine protein kinase, an activator of the DNA damage response in the face of DNA DSBs, which phosphorylates downstream substrates integrating with DNA repair procedure. Most ATM mutations are private mutations and, there are no mutational hotspots in the ATM gene.

Materials and Methods: We characterized an 8 years old AT patient using clinical features and exome sequencing methods.

Results: A homozygous single base pair deletion in exon 43 of the ATM gene (chr11:108188201delC) that results in a frameshift and premature termination of the protein 19 amino acids downstream to codon 2101 (p.Gln2101LysfsTer19: ENST00000278616) was detected.

Conclusions: This mutation led to fundamental alterations in ATM protein structure and representation of AT lastly. This family needs careful surveillance and the reported mutation is helpful in PND procedure for the next pregnancy and other managements of the family members.

This study was funded by Sarem Cell Research Center (SCRC) of Sarem Women's Hospital.

Polymorphism of a potassium/chloride transporter gene SLC12A5 is associated with autistic-like traits in healthy individuals

S. A. Zergoglu¹, T. Tunçali², H. D. Ozguven³, C. Kalaycioglu¹;

¹Ankara University Institute of Health Sciences, Department of Interdisciplinary Neuroscience, Ankara, Turkey, ²Ankara University School of Medicine, Medical Genetics Department, Ankara, Turkey, ³Ankara University School of Medicine, Department of Psychiatry, Ankara, Turkey.

Previous studies have indicated autistic-like traits to lie on a continuum with autism spectrum disorders in the general population. In a recent study,

a K-Cl cotransporter protein, KCC2 gene SLC12A5 on chromosome 20, which previously was linked to idiopathic generalized epilepsy, familial febrile seizures and schizophrasia, was reported to be associated with functionally-impairing variants in autism spectrum disorders. Here, we report a novel association of a polymorphism, rs9074, located in the 3'UTR region of SLC12A5 with autistic-like traits in a healthy population.

A total of 75 healthy volunteers aged between 18-30 participated to the study. Autistic-like traits were quantified on the autism-spectrum quotient (AQ) scale. AQ scores measured for each individual were comprised of five subscales of social skills, attention switching, communication, attention to details and imagination categories utilizing a previously validated version of the AQ in Turkish. SNP genotyping assays were performed with specific primers and probes in an RT-PCR platform.

rs9074 genotypes were distributed as GG:48%, GA:41.3%, AA:10.7% with allele frequencies in HWE. Total AQ (p=0.008), social skills (p=0.002) and attention switching (p=0.038) subscale scores were significantly higher in AA bearers compared to GG+GA genotypes (Mann-Whitney U test). AQ scores were normally distributed. A significant association between AA genotype and social skills scores (p=0.014) in subjects +0.5 SD above average for total AQ (normally distributed) were also noted (Fisher's exact test).

These results suggest a possible role of KCC2 in neurodevelopmental stages in liaison with autism spectrum disorders.

Ankara University Scientific Research Projects Funds (No.I3-L333-033).

The association analysis of CNTNAP2 gene (rs2710102 and rs759178) with autism in a South African population

Z. Arieff¹, Z. Noordien², C. Jacobs¹, J. Sharma¹;

¹University of the Western cape, CapeTown, South Africa, ²University of the Western cape, Cape Town, South Africa.

The association analysis of CNTNAP2 gene (rs2710102 and rs759178) with autism in a South African population.

Z. Arieff¹, Noordien Z¹, Jacobs CW¹, J. R. Sharma¹ ¹Department of Biotechnology, University of Western Cape, Private Bag X17, Bellville 7535, South Africa, South Africa,

Introduction: Autism is a highly heritable, heterogeneous, early onset neuro-developmental condition characterized by three core pervasive impairments. This condition is clinically heterogeneous with complex etiopathogenesis which can be conceptualized as a dynamic interplay between environment cues and predisposing genetic factors. Recent studies have reported that variants of the CNTNAP2 gene are associated both with language deficits and language delays in autism. So CNTNAP2 is considered as a strong candidate for the pathogenesis of autism spectrum disorders (ASD). **Material and Methods:** A case-control study was performed to identify association of two SNPs (rs2710102 and rs759178) of CNTNAP2 gene and ASD in a South African population. Genomic DNA was extracted from oral swab samples of 117 cases and 123 controls and SNP genotypes were determined. The Taqman @Real-Time PCR and genotyping assay were utilized to determine the genotypes. **Results and Conclusion:** None of the SNPs (rs2710102 and rs759178) within CNTNAP2 tested are associated significantly with ASD. These negative findings may be due to the limited sample size in the present study.

E-P09.11

Religious visual hallucinations in behavioural variant FTD (bvFTD) with progranulin mutations: a case report.

I. Manna¹, A. Fratto², M. Morelli², P. Perrotta², F. Calabria², G. Cascini³, C. Chiriaco³, A. Quattrone^{1,2};

¹CNR-1 Institute of Molecular Bioimaging and Physiology (IBFM), Section of Germaneto, Catanzaro, Italy, ²Institute of Neurology, Department of Medical and Surgical Sciences, Magna Graecia University, Catanzaro, Italy, Catanzaro, Italy, ³Neuroimaging Research Unit, Institute of Molecular Bioimaging and Physiology, National Research Council, Catanzaro, Italy, Catanzaro, Italy, ⁴Institute of Radiology, Division of Nuclear Medicine, Magna Graecia University, Catanzaro, Italy, Catanzaro, Italy.

Visual hallucination (VH) is a visual percept, experienced when awake, which is not elicited by an external stimulus. VHs are well described in several neurodegenerative disorders as dementia with Lewy body, prion diseases, Alzheimer's disease. At last, VHs are reported in Frontotemporal dementia (FTD), a genetically and pathologically heterogeneous neurodegenerative disorder. Mutations in MAPT, GRN and C9orf72 genes have been shown as the major causes of FTD. In particular, VHs are reported in about 30% of patients with behavioural-variant FTD (bvFTD) due to GRN mutations and in about 38% of cases with C9orf72 mutations. Here, we describe an unusual bvFTD clinical case of a 72-year-old woman, with autosomal dominant familial history of behavioural disorders, presented with a ten-

years clinical history of progressive mood symptoms such as anxiety, apathy, depression. After seven years from disease onset bilateral hand tremor, generalized slowness of movements and strong hyperreligiosity with visual religious hallucinations lasting for several minutes. The neuropsychological evaluation demonstrated a mild cognitive impairment more evident for executive functions. A 18F-fluorodeoxyglucose-PET showed hypometabolism in left fronto-temporal area, and 3 Tesla brain MRI demonstrated bilateral frontal and temporal lobes atrophy more predominant on left hemisphere. In this work, we reported an bvFTD patient carrying two variations in GRN gene (reference sequence NM_002087.2): p.Cys139Arg, and c.*78C>T. To our knowledge, this is the first report of a patient with a GRN mutation to have a peculiar bvFTD phenotype with hyper-religiosity and mystical VHs. Our data enlarge the spectrum of bvFTD phenotype related to GRN mutation.

E-P09.12

A genetics study for a Korean family with benign Rolandic epilepsy

J. Kim;

Ilsan Hospital, Goyang-shi, Korea, Republic of.

Benign Rolandic epilepsy is the most common cause of epilepsy in childhood. A lot of cases show autosomal dominant pattern. Although GRINA2A gene is known to be the most frequently causal gene of benign Rolandic epilepsy, it can explain only 7.5% of familial benign Rolandic epilepsy. Other recently found can explain a few cases. We report a family without mutation in known genes of benign Rolandic epilepsy. Exome sequencing was performed in TheragenEx Bio Institute. The data was analyzed by GATK version 3.4. The results were filtered out according to mutation frequencies reported in 1000 genome, Exome Aggregation Consortium, and Korean Exome studies. The missense mutations and mutations in splicing sites were selected using SIFT, POLYPHEN2, and SPIDEX. Gene functions were predicted by DAVID. According to results of exome sequencing, there was no possible mutation in the known causal genes such as DEPDC5, PRRT2, RBFOX1, RBFOX3, ELP4, and SRPX2. Among the genes with mutations of autosomal dominant pattern, DENND4B, TMPRSS7, ME1, AMIGO2, and KIZ 5 genes had loss of function mutations. Among the genes which had similar function of the known causal genes, FAM189B, TMEM247, SIDT1, GRAMD1C, FAM134B, CACFD1, NPDC1, TMEM135, TMEM132C, PQLC1, and SLC52A3 genes had mutations in the coding regions. We could not find out the causal mutation of benign Rolandic epilepsy in this family. However, we found that the new unknown genes could have major role in Korean benign Rolandic epilepsy families and we could suggest 13 possible causal genes. Other studies are needed for larger Korean.

E-P09.14

CGH-arrays analysis in a series of pediatric patients suffering from neurological diseases and/or congenital malformations of unknown etiology

M. Gamundi¹, B. Mañé¹, E. Borràs¹, I. Hernan¹, B. Pascual¹, R. Vidal¹, V. Delgado^{1,2}, R. Martorell¹, M. Carballo¹;

¹Unitat de Genètica Molecular, Hospital de Terrassa, Terrassa, Spain, ²Neurologia Pediàtrica, Hospital de Terrassa, Terrassa, Spain, ³Neonatologia, Hospital de Terrassa, Terrassa, Spain.

Background and aims:CGH-arrays (Comparative Genomic Hybridization Arrays) are powerful and innovative technologies whose implementation is allowing an extraordinary change in the diagnosis of various diseases, especially in the diagnostic and research of intellectual disability, autism and malformation syndromes. Our aim was to analyze, by CGH-arrays, a series of patients affected by several neurological diseases and/or malformations to try to determine the etiology of the disease in these patients.

Methods: A total of 66 pediatric index patients with normal karyotype were analyzed for Copy Number Variations by CGH-arrays using CGX™ 8-plex (Agilent Technologies). Proband patients were clinically classified as: autism spectrum disorders (ASD) (n=30), intellectual disability (n=17), malformation syndromes (n=9), psychomotor delay (n=8), hypotonia (n=1) and early puberty (n=1).

Results: 10 pathogenic (or probably pathogenic) variants and 21 variants of unknown significance were detected. Pathogenic or probably pathogenic variants were identified in 3 patients with psychomotor delay (and other features), 3 patients with intellectual disability, 3 patients with ASD and in one patient with hypotonia and malformations. 6 of the 10 variants were previously described and associated to known syndromes (Prader-Willi syndrome (n=1), 1q21.1 microdeletion syndrome (n=1), 16p11.2 microdeletion syndrome (n=1), 22q11 deletion syndrome (n=2), and a tetrasomy of 15q11.2 region (n=1)).

Discussion and conclusions: Array CGH is a rapid and cost-effective technique for postnatal screening of unknown syndromes, intellectual disability and autism spectrum disorders. Our experience shows that a 15% of pediatric patients derived for the analysis of Copy Number Variations present a pathogenic or probably pathogenic variant.

E-P09.15

Association Studies of DRD4 and COMT Genes Polymorphisms with Fear during Childbirth in Korean Pregnant Women

M. Kim;

The Catholic University of Korea, Kyunggido, Korea, Democratic People's Republic of.

Objective: The fear experienced during childbirth is affected by physiological, psychological and environmental factors. Dysfunctions of serotonin and dopamine neurotransmission are associated with the development of fear, pain and anxiety disorder. We examined the polymorphisms and frequency of mutations of the Dopamine receptor D4 (DRD4), Catechol-O-methyltransferase (COMT) genes and their association with the fear that Korean pregnant women experience during childbirth.

Methods: In this study, 5 SNPs were studied for understanding the fear during childbirth in 534 Korean pregnant women. The relationship between the fear during childbirth and genetic polymorphism was investigated by multiple regression analysis after adjusting for parity in 293 women who gave birth to a child vaginally and who performed the Delivery Fear Scale (DFS), which was the instrument used for measuring the fear during childbirth among 534 Korean pregnant women.

Results: The frequencies of each SNP in the Korean pregnant women (n=534) were DRD4 -521T>C 0.47 and COMT +1158C>G 0.30 and +1222G>A 0.32. No polymorphisms were found in the DRD4 +2526T>G gene. There was no genetic association between the DRD4 and COMT gene polymorphisms and fear during childbirth.

Conclusion: The results of this study show that these genes (DRD4, COMT) are less likely have an effect on the fear during childbirth. In order to understand the fear during childbirth, further studies will have to be focused on comprehensive research of the social, psychological, environmental factors and the interaction of the connected genes.

E-P09.16

Genetic variants on the CHRNA3/CHRNA5 genes associated with smoking quantities in a Chinese population in Taiwan

C. Wu¹, W. Y. Wu¹, C. Li¹, W. Chien¹, Y. Chang¹, H. Leu², C. Lai³, K. Hsueh⁴, L. Chen⁵, I. Y. Tsai⁶, K. Liang¹, M. Lin¹;

¹Institute of Public Health, National Yang-Ming University, Taipei, Taiwan, ²Healthcare Center, Taipei Veterans General Hospital, Taipei, Taiwan, ³Department of Family Medicine, Taipei Veterans General Hospital, Taipei, Taiwan, ⁴Department of Family Medicine, Kaohsiung Veterans General Hospital, Kaohsiung, Taiwan, ⁵Department of Psychiatry, Washington University, St. Louis, MO, United States, ⁶Institute of Health Policy and Welfare, National Yang-Ming University, Taipei, Taiwan.

Introduction: Tobacco smoking is one of the major risk factors for a number of chronic diseases and is the leading cause of preventable death in the world. Many genetic studies have been conducted to identify genetic variants for smoking behavior. The most widely replicated region is the nicotinic acetylcholine receptor subunit genes (CHRNA5-A3-B4) on chromosome 15q25. As most of the published genetic studies of smoking behavior were primarily European Americans or of European origin, it is of tremendous interest to elucidate if these gene variants play any role in the etiologies of smoking behavior in Chinese population in Taiwan.

Methods: We recruited 485 current smokers, 370 ex-smokers, and 1202 non-smokers, respectively, from the Healthcare Center in a Medical Center. We selected 6 SNPs on CHRNA5 (rs680244, rs16969968, rs518425) and CHRNA3 (rs578776, rs3743078, rs1051730) for genotyping.

Results: For male subjects, we found the CHRNA5 rs518425, the CHRNA3 (rs578776, rs3743078) contributed to the increase of smoking quantities by at least 4 cigarettes per day (CPD). Besides, we observed that CHRNA5 rs680244, and CHRNA3 (rs578776, rs3743078) were associated with heavy smoking among female smokers. We also found that CHRNA5 rs680244, and CHRNA3 (rs578776, rs3743078) were related to increase the quantities of smoking by 3 to 4 CPD.

Conclusion: Our results demonstrated that several distinct SNPs on the CHRNA3/CHRNA5 genes were associated with smoking quantities for different gender. To the best of our knowledge, this is the first report of the association between CHRNA3/CHRNA5 gene variations and smoking quantities in Chinese population.

E-P09.17

Double heterozygous missense variants in *CHRNA7* in a boy with autism spectrum disorder

C. Simao de Souza¹, J. Thevenon^{2,3}, Y. Duffourd², P. Kuentz³, C. Poe³, A. Masurel-Paulet², J. Poinot¹, L. Faivre^{2,3};

¹Service de pédopsychiatrie, Centre Hospitalo-Universitaire Dijon-Bourgogne, Dijon, France, ²Centre de Référence Maladies du développement et Syndromes Malformatifs, Centre Hospitalo-Universitaire Dijon-Bourgogne, Dijon, France, ³EA4271 GAD, Université de Bourgogne Franche Comté, Dijon, France.

Introduction: Dosage sensitivity of the *CHRNA7* gene, which encodes the $\alpha 7$ nicotinic acetylcholine receptor in the human brain, is known to have a major contribution to multiple neurodevelopmental disorders, including autism spectrum disorder (ASD), schizophrenia, and intellectual disability (ID). *CHRNA7* is included in the smallest region of overlap of the 15q13.3 deletions and duplications, a hotspot for Copy number variants (CNVs) due to the presence of segmental duplications, favoring non-allelic homologous recombination (NAHR) occurrence. Heterozygous or homozygous deletions are usually associated with a neurodevelopmental phenotype of high penetrance.

Case Report: Using exome sequencing after negative extensive genetic work-up in a 13-year-old Caucasian boy presenting with ASD, intellectual disability and developmental delay, with no facial dysmorphism or malformations, and normal growth, we identified two heterozygous missense mutations in the *CHRNA7* gene. The first one, p.Ala124Thr in exon 5 was inherited from his asymptomatic father, and the second one p.Tyr233Cys in exon 7, occurred *de novo*.

Conclusions: To our knowledge, this is the first report of ASD in a boy with double heterozygous missense variants in *CHRNA7*. Given the interest towards this gene in neuropsychiatric disorders, and the interest in the genetic dissection of ASDs, international data sharing will be of importance in order to determine if missense mutations could be responsible for neurodevelopmental phenotypes.

E-P09.19

DNA Repair Gene Variants and The Risk of Autism Spectrum Disorder

S. Dasedmir¹, M. Guven², K. C. Pekkok¹, H. Ulucan¹, B. Dogangun³, E. Kirtas³, M. T. Kadak³, M. Kucur⁴, M. Seven¹;

¹Istanbul University, Cerrahpasa Faculty of Medicine, Department of Medical Genetics, Istanbul, Turkey, ²Istanbul University, Cerrahpasa Faculty of Medicine, Department of Medical Biology, Istanbul, Turkey, ³Istanbul University, Cerrahpasa Faculty of Medicine, Department of Child and Adolescent Psychiatry, Istanbul, Turkey, ⁴Istanbul University, Cerrahpasa Faculty of Medicine, Department of Biochemistry, Istanbul, Turkey.

Introduction: Autism spectrum disorder (ASD) is a complex disorder, and its extreme heterogeneity further complicates our understanding of its biology. Epidemiological evidence from family and twin studies supports a strong genetic component in ASD etiology. Oxidative stress and abnormal DNA methylation have been implicated in the pathophysiology of ASD. Brain tissues from ASD cases showed higher levels of oxidative stress biomarkers than healthy controls in postmortem analysis. Association between oxidative stress and DNA damage has been well-known. Thus, we sought to investigate a potential link between DNA repair genes and ASD and analyze the role of XPD Asp312Asn and XRCC4 G-1394T gene polymorphisms for ASD in the Turkish population.

Material and Methods: Genotyping was conducted by PCR-RFLP based on 100 patients and 96 unrelated healthy controls.

Results: We, for the first time, demonstrated a positive association between XRCC4 gene variants and ASD risk. Frequencies of XRCC4-1394 T/G+G/G genotypes were higher in patients (%34) than the controls (%18.7). The statistical analysis revealed that the individuals who had XRCC4-1394 T/G+G/G genotype had an increased risk for ASD (OR = 2.23, 95% CI = 1.10-4.55). However, no significant association was found for XPD Asp312Asn polymorphism with the risk of ASD.

Conclusion: Our findings suggest that XRCC4 G-1394T polymorphism might be associated with ASD pathogenesis.

E-P09.20

Spectrum of *de novo* mutations in early onset severe epilepsy

H. O. Heyne, J. R. Lemke;
University of Leipzig, Leipzig, Germany.

The field of epilepsy genetics has been constantly evolving. Next Generation Sequencing techniques, such as whole exome sequencing (WES) or targeted panels significantly facilitated the identification of underlying genetic causes of these genetically heterogeneous disorders. Multiple studies have shown that *de novo* mutations play an important role in early onset severe epilepsy representing the vast majority of pathogenic causative variants in this disease. In this study we address the distribution of *de novo* mutations

in published as well as unpublished cohorts of patients with early onset severe epilepsy. We study *de novo* mutations derived from WES trios of epilepsy patients and compare them with *de novo* mutations in healthy control cohorts. With this analysis we aim to identify the most commonly affected genes and mutational spectra in early onset severe epilepsy. Further, we intend to generate confirming or refuting evidence on genes with yet uncertain or questionable association to epilepsy.

Henrike Heyne was supported by the Federal Ministry of Education and Research (BMBF), Germany, FKZ: 01EO1501.

Identification of rare genetic variants that cause hereditary essential tremor by high-throughput DNA sequencing

G. Houle^{1,2}, A. Accogli³, D. Spiegelman², P. A. Dion^{2,4}, N. Dupré⁵, G. A. Rouleau^{2,4};

¹Human Genetics Department, McGill University, Montreal, QC, Canada, ²Montreal Neurological Institute and Hospital, McGill University, Montreal, QC, Canada, ³Neurosurgery Department, Istituto Giannina Gaslini, Genova, Italy, ⁴Neurology and Neurosurgery Department, McGill University, Montreal, QC, Canada, ⁵Department of Neurological Sciences, Faculty of Medicine, Laval University, Québec, QC, Canada.

Essential tremor (ET) is one of the most common movement disorders and is characterized by a postural or motion tremor of a body part, primarily the upper limbs. Despite a strong genetic basis for an inherited predisposition to the development of ET, genetic factors are still poorly understood. Many studies have identified ET susceptibility loci, but genetic and phenotypic heterogeneity observed across individuals make the identification of definitive causative gene difficult. Only mutations the FUS gene has been identified as a highly penetrant and causative for familial ET. However, such mutations seem to explain only a small fraction of all ET cases. We hypothesize that other rare genetic variants cause or predispose to ET. To achieve this goal, we used high-throughput DNA sequencing to capture the sequence the protein-coding portion of the genome (exome) of 16 affected individuals from four large families with an apparent autosomal dominant transmission of the disease. By focusing on rare variants in a familial cohort, we hope to explain a significant portion of the missing heritability in ET, as well as to narrow our current insight on the key biochemical pathways implicated in this complex disorder. Moreover, our findings might lead to the development of new diagnostic tests, which will help physicians make a more accurate diagnosis. [CIHR Foundation Scheme# RN254517 - 332736]

Gomez-Lopez-Hernandez syndrome is autosomal recessive genetic inheritance? A Consanguineous marriage case

M. Elmas;
Afyon Kocatepe University, Afyonkarahisar, Turkey.

Gomez-Lopez-Hernandez syndrome (cerebello-trigeminal-dermal dysplasia) is a rare condition that includes abnormalities of the cerebellum (rhombencephalosynapsis), cranial nerves (trigeminal anesthesia), and scalp (alopecia). So far, 30 patients have been reported and one except all of them were sporadic observations. Our patient second-degree relatives of patients in her parents marriage is concerned. In her pedigree there are one relative man like her. Our patients had rhombencephalosynapsis and alopecia, but none had trigeminal dysfunction. In this respect, the term cerebello-trigeminal dermal dysplasia is potentially misleading. In conclusion, only rhombencephalosynapsis and alopecia are consistently present in GLHS and are required diagnostic criteria, while trigeminal anesthesia, dysmorphic features, and ataxia are inconsistent findings. A high index of suspicion is required to diagnose GLHS, particularly as alopecia tends to be hidden by surrounding scalp hair.

The patient was the third child for his 27-year-old mother and 31-year-old father. due to neural tube defects in prenatally brother passed a strict medical supervision. All controls in the first 16 weeks of pregnancy normally evaluated. After 16 weeks, the brain abnormalities began to be noticed. 17 weeks at the border brain hydrocephalus (14.5 mm) along with a full selection of inability to enlargement of the ventricles and the corpus callosum have been reported.

This syndromes genes unknown yet. For This families blood collected for WES analyse and examined.

Autosomal dominant cerebral small vessel disease associated with HTRA1 gene mutation in an Italian family

L. Veneziano¹, E. Mantuano¹, S. Romano², M. Spadaro¹, G. Amadoro¹, M. Frontali²; ¹Institute of Translational Pharmacology, National Research Council, Rome, Italy, ²Sant'Andrea Hospital, University of Rome La Sapienza, Rome, Italy.

Introduction: Cerebral small vessel diseases (CSVDs) are an important cause of stroke, cognitive impairment, and mood disorders among the elderly. Usually CSVD is sporadic, but early-onset monogenic forms of CSVD have been reported. CADASIL is one of the most common hereditary CSVD caused by autosomal dominant NOTCH3 gene mutations, while CARASIL is a rare autosomal recessive CSVD caused by HTRA1 gene mutations. More than 200 mutations are known in NOTCH3 gene and only 12 HTRA1 mutated CARASIL families have been reported so far.

Recently, heterozygous HTRA1 mutations have been described associated with an autosomal dominant form of CSVD with reduced penetrance, showing clinical features differing from those of CARASIL.

Patients and methods: We report a family with three affected individuals, referred for stroke and cognitive impairment segregating as an autosomal dominant disorder. Mutations in NOTCH3 and HTRA1 genes have been screened by Sanger sequencing. In silico prediction tools PolyPhen and SIFT have been used to predict the pathogenicity of the variants found. Skin biopsy of one patient was examined with transmission electron microscope.

Results: A heterozygous HTRA1 missense mutation segregating with the disease and predicted to be deleterious has been found. The mutation affects a highly conserved amino acid, which, if mutated, strongly reduce the HTRA1 proteolytic activity. The biopsy showed deposits of osmophilic material in the arterial wall, very similar to those characterizing CADASIL.

Conclusions: We confirm the dominant inheritance of some HTRA1 mutations, overlapping clinical, MRI and ultramicroscopic features of CADASIL, in absence of the typical CARASIL extra-neurological symptoms.

Investigation of TBP gene mutations in patients with Huntington Disease phenotype

M. Gökoğlu, H. Karabulut, Ö. Türedi, S. Altınar, C. Durmaz, E. Gokpinar, A. Vicdan, N. Yürür Kutlay, T. Tuncalı, A. Tükün, H. İlgin Ruhi; Department of Medical Genetics, Ankara University School of Medicine, Ankara, Turkey.

Introduction: CAG repeat expansion in HTT gene is found nearly in 99% of clinically diagnosed Huntington Disease (HD) patients. However, in our routine genetic services, we observe this mutation in only approximately two-thirds of patients suggesting a greater contribution of genetic heterogeneity. Since TBP gene repeat expansion responsible from SCA17 is the most frequent mutation found in patients with HD phenotype, we investigated TBP mutation in this patient group.

Materials and Methods: Archival DNA samples of 68 patients with HD phenotype without HTT expansion were included in this study. TBP gene CAG/CAA repeat sizes were investigated by polymerase chain reaction followed by fragment analysis on ABI3130 Genetic Analyzer.

Results: In this patient group, CAG/CAA repeat expansions of TBP gene were all found to be in normal range (below 40).

Conclusion: Determining genetic basis of patients with HD phenotype is clinically important for both of differential diagnosis and genetic counselling. On the other hand, due to its extremely low frequency in this group of patients, testing for TBP CAG/CAA repeat expansion in routine genetic analysis may be considered on a case-by-case basis.

E-P09.28

Association study of MAOB and COMT polymorphisms in Bulgarian patients with Parkinson disease

K. Mihova¹, S. Mhebrabian², R. Pavlova², S. Skelina², Y. Zhelev², A. Jordanova^{1,3}, R. Kaneva¹, L. Traykov², V. Mitev¹;

¹Department of Medical Chemistry and Biochemistry, Molecular Medicine Center, Medical University-Sofia, Sofia, Bulgaria, ²Clinic of Neurology, University Hospital „Alexandrovska“, Department of Neurology, Medical University-Sofia, Sofia, Bulgaria, ³VIB Department of Molecular Genetics, University of Antwerp, Antwerp, Belgium.

Background: Parkinson disease (PD) is the second most common neurodegenerative disease characterized by motor (tremor, rigidity, postural instability, bradyakinesia etc.) and non-motor features (cognitive impairment, memory, psychiatric and personality disorders) resulting by progressive degeneration of dopaminergic neurons of substantia nigra. Monoamine oxidase B (MAOB) and catechol-O-methyltransferase (COMT) genes are associated with pathogenesis of the neurocognitive impairment.

The Val158Met (rs4680, G>A) polymorphism in COMT and intron variant

c.1348-36T>C (rs1799836, T>C) in MAOB gene have been associated with various neuropsychiatric and neurodegenerative disorders. Several studies show that they are implicated in cognitive impairment and different neuropsychiatric features.

Materials and methods: In this study 148 patients with PD and 108 healthy controls, matched to the patients by age, gender and ethnicity (NC) were included. Different genotypes were determined using TaqMan assay (Applied Biosystems). Statistical analysis was done using Plink toolset and chi square test.

Results and discussion: The Val158Met and c.1348-36T>C polymorphisms did not show significant difference in allele frequency distribution between the PD and NC group. The common Val158 allele and the 158Met allele were with almost equal allele frequencies (P= 0.26, OR= 0.82). The same trend was observed with c.1348-36T>C variant - almost equal allele frequencies (P= 0.31, OR= 0.31).

Conclusions: Our findings showed no association of Val158Met and c.1348-36T>C with Bulgarian PD patients. However, the limited power of the sample warrants further research in enlarged cohorts.

E-P09.29

Association of I-selectin gene polymorphism and Multiple Sclerosis

S. Nasiri Takami;

Azad university, Damghan, Iran, Islamic Republic of.

Background and aims: Multiple Sclerosis is an autoimmune disease in the central nervous system that its etiology is not clear. L-selectin is a member of the selectin family of adhesion molecules which are important in the trafficking of leucocytes into the central nervous system. The aim of this study was evaluation of association of I-selectin polymorphism and severity of MS. **Methods:** Single nucleotide polymorphism of I-selectin gene phe206leu was analyzed in 144 patients with MS and 220 age and sex matched controls by using SSCP-PCR with specific primers method.

Results: There were significant differences in the alleles frequency of phe-206leu polymorphism between the patients and control group (p=0.0005). Moreover, genotype frequency of the polymorphism were significantly different between the patients and healthy group (p<0.0001). No association was found between phe206leu polymorphism and severity of MS (p=0.07).

Conclusions: The results concluded that the polymorphism at heterozygote position could increase risk of pathogenesis in Multiple Sclerosis. In addition, the results showed that the heterozygote frequency in MS patients with severe disability was 100%. However, in this case consideration of more MS patient's population with severe disability is required.

E-P09.32

Relationship Between Obsessive Compulsive Disorder (OCD) and HLA haplotypes in Turkish Childrens

Ü. H. Lüleyp¹, G. Karacaoğlan¹, P. Pazaracı¹, D. Alptekin¹, A. Y. Tahiroğlu¹, S. Çetiner¹, A. Yaman¹, D. Lüleyp²;

¹Çukurova University, Medical Faculty, ADANA, Turkey, ²Eylül University, Medical Faculty, Izmir, Turkey.

Obsessive compulsive disorder (OCD) was once thought to be extremely rare, but recent epidemiological studies have shown it to be the fourth most common psychiatric disorder in the world. There are not many studies about the relationship between OCD and HLA genes. In this study, we aimed to research the relationship between childhood onset OCD and HLA alleles. This study includes 49 children diagnosed with OCD in Department Of Psychiatry and 88 healthy children aged between 4-12 in University of Çukurova Adana/TURKEY. The DNA of the subjects are isolated from blood and HLA alleles are amplified by using PCR and are read by LABScanTM 100 equipment. Results are evaluated by using univariate analysis and multivariate logistic regression analysis. In our study, single copy of B14, DRB3.1 and DRB16 alleles are found to increase the risk of OCD, 10.04, 5.86 and 4.90 times respectively. Also, double copy of C4 allele is found to increase the risk of OCD 7.89 times. Correct classification rate is found to be 73.7% according to the multivariate logistic regression analysis performed by 4 alleles. Despite the study in a different population determined that the effects of alleles in DRB and C locus are independent from each other on Rheumatoid Arthritis, our findings related to the association between DRB and C locus, which are two important elements of autoimmunity, on OCD in Turkish population is remarkable.

E-P09.37

Evidence of increased Dysbindin promoter methylation in substance-induced psychosis

M. Bahar¹, M. Noruzinia², N. Beyraghi², Z. Rezaei²;

¹Tarbiat Modares University, Bahar Medical Laboratory, Tehran, Iran, Islamic Republic of, ²Tarbiat Modares University, Tehran, Iran, Islamic Republic of, ³Department of Psychiatry, Behavioral Sciences Research Center, Shahid Beheshti University of Medical Sciences, Tehran, Iran, Islamic Republic of.

Dysregulation of Dystrobrevin Binding Protein 1 or Dysbindin (DTNBP1) expression has been indicated in schizophrenia and other psychotic disorders. Genotyping investigations have failed to firmly implicate particular genotypes as significant risk conferrers. Here, we aimed to study the association of promoter CGIs methylation with the incidence and sub-phenotypes of psychosis.

In our study, we recruited patients suffering from schizoaffective (SZA), psychotic bipolar I disorder (BID) or substance-induced psychosis (n=42). In order to deconstruct psychosis to sub-phenotypes we used v4.0 Basic Psychiatric Rating Scale (BPRS). Also, we measured the levels of promoter methylation using Methylation-Specific High Resolution Melt analysis (MS-HRM) and MethylLight chemistries.

Contrary to previous reports, our results failed to show association between increased DTNBP1 promoter methylation and psychotic bipolar I and schizoaffective disorders. However, compared to SZA and BID cases and normal group, substance-induced psychosis showed more than two-fold-increase of promoter CGI methylation of DTNBP1 which survived multiple comparison (p<0.01). Moreover, these patients scored higher on BPRS in total and on certain sub-phenotypes.

Despite occasional use of other substances, methamphetamine was the main reported substance of abuse in our series of cases. Previously, methamphetamine-related psychosis has been shown to be associated with certain genotypes of dysbindin. Therefore, despite our small sample size, previous findings in this field, in addition to the significant CGI methylation increase which we observed warrant further investigation on DTNBP1 epimutations as potential biomarkers in methamphetamine induced psychosis. This study was funded by Tarbiat Modares University as a part of Dr. Massih Bahar thesis project.

E-P09.38

Genetics of language deficits in schizophrenia and autism: an evolutionary approach

A. Benítez-Burraco¹, E. Murphy², W. Lattanzi³;

¹University of Huelva, Huelva, Spain, ²University College London, London, United Kingdom, ³Università Cattolica del Sacro Cuore, Rome, Italy.

Both autism spectrum disorders (ASD) and schizophrenia (SZ) are highly prevalent cognitive disorders, entailing language deficits. Recent advances in genome-wide technologies have provided with a long list of candidate genes for SZ and ASD, but the gap between genes, the pathophysiology of SZ and ASD, and their distinctive cognitive and linguistic profiles still remains open. Our study aims to bridge this gap through an evo-devo approach that focuses on how language evolved in the species and that construes both conditions as poles of a continuum of modes of cognition, also encompassing typically-developing cognition. To this aim, we have performed literature mining and network analysis of known candidate genes for SZ and ASD and found that they are overrepresented among the gene believed to be important for the evolution of the human faculty of language. Many of these genes are common risk factors for both conditions. Additionally, we performed in silico data mining of previously published SZ and ASD microarray datasets and found that many of these genes important for language evolution (like CNTNAP2, DLX5, FOXP1, or ROBO2) are differentially expressed in the brains of schizophrenics and autists. We will conclude that the (substantially opposite) linguistic (dys)abilities seen in SZ and ASD patients may represent abnormal (but still related) ontogenetic itineraries for the human faculty of language and that the same factors that prompted the transition from an ape-like cognition to a human-specific cognition may explain the high prevalence of SZ and ASD, but also their related cognitive profiles.

Grant: FFI2014-61888-EXP

E-P09.45

a case of trisomy 12p syndrome

P. Tasdemir¹, M. Balasar¹, H. Caksen²;

¹Necmettin Erbakan University Meram Medical Faculty Department Of Medical Genetics, Konya, Turkey, ²Necmettin Erbakan University Meram Medical Faculty Department Of Pediatric Genetics, Konya, Turkey.

Introduction: Trisomy 12p Syndrome is a very rare chromosomal abnormality.

So far about 10 patients with whole chromosome 12p duplication are reported. Trisomy 12p Syndrome is characterized by craniofacial abnormalities, postnatal developmental delay, hypotonia and mental retardation. Clinical and dysmorphic features of the disease are similar to Pallister-Killian syndrome's (Mosaic Tetrasomy 12p).

Materials and Methods: Our case was referred to the hospital because of developmental delay, mental retardation and leukomalacia. Clinical findings were round face, high frontal bossing, low set ears, hypertelorism, epicanthus, strabismus, wide nasal bridge, short nose, long philtrum, thin upper lip and thick-everted lower lip. Audiogram, the heart and other system examinations were normal. He had been using antiepileptic drug due to epilepsy. He was born by C/S and his weight was 3100 gram. There were no significant feature in the analysis of pedigree. It was learned that all newborn metabolic disease tests were normal.

Results: The karyotype analysis results were evaluated as 47,XY,+mar. We proposed Array-CGH analysis. Array-CGH result was arr[hg19]12p13.33p11.1(230421-34756209)x3. We concluded that marker chromosome is consisted of chromosome 12's whole short arm. We diagnosed the patient as Trisomy 12p Syndrome. His parents' karyotype analyses were normal. Genetic counseling was given to family.

Conclusions: The case's clinical findings were similar to Pallister-Killian syndrome's (Mosaic Tetrasomy 12p). In the literature it is reported that trisomy 12p Syndrome and Pallister-Killian syndrome's facial appearance similarity is associated with the enhancement of gene dosage on 12p13.31 region. This rare disease is presented here in order to contribute to the literature.

Genetic investigations in Hungarian patients affected by amyotrophic lateral sclerosis

K. Tripolszki¹, N. Nagy¹, P. Klivényi², J. Engelhardt², M. Széll¹;

¹University of Szeged, Department of Medical Genetics, Szeged, Hungary, ²University of Szeged, Department of Neurology, Szeged, Hungary.

Introduction: Amyotrophic lateral sclerosis (ALS) is an untreatable neurodegenerative disease characterized by neuronal loss and degeneration of the upper and lower motor neurons. Patients generally have a pure ALS phenotype, with degeneration affecting mainly neurons of the motor cortex, brainstem, and spinal cord. Affected individuals usually die of respiratory failure within 3-5 years of disease progression. Approximately 5-10 % of patients with ALS have an inherited form of the disease, nevertheless the difference between hereditary and sporadic ALS seems to be artificial. Therefore, genetic factors play a key role in all types of ALS. Our objective was to screen the variation of 3 candidate genes in Hungarian patients with ALS.

Materials and methods: DNA from the patients was extracted from peripheral blood using standard protocols. Using targeted high-throughput sequencing, we screened mutations in the FUS, SETX and C9orf72 genes in 28 Hungarian patients with ALS.

Results: Genetic analysis revealed a putative novel mutation in exon 7 of the SETX gene at position 791 where an A to G (c.791A/G) substitution was identified, resulting in an asparagine to serine amino-acid exchange (N264S). The detected missense mutation is localized in the amino-terminal domain of the senataxin protein, which has a critical function in protein-protein interaction. In silico analyses suggested that the identified variation might be a pathogenic mutation.

Conclusion: Our results might contribute to the development of a Hungarian population-specific mutation panel and to the better understanding of ALS.

E-P10.03

Whole Exome Sequencing Identifies a Novel SACSIN Mutation in an Extended Omani Family Segregating ARSACS and Epilepsy

P. Scott, A. Al-Futaisi, N. Al-Yarubi, A. Al-Habsi, F. Al-Murshedi;

Sultan Qaboos University Hospital, Muscat, Oman.

Autosomal recessive cerebellar ataxias (ARCA) are a heterogeneous group of rare neurological disorders affecting both the central and the peripheral nervous systems. Among these, autosomal recessive spastic ataxia of Charlevoix-Saguenay (ARSACS) is a progressive neurological disorder that it is caused by homozygous or compound heterozygous mutations in SACS gene, encoding saccin. Here, we described the first ever molecularly-confirmed diagnosis of ARSACS in the Arabian Peninsula achieved by a combination of homozygosity mapping and whole exome sequencing. In this multigenerational consanguineous Omani family, six affected family members share the phenotype of developmental delay, progressive ataxia, spasticity and demyelinating neuropathy as well as generalised tonic clonic seizures in

the proband. The variant c.13454T>C (p.Leu4485Ser) segregated with the disease and all assessed genotypes were consistent with health status. The missense variant appears to be novel, i.e. not in dbSNP, ExAc, LOVD and ClinVar. The amino acid substitution affects an evolutionarily conserved residue and *In silico* tools predict this variant to be pathogenic. Interestingly, this Omani family also presented with epilepsy, a feature documented but rarely observed in saccin-related ARSACS.

Expansion of 45 CAG repeats in the coding region of the ATXN2 gene: spinocerebellar ataxia. Genetic counselling-phenomenon of anticipation

S. Izquierdo-Álvarez¹, M. Palacín-Larroy², A. Rodríguez-Valle¹, M. D. Miramar-Gallart¹, M. J. Alcaine-Villarroya¹, A. B. Lasiera-Monclús¹, E. Barrio-Ollero³, J. I. González-Hevia¹; ¹Genetic/University Hospital Miguel Servet, Zaragoza, Spain, ²Neurology Service. Hospital Ernest Lluch, Calatayud, Spain, ³Faculty of Medicine. University of Zaragoza, Zaragoza, Spain.

Introduction: SCA2 presents in the third or fourth decade with truncal ataxia, dysarthria, slowed saccades and less commonly ophthalmoparesis and chorea. The disease is caused by mutations in the ataxin 2 gene ATXN2 (12q23-q24.1). The normal size of the CAG repeat is 15-24; 35 repetitions or more are associated with clinical manifestations of SCA2.

Material and Methods: patient of 22 years with progressive cerebellar ataxia 4-5 years more sensory polyneuropathy evolution. Mother with severe cerebellar involvement and behavioral disorders. In addition, a grandmother with neurological disease of unknown origin of later onset. Possible unstable CAG triplet expansions located in said region encoding genes associated with the development of spinocerebellar ataxia autosomal dominant inheritance were determined by Triplet-repeated Primed PCR (Genetic study: Labgenetics S.L. Madrid)

Results: The patient had a pathological expansion of 45 CAG repeats in the coding region of the ATXN2 gene. There is an inverse relationship between the number of CAG repeats and the age at which the disease. Appropriate genetic counseling was performed and her mother was studied with 53 years (41 CAG repeats; mutated allele with complete penetrance). Cerebellar ataxia has an autosomal dominant inheritance, in which patients with this disease usually have an affected parent.

Conclusions: In SCA2 a genetic phenomenon called anticipation occurs because the offspring of a patient affected with this disease usually have a higher number of repetitions than parents, so that the onset of the disease usually go ahead and have a more severe phenotype, especially if the parent is male.

New deletion c.2265 delT in CLCN1 gene in a case of Becker Myotonia

A. Lafuente, M. Ortiz, F. Gonzalez, G. Pi, A. Zuñiga; Hospital De La Ribera, Alzira (Valencia), Spain.

Clinical myotonia impairs muscle relaxation after voluntary intense contraction. Myotonia congenita (MC) is an inherited myotonia due to mutations in the CLCN1 gene encoding the skeletal muscle ClC-1 chloride channel. Loss-of-function mutations of ClC-1 channel reduce the sarcolemmal chloride conductance, which, in turn, increases sarcolemma excitability and causes a delayed relaxation manifesting as a clinical and electrical myotonia. Both dominant and recessive inheritance patterns are found in MC families. Becker myotonia congenita, the recessive form, is typically more severe and has an earlier onset than the dominant one, Thomsen myotonia congenita (TMC). TMC often has a wider range of presentations, including subclinical to moderately severe forms. Consequently, these two entities may be distinguished by inheritance pattern, age at onset, and phenotype.

Proband was a male of 6 yo and he was born from non-consanguineous parents. His family history was negative for neuromuscular disorders, only his father referred muscle cramps without muscular hypertrophy. Since birth, the patient presented delayed muscle relaxation, but no painful contractions induced by cold or by emotional stress were recorded. Since 5 yo, he noticed numbness in both legs after sitting for 10-15 minutes, and walked awkwardly. He referred repeated movements can temporarily alleviate their muscle stiffness, a phenomenon known as the warm-up effect. CK levels were normal; EMG showed myotonic discharges in examined muscles. The DNA sequencing showed homozygosity for a non-described previously deletion c.2265 delT (NM.000083) in CLCN1 gene. Patient was diagnosed as Becker Myotonia because his condition was inherited in an autosomal recessive pattern.

A novel PLP1 mutation in a Moroccan family with congenital Pelizaeus-Merzbacher disease

J. Lyahyai¹, B. Ouled Amar Bencheikh^{2,3}, S. C. Elalaoui⁴, M. Mansouri¹, L. Boualla¹, A. Dionne-Laporte^{3,2}, D. Spiegelman^{3,2}, P. Dion^{2,3}, P. Cossette⁵, G. Rouleau^{2,3}, A. Sefiani^{1,4}; ¹Centre de Génétique Humaine, Faculté de Médecine et Pharmacie de Rabat. Mohammed V University in Rabat, Rabat, Morocco, ²Department of Neurology and Neurosurgery, McGill University, Montreal, QC, Canada, ³Montreal Neurological Institute and Hospital, McGill University, Montreal, QC, Canada, ⁴Département de Génétique Médicale, Institut National d'Hygiène, Rabat, Morocco, ⁵Molecular Diagnostic Laboratory and Division of Medical Genetics, CHU Sainte-Justine, Montreal, QC, Canada.

Introduction: Epilepsy regroups a common and diverse set of chronic neurological disorders that are characterized by spontaneous, unprovoked, and recurrent epileptic seizures. Epilepsies have a highly heterogeneous background with a strong genetic contribution and various mode of inheritance. X-linked epilepsy usually manifests as part of a syndrome or epileptic encephalopathy. The variability of clinical manifestations of X-linked epilepsy may be attributed to several factors including the causal genetic mutation, making diagnosis, genetic counseling and treatment decisions difficult. We report the description of a Moroccan family referred to our genetic department with X-linked epileptic seizures as the only initial diagnosis.

Methods: Knowing the new contribution of Next-Generation Sequencing (NGS) for clinical investigation, and given the heterogeneity of this group of disorders we performed a Whole-Exome Sequencing (WES) analysis and co-segregation study in several members of this large family.

Results: We detected a novel pathogenic PLP1 missense mutation c.251C>T (p.Ala84Asp) allowing us to make a diagnosis of Pelizaeus-Merzbacher Disease for this family.

Conclusions: This report extends the spectrum of PLP1 mutations and highlights the diagnostic utility of NGS to investigate this group of heterogeneous disorders.

Diagnosis of Duchenne Muscular Dystrophy using MLPA in Brazilian Patients

A. T. Dias^{1,2}, É. A. Zanardo¹, F. A. R. Madia¹, T. V. M. M. Costa¹, C. Milani¹, J. G. Damasceno¹, G. M. Novo-Filho¹, M. M. Montenegro¹, A. M. Nascimento¹, M. Rocha^{1,3}, C. A. Kim⁴, M. B. R. Dutra⁵, F. B. Piazzon^{1,6}, F. Kok^{5,6}, E. Zanoteli⁷, L. D. Kulikowski^{1,3,4}; ¹Laboratório de Citogenômica do Departamento de Patologia da Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil, ²OMIKA Consultoria em Genética Ltda, São Paulo, Brazil, ³Centro de Reprodução Humana e Genética do Departamento de Saúde Coletiva da Faculdade de Medicina do ABC, Santo André, Brazil, ⁴Unidade de Genética - Departamento de Pediatria - Instituto da Criança do Hospital das Clínicas da Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil, ⁵Departamento de Neurologia da Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil, ⁶Mendelics Genomic Analysis, São Paulo, Brazil.

Duchenne muscular dystrophy (DMD) is a recessive X-linked disorder mainly caused by mutations in the dystrophin gene. Seventy (70%) of cases are related to exonic deletions or duplications. Multiplex Ligation-dependent Probe Amplification (MLPA) is a fast and efficient method to evaluate exonic deletions and duplications of the dystrophin gene and to predict the reading-frame of RNA level result. We investigated 49 patients with dystrophinopathy using P034 and P035 MLPA Kits - DMD mixes 1 and 2 (MRC Holland, Netherlands). The analysis was performed using GeneMarker Software (SoftGenetics, LLC). Our results revealed 35 patients (71,43%) with exonic deletions; 5 patients (10,20%) with exonic duplications and 9 patients (18,37%) with normal exonic copy number in the Dystrophin gene. Using Leiden Open Variation Database (LOVD 3.0) we found 85,7% out-of-frame deletions, 8,6% in-frame deletions and 5,7% with uncertainly prediction in the 35 patients. Five (5) patients with duplications presented 100% out-of-frame duplications. The frame of mutation is related to dystrophin production (in-frame mutation with partial protein production and out-of-frame with absent or minimal protein levels). Thus, the MLPA is the most appropriate first-tier test to be applied in investigation of patients with DMD. The accurate genotype-phenotype correlation and the comprehensive analysis of the DMD mutational spectrum is an important tool to select potential candidates for mutation-specific therapies.

Grants: FAPESP: 09/53105-9; FINEP-CT INFRA 0160/12 SP8.

E-P10.12

A 25 years of Duchenne/Becker molecular diagnosis in Spain

R. Núñez, L. Pascual, C. Gómez, C. Prior, H. Méndez, R. de Sancho, N. Chacón, P. Lapunzina, P. Martínez, J. Molano; Hospital La Paz, Madrid, Spain.

Introduction: Dystrophinopathies are the most common neuromuscular disorder. The disease has an X-linked inheritance and is caused by mutations in the dystrophin gene.

The most common mutations are large deletions and duplications of the

gene.

Dystrophinopathies are divided in two different clinical phenotypes, the severe form, Duchenne muscular dystrophy (DMD) and the milder form, Becker muscular dystrophy (BMD).

The objective is to describe the dystrophin mutations found in molecular diagnostic testing of dystrophinopathies in the last 25 years in La Paz Hospital (Spain).

Materials and methods: We have reviewed patients from hospitals of all over Spain, (1990-2015) with clinical suspicion of DMD/BMD. We included 136 patients with a confirmed diagnosis by molecular techniques in our laboratory.

The molecular diagnosis was made by PCR-Multiplex and/or MLPA (SALSA-P034-P035, MRCHolland). Patients with no deletions and no duplications were sequenced by Sanger or NGS.

Results: Among the 136 patients, 133 were men including 75 DMD (76%deletions, 11%duplications and 13%point mutations) and 58 BMD (90%deletions, 7%duplications and 3%point mutations). The most frequent deletions were in hotspot regions, exons 45-55 and 2-19 (DMD=23, BMD=36) and 12 novel mutations were found.

The remaining 3 patients were symptomatic women without family history, 2 adults and 1 child, all three with deletions.

Conclusions: The diagnosis of dystrophinopathies can currently be accomplished by the new molecular techniques (MLPA and NGS) up to 95%. RNA analysis could be useful to detect defect in DMD expression and deep intronic mutations.

Dystrophinopathy has to be considered in women with muscular dystrophy symptoms.

E-P10.18

Biallelic inheritance of a missense and a novel frameshift mutation in an individual with malignant hyperthermia susceptibility

C. L. Goldsmith, D. A. Dymant;

Children's Hospital of Eastern Ontario, Ottawa, ON, Canada.

Malignant hyperthermia susceptibility (MHS) is an autosomal dominant disorder of calcium regulation in skeletal muscle. The features of an MHS event include tachycardia, increased body temperature, muscle rigidity and rhabdomyolysis upon exposure to certain anesthetic agents. MHS is genetically heterogeneous condition, though the majority of causative mutations are found in RYR1. We report a patient who experienced an MHS-event at the age of 5 years during routine surgery. Her parents subsequently underwent muscle biopsies and caffeine-halothane contracture testing (CHCT). These results were deemed positive for both her parents. Multiple relatives in the father's family also had positive CHCT test results. We initiated genetic testing of the proband using a next generation sequencing panel including RYR1, CACNA1S and STAC3 and this revealed that she was heterozygous for a mutation in exon 63 of the RYR1 gene c.9301G>A (p.Glu3104Lys) inherited from her mother) and a variant in exon 50 c.8018delA which is predicted to result in a frameshift and premature protein termination (p.His2673Profs*73) inherited from her father. To our knowledge this variant has not been previously reported with MHS or other RYR1-related disease (central core disease, multimicore disease). The proband and her parents are healthy and do not have any clinical findings consistent with an underlying myopathy. No additional variants or mutations in RYR1 were identified in the father after complete gene sequencing. Given his positive CHCT, the father and his relatives may have MHS due to an as yet unidentified mutation in RYR1 or other MHS-related gene.

Cd95l in multiple sclerosis patients: results from a case-control study

b. mohammad hossein pour;

Shahid Beheshti University of Medical Sciences, tehran, Iran, Islamic Republic of.

Introduction: Multiple sclerosis (MS) is the most common chronic inflammatory demyelinating disease of the central nervous system (CNS). Elimination of autoreactive T cells by activation induced cell-death (AICD) is considered to be one of major process in MS. The aim of this investigation were to evaluate expression level of FasL in whole blood from patients with Relapsing-Remitting (RR) form of MS, and to survey the association of FasL expression with risk, EDSS and duration of the disease. **Methods:** We compared FasL expression in 50 RR-MS patients with 50 healthy controls by TaqMan Real time PCR technique. Albeit there was an expression decrease, no statistically significant difference was found between total RR-MS patients and controls. **Results:**our results showed a clear association between FasL expression of females especially older than 40 years with risk of the disease

(p= 0.04, 95% CI= 0.387-1.14; p= 0.003, 95% CI= 0.139-3.12, respectively). Moreover, there was not a significant correlation between EDSS and duration of the disease and FasL expression. This finding make a valuable question what is the principal concept for this significant association between FasL expression and risk of RR-MS in females who are older than 40 years. In this study, we failed to draw an exact expression-phenotype correlation which may be due to limited statistical confirmation as a result of the small sample size and needs more investigation. **Conclusions:** These findings may possibly reflect differences in the pathogenic mechanisms associated with the failure of AICD observed in this group of MS patients.

E-P10.22

Mutation analysis of 4 spinocerebellar ataxia (SCA) types in patients from southern Turkey

P. Pazarci, H. Kasap, A. F. Koc, S. Altunbasak, M. A. Erkoç;

Cukurova University Faculty of Medicine, Adana, Turkey.

Introduction: Spinocerebellar ataxias (SCA) are complex clinical and genetically heterogeneous, mostly autosomal dominant neurodegenerative diseases. At present more than 30 hereditary SCA types were associated with different gene mutations. In this study, the frequency distribution of 4 SCA types 1, 2, 3 and 6 in Turkish population was investigated with respect to clinical features.

Materials and methods: 159 patients who received diagnosis of SCA and 42 healthy controls from Adana, Mersin, Gaziantep, Hatay and Osmaniye provinces were included in the study. DNA samples were isolated from 2 mL blood samples and the number of tri-nucleotide repeats (TNRs) for each SCA type was detected by PCR-RFLP technique and sequencing.

Results: 4 SCA types were studied. Two types, SCA1 and 3, were positive and all heterozygous for expansions. SCA1 had relatively higher frequency, 4.4%, than SCA3, 0.6%. Clinical data of patients were also evaluated to correlate with the increased TNR numbers.

Conclusions: This study being the first mutation record of SCAs in this area indicated that 5.0% of cases belonged to 2 types, SCA 1 and 3.

E-P10.23

Ullrich syndrome: Identification of novel mutations in two Mexican families

C. Sanchez-Acosta¹, L. Plaza-Benhumea², L. Gonzalez-Huerta³, M. Martin de Saro⁴, S. Cuevas-Covarrubias⁵;

¹Departamento de Neurologia, Hospital Materno Perinatal Monica Pretelini Saenz, ISEM, Edomex, Mexico, ²Genetics Department, Children Hospital IMIEM, Edomex, Edomex, Mexico, ³Genetica, Hospital General de Mexico, Mexico City, Mexico, ⁴Hospital Materno Infantil ISSEMyM, Toluca, México, Edomex, Mexico, ⁵Genetica, Facultad de Medicina, Hospital General de Mexico, Universidad Nacional Autonoma de Mexico, Mexico City, Mexico.

Introduction: Ullrich syndrome (US) refers to a muscular deficiency of collagen VI due to recessive and dominant mutations in the collagen VI genes. US has a prevalence of 1-9/1,000,000 in newborns, it is clinically heterogeneous although the majority of patients harbor the classical phenotype. Clinical characteristics are neonatal muscle weakness, proximal joint contractures, hyperlaxity of the distal joints, failure to thrive, lack of independent ambulation, and severe respiratory damage; in sometimes, other systemic anomalies are also present. Mutations in collagen VI genes (COL6A1, COL6A2, and COL6A3) occur in about 40% of the patients with US; they affected the alpha chains of collagen VI. Patients with mutations in these genes also can present Bethlem myopathy. **Objective:** To describe two novel mutations in the COL6A1 and COL6A3 genes in two Mexican families with US. **Material and Methods:** Genomic DNA was analyzed through whole exome sequencing, PCR and DNA sequencing analysis in US patients, non-affected members of the family and in 100 normal controls. **Results:** We identified two novel mutations in COL6A1 (p.344delG) and COL6A3 (p.R1998*) genes, respectively. These mutations were not present in non-affected members of the family and in 100 normal controls; this allows to discard a possible polymorphism. **Discussion and Conclusion:** Modeling proteins of the mutant genotype confirmed the deleterious effect of these molecular changes in both cases. US is as disease with a heterogeneous clinical spectrum, in this study we identified two novel mutations; this finding enriched the genomic spectrum observed in US.

Distal 14q trisomy - cytogenetic and clinical assessment of a family with a recurrent t(14;15)(q31.1;q26)

D. A. Ozunu¹, M. Gabriela¹, V. Plaiasu¹, M. Stoian^{2,3}, P. Gurban², G. Dinulescu², C. Diaconu⁴;
¹Mother and Child Care Institute „Prof. Dr. Alfred Rusescu”, Bucharest, Romania,
²Personal Genetics Medical Center, Bucharest, Romania, ³University of Medicine and Pharmacy „Carol Davila”, Discipline of Medical Genetics, Bucharest, Romania, ⁴Institute of Virology „Stefan S. Nicolau”, Bucharest, Romania.

Balanced chromosome translocations in either parent increases the risk of recurrent miscarriage, unbalanced chromosome rearrangements, congenital malformations, and mental retardation in liveborn offspring. Structural chromosomal aberrations can result in genetic disease due to trisomy and/or monosomy of chromosomal segments.

Chromosome 14 is often involved in chromosome rearrangements. Individual cases of partial trisomy 14q have been previously reported in the literature, in many instances resulting from parental translocations or pericentric inversions. Cases of partial trisomy 14q with a duplication of 14q31-->qter are rare and present only minor anomalies of dysmorphic features, prominent nasal, growth retardation and moderate mental retardation. Here, we present the case of a boy of 2y7mo that was clinically assessed with facial dysmorphism, anomalies of the members, axial hypotonia and psychomotor delay. After karyotype analysis, we determined that the patient has a partial trisomy for the distal part of the long arm of chromosome 14 (14q31-->qter), confirmed by aCGH. The chromosomal abnormalities resulted from a paternal balanced translocation involving chromosomes 14 and 15 [46,XY, t(14;15)(q31;q26)], a rearrangement also found for the brother of the proband.

The inheritance and identity of the identified translocation was ascertained by extensive familial cytogenetic, FISH and aCGH studies.

Acknowledgments: This work was supported by Objective 3.3 of Romanian Ministry of health Program VI and by PN-II-PT-PCCA-2013-4-133 grant

E-P11.02

19q13.11 microdeletion with minimal overlapping region for syndrome

K. T. Abe, I. M. P. O. Rizzo, A. V. Coelho, N. Sakai Jr, D. R. Carvalho, C. E. Speck-Martins;
 SARAH Network of Rehabilitation Hospitals, Brasília – DF, Brazil, BRASILIA, Brazil.

The 19q13.11 microdeletion syndrome (MIM 613026) is a clinically recognizable condition that recently has been identified by using microarray for genome-wide screening. We report a 9 year-old male patient with 3,7Mb deletion on 19q13.11 including the critical and minimal overlapping region (MOR) and compare our findings with those cases reported in the literature. The present patient shares several main features with the previously reported patients with 19q13.11 microdeletion syndrome including intrauterine/postnatal growth retardation and microcephaly, facial dimorphism, speech disturbance, developmental delay, hypospadias, and ectodermal dysplasia with cutis aplasia in midline scalp. In addition, brain abnormalities and ectrodactyly in hands and feet were confirmed. First diagnostic hypothesis was ectrodactyly-ectodermal dysplasia-clefting (EEC) syndrome.

The MOR encompass four zinc finger (ZNF) genes (ZNF302, ZNF181, ZNF599, ZNF30). As these ZNF act as transcription factors in brain differentiation, the haploinsufficiency of part of ZNF cluster set may be involved in the development of cognitive functions of that syndrome. Proximal to the MOR, UBA2 belongs to a protein complex with acetylation activity and several transcription factors, hormone receptors, and signaling proteins related to brain and sexual development are regulated by this post-translational modification could contribute to the clinical characteristics observed in patients.

In conclusion, we reported an additional patient affected by 19q13 microdeletion syndrome, whose characteristics may contribute to reinforce the minimal region associated and to focus on a few genes potentially responsible for the phenotype. In addition, we suggested that suspected cases of EEC syndrome could be tested to 19q13.11 microdeletion.

E-P11.03

First Bulgarian case of Sotos syndrome caused by 5q35 microdeletion

D. Avdjieva-Tzavella¹, S. Hadjidekova², S. Bichev³, M. Pancheva², H. Kathom¹, B. Rukova², D. Toncheva², R. Tincheva¹;

¹Department of Clinical Genetics, University Pediatrics Hospital, Medical University, Sofia, Bulgaria, ²Department of Medical Genetics, Medical University, Sofia, Bulgaria, ³National Genetic Laboratory, University Hospital “ Majcin Dom”, Sofia, Bulgaria.

Introduction: Sotos syndrome (SoS) is an autosomal dominant overgrowth syndrome characterised by a distinctive facial dysmorphism, macrocephaly, variable delays in cognitive and motor development, and advanced bone age. Most cases of SoS are caused by intragenic mutations of the *NSD1* gene or 5q35 microdeletions. The clinical presentation is independent of the underlying *NSD1* defect, although patients with microdeletions had less prominent overgrowth and more severe learning disability than cases with mutations.

Materials and Methods: The patient, a one-year-old boy, was referred to genetic evaluation because of the developmental delay. He was born at term after complicated pregnancy. Birth weight was 3900 g and length was 52 cm. Physical examination revealed: dolichocephaly, prominent forehead, hypertelorism, down-slanted palpebral fissures and elongated face. His weight, height and head circumference were in normal range. The abdominal ultrasonography revealed a malrotated right kidney.

The genome profiling of the proband was carried out by oligo array CGH. Agilent ISCA, 4x44, v2.0, with 35 kbp backbone resolution were used. The slides were scanned on Agilent fluorescent scanner G2505C and analyzed by BlueFuse Multi, v 4.2. (20289) (BlueGnome, Cambridge, UK).

Results: The oligo array CGH for the patient revealed deletion of 5q35 region (5q35.2-5q35.3). The deletion was 1.66 Mb in size and encompassing *NSD1* gene. The array CGH results were confirmed by MLPA.

Conclusions: Point mutations in *NSD1* are common in Caucasian patients with SoS while submicroscopic deletions at 5q35 occur in approximately 10%. The present report will contribute to further understanding of genotype-phenotype correlation in Sotos syndrome.

E-P11.04

8p duplication in a newborn with hypotonia and peculiar phenotype

G. M. Varo Sánchez, E. Simarro Rueda, A. M. Gómez Pastor, M. L. Quintanilla Mata, L. Navarro Casado;

Hospital General Universitario de Albacete, Albacete, Spain.

Introduction: We present a newborn male patient with hypotonia and peculiar phenotype: microcephalia, microretrognathia, low hairline, hypospadias, dorsal redundant prepuce, hypermobile hips and clinodactilia. Mother's pregnancy was full-term. His birth, weight and length were normal. Parents were no relatives and they had a healthy daughter with 2 years old.

These clinical findings made the neonatologist to apply for a karyotype analysis.

Multiple birth defects are associated with an unbalanced structural chromosomal rearrangement in proportion at 5%.

Material and methods: Cytogenetic analysis was performed on the patient's peripheral blood. Microarray-CGH method was used for define the duplication region.

Results: Patient's karyotype analysis was 46,XY,dup(8)?(p11p23). Microarray CGH was performed and detected arr[hg19] 8p12p11.21 (35,930,261-41,251,797)x3. The parents karyotype analysis were normal.

Conclusions: The 46,XY,dup(8)?(p11p23) karyotype suggests a duplication in the region of 8p11p23. Microarray-CGH confirms the cytogenetic finding, limiting the duplication to 8p12p11.21, suggesting a causal nature.

In this case is a chromosomal abnormality de novo and it was confirmed with a normal karyotype of the parents, as the majority of the cases of duplication 8p.

Currently, the patient is 3 years old and he has an important psychomotor retardation. Besides, he shows data from autism with lack of expressive language.

E-P11.05

Rare plurimalformative syndrome marked by dermatological phenotype associated with unbalanced chromosomal anomaly

V. Plaiasu¹, D. Ozunu², G. Motei², A. Coltoiu³, M. Stoian⁴, P. Gurban⁵, G. Dinulescu⁵, C. Diaconu⁶;

¹IOMC Prof.dr.Alfred Rusescu - Genetics Department, Bucharest, Romania, ²IOMC Prof.dr.Alfred Rusescu-Genetics Department, Bucharest, Romania, ³IOMC Prof.dr.Alfred Rusescu-Dermatologic Department, Bucharest, Romania, ⁴Personal Genetics-Medical Genetics Center; Discipline of Medical Genetics, University of Medicine and Pharmacy “Carol Davila”, Bucharest, Romania, ⁵Personal Genetics-Medical Genetics Center, Bucharest, Romania, ⁶Institute of Virology “Stefan S. Nicolau”, Bucharest, Romania.

The genetic analysis of patients with multiple congenital abnormalities is a very important aid in understanding the future prognosis and development. Individually, rare chromosome disorders are extremely uncommon, with some being actually unique. Rare chromosome disorders include extra, missing or re-arranged chromosome material. Management of the condition involves early diagnosis, genetic counselling and multidisciplinary approach. We report the case of a 16-years-old female patient. She was born at term by vaginal delivery with birth weight 2100g. At the age of 12 months she showed developmental delay, she walked alone at age of 20 months and she

talks very difficile.

The patient presents a rare association of facial dysmorphism, hypopigmented phenotype with multiple lentigines, skeletal involvement with thoracic kyphosis and limited extension movements of the elbows, intellectual disability with moderate cognitive impairment. Cerebral MRI revealed corpus callosum agenesis and polymicrogyria and cardiac ultrasonography showed valvular pulmonary stenosis.

Conventional karyotype of the proband identified a constitutional derivative chromosome 9, with partial deletion of the short arm: 46,XX,del(9)(p22), confirmed by arrayCGH analysis, the deleted region containing 57 OMIM genes. The mother's constitutional chromosomal analysis was normal and the paternal karyotype was not performed because the father died by lung cancer. We cannot exclude the paternal origin of the unbalanced chromosomal anomaly.

Our patient is in agreement with the consensus phenotype of this rare condition, except skin pigmented findings. Probably some genes from the deleted region contribute to particular dermatologic feature for this syndrome. This work was supported by PN-II-PT-PCCA-2013-4-133 grant

E-P11.06

A novel splice site JAG1 mutation in a Turkish girl with Alagille Syndrome

A. Turkyilmaz, B. B. Geckinli, K. Delil, M. A. Soylemez, E. Arslan Ates, H. Simsek, M. Avsar, A. I. Guney, A. Arman, P. Ata;
Medical Genetics Department, Marmara University Medical School, Istanbul, Turkey.

Alagille Syndrome is characterized by characteristic facial phenotype, paucity of bile ducts and cholestasis, congenital heart defects involving pulmonary stenosis, skeletal and ocular anomalies. It is caused by heterozygous mutation in the Jagged-1 gene (JAG1) on chromosome 20p12. Our patient is a 6 year-old girl who was referred to our clinic because of neonatal jaundice, failure to thrive, and pulmonary stenosis. She was born with normal physical parameters at term to unrelated parents. On her physical examination, her weight was 17 kg (10 P), length 104 cm (3 P), and head circumference 49,5 cm (10-25 P). Major clinical findings were, a broad forehead, triangular face, deep-set eyes, pointed chin, fascial xanthomas, palmar erythema, dry and excoriated skin secondary to generalized pruritus. Eye examination showed chorioretinal atrophy. Echocardiography revealed pulmonary stenosis and patent ductus arteriosus. Biochemical levels of alanine aminotransferase, aspartate aminotransferase, gamma-glutamyl transpeptidase, alkaline phosphatase and conjugated bilirubin were increased. In liver biopsy, multinucleated giant cell transformation of hepatocytes, periportal hepatocyte and bile duct cholestasis, mild bile ductular proliferation and portal tract neutrophilic inflammation were determined. DNA sequence analysis of JAG1 gene showed a novel de novo heterozygous donor splice-site mutation in JAG1 (c.439 +1 G>A) in intron 3 likely to disturb normal splicing. Our case has a novel mutation that hasn't been reported previously. The patients' molecular identification is important for differential diagnosis of cholestasis and genetic counseling.

E-P11.08

First the gene, then the syndrome: reverse syndromology illustrated by a child with a BCOR mutation

S. Seneca^{1,2}, K. Stouffs^{1,2}, A. Gheldof², M. Bonduelle¹, L. De Meirleir^{3,2}, K. Keymolen¹;
¹UZ Brussels, Center for Medical Genetics, Brussels, Belgium, ²Neurogenetics Research Group, Reproduction Genetics and Regenerative Medicine Research Group, Vrije Universiteit Brussel, Brussels, Belgium, ³Paediatric Neurology Unit, Department of Paediatrics, UZ Brussel, Brussels, Belgium.

Introduction: Mutations in the BCL6 Corepressor (BCOR) gene, located on Xp11.4, are linked to OculoFacioCardioDental syndrome (OFCD, MIM 300166). It affects both male and female patients and ophthalmological symptoms are often predominant. Materials and Methods: Exome sequencing was performed in a boy of Caucasian, non-consanguineous and healthy parents. He has one younger healthy sib. Intrauterine growth retardation was observed from 32 weeks of gestation on and he was born at 40 weeks with a weight of 2485 g and length of 46 cm. Severe pulmonary hypertension made ECMO necessary in the neonatal period. The child has delayed psychomotor development and attends a special school. At the age of 4 years, he still needs tube feeding because of severe feeding difficulties. Cardiac ultrasound shows a persistent ductus arteriosus and ophthalmological examination reveals mild microcornea. Facial gestalt is characterized by small palpebral fissures, synophris, bilateral epicanthic folds, small ears, thin upper lip and widely-spaced small teeth. Pro-and supination are limited due to radio-ulnar synostosis. Hypospadias and cryptorchidism are present. Results and conclusions: Exome sequencing showed the presence of

a hemizygous variant, c.5000C>T, p.Ser1667Leu in the BCOR gene (RefSeq: NM_001123385.1). This alteration of a highly conserved amino acid is predicted to be pathogenic (SIFT score 0.01, MutationTaster score 1, PolyPhen score 1.000). This change has not been detected in dbSNP, and ExAC shows a very low population frequency (2.3x10⁻⁵). The observed clinical features seen in this patient correspond very well with the phenotype for alterations in the BCOR gene as reported in the literature.

E-P11.09

Identification of a denovo novel missense mutation in FBN2 gene in a Turkish boy with Beals Syndrome

D. Kan Karaer, K. Karaer;
Department of Genetic Dr.Ersin Arslan Research and Training Hospital, Gaziantep, Turkey.

Beals syndrome is an autosomal dominantly inherited connective tissue disorder, which is also known as Beals-Hecht syndrome or Congenital contractural arachnodactyly (CCA), is classified as distal arthrogyriposis syndrome Type 9 and characterized by multiple flexion contractures, arachnodactyly, severe kyphoscoliosis, abnormal pinnae and muscular hypoplasia. It is caused by a mutation in FBN2 gene on chromosome 5q23.

A newborn boy was referred to genetic counselling because of congenital anomalies and dysmorphic features. He was born to healthy non-consanguineous parents. The child had had features of a long and narrow face, bilateral crumpled helix of the ears, bilateral arachnodactyly, clenched position of the hands and flexion contractures of the elbows and knees. The parents had no known history of familial birth defects. A mutation analysis of FBN2 gene was requested. The results revealed a previously unpublished sequence variant a missense c.3973G>A (p.D1325N) in a heterozygous state. In silico analysis (Mutation Taster, SIFT and PolyPhen) predicts this mutation as potentially deleterious. Sequencing of 30th exon of FBN2 gene of both parents was performed, but the variant was not found, confirming a denovo event. Functional studies and more reports are required to understand for the affect of the mutation and genotype-phenotype correlation.

E-P11.10

A new case of campomelic dysplasia with dextrocardia and without sex-reversal

I. Augustin¹, O. Păvăloaia², M. Pânzaru³, V. Martiniuc⁴, M. Grămescu⁵, L. Păduraru⁵, M. Stamatin⁵, M. Târnavan⁶, M. Onofriescu⁶, E. Gorduza^{3,4};

¹Student, University of Medicine and Pharmacy "Grigore T. Popa" Iași, Romania, Iasi, Romania, ²Medical Genetics resident, University of Medicine and Pharmacy "Grigore T. Popa" Iași, Romania, Iasi, Romania, ³Medical Genetics Department, University of Medicine and Pharmacy "Grigore T. Popa" Iași, Romania, Iasi, Romania, ⁴Medical Genetics Department, "Cuza-Vodă" Obstetrics and Gynaecology Hospital Iași, Romania, Iasi, Romania, ⁵Neonatology Department, University of Medicine and Pharmacy "Grigore T. Popa" Iași, Romania, Iasi, Romania, ⁶Obstetrics and Gynaecology Department, University of Medicine and Pharmacy "Grigore T. Popa" Iași, Romania, Iasi, Romania.

We report a 3 days old male with plurimalformative syndrome, characterized by disharmonic shortstature, macrocephaly, high forehead, high anterior hairline, flat occiput, wide fontanel, low-set, posteriorly rotated ears, hypertelorism, nose with anteverted nostrils, wide and flat bridge, short, deep philtrum, microretrognathia, microstomia, cleft palate, short neck, chest hypoplasia, dextrocardia, short and curved limbs, talipes equinovarus, muscle hypotonia. The X-rays indicated reduced cranial, pelvic, tibial and fibular ossification, absence of nasal and sternal ossification, cervical kiphosis, 11 pairs of ribs, flat and short vertebral bodies, short humerus with widened distal epiphysis, shorted and curved forearm's bones and femur and hepatomegaly. Karyotype is normal. Prenatal ultrasonographic investigation of patient indicated a IUGR and short limbs. Based on these features the prenatal diagnostic supposition was achondroplasia. The diagnosis was: campomelic dysplasia (CD). CD is a rare plurimalformative syndrome (1/40.000-1/80.000 newborns) generated by mutation in SOX9 gene that codes a transcription factor expressed in embryonic stage. It controls sexual and skeletal development. Mutations are de novo and transmitted in autosomal dominant manner. In majority of 46,XY CD fetuses present a sex-reversal. Prognosis of CD is negative, 90-95% of patients died in neonatal period of respiratory insufficiency. The CD surviving patients need cardiologic, psychiatric, orthopaedic, ophthalmologic and ERT survey. The particularities of our case are absence of sexual ambiguity and presence of dextrocardia.

E-P11.11

Is so much chromosome aberrations compatible with life?

O. Demirhan¹, S. Kuleci², & Uslu¹, N. Cetinel¹;

¹Çukurova University, Faculty of Medicine, Dept. of Medical Biology, Adana, Turkey,

²Çukurova University, Faculty of Medicine, Dept. of Chest Diseases, Adana, Turkey.

Most chromosome abnormalities (CAs) are so harmful that the embryo or fetus does not survive long enough to be born. And how much of CAs are compatible with life? We performed cytogenetic analysis by G-banding in an adult girl, aged 23 years, with hundreds of CAs, and she died after some time. While she has been evaluating for diffuse parenchymal lung disease, she was considered to have a possible genetic disorder, and asked to Department of Genetics for genetic evaluation. We observed that there were at least one or more structural and/or numerical CAs in a cell of a person. The numerical and structural aberrations were found in 94.3% of cells analyzed. However, the karyotype results were normal in 5.7% of all cells. The ratio of numerical CAs was 64.2%. These CAs were a very serious and very important genetic instability. However, these hundreds of CAs had reflected to clinic appearance with only atypical facial and growth retardation. Genomic instability is caused by DNA damage, aberrant DNA replication or uncoordinated cell division, which can lead to CAs and gene mutations. Is that so much chromosome irregularity present in a person compatible with life, and live up to a twenty-three years old?

E-P11.14

Monosomy 2q37.2 phenotype: 18-years follow-up case report

N. Rumiantseva¹, O. Khurs²;

¹Republican Scientific and Practical Center, Minsk, Belarus, ²Republican Scientific and Practical Center „Mother&Child“, Minsk, Belarus.

Monosomy 2q37-qter (AHO-like syndrome, OMIM 600430) shows variable manifestations depending from various deletion's size and different genes lost. Combination of moderate mental delay, overweight, brachydactyly type E (BDE) noted as recognizable pattern.

Case report. Patient's karyotype was confirmed by FISH: 46,XX,del(2)(q37.1~q37.2)dn; loss started distally from D2S2633/D2S206 (investigation was carried out by A.Polytiko, T.Liehr, Jena, Germany). Proposita (G1, P1, BW=3100g, BL=51cm, OFC=34cm) had normal neonatal history and metabolic data. In infancy girl showed hypotonia, umbilical hernia, sitting at 7 months, walked since 1 year 2 months. Toddlers period: speech delay (normal hearing), muscle weakness, wide-based gait, seizures, mild thorax deformation, hypermethrophia, astigmatism. Childhood: mental retardation, poor speech, impulsive/aggressive behaviour, reduced attention, autistic signs, cognitive deficit, overweight, vertebrae degenerative changes, short 3,4-th fingers/toes. At 18 years old: height=156cm (<10th centile), obesity (weight=80kg; >97th centile), intellectual disability, low capacity of communication, facial dysmorphisms (narrow palpebral fissures, deep-set eyes, broad nasal tip, thin upper lip), nevuses, skeletal abnormalities: short neck, Schmorl's hernias (Th11-L2), kyphosis (corset), BDE hands/feet, pes planus, hallux valgus. Normal menarche, mammary hypoplasia. US, MRI studies: normal brain, heart, hepar; abnormal gallbladder shape, retroperitoneal renal ectopia.

Conclusion. According to deletion's breakpoint the patient had haploinsufficiency of numbers genes located distally ARL4C, including candidate genes for mental/ behavior disturbances, overweight, BDE (HDAC4, PER2, GPC1, TWIST2, etc), and displayed a wide spectrum of clinical features both typical and uncommon. Patients with subtelomeric unbalance presented a longer lifespan but suffered from mental impairment/social disability and need for medical care corrected individually at each life's stage.

E-P11.15

Case report: A novel missense mutation in BMPER gene

S. Asadollahi^{1,2}, S. Mohammadi¹, S. Seyedhassani¹;

¹Dr seyedhassani genetic center, Yazd, Iran, Islamic Republic of, ²Shahid Sadoughi University of Medical Sciences and Health Services, Yazd, Iran, Islamic Republic of.

Introduction: Diaphanospondylydysostosis (DSD, MIM 608022) is a rare, recessively inherited, prenatal lethal skeletal dysplasia characterized by severe deficiency of vertebral body and sacral ossification, reduced rib number and cystic kidneys.

Case presentation: Sample was belong to an aborted fetus, which was aborted at 36 weeks of gestational age due to multiple congenital anomaly. Parents are first degree relatives and they had a previous abortion at 32 weeks of gestation due to Hydrops Fetalis. The aborted fetus had abnormal nose, low-set ear, hypoplastic lung, Polyhydramnios and Hydrops Fetalis. Nuchal translucency was reported out of range (4mm) at 12 weeks of gestation. Amniocentesis for chromosomal aneuploidy as well as fetal autopsy

was reported normal.

Material & Methods: Whole Exome Sequencing was performed using sample from proband to evaluate all exons of protein-coding genes as well as some important other genomic regions by next generation sequencing method. We identified one deleterious novel homozygous missense mutation in *BMPER* (NM_133468) gene. Then we performed PCR and Sanger sequencing on Proband and her parents to confirm this mutation.

Results: The mutation in *BMPER* gene was in exon8:c.C664T:p.P222S. Assessment of the parents showed that they were in heterozygous state in this position. This mutation is not reported in the literature. Bioinformatics analysis by SIFT, Polyphen and Mutation Taster predicted the pathogenicity of this mutation. The CADD_phred was 28.2.

Conclusion: Based on the above evidence, this data can be used in early diagnosis of fetal anomalies and effective genetic counseling in this family.

E-P11.18

New deletion in EVC and EVC2 genes causing Ellis-van Creveld syndrome

E. Sarasola Díez¹, S. Merino-Fernández¹, M. Fernández Cuesta², C. Ruiz Espinoza², M. Trujillo-Tiebas^{3,4}, V. Ruiz Pérez², M. García-Barcina¹;

¹Genetics Unit - Basurto University Hospital (Osakidetza/Servicio Vasco de Salud), Bilbao, Spain, ²Pediatrics Service - Basurto University Hospital (Osakidetza/Servicio Vasco de Salud), Bilbao, Spain, ³Instituto de Investigación Sanitaria de la Fundación Jiménez Díaz (IIS-FJD), Hospital Universitario Jiménez Díaz, Madrid, Spain, ⁴Centro de Investigaciones Biomédicas en Red en Enfermedades Raras (CIBERER), Madrid, Spain, ⁵Instituto de Investigaciones Biomédicas „Alberto Sols“, IdiPAZ, UAM-CIBERER - ISCIII, Madrid, Spain.

We describe a family with three children: the first, died at birth due to cardiac complication associated to the diagnosis of Ellis-van Creveld syndrome (EvCS); the second was a healthy female, and the third one who was referred to our Genetic Counselling consultation at 31 years old. The later, showed normal intelligence, short stature (1,45cm), short ribs, maxilar hypoplasia, oligodontia and hypoplastic nails. She referred that at birth she presented interauricular communication and patent ductus arteriosus, bilateral hexadactily and some ovoid vertebral bodies.

The EvCS and Weyers acrofacial dysostosis (WAD) are allelic disorders that differ in inheritance and clinical severity. EvCS is inherited as an autosomal recessive trait with variable expression characterized by short ribs, polydactyly, short stature and ectodermal and heart defects. Mild expression of these features, alone or in combination, have been observed in parents of patients affected of EvCS and are interpreted as manifestations of heterozygosity (so-called WAD).

In order to define the mode of inheritance in this family, the molecular study of EVC and EVC2 was performed, showing a truncating mutation in EVC gene but no other point mutation or small deletion/insertion nor in EVC2. This molecular finding not fully supported our clinical data. The development of a new MLPA kit (P456, MRC-Holland) allowed us to detect a heterozygous deletion encompassing part of EVC2 gene and the first exon of EVC gene, confirming the diagnosis of EvCS in our patient and, therefore, providing the adequate Genetic Counselling in this family.

E-P11.19

De novo 15q26.2q26.3 duplication and 15q26.3 deletion in a patient with an anomalous parietal sutures

B. Aleksūniene¹, L. Cimbalistienė¹, V. Diršė², E. Gineikiene², R. Marcinkutė¹, A. Utkus¹;

¹Department of Human and Medical Genetics, Faculty of Medicine, Vilnius University, Vilnius, Lithuania, ²Hematology, Oncology and Transfusion Medicine Center at Vilnius University Hospital Santariškių Klinikos, Vilnius, Lithuania.

The combination of 15q26 duplication and deletion has not been described previously. We present a de novo 15q26.2q26.3 duplication and 15q26.3 deletion in a patient with the anomalous right parietal sutures (bipartite parietal bone) and dysmorphic facial features.

The proband is the first-born female child of non-consanguineous parents. At birth she was weighted 4042 g (90th centile) with the length of 56 cm (above 97th centile). The following dysmorphic features were noted: epicanthic folds, small nose, wide nasal bridge, opened mouth, narrow palate, small mandible and a simian crease in her left hand. At the age of two years she was diagnosed with mild developmental delay, retarded speech development and myotony. At the age of 29 months her weight was 14700 gr (90th centile), height 100 cm (97th centile) and head circumference 49 cm (90th centile). The ultrasound examination of internal organs, including renal, was normal.

Chromosome analysis of peripheral blood lymphocytes revealed a normal karyotype 46,XX. Whole-genome SNP array was carried out and identified a de novo 15q26.2-q26.3 duplication 5.6 Mb in size and adjacent terminal

15q26.3 deletion 709 Kb in size. Detected chromosomal alterations on chromosome 15 was confirmed by real-time PCR and FISH. The duplication/deletion regions encompass over 20 genes, including NR2F2, IGF1R, MEF2A and SNRPA1 genes. IGF1R gene encodes an important component of the insulin-like growth factor axis and is critical to pre- and postnatal growth. Increased dosage of IGF1R might be responsible for the patient's phenotype and could lead to overgrowth.

E-P11.20

Interstitial deletion of chromosome 4p - case report and review of the literature

A. Mitroi¹, A. Apostol¹, M. Aschie², G. Cozaru¹, C. Brinzan¹;

¹Emergency Clinical County Hospital of Constanta, Constanta, Romania, ²Ovidius University of Constanta, Constanta, Romania.

To date interstitial deletion of chromosome 4p, extending from p14 from p16.1, have been described in a few cases. This proximal 4p deletion is characterized by variable degree of mental retardation, characteristic facial appearance and minor dysmorphic features.

We report a 3-year old boy with interstitial deletion in the short arm of chromosome 4p with the karyotype 46,XY,del(4)(p15.3p16.1),9qh+. For a precise delineation of the deleted region array CGH was performed. The proband's phenotype was compared with previously reported cases with similar deletion. Our case present mild mental retardation, normal growth, craniofacial dysmorphism, pectus excavatum, left undescended testes and clinodactyly of the toes. Until now our patient didn't developed epilepsy unlike other described cases and additionally has erythrocytosis with microcytosis.

E-P11.21

A Portuguese 3-generation family with KBG syndrome due to a novel mutation in ANKRD11 gene

A. M. Travessa, P. Dias, A. Medeira, A. B. Sousa;

Department of Genetics, Hospital de Santa Maria/CHLN, Lisboa, Portugal.

Introduction: KBG syndrome (OMIM 148550) is a rare disorder characterized by intellectual disability, macrodontia of the upper central incisors, typical craniofacial dysmorphism, short stature and costovertebral anomalies. KBG syndrome is caused by haploinsufficiency of the ANKRD11 gene, located at 16q24.3.

Case report: Index patient is a 42-years-old female, referred for evaluation for short stature, facial dysmorphism and mild intellectual disability. Detailed description of this patient and other affected members is provided, including photos and X-rays images. Common features to all were growth retardation/short stature, mild developmental delay/intellectual disability, typical KBG syndrome facial dysmorphism including macrodontia of the upper central incisors, and characteristic short hands with brachy-clinodactyly of the 5th finger. In the index patient's son (age 21), a cervical rib and schisis of the posterior arch of S1 were identified. Her younger daughter (age 2) had an additional history of hypotonia, congenital hearing loss and EEG with epileptic abnormalities at 15 months of age.

Methods and results: Chromosomal abnormalities were excluded in the index patient by array CGH analysis. Subsequently, a heterozygous one-nucleotide frameshift duplication c.4384dup (p.Arg1462Lysfs*92), leading to a premature stop codon, was identified in ANKRD11 gene by Sanger sequencing, confirming KBG syndrome. Molecular confirmation of the diagnosis in the index patient's affected descendents was performed.

Conclusions: Clinical dysmorphological evaluation allowed the diagnosis of KBG and direct analysis of ANKRD11 gene revealed a novel mutation in a family with five affected patients. We aim to contribute to a better characterization of this autosomal dominant condition, highlighting its distinctive features.

E-P11.22

Kleefstra syndrome in a girl of 4 months

C. Garrido^{1,2}, D. Escué¹, M.A. Caamaño¹, A. Morales¹, A. Torrents¹, M.M. Sánchez², E. Geán¹;

¹Reference Laboratory, L'Hospitalet de Llobregat (Barcelona), Spain, ²Hospital de León, León, Spain.

Introduction: Kleefstra syndrome (OMIM: 610253) is a rare genetic condition caused by a heterozygous microdeletion in about 75%, and by EHMT1 pathogenic variant in the remaining 25%. This syndrome comprises ID, childhood hypotonia and distinctive facial features. In the reviewed literature, to our knowledge only 114 cases were published so far, so the incidence is unknown in general population. The array CGH is a very powerful tool that can help us to diagnose patients with a deletion of EHMT1.

Case report: We report a case of a blood study for arrayCGH study with a wide clinical history. The clinical features of this girl of about 4 months were, psychomotor retardation with pathological motor development, axial hypotonia, lack of head control, heart disease (ASD + VSD + pulmonary stenosis), microcephaly, upper lip V-inverted-shaped, and clear skin. Consanguinity (parents cousin's brothers). Normal studies for: cytogenetic analysis, CATCH-22, cerebral ultrasound and ophthalmologic evaluation.

Results: After the processed arrayCGH by Agilent platform of 60K, we found a deletion of the genome region of the chromosome (9)(q34.4): arr[hg18] 9q34.3(138.395.514-140.138.805)x1

Conclusions: The increasing use of array CGH in clinical cytogenetic laboratories provide an efficient method to find out the causes of the pathology of the patients underdiagnosed. In familiar cases it could be a powerful tool for a good genetic counselling for future pregnancies. This must be the first test in patients with clinical features susceptible of study.

E-P11.23

Novel CEP290 mutation causing Leber congenital amaurosis in Bedouin kindred

M. Drabkin¹, D. Halperin¹, Y. Perez¹, L. Gradstein², O. S. Birk^{1,3};

¹The Morris Kahn Laboratory of Human Genetics, National Institute for Biotechnology in the Negev, Faculty of Health Sciences, Ben-Gurion University of the Negev, Be'er Sheva, Israel, ²Department of Ophthalmology, Soroka University Medical Center and Clalit Health Services, Ben Gurion University, Be'er Sheva, Israel, ³Genetics Institute, Soroka University Medical Center, Ben Gurion University, Be'er Sheva, Israel.

CEP290 mutations have been previously associated with several syndromes, including Leber congenital amaurosis, Senior-Loken syndrome, Joubert syndrome, Meckel syndrome and possibly Bardet Biedl syndrome. Four individuals of large consanguineous Bedouin kindred presented with Leber congenital amaurosis with severe mental retardation. Genome-wide linkage analysis (Affymetrix 250K SNP array) identified a single 9Mbp homozygous locus in chromosome 12 unique to the affected individuals (rs2163903-rs1069742; maximum LOD score 3.6 at D12S1598). Filtering of whole exome sequencing data of an affected individual for known benign variants within this locus using open access databases (HapMap, EVS and 1000 genomes) and our in-house data of over 100 ethnically matched exomes, identified a single putatively deleterious homozygous mutation within this Locus: c.2010_2011delA p.Ile556Phefs*17 in CEP290. The mutation segregated as expected within the kindred and was not found in a homozygous state in further 200 ethnicity-matched controls. CEP290 encodes a centrosomal protein involved in ciliary assembly and ciliary trafficking. The phenotype caused by the novel CEP290 p.Ile556Phefs*17 truncating mutation is of Leber congenital amaurosis. The molecular developmental mechanisms through which different syndromes evolve due to mutations affecting various positions in CEP290 are yet to be elucidated.

E-P11.24

Linear nevus sebaceous syndrome: a case report

D. Pantaleo¹, M. C. Cutrupi¹, M. R. Pizzino¹, M. Crapanzano¹, C. Pidone¹, I. Loddò², S. Briuglia¹;

¹Department of Paediatric Science Messina, Messina, Italy, ²University of Messina, Messina, Italy.

Introduction: Linear nevus sebaceous syndrome (LNNS) is a congenital neurocutaneous disorder with linear epidermal nevus. LNNS is a rare sporadic disease (<1:10.000).

Case report: we report a 10 years boy with nevi on left side of face and midline of neck. Family history was negative. He had refractory partial seizures and developmental delay. Brain MNR showed hemimegalencephaly. EEG had epileptiform bursts. There were retinal anomalies, coloboma, severe ocular hemangiomas and kyphoscoliosis. A diagnosis of LNNS was considered. Excisional biopsy of nevus confirmed diagnosis of verrucous epidermal nevus with sebaceous anomalies.

Conclusion: LNNS manifestations include linear epidermal nevus, seizures (75%), developmental delays (40%), ocular and skeletal involvement. This rare disease is hypothesized to result from postzygotic mosaic mutations in HRAS or KRAS genes. Isolated congenital sebaceous nevi are more frequent (1:1000). The risk of association with other organ involvement is greater when typical midline nevus has been identified. LNNS is a serious disease, because of cosmetic impact, malignant potential and severity of clinical manifestations. This case shows a very serious expression of LNNS, because of the organs involvement is in a very severe form. The diagnosis is difficult and late. It makes us think about the importance of early diagnosis and all children with a suspected diagnosis of LNNS should undergo a multidisciplinary follow up.

The rare constitutional chromosomal aberration dic(X;Y) (p22.3;p11.3) in an adult male with hematological malignancy

L. Pavlistova¹, S. Izakova¹, L. Bartuskova¹, M. Langova², P. Malikova³, Z. Zemanova¹, K. Michalova^{1,4};

¹Center of Oncocytogenetics, IMBLD, General Teaching Hospital and First Faculty of Medicine, Prague 2, Czech Republic, ²Department of Medical Genetics, Thomayer's Hospital, Prague 4, Czech Republic, ³Department of Clinical Hematology IKEM, Prague 4, Czech Republic, ⁴Department of Cytogenetics, Institute of Hematology and Blood Transfusion, Prague 2, Czech Republic.

Constitutional translocations of gonosomes are very rare in humans and the breakpoints Xp11 and Yq11 were identified as the most frequent. Patients with breakpoints on Yp represent the not numerous subgroup of constitutional t(X;Y) giving rise to dicentric chromosome. The phenotype is variable because more factors play role: breakpoints on X and Y, presence/loss of SRY gene locus, mosaicism and X inactivation pattern.

Cytogenetic examination of bone marrow sample in 63 years old male patient with primary myelofibrosis proved the karyotype 46,X,dic(X;Y) (p22.3;p11.3)[20]. Acquired aberrations related to the myeloproliferative disorder were not identified. Beside the clone with 46,X,dic(X;Y) (p22.3;p11.3)[20], the cell line 45,X[10] was found by examination of PHA stimulated peripheral blood. FISH with probe for SHOX and SRY genes and subtelomers of Xp/Yp (Cytocell, Abbott Molecular) proved deletion of both subtelomeric regions, SHOX gene and conserved SRY locus on dicentric chromosome. The finding was verified by mFISH (24XCyte, MetaSystems) and array CGH/SNP (BlueGnome).

Our proband have the short stature, Madelung deformity of the forearm and ear's skin abnormality. The elevation of gonadotropins and reduced level of testosterone indicate the gonadal dysfunction associated with two hereditary syndromes: heterozygous deletion of SHOX gene with Léri Weill dyschondrosteosis and additional copy of almost whole X chromosome with Klinefelter's variant syndrome.

Constitutional karyotype 46,X,dic(X;Y)(p22.3;p11.3)/45,X of adult male detected in his peripheral blood and bone marrow is presented. Results of examination by clinical geneticist, cytogenetic, molecular cytogenetic, clinical and laboratory data will be discussed in detail in the poster. Supported by grants RVO-VFN64165 a GCAS-1201-00-7-846.

E-P11.26

Meier-Gorlin (ear-patella-short stature) syndrome: A rare clinical entity

Ö. Akgün Doğan¹, P. Simsek Kiper¹, Y. Alanay², G. Utine¹, K. Boduroğlu¹;

¹Hacettepe University, Faculty of Medicine, Department of Pediatrics, Division of Pediatric Genetics, Ankara, Turkey, ²Acibadem University, School of Medicine, Department of Pediatrics, Division of Pediatric Genetics, Istanbul, Turkey.

Meier-Gorlin (ear-patella-short stature) syndrome is a rare autosomal recessive syndrome characterized by severe prenatal and postnatal growth retardation, bilateral microtia, and absent or very small patella. The patients generally show a borderline cognitive functioning and a cheerful and friendly personality has been described by several authors. Homozygous or compound heterozygous mutations in *ORC1*, *ORC4*, *ORC6*, *CDT1* or *CDC6* have been described in the genetic etiology so far, however, in about 20% of cases, molecular etiology remains to be elucidated. We here report on clinical findings of 3 patients from 2 families presenting with facial features along with profound developmental delay. Patient 1 was born at term with a birth weight of 1750 gr (< 3rd centile) and a length of 41 cm (< 3rd centile) to consanguineous parents. She was referred to our center with the complaints of developmental delay and growth retardation at the age of 1. She had dextrocardia, nephrolithiasis, and scoliosis as well. Patient 2 and Patient 3 were siblings. They were born to consanguineous parents at term with birth weights of 2700 gr (3rd-10th centiles) and 2600 gr (3rd-10th centiles), respectively. The birth lengths were not noted. They were referred to our center at the ages of 7 and 4, respectively. Both of them had facial features, developmental delay and growth retardation along with anxiety and hyperactive behavior such as fidgeting or impulsive actions. Molecular analysis of the patients presented here is still going on.

E-P11.27

Microduplication 5q35: possible dosage effect of the NSD1 gene

U. E. Siebers-Renelt, C. Mueller-Hofstede, P. Wieacker, A. Röpke; Institut für Humangenetik, Muenster, Germany.

We report on a 15-year old boy with mild mental retardation, short stature (<3rd centile), microcephaly (<3rd centile) and minor craniofacial dysmorphism. Conventional chromosome analysis revealed an apparently normal male karyotype (46,XY, GTG banding, BN 550). Array-CGH analysis (Agilent 400K microarray) uncovered a duplication of approx. 2.1Mb in the chromosomal region 5q35.2-q35.3 comprising 43 genes including the NSD1 gene. This finding was confirmed by qPCR. The interstitial character of the microduplication was proven by FISH analysis (ish 5q35.2 (RP11-627M5 enh)). Blood samples of the parents were not available.

Deletions of the NSD1 gene, located in 5q35.3, are a known cause of Sotos syndrome which belongs to the overgrowth syndromes. The Sotos critical region spans over 1.9Mb and is flanked by two low-copy repeat regions (Kurotaki et al 2005). This genomic architecture predisposes to non-allelic homologous recombination. The size and the location of the microduplication in our patient are located in the same regions suggesting a common mechanism of the generation of the genomic imbalance as already described for other chromosomal regions (e.g. 22q11.2). The main features of our patient with a microduplication 5q35 are postnatal growth retardation, microcephaly without structural brain defects and a mild to moderate mental retardation. This is in accordance to other patients with a microduplication 5q35 reported so far (Novara et al 2014). In part, the phenotype is reciprocal to Sotos syndrome suggesting a dosage effect of the NSD1 gene on growth, although the exact mechanism of NSD1 function is not known in detail yet.

E-P11.28

A novel SF3B4 pathogenic splice variant in a 21-week-old fetus with Nager syndrome

M. Calvello¹, J. Kohlhasse², T. Rizzuti³, S. Boito⁴, M. F. Bedeschi¹, F. Natacci¹, F. Lalatta¹;

¹Clinical Genetics Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy, ²Center for Human Genetics, Freiburg, Germany, ³Pathology Unit, Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Milan, Italy, ⁴Obstetric Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy.

Introduction: Nager syndrome (Acrofacial Dysostosis type 1) is characterized by craniofacial and preaxial limb anomalies. Since 2012 various loss-of-function point-mutations in SF3B4 have been identified in approximately 60% of patients with Nager syndrome. We report a 21-week-old fetus with Nager syndrome features all ascribed to a previously unreported SF3B4 mutation.

Case description: A 36-year-old woman was referred to our department at 20 weeks of gestation when morphologic ultrasound revealed severe micrognathia. A level II scan confirmed this finding and detected upper limb anomalies (short humerus, ulnar hypoplasia, undetectable radial skeleton). The couple was informed of the fetal prognosis and chose termination. Autopsy revealed severe micrognathia, low-set ears with hypoplastic antihelix, bilateral thumb agenesis, short long bones with bilateral radial aplasia and bowed ulnas, and bilateral clubfoot. Molecular analysis of the SF3B4 gene was performed on DNA extracted from amniocytes sampled before termination and from peripheral blood of both parents. A heterozygous variant c.34+1G>A in intron 1 of the SF3B4 gene was identified in fetal DNA but in neither of the parents' DNA, indicating a de novo event.

Conclusions: Since the variant detected in fetal DNA destroys the native splice donor site of intron 1, likely leading to exon skipping or to the usage of a cryptic splice site with possible nonsense mediated mRNA decay or to formation of a truncated protein, we regard our variant as a likely pathogenic mutation. Our results are in agreement with previous observation of loss-of-function mutations adding a pathogenic splice variant to the SF3B4 mutational spectrum.

E-P11.29

Identification of a denovo novel missense mutation in SMARCA2 gene in Turkish girl with a less affected phenotype of Nicolaides-Baraitser Syndrome

K. Karaer¹, Z. Yuksek²;

¹Dr.Ersin Arslan Training and Research Hospital Department of Medical Genetic, Gaziantep, Turkey, ²Medical Genetics Clinic, Women and Children Hospital, Mersin, Turkey.

Nicolaides-Baraitser syndrome (NCBRS) is characterized by sparse scalp hair; characteristic coarse facial features prominence of the interphalangeal joints and distal phalanges, seizures and speech delay with developmental delay/intellectual disability. Recent studies reported patients with NCBRS

having mutations in SMARCA2 gene and inherited in autosomal dominant manner.

A 3 years-5 months-old girl was referred to genetic counselling because of mild intellectual disability and dysmorphic features. She was born to healthy non-consanguineous parents. The child had hair loss, coarse facial features (prominent eyes, prominent and thick eyebrows, wide and open mouth) and seizures. The family history is negative. A mutation analysis of SMARCA2 gene was requested. The results revealed a previously unpublished sequence variant a missense c.3389G>T (p.G1130V) in a heterozygous state. In silico analysis (Mutation Taster, SIFT and PolyPhen) predicts this mutation as potentially deleterious. Sequencing of 24th exon of SMARCA2 gene of both parents was performed, but the variant was not found, confirming a *de novo* event.

Thus, clinical data of this family were presented by moderate or mild form of the disease. Functional studies and more reports are required to understand for the affect of the mutation and genotype-phenotype correlation.

E-P11.30

Noonan syndrome and spinal muscular atrophy - an unusual combination

N. Beznikow¹, A. Potulska - Chromik², A. Abramowicz¹, A. Landowska¹, M. Gos¹, A. Kostera - Pruszczyk², E. Obersztyn¹;

¹1. Department of Medical Genetics, Institute of Mother and Child, Warsaw, Poland, Warsaw, Poland, ²2. Department of Neurology, Medical University of Warsaw, Warsaw, Poland.

We report an unusual combination of Noonan syndrome (NS) and spinal muscular atrophy (SMA) diagnosed in a 17-year-old boy admitted to the Department of Neurology because of gait disturbance and leg tremors. He was born by C-section at 36 weeks of gestation to non-consanguineous parents with unremarkable family history. His birth weight was 3090g (50-75pc), body length 55 cm (>95pc) and (OFC) 33 cm (25-50pc). Lymphedema of the dorsal part of the hand and foot were found after birth. Psychomotor development was normal, however, mild intellectual disability and learning difficulties were noted at school age. On physical examination at age of 17 years he presented with short stature (body height 165,4 cm (-2,02 SD), microcephaly (head circumference 52,8 cm (-2,89 SD), pulmonary valve stenosis, webbed neck, widely spaced nipples, pectus excavatum, scoliosis, myopia, nystagmus, easy bruising and delayed puberty. Dysmorphic features (ptosis, bulbous nasal tip, pointed chin, protruding ears, tall forehead) were typical for NS. Neurological examination revealed proximal and distal muscle weakness and atrophy, foot deformity and walking difficulties disturbances. EMG and muscle biopsy demonstrated neurogenic changes. The Sanger sequencing revealed the presence of known pathogenic -c.922A>G (p.Asn308Asp) mutation in PTPN11. Also, the homozygous deletion of SMN1 exon 7 was found with PCR-RFLP technique. Therefore, the clinical diagnosis of both Noonan syndrome and spinal muscular atrophy were confirmed and to our knowledge this is the first report of NS associated with SMA.

The study was supported from the NCN grant UMO - 2013/09/B/NZ2/03164

E-P11.31

Noonan-like syndrome with loose anagen hair identified by exome sequencing

M. Miramar¹, A. Rodríguez¹, S. Izquierdo¹, A. Lasierra¹, M. Alcaine¹, J. González¹, J. Peña¹, J. López¹, J. Botet², S. Alvarez²;

¹Hospital Universitario Miguel Servet, Zaragoza, Spain, ²Nimgenetics, Madrid, Spain.

Introduction: Noonan-like syndrome with loose anagen hair (NS/LAH; OMIM 607721) is a RASopathy characterized by craniofacial features resembling Noonan syndrome, cardiac defects (dysplasia of the mitral valve and septal defects), cognitive deficits and behavioral issues, reduced growth, darkly pigmented skin and an unique combination of ectodermal anomalies. A distinctive trait of NS/LAH is its association with easily pluckable, slow growing, sparse, and thin hair. This rare condition is due to the invariant c.4A > G missense (p.Ser2Gly) change in SHOC2 gene, located in 10q25. This gene encodes a protein that consists almost entirely of leucine-rich repeats, a domain implicated in protein-protein interactions. The protein acts in the RAS/ERK MAP kinase signaling cascade. The p.Ser2Gly mutation creates a new recognition site for N-terminal myristoylation, causing aberrant targeting of SHOC2 protein to the plasma membrane and impaired translocation to the nucleus upon stimulation with growth factor. Here we report one NS/LAH case identified by exome sequencing.

Materials and methods: The patient was a seven years old female with psychomotor delay and facial dysmorphisms (easily pluckable, sparse and thin yellow hair, relative macrocephaly and low-set ears), failure to thrive (with GH treatment), atrial septal defect, skin anomalies and epiphyseal dysplasia.

An exome study was performed by an external laboratory (Nimgenetics, Madrid).

Results: The analysis of clinical exome (5678 genes) revealed the pathogenic c.4A>G mutation in SHOC2 gene associated with NS/LAH.

Conclusions: The present study emphasizes the clinical utility of exome sequencing for rare diseases and it broadens the phenotype spectrum associated with NS/LAH syndrome.

E-P11.33

3 year old girl with a pure de novo 46 Mb duplication of 3p21.31

K. Vinorum, S. Keim, M. Fannemel;
Oslo University Hospital, Oslo, Norway.

A 3 year old girl with a *de novo* partial 3p trisomy (karyotype 4, XX, der (14), t(3;14)(p21.31;p11), confirmed by array CGH; arr3pterp21.31(248593-46581062)x3. Born to healthy, unrelated Norwegian parents. Normal pregnancy until gestation week 39 when the mother reported reduced fetal movement. Ultrasound revealed hydrocephalus and hydronephrosis. Sectio was performed due to poor CTG.

BW 25th percentile, BL 75th percentile and HC 75th percentile. The patient had ASD, perimembranous VSD and patent ductus arteriosus. She developed heart failure and had heart surgery at two weeks of age. Hydrocephalus was confirmed and she had an increasing head circumference to 97,5th percentile at the age of 2 months. Her weight and length were at the 25th percentile. MRI of the brain revealed bilateral arachnoidal cysts and accumulation of extracerebral fluid in both lateral ventricles which has been shunted. She has hydronephrosis on right hand side and multiple cysts on left kidney. At the age of 3 years, her weight and length has dropped to 2,5th percentile, and the head circumference normalised (50th percentile).

The patient has severe delayed psychomotor development. She can walk with support and can say a couple of words. She is dysmorphic with hypertelorism, bilateral coloboma, wide mouth and exaggerated Cupids bow. The findings are consistent with previous publications of other partial trisomy 3p patients. Pure trisomy 3p is rare and described in only very few cases.

E-P11.35

The use of different types of chromosomal analyses in clarification of aetiology of a plurimalformative syndrome

M. Grămescu¹, L. Caba¹, M. Pânzaru¹, L. Butnariu¹, E. Braha¹, R. Popescu¹, S. Popa¹, C. Rusu¹, V. Plăiașu², V. Martiniuc³, L. Păduraru¹, M. Stamatin¹, E. Gorduza¹;

¹"Grigore T. Popa" University of Medicine and Pharmacy Iași, Iași, Romania, ²National Institutes for Mother and Child Bucharest, Romania, Bucharest, Romania, ³"Cuza Vodă" Obstetrics and Gynecology Hospital, Iași, Romania.

We present a boy born at 35 WA with IUGR, after a pregnancy without medical follow-up. Anthropometric data - W - 2100 gr, H - 44 cm, OFC - 29 cm - confirmed growth retardation. The boy presented a plurimalformative syndrome characterised by: microcephaly, dolicocephaly, broad, flattened nasal root, micrognathia, abnormal years, abnormal big toe, micropenis, atriocentric defect. To clarify the aetiology of plurimalformative syndrome imposed the chromosomal analyse, we made GTG banding chromosomal analyse. The chromosomal formula was 46,X,Y,qh+,1qh+,der(13;18)(q12;p11.2). We applied the C banding that confirmed the presence of one centromere. To clarify the chromosomal anomaly, we applied FISH analyse with Metasystem probes for prenatal detection of aneuploidy. Probes for chromosomes 13 and 21 are locus specific, while probe for chromosome 18 is centromeric. The analyse of derivative chromosome confirmed the presence of two fluorescent signals: one blue (specific for chromosome 18) and one green (specific for chromosome 13). Also, we made FISH analyse with Cytocell probes for subtelomeric region of 18p (74G18) and 18q (dJ964M9) and we found on the derivative chromosome the absence of 18p probe and the presence of 18q probe in a normal position at one end of derivative chromosome. The analyses made by us confirmed the association of a *cvasicomplete* trisomy 18 with a small monosomy 13. In conclusion, this case shows the importance of different type of chromosomal analyses for confirmation of aetiology in plurimalformative syndrome. This study was supported by founding of PN-II-PT-PCCA-2013-4-133 Program of UEFISCDI (National Romanian organism of research).

The prevalence of chromosome abnormalities in postnatally diagnosed cases of Thai population

P. Sa-ingrum, P. Niamrot, S. Dokduang, W. Buchachat, R. Parinayok, B. Rerkamnuaychoke;

Human Genetics Laboratory, Department of Pathology, Faculty of Medicine Ramathibodi Hospital, Mahidol University, Bangkok, Thailand.

Introduction: Chromosome abnormalities include missing, extra, or irregular portion of chromosome material. There are two basic groups: numerical and structural abnormalities. Postnatal cytogenetic testing is routinely used on: (1) patients with suspected aneuploidy, (2) phenotypically normal individuals with repeated pregnancy loss or (3) family history of chromosome rearrangement. The aim of this study is to describe the prevalence of various types of chromosome abnormalities in postnatal cases.

Materials and Methods: In retrospective study at Ramathibodi hospital over a period from 2013-2015, chromosome abnormality data were derived from postnatal cases. Blood samples of 1,012 patients requested for cytogenetic analysis were cultured and chromosome preparation was performed. Karyotype analysis was done on 20 G-banded metaphase spreads.

Results: The chromosome abnormalities were present in 173 patients (17.09%). Among these, there were 102 female and 71 male. The autosomal chromosome aneuploidies were identified in 45 cases (26.01%). They were common aneuploidies: trisomy 13, 18 and 21. Sex chromosome abnormalities of Turner syndrome and Klinefelter syndrome patients were detected in 66 cases (38.15%). The structural chromosome abnormalities including deletion, duplication, translocation or inversion were found in 62 cases (35.84%).

Conclusions: We determined the frequency of chromosomal aberration among different groups of referrals suspected of chromosomal abnormalities. Our data provides cytogenetic information of Thai patients. Our data is important to support clinician decision and plan for patient care management.

E-P11.38

A case of Noonan syndrome with coarctation of aorta

B. S. Eklıođlu¹, M. Balasar², P. Taşdemir², M. E. Atabek²;

¹Necmettin Erbakan University Medical Faculty, Department of Pediatric Endocrinology, KONYA, Turkey; ²Necmettin Erbakan University Medical Faculty, Department of Medical Genetics, KONYA, Turkey.

Introduction: Noonan syndrome (NS) is characterized by short stature, congenital heart defect, developmental delay of variable degree, broad or webbed neck, superior pectus carinatum or inferior pectus excavatum, cryptorchidism and characteristic facies. This disorder has an autosomal dominant inheritance pattern. The incidence of Noonan syndrome is estimated to be 1/1000-2500 live births. Despite being one of the most common seen in rare diseases, Noonan Syndrome can not be diagnosed with sufficient frequency. Our case was referred to the hospital because of growth retardation. Physical examination findings were prominent-low set ears, high arched palate, downslanting palpebral fissures, epicanthal folds, low nasal bridge, upturned nose, bilateral ptosis, strabismus and pectus excavatum. Measurements of height, weight and head circumference were under 3 percentile. Nearly minimal coarctation of the aorta was defined in echocardiography. Neuro-motor and endocrinological examination was normal. **Materials and Methods:** Conventional cytogenetics analysis and PTPN11 gene mutation analysis were performed. **Results:** The result of karyotype analysis was 46,XY. The patient was diagnosed as Noonan Syndrome. PTPN11 gene mutation analysis was performed. Heterozygous mutations in 13.exon were identified [p.Pro491Ser (c.1471C>T)]. His father also had similar clinical findings. PTPN11 gene mutation analysis was planned for his father. Genetic counseling was given to family. **Conclusions:** PTPN11 gene mutation was identified in %50 of affected individuals. PTPN11 gene mutations increase the risk of malignancy a threefold in Noonan Syndrome. This case is presented here in order to emphasize that Noonan syndrome should be considered when the patient is male, short statured and suffering from coarctation of the aorta.

Rubinstein-Taybi: an 8-year follow-up of a male patient

N. O. Dávalos Rodríguez¹, S. A. Alonso-Barragán¹, M. A. Aceves-Aceves¹, I. M. Salazar-Dávalos¹, M. G. González-Mercado^{1,2}, J. J. Magallanes-Ordoñez², C. A. Ramírez-Aréchiga⁴, D. García-Cruz¹, I. P. Dávalos-Rodríguez^{1,2};

¹Instituto de Genética Humana Dr. Enrique Corona, CUCS, Universidad de Guadalajara, Guadalajara, Mexico, ²División de Genética, CIBO, IMSS, Guadalajara, Mexico,

³Doctorado en Farmacología, CUCS, Universidad de Guadalajara, Guadalajara, Mexico,

⁴Departamento de Bienestar y Desarrollo Sustentable, Centro Universitario del Norte, U de G, Colotlán, Mexico.

Introduction: The syndrome Rubinstein-Taybi (RSTS) is an autosomal dominant syndrome. RSTS1 is caused by heterozygous mutation. RSTS is characterized by mental retardation, delayed growth, microcephaly, facial dysmorphism, broad thumbs and first toes, among others. Approximately 99% of RSTS occur sporadically. The birth prevalence is 1/125000 and diagnosis is based in clinical characteristics in most cases (Milani et al, 2015).

Objective: To present an 8-year follow-up of a male patient with RSTS. **Case report:** We describe a 13 years old male who at birth was diagnosed with congenital heart disease and bilateral undescended testes. At age one he is diagnosed with strabismus which was surgically corrected at 3. At 2 an orchiopexy was performed. At 4 he presented psychomotor development, generalized hypertrichosis, facial dysmorphological features, allergic rhinitis, intellectual disability, expressive language disorder and hetero aggressive behavior. Cranial CT scan, renal and abdominal ultrasound were normal. Physical examination showed low frontal hairline, arched thick eyebrows, prominent baked nose, micrognathia, high-arched palate and dental malocclusion, low set dysplastic ears, asymmetric thorax, broad thumbs and big toes. At 6 cardiological evaluation was normal and at 8 he continues with allergic rhinitis and conduct disorders.

Conclusions: Clinical findings permit the diagnosis of RSTS in this patient. Multicenter studies are focused in establishing standard diagnostic criteria, providing professional management and follow-up care of RSTS (Milani et al. 2015). RSTS can present brain malignant tumours and hematological disorders. Early diagnosis of RSTS permits a multidisciplinary approach, optimal follow-up and opportune treatment to prevent complications.

Conclusions: Clinical findings permit the diagnosis of RSTS in this patient. Newborn with Smith-Magenis syndrome

E. Simarro Rueda, G. M. Varo Sánchez, M. L. Quintanilla Mata, A. M. Gómez Pastor, L. Navarro Casado;

Hospital General Universitario de Albacete, Albacete, Spain.

Introduction: Smith-Magenis syndrome is a complex disorder that causes mental retardation of varying severity along with a number of congenital anomalies. Its prevalence is 1/15,000 newborns.

We present a patient with 17 days old to perform a karyotype in peripheral blood. She presents a peculiar phenotype: midface hypoplasia, epicanthus and wide nasal root, short and broad hands and feet, left single palmar crease.

Material and methods: Chromosomal analysis were performed on peripheral blood lymphocytes. Fluorescent in situ hybridization (FISH) studies and microarray CGH method were applied in order to confirm the chromosomal deletion.

Results: The karyotype analysis was 46,XX,del(17)(p11.2).ish17p11.2(LSI SMSx1), which corresponds to a woman with Smith-Magenis syndrome. Fluorescent in situ hybridization studies (FISH: LSI SMS Sp Orange/LSI RARA Sp Green) and microarray CGH methods confirm the deletion.

Conclusions: Patient with Smith-Magenis syndrome (17p11 deletion) causes global developmental delay. Family chromosomal rearrangements involving a deletion in 17p11.2 are rare. The risk of recurrence in another pregnancy would be low, at around 1 % for germline mosaicism.

Despite the difficulty of the karyotype to detect microdeletions, in this case we could identify the microdeletion by this method, which it was subsequently confirmed by FISH and microarray CGH methods.

E-P11.44

The Clinical Characterization of a Patient with 4p15 Deletion

S. Zeybek¹, G. Cetin¹, V. Caner¹, M. Ozturk¹, C. Semerci¹, G. Bagci¹, H. Ergin²;

¹Pamukkale University, School of Medicine, Department of Medical Genetics, Denizli, Turkey, ²Pamukkale University, School of Medicine, Department of Pediatrics, Denizli, Turkey.

The Wolf-Hirschhorn syndrome (WHS) is characterized by severe growth and mental retardation, closure defects (cleft lip or palate, coloboma of the eye, and cardiac septal defects) and typical craniofacial features consisting of 'Greek warrior helmet' appearance of the nose, microcephaly, high anterior hairline with prominent glabella, widely spaced eyes, downturned corners of the mouth, and poorly formed ears with pits/tags. The diagnosis of Wolf-Hirschhorn syndrome is established by detection of a heterozygous deletion of the Wolf-Hirschhorn syndrome critical region (WHSCR) within 4p16.3 at ~1.4-1.9 Mb from the terminus. The most common breakpoint is 4p15 in deletions of 4p and therefore the syndrome is described under this aberration. We aimed to compare the Wolf-Hirschhorn contiguous gene syndrome and 4p deletion syndrome features with the patient presented here, who was a one month old girl with hypotonia, congenital heart disease, microcephaly, microphthalmia, coloboma of the right iris, incomplete cleft palate, club foot, prominent perineal raphe and typical craniofacial features of WHS such as Greek warrior helmet appearance; on the basis of breakpoint regions.

E-P11.45

Sex reversal in a severely malformed newborn with Xp duplication due to the maternal X;10 translocation

E. Sukarova-Angelovska, M. Kocova, G. Ilieva, V. Anastasovska; University Pediatric Clinic, Skopje, Macedonia, The Former Yugoslav Republic of.

Chromosomal rearrangements represent a rare cause of sex reversal, involving sex chromosomes and autosomes (deletions of 9p, 10q, 12q, etc), all with variable clinical presentation. Translocation between Xp and autosome disables inactivation of the translocated portion of X chromosome, and overexpresses the DAX1 gene located on DDS region.

A severely malformed newborn was born after a complicated pregnancy. Dysmorphic features were distinct, including microcephaly, wide forehead, narrow eyelids, wide nose, micrognathia, unruly hair, narrow shoulders, arthrogyrosis preferably on arms and hypoplastic female external genitalia with no palpable gonads. The baby had dilated aortal root, vesicoureteral reflux and enlarged CNS ventricles. Ultrasonography of the genitalia showed streak müllerian structures and small underdeveloped testes in the lower abdomen. Due to the severe neurological impairment the baby died within the first months. Chromosomal finding represents translocation between chromosomes X and 10, 46, XY, t (X; 10) with a breakpoint on Xp21, which was inherited from the mother. FISH study including Xp and Xq probes confirmed duplication of Xp. Subtelomeric deletion of 10q was not found.

Duplication of dosage sensitive region on Xp is well established cause for male to female sex reversal. A variety of clinical presentations of Xp were described in the literature, mostly depending on the involved autosome. Loss of the autosomal segment of chromosome 10 was not found in our patient, therefore we can assume that overexpression of other genes on Xp on PAR1 region could be the cause for additional features of our patient (radioulnar synostosis, microcephaly, severe dysmorphism).

Recent and rare chromosomal abnormalities in acute leukemias - a 5 years study

S. Papuc¹, A. Tutulan-Cunita¹, M. Cristea¹, I. Borcan¹, H. Bumbea², D. Cisleanu², M. Tevet³, V. Popov³, C. Dragan³, N. Berbec⁴, S. Angelescu⁴, A. Vladareanu², A. Arghir¹; ¹Victor Babes National Institute of Pathology, Bucharest, Romania, ²Emergency University Clinical Hospital, Bucharest, Romania, ³Colentina Clinical Hospital, Bucharest, Romania, ⁴Coltea Clinical Hospital, Bucharest, Romania.

Acute leukemias (ALs) are a heterogeneous group of disorders characterized by clonal proliferation of lymphoid / myeloid progenitor cells. Many genetic lesions are described across ALs subtypes, from recurrent reciprocal translocation to focal copy number changes and point mutations. The genetic findings, alongside hematologic and immunophenotypic data, provide valuable diagnostic and prognostic information.

We report on the results of genetic investigations in 101 adult patients with acute leukemias referred to our laboratory since 2011.

Seventy seven acute myeloid leukemias (AML), 23 acute lymphoid leukemias (ALL) and one biphenotypic leukemia (BAL) were investigated. Bone marrow aspirate was used for morphological, cytochemical, flow cytometry and chromosomal studies. Cytogenetic investigations were performed on GTG-banded slides. FISH with locus specific probes (commercial and „home-made“) was applied for molecular characterization.

58% of AML patients showed chromosomal anomalies; ~70% of ALL harboured cytogenetic changes, BCR/ABL1 translocation being the most frequently detected (30% of ALL patients). Besides the frequently reported recurrent chromosomal anomalies, with known prognostic impact, some rare or complex abnormalities were detected in our patient group. Among the latter, complex karyotypes with various chromosomes affected, low level amplification of KMT2A through unbalanced translocations and other structural rearrangements (ring chromosome) were identified.

The cytogenetic data contributed to diagnostic refinement (e.g. acute leukemia with recurrent genetic abnormalities), prognosis evaluation, disease monitoring, and guidance of therapeutic strategies (tyrosine-kinase inhibitors in t(9;22) ALL) in our patient group. Our study proves once more the value of genetic testing that informs diagnosis and prognosis in hematology.

E-P12.002

Polymorphism in the lymphotoxin-alpha gene, position +250 (G>A) associated with acute lymphoblastic leukemia in Serbian Children

R. Milicevic¹, L. Brankovic¹, D. Jugovic¹, D. Radulovic¹, H. Stamenkovic¹, A. Milicevic²; ¹Pediatric Clinic, Nis, Serbia, ²Institute for clinical pathology and pathologic anatomy, Nis, Serbia.

Introduction: Lymphotoxin (LT) alpha, a member of the tumor necrosis fac-

tor cytokine su-perfamily. Tumor necrosis factor alpha (TNF-α) and Lymphotoxin alpha (LT-α) have been shown to play an important role in the pathogenesis of lymphoproliferative diseases. Both cytokines regulate cell-survival and cell -death in leucemic cells. LT -α has a well defined role in secondary lymphoid organogenesis and it also controls cellular proliferation and differentiation . Since LT alpha is a potent controller of cell functions, it would be of interest to demonstrate that deregulation of LT- α production in acute lymphoblastic leukemia patients is genetically determined. . Materials and Methods: We investigated frequencies of polymorphic alleles and a possible association of LT alpha polymorphisms +250(G>A), with increased risk for acute lympho-blastic leukemia (ALL). Genotype was analyzed using the polymerase chain reaction-restriction fragment length polymorphism technique with genomic DNA isolated from peripheral blood lymphocytes. The research was performed on the DNA samples of 75 children suffering from ALL and 46 healthy individuals.

Results: The following genotype frequencies were found: 53% (G/A), 17%, (G/G) and 29% (AA) in ALL patient. Genotypes in healthy individuals were: 50% (G/A), 2,2% (G/G) , 48% (A/A). The frequencies of AA genotypes were higher in healthy individuals than in children with ALL .

Conclusion: A statistically significant difference was found in the genotype frequencies between ALL patients and controls. Our results point to the association between lymphotoxin-α +250 polymorphism and increased ALL risk in Serbian children.

E-P12.003

Modulation of prognosis in acute myeloid leukaemia with concomitant trisomy 4 and double minutes - a molecular mechanism of micronuclei

L. L. P. Siu, W. S. Wong, H. F. Wong, K. F. Wong;

Department of Pathology, Queen Elizabeth Hospital, Kowloon, Hong Kong.

Introduction: We described a case of acute myeloid leukaemia (AML) with concomitant trisomy 4, double minutes (dmin) and heterozygous deletion of MYC. The role of the micronuclei in preferentially capturing the dmin and possibly its therapeutic potential in AML with a dmin karyotype was illustrated.

Materials and Methods: A 79-year-old woman presented with leukocytes of 4.8x10⁹/L and 9% blasts. Conventional cytogenetics was performed on the bone marrow after overnight synchronised culture. Fluorescence *in situ* hybridization (FISH) with IGH/MYC/CEP8 tri-colour dual-fusion probe (Vysis) was performed on both cultured cell pellet and May-Grunwald Giemsa stained bone marrow smears.

Results: Karyotypic analysis showed 47,XX,+4,5~80dmin[19]/46,XX[1]. FISH showed MYC amplification in the dmin, but the MYC gene in one of the chromosomes 8 was deleted in all metaphases with presence of dmin. Multiple micronuclei formation by budding around the interphase nuclei was found in the cultured sample. The micronuclei were varied in size, with some being large and harbouring numerous MYC signals. In the myeloblasts of uncultured sample, only occasional micronuclei were found and they were tiny in size.

Conclusion: FISH study has demonstrated the difference in micronuclei formation due to MYC amplification in neat and cultured samples. It is tempting to speculate that the dmin-type micronuclei are formed during the S-phase in synchronised culture as a result of entrapment and elimination of dmin. Further study on cellular differentiation pathway may facilitate the understanding of dmin-type micronuclei in disease modulation.

E-P12.004

Acute myeloid leukemia with a rare variant b3a3 (e14a3) BCR-ABL1 fusion transcript

D. Kim, S. Shin, S. Lee, J. Choi;

Department of Laboratory Medicine, Yonsei University, College of Medicine, Seoul, Korea, Republic of.

Introduction: BCR-ABL1 fusion transcript is generally known as a recurrent genetic abnormality in chronic myelogenous leukemia and acute lymphoblastic leukemia. Besides, BCR-ABL1 fusion gene has been also reported in acute myeloid leukemia (AML) usually as an additional cytogenetic defect. Here, we report a patient who diagnosed AML with a rare variant b3a3 BCR-ABL1 fusion transcript.

Materials and Methods: A 52-year-old female came to the out-patient clinic for generalized weakness. Peripheral blood analysis showed white blood cell count 55.97 x 10⁹/L with 66% blast; hemoglobin was 8.2 g/dL, platelet count 105 x 10⁹/L. The bone marrow examination showed a hypercellular marrow loaded with large-sized leukemic blasts with moderate amount of granular cytoplasm in 38.3% of all nucleated cells.

Results: Molecular genetic analysis using multiplex RT-PCR; Hemavision kit (DNA Technology, Aarhus, Denmark) showed positive in M6B lane with the product of approximately 300 base pairs. To confirm the subtype of *BCR-ABL1* translocation, sequence analysis was performed, and revealed as b3a3 breakpoint. The patient was underwent induction chemotherapy, tyrosine kinase inhibitor therapy and peripheral blood stem cell transplantation; however, relapsed after 2 year and died with systemic infections.

Conclusions: *BCR-ABL1* fusion transcript is found in 3% of AML, and known as a poor prognostic factor in AML. To our best knowledge, it is the first case of AML with *BCR-ABL1* b3a3 fusion transcript. In addition, clinical laboratories should be aware that rare type fusion transcripts such as b3a3 may escape detection when using assays which utilize primers complementary to *ABL1* exon a2.

Up-regulation of LATS2 gene associates with acute myeloid leukemia

M. Gholami¹, S. Manoochehrabadi¹, H. R. Heidari-Rostami¹, H. Jalaeekho², A. Movafagh¹, R. Mirfakhraie¹;

¹Shahid Beheshti University of Medical Sciences, Tehran, Iran, Islamic Republic of.

²Emam Reza Hospital, AJA University of Medical Sciences, Tehran, Iran, Islamic Republic of.

Introduction: Acute myeloid leukemia (AML) is the most common acute leukemia in adults, that is heterogeneous with respect to presentation and clinical outcome. Currently, cytogenetic findings represent the most powerful prognostic factor in AML; however, about 35 to 50 percentage of the patients have a normal karyotype. Molecular markers allow precise classification of AML patients. Recent clinical studies have indicated that the expression level of LATS2 correlates with clinical course of some malignancies. The aim of the present study was to analyze the expression level of the LATS2 gene in acute myeloid leukemia (AML) patients. Materials and methods: Using quantitative real-time PCR, the expression level of the LATS2 gene was detected in peripheral blood samples from 32 patients with de novo AML and 10 normal controls.

Results: LATS2 gene was significantly over-expressed in AML patients compared to normal subjects. Significant LATS2 over-expression was also detected in all FAB types except for the M3.

Conclusion: The present work provides the first evidence of the overexpression of LATS2 in AML patients and suggests that the gene might play a role in the disease development and hence may be a potential therapeutic target for AML treatment.

E-P12.006

Analysis of The Molecular Markers in 49 AML Patients

E. Arslan Ates, O. Kara, A. Türkyılmaz, H. Şimşek, M. Söylemez, K. Delil, B. B. Geçkinli, T. Toptaş, P. Ata, A. Arman, A. T. Tuğlular, I. Güney;

Marmara University Pendik Training and Research Hospital, Istanbul, Turkey.

Introduction : Acute myeloid leukemia is a cancer characterized by overproliferation of immature myeloid cells. Besides chromosomal rearrangements, FLT3, NPM1 and CEBPA mutations are related with prognosis.

Aim: The aim of this study is to establish the frequency of CEBPA, NPM1 and FLT3-ITD mutations in our AML group and to evaluate the clinical outcomes of mutation carriers.

Materials and Methods: Forty-nine patients who were diagnosed as AML in our University Hospital between 2014-2015 were investigated for FLT3-ITD, NPM1 and CEBPA mutations by Sanger sequencing. Clinical and genetic characteristics of 13 patients having a mutation in at least one of these genes were presented here.

Results: We investigated 13 patients aged between 22-73. Bone marrow karyotype analyses of 10 patients were normal whereas Trisomy 8 were detected in two cases and cytogenetic evaluation was not successful in one patient. In molecular analyses FLT3-ITD, NPM1 and CEBPA mutations were detected in five, seven and five patients respectively. Three of these mutations were novel. In the study group, out of four patients who died with a diagnosis of refractory AML, two were carrying FLT3-ITD and NPM1 mutations, one was carrying FLT3-ITD mutation and one was carrying NPM1 mutation. Conclusions: In this study 13 of 49 patients had a mutation at least in one of FLT3 (%10.2), NPM1 (%14.2), CEBPA (%10.2) genes. To further understand the genotype-phenotype correlation in terms of these genes, we present the clinical and genetic evaluations to contribute to larger studies.

Two different nucleotide substitutions of APC Gene in a family with familial adenomatous polyposis

B. Eser, M. Yildar;

Balikesir University, Balikesir, Turkey.

Introduction: Familial Adenomatous Polyposis (FAP) is an autosomal dominant syndrome leading to colorectal cancer. This disease appears as a result of germline mutation in Adenomatous Polyposis Coli (APC) gene. Although many studies have been conducted, the genotype-phenotype correlation between APC gene mutations and colorectal and extracolonic involvements of the disease could not be clearly detected. The aim of the present study is to report the association between two different nucleotide substitution detected in a family with FAP and phenotypes of the family members.

Materials and Methods: Clinical and colonoscopic data of the proband with FAP and family members were collected. DNA sequencing of the APC gene was applied to the family members.

Results: In the proband with FAP phenotype and extracolonic involvement, p.His1172Gln (c.3516delT) was detected in exon 15 of the APC gene. Furthermore, p.His1172Gln (c.3516delT) and in addition to this mutation, p.Met1413Val (c.4237 A>G) were detected in exon 15 in both daughters (which have FAP and attenuated FAP) of the proband. Similarly, p.Met1413Val (c.4237 A>G) nucleotide change was found in the mother of the girls. However, colonoscopic findings of the mother were normal.

Conclusions: Single nucleotide change in codon 1413 may be a polymorphic variant. However, we believe that deletion T in codon 1172 of APC gene is associated with FAP, attenuated FAP and extracolonic FAP involvement. Along with common use of genetic tests in the clinical practice, genotype-phenotype correlation may be recognized better and useful for early diagnosis and prevention of familial cancer syndromes.

Gene-expression patterns in relapsed B-cell acute lymphoblastic leukemia and potential therapeutic targets

Y. Erbilgin¹, B. Islek², S. Firtina², O. Hatirnaz Ng¹, A. Ina³, P. Dogan³, T. Celkan⁴, Z. Karakas⁵, N. Sarper⁶, M. Sayitoglu¹, U. Ozbek¹;

¹Department of Genetics, Institute for Experimental Medicine, Istanbul University, Istanbul, Turkey, ²Department of Genetics, Institute for Experimental Medicine, Istanbul University, Istanbul, Turkey, ³Department of Genetics and Bioengineering, Istanbul Bilgi University, Istanbul, Turkey, ⁴Department of Pediatric Hematology Oncology, Cerrahpasa Medical Faculty, Istanbul University, Istanbul, Turkey, ⁵Department of Pediatric Hematology, Istanbul Medical Faculty, Istanbul University, Istanbul, Turkey, ⁶Pediatric Hematology Division, Kocaeli Medical Faculty, Kocaeli University, Istanbul, Turkey.

Introduction: Relapsed acute lymphoblastic leukemia (ALL) ranks as the fourth most common childhood malignancy. To identify targets for new therapies, a through understanding of the genetic lesions contributing to establishment of the leukemic clone and resistance to therapy is required. The goals of the study were to provide an explanation for the observed differences in outcome among patients who relapse early and to define high-risk patients much better.

Materials and Methods: We examined gene-expression profiles in 20 childhood B-cell ALL and healthy B-cell subsets by using "Illumina HumanHT-12 v4 Expression BeadChip" technology. According to the differential analysis, selected eight genes had been validated in a larger B-ALL cohort (n=81 patients) by using Quantitative Real-Time PCR.

Results and Conclusions: Diagnose patients who had relapse showed differential expression in cell cycle, apoptosis, purine/pyrimidine metabolism, and different cancer pathways. Many of these pathways have been implicated in tumorigenesis previously and are attractive targets for intervention strategies. After the validation process, aberrant PMAIP1 and RASD1 expression had been linked with relapsed. PMAIP1 is related with ERK Signaling and apoptosis, RASD1 is related with MAPK targets. However, further studies are required to understand the impact of RASD1 and PMAIP1 genes in drug resistance in B-cell ALL.

The study was supported by The Scientific and Technological Research Council of Turkey (TUBITAK Project Number:114S038), Istanbul University Scientific Research Project (IU. BAP Project Number: 11021), Istanbul Development Agency (ISTKA TR10/15/YNK/0093).

Amplification of chromosome 21 in childhood all is associated with a poor outcome and is often without a TEL/AML1 fusion: report of 115 patients from northern Turkey

H. Mutlu Albayrak¹, G. Oğur¹, S. Özdemir², U. Abur¹, O. Akar¹, E. Altundag¹, A. Yilmaz¹, C. Albayrak¹;

¹Ondokuz Mayıs University Medical Faculty Department Of Genetics, Samsun, Turkey,

²Ondokuz Mayıs University Medical Faculty Department Of Pediatrics, Samsun, Turkey.

Introduction. Leukemia is the most common form of childhood cancer. Genetic analysis holds a true prognostic value for childhood leukemia. The aim of this study was to evaluate the impact of cytogenetics and fluorescent in situ hybridization (FISH) analysis in childhood ALL.

Materials-Methods. 115 childhood ALL patients were evaluated for cytogenetics and FISH (BCR/ABL, TEL/AML1 and MLL)

Results. Cytogenetic aberration was found in 54.4% of patients. Hyperdiploidy rate was %12 with gains for chromosomes 4, 14 and 21. Hypodiploidy rate was 1.7%. FISH aberration was found in 52.2% of patients. Polysomy 21 (amplification 21) was the most frequent anomaly (25.2%). TEL/AML1 fusion rate was 13.9% whereas BCR/ABL fusion rate was 3.5%. TEL/AML1 fusion was found less in group with polysomy 21. MLL rearrangement rate was 5.4%.

No relapse was found in patients with TEL/AML 1 fusion. One patient died of sepsis. Overall survival rate of patients with positive TEL/AML1 fusion was high.

Mortality rate of the patients with a BCR/ABL fusion, was higher (50%); the survival rate was shorter (25%) when compared to those who did not have the fusion. The group with amplification 21 also showed a higher rate of relapse (17%) and mortality (10%) and a shorter survival rate.

Conclusion. Polysomy 21 is not rare in childhood ALL; it is a poor prognostic indicator with rates not as high but similar to bcr/abl fusion. TEL/AML1 predicts a good prognosis. It was of interest to note that existence of polysomy 21 decreased the rate of TEL/AML1 fusion.

A case of Trisomy 4 with AML M5

P. Oltulu¹, P. Taşdemir², M. Balasar², H. Çiçil³;

¹Necmettin Erbakan University Medical Faculty, Department of Pathology, KONYA, Turkey,

²Necmettin Erbakan University Medical Faculty, Department of Medical Genetics, KONYA, Turkey,

³Necmettin Erbakan University Medical Faculty, Department of Hematology, KONYA, Turkey.

Introduction: Acute myeloid leukemia (AML) characterized by clonal proliferation of myeloid precursor cells is a type of hematopoietic neoplasm. AML constitutes 80% of adult acute leukemia. The average age for diagnosis in adults is 65 and its incidence increases with advanced ages. Solely trisomy 4 abnormality is a rare cytogenetic finding in AML cases and until today it has been reported in cases with AML M1, M2 and M4. We presented here a case of AML M5 determined solely trisomy 4 in cytogenetic analysis.

Materials and Methods: The patient's bone marrow tissue was performed conventional cytogenetic analysis and AML-MDS FISH Panel (del5q, PML/RAR α , del P53, AML1/ETO, MLL, 7q del, CBF β /MYH11, 20q del)(Cytocell, UK), 4p16.3 and 4qter FISH probes.

Results: The female patient has admitted to the hospital because of extreme weakness and pain. She was 72 years old and her peripheral blood count analysis were abnormal. She was diagnosed as Acute Monocytic Monoblastic Leukemia (AML M5) with histopathological examination of bone marrow. AML-MDS FISH Panel was normal. The result of bone marrow cytogenetic analysis was 47,XX,+4[5] /46,XX[13]. 4p16.3 and 4qter FISH probes were performed, thus trisomy 4 was confirmed. The patient was taken to the intensive care unit due to worsening in her general medical condition and died within 2 days.

Conclusions: Some cytogenetic abnormalities is associated with prognosis in AML. The prognostic significance of solely trisomy 4 abnormalities in AML patients are unknown and as far as we know trisomy 4 abnormality with AML M5 is presented the first time in the literature.

Molecular cytogenetics findings of clinically suspected acute myeloid leukemia and/or myelodysplastic syndrome (AML/MDS) patients

B. Sarikepe¹, S. Zeybek¹, G. Gonen¹, Y. Eyuboglu Tanriverdi¹, O. Boz¹, E. Ceylan¹, E. Tepeli¹, G. Cetin¹, I. Sari², F. Duzcan¹, V. Caner¹;

¹Pamukkale University School of Medicine Department of Medical Genetics, Denizli, Turkey,

²Pamukkale University School of Medicine Department of Hematology, Denizli, Turkey.

Acute myeloid leukemia (AML) is a heterogeneous group of aggressive neoplasms and the most common type of adult acute leukemia, with a median

age of 67 years at diagnosis. Since high quality metaphase spreads are hard to obtain from bone marrow samples of the patients with AML/MDS it is quite difficult to detect the chromosomal abnormalities in AML/MDS using conventional cytogenetic analysis with standard G-banding. Fluorescence in situ hybridization (FISH) is a very simple and useful technique that is applied by many cytogenetics laboratories around the world for routine diagnosis of AML/MDS.

Here we report the FISH results of 185 patients who were referred to our laboratory with pre-diagnosis of AML/MDS between January 2014 and January 2016. A total of 141 patients had normal FISH results while the most frequent abnormalities were MLL translocation (10/185, 5.4%), PML/RAR translocation (4/185, 2.1%), and trisomy 8 (4/185, 2.1%). We also detected complex rearrangements in five patients (2.7%). Moreover, we analyzed the relation between chromosomal abnormalities and clinicopathological parameters.

In conclusion, a significant proportion of AML/MDS patients with normal karyotype has clones of cytogenetically abnormal cells which may play an important role in the development and/or progression of the disease. It is important to determine the presence or absence of specific chromosome and/or gene alterations by FISH analysis for the prognosis and survival of the patients.

Aurora kinase inhibition affects cell cycle and apoptosis in breast cancer

Ç. Kayabaşı, B. Özmen Yelken, T. Balci, A. Aşık, S. Gonca, F. Söğütü, R. Gasimli, S. Yılmaz

Süslüer, Ç. Biray Avci, C. Gündüz;

Ege University Faculty of Medicine, Department of Medical Biology, Izmir, Turkey.

Breast cancer remains the most common malignancy in women. Dysregulated FGFR is a significant risk factor in breast cancer. Aurora kinases are serine/threonine kinases that plays crucial roles in cell division including mitosis checkpoint and chromosomal segregation. CCT137690 is a novel Aurora kinase inhibitor. In this study we aimed to evaluate the anti-cancer effects of CCT137690 in human breast cancer cells.

Cytotoxicity of aurora kinase inhibitor CCT137690 (24 nM-50 μ M) on estrogen receptor-positive human breast cancer cell line MCF-7 and normal human fibroblasts WI-38 were evaluated with xCELLigence real time cell analysis system. Effects on apoptosis and cell cycle in MCF-7 and WI-38 cells with exposure to IC50 dose of CCT137690 are detected with AnnexinV-EGFP Apoptosis Detection Kit and Cycletest Plus DNA Reagent Kit with FACS, respectively.

For MCF-7 and WI-38 cell lines IC50 doses of CCT137690 were found as 4.5 μ M and 9.19 μ M, respectively. It was shown that CCT137690 induced apoptosis 3.6 fold in MCF-7 and 2.1 fold in WI-38 compared to untreated control cells. In addition to apoptotic effects, CCT137690 caused cell cycle arrest at G2/M in MCF-7 cells significantly.

In conclusion, inhibition of aurora kinases is a novel approach for treatment of malignant disorders. Considering infinite division capacity of the cancer cells, inhibiting cancer cell cycle in G2/M and leading cancer cells to apoptosis more than normal cells indicates that CCT137690 can be a potential anti-cancer agent for targeting breast cancer cells.

Determination of apoptosis and changes on cell cycle genes expressions in HL60 cell line induced with bendamustine

S. Kıpçak¹, B. Özel¹, Ç. Aktan¹, B. Tezcanlı Kaymaz¹, Ç. Biray Avci¹, B. Kosova¹, G. Saydam², N. Selvi Günel¹;

¹Ege University, Department of Medical Biology, Izmir, Turkey, ²Ege University, Department of Hematology, Izmir, Turkey.

Introduction: Acute promyelocytic leukemia (APL), is a subtype of Acute myeloid leukemia (AML) and characterized by aberrant morphology of promyelocytes. The most specific chromosomal disorder that occurs in APL patients is (15;17) translocation. This translocation produce a PML-RAR α fusion protein. Bendamustine is a water soluble, microcrystalline powder with amphoteric properties and it acts as an alkylating agent and also has purine analog activity. Bendamustine has more moderate toxicity profile than the other alkylating agents. In our study, it is aimed to investigate cytotoxic and apoptotic effects of bendamustine on APL cell line HL60. Also we aimed to evaluate the effect of bendamustine on HL60 cells according to the expression of genes including cell cycle, mitotic catastrophe, apoptosis.

Materials and Methods: Cytotoxic effect of bendamustine on HL60 cell line was assessed by WST-1 assay, Annexin V and Apodirect Tunnel assay are used for apoptotic effect. Also the effect of bendamustine on expression levels of genes in HL60 was determined by quantitative RT-PCR relatively.

Results: Bendamustine significantly induces apoptosis in dose dependent manner on HL60 cells. After the 48 hours treatment with bendamustine, expression levels of apoptosis related CASP7, CASP8, CASP9 genes were upregulated 2.4, 5.7, 6.8 fold in HL60 cells, relatively. Also expressions of mitotic catastrophe related genes Plk1 downregulated 2.5 fold and Plk2 which as known as tumor suppressor gene, upregulated 17 fold. Conclusion: Our data suggest that Bendamustine is effective on cell death mechanisms such as apoptosis ve mitotic catastrophe and can be used in supplement APL treatment.

Copy number variations associated with tumor progression in invasive bladder cancer

O. S. Antonova¹, S. Hadjidekova¹, Z. Hammaoudeh¹, R. Staneva¹, V. Hadzhyskiya², G. Stamenov³, C. Slavov⁴, D. Toncheva⁵;

¹Department of Medical Genetics, Medical University- Sofia, Sofia, Bulgaria, ²Clinic of nuclear medicine, University Hospital Aleksandrovska, Sofia, Bulgaria, ³MBAL Nadezhda, Sofia, Bulgaria, ⁴Department of urology, University Hospital Aleksandrovska, Sofia, Bulgaria.

Background: The aim of this study was to detect copy number variations (CNVs) and to evaluate their association with tumor progression in non-invasive and muscle-invasive bladder carcinomas in Bulgarian patients.

Materials & Methods:

Bladder tumor samples were collected, frozen at -20 °C and histologically confirmed as primary transitional cell carcinomas. The DNA was isolated by phenol-chloroform extraction and aCGH analysis was performed on twelve tumors in stages pTa, pT1, pT2, pT2a and pT2b on CytoChip Oligo aCGH, 4x44K format (Illumina). Data was analyzed by BluefuseMulti software v4.2. The clinical significance was further evaluated by literature and database search.

Results and discussion: The DNA microarray showed an increased genomic instability and revealed numerous nonspecific chromosomal aberrations in the transitional cell carcinomas - 75 pathogenic deletions and duplications, 3 benign CNVs and 14 variants of uncertain clinical significance. A total of 24 recurring chromosomal regions with pathogenic CNVs were identified. Genomic imbalance in four of these regions, containing more than 200 genes, is present in 50% of the tumors with aberrations (pT1, pT2 and pT2b). A detailed survey was performed for all of these genes and 31 of them were found to be probably associated with the process of tumorigenesis. Of these, 10 are already reported by other scientific groups as candidate-oncogenes for uroepithelial tumours. Our group reports for the first time that genes FLJ46066, LPP, CLDN16, STK3 and TTK could be potential candidate-oncogenes in the progression of bladder cancer.

E-P12.018

BRCA1 and BRCA2 mutations in ovarian cancer patients with brain metastases

T. Dubrovina, A. Semyanikhina, O. Arkhipova, M. Filipova, A. Danishevich, D.

Nashkletashvili, L. Lyubchenko;

FSBI „Russian cancer research center named after N.N. Blokhin“, Moscow, Russian Federation.

Introduction: Brain metastases from ovarian cancer are a rare event. It occurs in 1-12% cases. Molecular pathways of ovarian cancer metastatic behavior are the subject of scientific and clinical research and still remain unclear. Several studies have shown that the loss of *BRCA1* function may be involved in the phenomenon of brain metastases from ovarian cancer.

Materials and methods: To research the implication and frequency of germline mutations in *BRCA1* and *BRCA2* genes we examined their structure in order to detect 185delAG, 4153delA, 5382insC, 3875del4, 3819del5, C61G, 2080delA mutations in *BRCA1* and 6174delT mutation in *BRCA2*. Genotyping was performed on DNA samples extracted from peripheral blood specimens of 11 patients with ovarian cancer and brain metastases using «BRCA SNP genotyping Kit» by DNA-Technology. The median age at diagnosis was 53,2 years. One patient had endometrioid carcinoma, the other had serous adenocarcinoma. 50 % of patients had a family history with malignant tumours.

Results: *BRCA1* and *BRCA2* mutations were identified in six cases. The most frequent *BRCA1* 5382insC mutation was detected in four of all cases. One patient had *BRCA1* 4153delA, the other - *BRCA2* 6174delT.

Conclusion: Our results confirm the hypothesis that mutations in *BRCA1* and *BRCA2* genes can be implicated in a brain metastasis process. It has been reported that patients with *BRCA*-associated ovarian cancer have a better prognosis and a good therapeutic response in comparison to sporadic cases. There is a possibility that these distinctions correlate with brain metastases at the terminal stage of the disease.

Breast cancer is one of the most common cancer types seen in women. Around 10% of overall breast cancer cases have family history. Carriers of *BRCA1/BRCA2* germline mutations from families with high cancer risk have been estimated to have a 65-85% lifetime risk of developing breast/ovarian cancer. In addition to pathogenic alterations of *BRCA1/BRCA2* genes, several polymorphisms have also been reported. Many of these polymorphisms are shown to have protective or possible causal effect on breast cancer formation. Interestingly, several studies showed that some of these polymorphisms tend to occur together although their effects are opposite. In this study, *BRCA1/2* single nucleotide polymorphisms (SNPs) were examined for the identification of haplotypes and to evaluate the prevalence of these haplotypes among sporadic early-onset breast cancer patients, familial breast cancer patients, and healthy high risk females in multiple-ethnic regions of Turkey.

Peripheral blood DNA samples from 271 subjects were investigated by next-generation sequencing (NGS) using Illumina-MiSeq. Genomize-Seq and SeqPilot softwares were used for analysis of NGS data. Mutations in the coding gene sequence were screened and all observed mutations have been checked for their pathogenicity at HGMD. Statistical evaluation was carried out using by their in-house developed Python scripts.

c.4837A>G, c.3113A>G, c.2311T>C, c.4308T>C, c.4485-63C>G, c.-19-115T>C, c.2082C>T, c.3548A>G in *BRCA1*, and c.426-89T>C, c.1365A>G, c.2971A>G, c.7435+53C>T, c.865A>C, c.425+67A>C in *BRCA2* were determined as a haplotype in population of Turkey. Our study indicates a high incidence of one haplotype in *BRCA1* gene and one haplotype in *BRCA2* gene in our study population.

Common BRCA1/2 genes mutations test - rapid but insufficient analysis for HBOC diagnosis

R. Vainoriene¹, O. Liaugaudiene^{1,2}, V. Asmoniene¹;

¹Hospital of Lithuanian University of Health Sciences Kauno klinikos, Kaunas, Lithuania, ²National Cancer Institute, Vilnius, Lithuania.

Introduction: *BRCA1/2* genes mutations are the most common cause of hereditary breast and ovarian cancer (HBOC). We present an analysis of monoinstitutional cohort of unrelated *BRCA1/2* mutations carriers.

Methods: We analyzed 230 *BRCA1/2* tests for 5 *BRCA1* and 1 *BRCA2* mutations performed in 2015. Data on 23 *BRCA1* mutation carriers were collected. The results were compared with data on Lithuanian and European *BRCA1/2* mutation carriers.

Results: Three *BRCA1* mutations were identified in 10% of patients tested for HBOC (39.1% 4153delA, 34.8% 5382insC, 26.1% 300T>G). Other two *BRCA1* mutations (185delAG, 2080delA) and *BRCA2* mutation 6174delT were not detected. Among *BRCA1* mutation carriers 82.6% have positive family history; 47.8% have breast cancer; 34.8% have triple negative breast cancer; 34.8% have ovarian cancer. A study of Janavicius and al. (2014) identified *BRCA1/2* mutations in 29% of patients selected for genetic testing (*BRCA1* - 25.9%). The most common *BRCA1/2* mutation was also 4153delA - a Baltic founder mutation. Our tested mutations amount for 76.7% of found *BRCA1/2* mutation in Lithuanian carriers. European studies of full or nearly full sequence analysis of *BRCA1/2* genes revealed higher prevalence of pathogenic mutations in high-risk women (see table 1).

Conclusion: Identified mutation rate significantly differs from other Lithuanian and Europe studies and is insufficient. Despite of rapidity and convenience of common mutation testing, full gene sequence analysis is recommended to diagnose HBOC syndrome.

Study	Number of individuals	Prevalence of BRCA1/2 mutations	Type of BRCA1/2 genes analysis	Nationality
Current study	230	10%	Common mutations	Lithuanian
Janavicius and al. 2014	753	29%	Full genes sequences	Lithuanian

Familial breast cancer with no phenotype/genotype correlation: case study

M. Janikova^{1,2}, R. Kratochvilova¹, H. Synkova¹, R. Vrtel¹, R. Vodicka¹, R. Slavkovsky³, T. Veberova¹, V. Curtisova¹, M. Prochazka¹;

¹Department of Medical Genetics, University Hospital and Palacky University Olomouc, Olomouc, Czech Republic, ²Department of Clinical and Molecular Pathology, University Hospital and Palacky University Olomouc, Olomouc, Czech Republic, ³Institute of Molecular and Translational Medicine, University Hospital and Palacky University Olomouc, Olomouc, Czech Republic.

Introduction: Application of BRCA1/2 testing to clinical praxis provided much information about one of the most frequent familiar cancer - breast and ovarian cancer. Usually, family members carrying pathogenic variant in these genes have higher risk of cancer than non-carriers. These family members are screened in earlier age and more frequently than the rest of population. It can help to distinguish cancer in earlier stages and these patients have bigger chance for successful treatment. Sometimes, phenotype of family members does not fit to their genotype.

Materials and Methods: We searched pathogenic variants in BRCA1/2 genes using massive parallel sequencing. We used BRCA MASTR™ Dx kit (Multiplicom) and platform MiSeq (Illumina). We used Sanger sequencing for confirmation and for testing family members.

Results: We identified previously described pathogenic variant in BRCA1 gene (rs80357609) in mother born in 1950. She developed breast cancer in 1995. Therefore, we tested her daughters for the presence of this variant. We have found that one daughter (born in 1976) carries this variant but she is still without symptoms. The second daughter (born in 1971) does not carry this variant but she developed breast cancer in the same age as her mother.

Conclusions: We identified family with breast cancer history whose family members' genotype does not fully correlate with their phenotype. It might be caused by phenomenon known as phenocopy, which is non-hereditary, environmentally induced trait. It could explain the same phenotype of daughter non-carrying pathogenic variant as her mother with BRCA1 mutation has.

E-P12.023

Pathogenic splice mutation (c.632-3C>G) in the BRCA2 gene in a family with breast cancer

C. D. Castelão¹, I. R. Silva¹, M. Carmo-Fonseca¹, A. Berta²;

¹Genomed, Lisbon, Portugal, ²Hospital de Santa Maria, Lisbon, Portugal.

Introduction: Woman with inherited inactivating mutations in the tumor suppressor genes BRCA1 or BRCA2 have an increased risk of developing breast and ovarian cancers, while BRCA2 mutation carriers have in addition increased risk for other cancer types including male breast cancer. However, pathogenic mutations in BRCA1 or BRCA2 genes are only detected in approximately 25% of patients with a strong family history, while almost 1,800 distinct sequence variants have been described with uncertain clinical significance.

Methods: The entire coding region and splice site junctions of the BRCA1 and BRCA2 genes were amplified by PCR and analyzed through direct Sanger DNA sequencing.

Results: A female proband diagnosed with breast cancer was selected for BRCA1 and BRCA2 genetic testing according to established criteria. A heterozygous intronic variant within intron 7 of the BRCA2 gene, c.632-3C>G (rs568027879) was identified. The same variant was detected in two other affected family members, one female and one male. In silico analysis performed with multiple tools predicted an impact in the splicing pattern. This variant was not reported in the Breast Cancer Information Core Database (BIC). However, it is described in the Universal Mutation and ClinVar databases as a variant of unknown significance.

Conclusions: We report, for the first time, co-segregation data for a BRCA2 splicing variant in three family members, including one male, diagnosed with primary breast cancer. This strongly suggests that the variant c.632-3C>G is a novel pathogenic splicing mutation.

E-P12.027

The polymorphisms of genes involved in DNA methylation process among leukemia and breast cancer patients from Ukraine

I. Dmytruk¹, H. Makukh¹, M. Thyrcus¹, N. Kitsera¹, I. Tsybalyuk²;

¹Institute of Hereditary Pathology National Academy of Medical Sciences of Ukraine, Lviv, Ukraine, ²West Ukrainian Specialized Children's Medical Center, Lviv, Ukraine.

Introduction. Aberrant DNA methylation and synthesis are key epigenetic factors in tumorigenesis. Folate metabolizing enzymes may influence the bioavailability of methyl groups and synthesis of nucleotides, whereas DNA methyltransferases are involved in epigenetic regulation of gene expression. We made a suggestion that genetic variants of folate metabolizing enzymes and DNA methyltransferase may lead to differences in susceptibility to cancer development.

Materials and Method. Genotyping of MTHFR 677C>T, MTR 2756A>G, TS 3R2R, TS 3R G>C and DNMT3B -149C>T and DNMT3B -579G>T was performed in 60 patients with leukemia, 90 patients with breast cancer and in 100 healthy persons without cancer pathology in anamnesis. The molecular-genetic analysis was performed by Polymerase Chain Reaction and Restriction Fragment Length Polymorphism analysis. Statistical analysis was conducted by Chi-square tests and odds ratio (OR) calculation.

Results. We did not observe any significant differences in genotype frequencies of the MTHFR, TS and DNMT3B polymorphisms between the cases and controls. The MTR 2756AA genotype frequency was significantly higher in patients with breast cancer vs control (0.67 vs 0.50, p= 0.02). The increased risk of breast cancer development was associated with MTR 2756AA genotype (OR=2.00, CI - 95%:1.11 - 3.60) and MTR 2756A allele (OR=1.75, CI - 95%:1.08 - 2.84). The frequency of genotypes and alleles of MTR 2756 A>G polymorphism did not exhibit statistical differences between patient with leukemia compared to control.

Conclusions. Our findings show that West Ukrainian inhabitants carrying at least one MTR 2756A allele have a significantly increased risk of breast cancer.

Use of „Myriad My Hereditary Cancer Risk“ test in patients with familial early-onset breast cancer and / or multiple tumors.

I. Antonucci¹, M. Provenzano¹, L. Sorino¹, G. Calabrese², G. Palka², L. Stuppia¹;

¹Department of Psychological, Health and Territorial Sciences (DISPUTer), School of Medicine and Health Sciences, "G. d'Annunzio" University, Chieti-Pescara, chieti scalo, Italy, ²Department of Medical, Oral and Biotechnological Sciences, School of Medicine and Health Sciences, "G. d'Annunzio" University, Chieti-Pescara, chieti scalo, Italy.

Introduction: Breast (BC) and ovarian (OC)cancer are a leading cause of death worldwide and BRCA1/2 genes are the most commonly mutated genes, but additional genes associated with inherited forms are emerging. In the present study we have validated Myriad myRisk Hereditary Cancer panel in a cohort of 18 patients with a family history of BC, using Next Generation Sequencing (NGS).

Materials and Methods: For the screening „Myriad My Hereditary Cancer Risk“, 17 patients were selected on the basis of the following criteria: a) early onset (<40 years); b) evidence of dominant Mendelian transmission; c) bilateral BC or multiple tumors.

Results : The results showed two pathogenetic mutations in 2 patients (11,8%) in the BRCA2 and in the APC gene. Furthermore, six patients (35,3%) showed variants of uncertain significance in the following genes: PALB2, PMS2, ATM, BRIP1 e CHEK2.

Conclusions : The preliminary data show that „Myriad My Hereditary Cancer Risk“, panel can be extremely useful and NGS approach is particularly suitable to study patients with BC early and / or family history of multiple cancers.

Biological activity of fatty acids in breast and prostate cancer cell lines

S. S. Villa Vasquez^{1,2}, M. E. Marquez^{1,2}, M. Camargo²;

¹Animal Biotechnology group, Universidad Nacional de Colombia, Medellin, Colombia, ²Genetics, Regeneration and Cancer group, Universidad de Antioquia, Medellin, Colombia.

Breast and prostate cancer are the main causes of death worldwide and new therapies or dietary factors influencing cell survival of these cancers are worth investigation. Studies in tumour cell lines suggest that omega-3 fatty acids reduce cell viability, whilst omega-6 increases proliferation. Few studies investigated the genotoxic effect of some acids but a genoprotective effect of eicosapentaenoic acid (EPA) has been found. In this study, we investigated plating efficiency, cytotoxic and genotoxic effect of alpha-linolenic

acid (ALA), EPA, docosahexaenoic acid (DHA), linoleic acid (LA), arachidonic acid (AA) and oleic acid (OA) in prostate and breast cancer cell lines.

Cytotoxicity at 25µM, 50µM, 100µM and 150µM of each fatty acid was measured by MTT and Trypan-Blue in MCF-7 and PC-3 cells. Genotoxicity was evaluated by comet assay and plating efficiency done to evaluate capacity colony formation from single cells. Experiments were done in triplicate. DHA, EPA and AA reduce viability in more than 50% of cells. 100% of cytotoxicity was found in PC-3 and MCF-7 cells treated with highest concentrations of EPA and DHA respectively. Unexpectedly, LA had similar effect reducing viability to less than 15%. Relative plating efficiencies lower than 30% were obtained in cells treated with EPA, DHA and AA after 10 days post re-plating. In contrast, EPA caused significant DNA damage ($p < 0,05$) in both cell lines and LA in MCF-7 cells.

These results suggest that EPA, DHA and AA inhibit proliferation and have long-term effect in tumour cells, therefore their intake can be an adjunctive cancer therapy.

Coexistence of t (8; 14) and t (11; 14) translocations in a Burkitt's Lymphoma Patient

S. Karauzum Berker¹, S. Yakut¹, K. Yalcin², A. Kupesiz³, E. Guler³;

¹Akdeniz University, Faculty of Medicine Department of Medical Biology and Genetics, Antalya, Turkey, ²Akdeniz University, Faculty of Medicine Department of Pediatric Haematology and Oncology, Antalya, Turkey, ³Akdeniz University, Faculty of Medicine Department of Haematology and Oncology, Antalya, Turkey.

Non-Hodgkin's lymphoma is a subset of the Burkitt's lymphoma and the most common chromosomal abnormality is t (8; 14) translocation in this B-cell lymphoma. 14-year-old Afghan boy was admitted with increasing swelling in the back of the neck for two months. Burkitt's lymphoma has been reported in a biopsy. Chromosomal analysis was done from the patient's bone marrow aspiration material. His karyotype was designed as 46, XY, t (8; 14) (q24; q32) [18] / 46, XY, dup (1) (q23q32), t (8; 14) (q24; q32) [12]. Also t (11; 14) (q13; q32) translocation, often seen in adult mantle cell lymphoma, was found 100 % interphase cells by molecular cytogenetic methods in the same patient. In patients with suspected bone marrow blasts at a rate of 60% blasts and CSF analysis it was considered Stage IV Burkitt's lymphoma and protocol of NHL BFM 95 risk group 4 chemotherapy was started. It has been observed in visible shrinkage of the mass in the neck after a course of treatment. It has been presented for the first time a double hit lymphoma derived from the coexistence of t (8; 14) and t (11; 14) translocations in a child patient with Burkitt's lymphoma diagnosed. Because of the good response to the treatment, clinical and genetic findings of the Burkitt's lymphoma patient will be discussed with the literature.

E-P12.031

Is Ganoderma lucidum effective for cancer treatment?

H. Ecevit¹, B. Gogebakan, K. Gunduz, D. Sonmez, M. Izmirlı; Mustafa Kemal University, Hatay, Turkey.

Ganoderma lucidum is a species of mushroom that has been used for a healthier lifestyle, to extend the human life and the treatment of various diseases involving cancer, autoimmune diseases. Lung cancer is the most common cancer among men and women. There are several mechanisms including cell cycle programming and apoptosis cause lung cancer. p21 plays an important role as tumor suppressor gene in cell cycle and Bcl-2, caspase3, caspase8, caspase9 in apoptosis. Therefore, we aimed to evaluate above mentioned parameters. For this purpose, Ganoderma lucidum extract dissolved in DMSO and was prepared in appropriate concentrations in the cell culture medium. A549 was exposed to 0-1000 µmol/ml concentrations of the Ganoderma lucidum extract at 24, 48 and 72 hours. Cell viability was evaluated through MTT. The expression levels of genes were evaluated with RT-qPCR. MTT assay results were statistically significant in cells treated with 400 µmol/ml concentration of Ganoderma lucidum extract in 24 and 48 hours exposure period than upper concentrations ($p > 0,05$; 95% CI: -0,34 to 0,01 and $p = 0,0001$; 95% CI: -0,54 to -0,15 for 24 and 48 hours respectively). The expression level of p21 in mentioned treat dose and periods were statistically significant when compared to control group ($p = 0,03$; 95% CI: 0,004 to 0,06). Consequently, we demonstrated that the Ganoderma lucidum extract was increased A549 cell proliferation and inhibited the release of p21. So, Ganoderma lucidum is shown to have a stimulant effect on cell proliferation via suppressing the p21 expression but not apoptosis.

Lactobacilli differentially modulate Wnt/ β-catenin, mTOR and HIF-1 pathways in HeLa cell lines

a. abedin do;

Shahid Beheshti University of Medical Sciences, tehran, Iran, Islamic Republic of.

Introduction: *Lactobacilli* are a group of beneficial bacteria whose anti-cancer effects have been evaluated in different cancer cell lines as well as animal models and human subjects. Such anticancer effects can be exerted via different mechanisms such as modulation of immune response as well as inhibition of pathogens colonization. In addition, *lactobacilli* have direct cytotoxic effects against cancer cells which may be exerted through modulation of expression cancer related pathways.

Materials and Methods: In order to find the mechanism of anticancer effects of two *lactobacilli* strains, we analyzed expression of some Wnt/ β-catenin, mTOR and HIF-1 pathways genes with real-time PCR in HeLa cell lines following treatment with *Lactobacillus. crispatus* (LC) and *Lactobacillus. rhamnosus* (LR) culture supernatants.

Results: the expression of *CCND1* as a marker of cell proliferation, survival, and angiogenesis, has been decreased following LR and LC treatments. In addition, the expression of *SFRP2*, an antagonist of Wnt pathway, has been increased. Furthermore, we have demonstrated the downregulation of *ELF4E* expression following LC treatment. However, moderate decreases have been detected in expression of *HIF-AS1* following treatment with LC and expression of *SHARP1* as a result of LR treatments, after treated with LC, expression of *VHL* decreased that this result was unexpected.

Conclusions: *lactobacilli* can modulate expression of Wnt/ β-catenin, mTOR and HIF-1 pathways genes in HeLa cell line. Between these three pathways Wnt/ β-catenin, which is second hit in cervical cancer, showed the most change after treated with *lactobacilli*.

E-P12.034

Apoptotic Effects of Novel Benzimidazole Derivates On A549 Cell Line

G. Gulbol Duran¹, N. Duran¹, O. Algu², A. Yildirim¹, M. Yaldız¹, A. Yoldas²;

¹Mustafa Kemal University, Hatay, Turkey, ²Mersin University, Mersin, Turkey,

³Kahramanmaraş Sutcu Imam University, Kahramanmaraş, Turkey.

Background and Aim: Malignant cells are characterized by a number of alterations in controlling proliferation, differentiation, and apoptosis. New drug researches which inhibit the proliferation of cancer cells are quite important because of the drug resistance and side effect used in conventional cancer therapy. Benzimidazole derivates have been reported to be significant anti-proliferative activities. In this study we aimed to investigate the proliferative and anti/pro-apoptotic effects of new benzimidazole derivates on human lung adenocarcinoma epithelial cell line (A549).

Materials and Methods: Human Embryonic Kidney cells (HEK 293) and A549 cells were used in this study. A549 cells were treated with various concentrations of benzimidazole derivates. The expression levels of p53, Bcl-2, Bax, caspaz-3 and NF-KB genes were analyzed in treated and control groups.

Results: In this study, the compounds was found to inhibit the cell growth at S phase. The compounds have been found to increase the expression of p53 gene. It was determined that the ratio of p53 expression increased in proportional to the incubation time. While, the compounds were found to be statistically significant reduction in the levels of antiapoptotic genes (bcl-2 and Bcl-XL), NF-KB level was found that the significantly increased. Also, caspase-3 activity in cancer cell line was observed significantly higher than compared to the control group ($p < 0.01$).

Conclusion: Benzimidazole derivatives compounds were found to be highly effective against human lung adenocarcinoma epithelial cells. These compounds found to be very promising compounds in the treatment of cancer therapy.

A Novel Translocation t(10;12)(q24;q13) In Childhood ALL

T. Akan Duman¹, A. G. Zamani¹, U. Çalışkan², H. Tokgöz², M. S. Yıldırım¹;

¹Department of Medical Genetics, Meram Medical Faculty, Necmettin Erbakan University, KONYA, Turkey, ²Department of Pediatric Hematology, Meram Medical Faculty, Necmettin Erbakan University, KONYA, Turkey.

Acute lymphoblastic leukemia (ALL) is a malignant blood disorder characterized by clonal expansion of leukemic cells in the bone marrow, lymph nodes, thymus, or spleen. It is the most common childhood cancer. ALL accounts for 76% of among major types of leukemia and 43% of all deaths of pediatric leukemia patients in United States. Because of the diagnostic, prognostic and therapeutic value of the chromosomal findings, cytogenetic

analyses is important in ALL. Either in chromosome number (ploidy) or as structural changes as translocations, deletions and inversions are found in 90% of children with ALL. Translocations are the most common changes among structural abnormalities. In acute leukemias, structural abnormalities of chromosome 12 are well known. While the most frequently, the break occurs in the short arm, changes at the long arm are very rare.

A 12-year-old female patient had been diagnosed as ALL five years ago. She had chemotherapy along three years. 15 months after chemotherapy, she consulted at haematology with knee pain. Atypical blasts were shown in her control peripheral blood smear. Bone marrow aspirate examination was made and patient accepted as early isolated bone marrow relapse. Her bone marrow karyotype was as 46,XX[3]/46,XX,t(10;12)(q24;q13)[5] and 66% deletion on p16 gene was found in ALL FISH panel.

According to our knowledge, t(10;12)(q24;q13) is a novel translocation in childhood ALL. So that we report this case in order to contribute the literature.

A novel cytogenetic aberration is extra isochromosome 4q in chronic lymphocytic leukemia patient

E. I. Atlı¹, H. Gürkan¹, G. E. Pamuk², C. Akurut¹, H. Tozkar¹, A. M. Demir³;

¹Department of Medical Genetics, Faculty of Medicine, Trakya University, Edirne/Turkey, Edirne, Turkey, ²Department of Haematology, Faculty of Medicine, Trakya University, Edirne, Turkey, ³Department of Haematology, Faculty of Medicine, Trakya University, Edirne, Turkey.

Introduction: The genetic characterization of chronic lymphocytic leukemia (CLL) has made significant progress over the past few years. Chromosomal abnormalities are detected in up to 80% of patients.

Materials and Methods: Our patient was diagnosed with CLL stage 2 on 2012 and followed since then by hematology clinic. She is 63 years old. Bone marrow (BM) biopsy made and hypercellularity showing infiltration of atypical cells with CD5+, CD20+, CD23+ were determined. Hypoplasia are detected in myeloid/erythroid series and stage2 reticular fibers proliferation were detected. Patient was followed up without medication. While follow-up of patients WBC:57300 HB:5,36 PLT:99700 are determined in may 2014. According to the patient's flow results CD5+, CD23+, FMC7+ were detected. Mature, small lymphocytes and smudge cell was found in the patient's peripheral blood smear. In USG imaging multiple lap was found in abdomen and multiple neck lymph nodes was detected. Patient BM aspiration were performed in 2014 and hypercellularity was found to contain 54% of atypical lymphocytes in the BM.

Results: Cytogenetic and FISH analysis is made from the patient's BM. According to the results of karyotyping and FISH 47, XX,+i4q is determined. According to literature, extra isochromosome 4q is reported by our case for the first time in CLL. She was diagnosed with stage 4 CLL and FCR treatment was initiated.

Conclusions: Our patient showed disease progression compared to previous results. So we offer that this evidence can be considered in terms of triggering the disease's progression or as a result of disease progression i4q was occurred.

E-P12.037

Impact of fluorescent in situ hybridization (FISH) aberrations and *cllu1* expression on the prognosis of chronic lymphocytic leukemia (CLL)

U. Abur¹, G. Ogur¹, O. Akar¹, E. Altundag¹, S. Aymelek¹, M. Turgut²;

¹Ondokuz Mayıs University Medical Faculty Department Of Genetics, Samsun, Turkey, ²Ondokuz Mayıs University Medical Faculty Department Of Hematology, Samsun, Turkey.

Introduction. The impact of genetic changes and *CLLU1* expression in CLL patients were studied.

Materials-Methods. 156 patients were analyzed by FISH (LSI D13S139, LSI 13S25, LSI ATM, LSI P53, CEP12, IGH probes). FISH abnormalities were correlated with age, sex, WBC, Rai stage, survival, LDH, β_2 microglobulin and treatment. *CLLU1* expression was also quantified.

Results. FISH aberrations were found in 62% of patients: 13q14 deletion, 66.6%; trisomy 12, 27%; ATM deletion, 19%, TP53 deletion, 8% and IGH rearrangement 20%. Mortality rate was 40% with del 11q22 and del 17p (Tp53), 28% with del 13q14, 15% patients with trisomy 12. Overall survival was 98 \pm 22mo for del 13q14, and 69 \pm 19mo for del 11q22. Need of medication was 89% for del 11q22 and del 17p, 42% for others. The most frequent abnormality in progressive disease was ATM and TP53 deletion. Majority of the patients with stable disease showed heterozygous 13q14 deletion. Patients with homozygous 13q deletions yielded a shorter overall survival. Patients with IGH rearrangements yielded double increased mortality and treatment rate and shorter overall survival. There was no *CLLU1* expression in healthy controls; in patients 1x 10⁻⁴ *CLLU1* expression was detected.

Higher *CLLU1* expression was shorter survival and more patients needed medication (46% versus 21%).

CONCLUSION: Routine usage of FISH analysis is still indicated for prognostic evaluation of the CLL patients. Special consideration is needed for the poor prognostic implication of del 11q22, del 17p, IGH rearrangement and homozygous del 13q14. *CLLU1* expression seems to have correlation with poor prognosis.

E-P12.038

Downregulation of apoptosis-related miRNAs in chronic lymphocytic leukemia

Z. Lasabová^{1,2}, M. Vážan¹, M. Grendar¹, Z. Jedinakova³;

¹Comenius University in Bratislava, Jessenius Faculty of Medicine, Biomedical Center Martin, Martin, Slovakia, ²Comenius University in Bratislava, Jessenius Faculty of Medicine, Dept. of Molecular Biology, Martin, Slovakia, ³Comenius University in Bratislava, Jessenius Faculty of Medicine, Department of Hematology and Transfusiology, Martin, Slovakia.

Introduction: Chronic lymphocytic leukemia (CLL) is the most common type of leukemia in adults with characteristic accumulation of monoclonal mature, functionally incompetent CD5+ lymphocytes co-expressing CD23 and CD19. We have focused on the deregulation of apoptosis-related microRNAs (miRNAs) in CLL.

Material and methods: The microRNAs were extracted from peripheral blood of ten newly diagnosed patients with CLL without treatment and eight controls. There was designed a microplate with miRNAs which are documented to be involved in apoptosis in CLL - mir-222, mir-21, mir-143, mir-21 and mir-29, and miRNAs involved in apoptosis with an unknown role in CLL - mir-149, mir-200c, mir-204, mir-210, mir-221, mir-409, mir-449, let-7c, let-7g and mir-708. After stem-loop primer reverse transcription, the samples were analyzed using TaqMan chemistry and evaluated by delta-delta Ct algorithm with 7500 Software v2.0.1. Differences in relative gene expression were analyzed by Wilcoxon test of the mean RQ=1 at the significance levels p < 0.05.

Results: Application of the Wilcoxon test of the mean to test statistical significance for the differential miRNA expression showed that the downregulation is statistically significant for mir-133b, mir-143, mir-149, mir-200c, mir-204, mir-221, mir-222, mir-409 and mir-708.

Conclusion: The downregulation of miRNAs expression can be caused by their promoter methylation which was already demonstrated for mir-708 in CLL. We are going to validate these results on the larger patient's cohort and to analyze the role of miRNA methylation in the downregulation of these miRNAs.

Supported by Biomedical Center Martin (ITMS 26220220187) and VEGA 1/0102/15.

Aurora Kinase Inhibitor CCT137690 can Induce Apoptosis on Chronic Myeloid Leukemia Cells

A. Asik¹, C. Kayabasi¹, B. Ozmen Yelken¹, T. Balci¹, S. Gonca¹, F. Sogutlu¹, R. Gasimli¹, S. Yilmaz Susluer¹, C. Biray Avci¹, C. Gunduz¹;

Ege University, Faculty of Medicine, Department of Medical Biology, Izmir, Turkey.

Chronic myeloid leukemia (CML) is a clonal myeloproliferative disease resulting from neoplastic transformation of multipotent stem cells. It is characterized by the Philadelphia chromosome (Ph) occurred in 95% of cases, resulting from translocation t(9;22)(q34;q11.2) which leads to the formation of Bcr-Abl fusion gene encoding a product involved in CML pathogenesis. Aurora kinases are the most important serine/threonine protein kinases regulating function of centrosomes, spindles and kinetochores. It has been reported that aurora A and B have overexpression in various malignancy such as breast, colon, neuroblastoma, pancreas and over cancer. However, it has been indicated that Bcr-Abl induce the expression of these kinases in CML cells and claim that aurora kinase inhibitors have potential advantage in treatment of CML. CCT137690 is a highly selective aurora kinase inhibitor. In this study, we aimed to determine the apoptotic effect of CCT137690 on KU812 human chronic myeloid leukemia cells.

WST-8 assay was done to determine cytotoxic effect of CCT137690 on KU812 cells and IC50 dose was found 6.24 μ M for 48 h. The effect of IC50 dose on apoptosis and cell cycle was evaluated with Annexin V-EGFP Apoptosis Detection Kit and BD Cycletest Plus DNA Reagent Kit, respectively. The IC50 dose CCT137690 was found to induce apoptosis in 9-fold compared to control and to arrest cell cycle at G2/M phase.

In conclusion, this study has supportive quality for opinion that aurora kinase inhibitors have potential advantage in treatment of CML, because of that CCT137690 highly induce apoptosis and cause cell cycle arrest.

E-P12.042

BCR-ABL1 positive chronic myeloid leukemias with cryptic rearrangements without Philadelphia chromosome: two case reports

C. Correia^{1,2}, S. Lisboa¹, S. Bizarro¹, M. J. Oliveira², N. Salgueiro², L. Torres¹, J. Vieira¹, N. Cerveira¹, S. Castedo², M. R. Teixeira¹;

¹Portuguese Oncology Institute, Porto, Portugal, ²GDPN, LABCO, Porto, Portugal.

Introduction: Chronic myeloid leukaemias (CML) usually harbour a reciprocal chromosomal translocation t(9;22) that results in the Philadelphia chromosome, leading to the formation of the *BCR-ABL1* fusion gene. In a minority of CML patients, the *BCR-ABL1* chimera can be formed through cytogenetically cryptic rearrangements and present an apparently normal karyotype. In order to correctly identify all the patients that can benefit from a TKI therapy, a multidisciplinary approach should be taken.

Materials and methods: Classical cytogenetics, molecular studies and fluorescence in situ hybridization (FISH) were performed in bone marrow samples of two CML cases.

Results: Karyotype analysis of both cases did not show chromosomes 9 and 22 rearrangements. Molecular analysis revealed the presence of the *BCR-ABL1* fusion gene. FISH studies showed the occurrence of the *BCR-ABL1* fusion in chromosome 9 in both cases.

Conclusion: These two examples demonstrate the importance of a multidisciplinary approach to establish a correct genetic diagnosis and characterization of CML cases.

E-P12.043

The evaluation of the effects of dasatinib on protein expression and the enzymatic activity of PP2A catalytic and regulatory subunits that are dasatinib-treated K652 cell line

B. Özel¹, S. Kıpçak¹, Ç. Aktan¹, Ç. Biray Avcı¹, C. Gündüz¹, G. Saydam², N. Selvi Günel¹;

¹Ege University Department of Medical Biology, Izmir, Turkey, ²Ege University Department of Hematology, Izmir, Turkey.

Introduction: Chronic myeloid leukemia (CML) is characterized by increased tyrosine kinase activity due to BCR/ABL translocation. Dasatinib is tyrosine kinase inhibitor that is more effective than imatinib but 20% of patients don't respond to treatment. Therefore, other molecular approaches should be investigated. For that purpose, protein phosphatase 2A (PP2A) that is found genetically altered or functionally inactive in CML, may be promising therapeutic target. PP2A is consist of three subunits and involved in many cellular function. In our study, we aimed to evaluate PP2A enzyme activity and protein level in dasatinib treated K562 cell line.

Materials and Methods: The cytotoxic effect of dasatinib was evaluated by WST-1 analysis. Apoptosis was determined by Annexin V and Apo-Direct Tunel assays. Okadaic acid (OA) was used as PP2A inhibitor. The changes of PP2A enzyme and protein levels were observed by serine/threonine phosphatase and western blot analysis, respectively.

Results: The cytotoxic effect of dasatinib in K562 cells was found 4.6 nM at 48th hour. According to Annexin V, apoptosis was increased 2.35 and 3.76 fold by treating with dasatinib and 2.5 µM and 25 µM OA combination, respectively. According to Tunel assay, apoptosis was induced 16.45 and 49.38 fold in same order. The PP2A enzyme activity decreased compared to control at 72nd hour. Protein level of PP2A catalytic subunit decreased compared to control by dasatinib treatment.

Conclusions: We found that PP2A has major role in cell homeostasis and apoptosis. Thus, we could say that targeting PP2A inhibitors may be promising therapeutic approach for CML.

E-P12.046

Detection of KRAS codon 12 and 13 mutations by Allele-specific polymerase chain reaction assay

N. Chaichanawongsaraj;

Faculty of Allied Health Sciences, Chulalongkorn University, Bangkok, Thailand.

Introduction: Mutations of *KRAS* gene at codon 12 and 13 are resistant to targeted therapies with anti-epidermal growth factor receptor (EGFR) antibodies in colorectal cancer. Detection of *KRAS* mutations is critical for effective and appropriate treatment for individual patients. The aim of the present study was to develop Allele-Specific PCR (AS-PCR) assay for analysis of the mutational status of *KRAS* codons 12 and 13, at nucleotides 34, 35 and 38.

Materials and Methods: DNA was extracted from 41 formalin-fixed paraffin-embedded (FFPE) colorectal cancer tissues. The AS-primers for specific amplifying wild-type *KRAS* were established. The assay has been validated with pyrosequencing method. The sensitivity and limit of detection were determined.

Results: Three AS-primers were successfully distinguished wild-type *KRAS*

from the mutant alleles at nucleotides 34, 35 and 38. The limit of detection was detected at 50-55% mutant allele with the lowest amount of DNA at 10 ng/ul. The results of AS-PCR assay were in good concordance with pyrosequencing only in samples with % mutant alleles greater than 60%. The sensitivity and specificity of our AS-PCR were 43.33% and 100%, respectively. **Conclusions:** We demonstrated that AS-PCR specific for wild-type *KRAS* at nucleotides 34, 35 and 38 could detect mutations in highly mutant enriched tumor samples.

This work was granted by Faculty of Allied Health Sciences Fund 2014 (AHS-CU 58004).

E-P12.047

Therapeutic potential of post-transcription MCM4 gene silencing for colorectal cancer treatment

A. Kuzevanova, A. Korotaeva, A. Alimov, A. Karpukhin;

Research Centre of Medical Genetics, Moscow, Russian Federation.

Introduction: The RNAi based approaches for cancer treatment implies searching for new targets genes. The MCM4 gene encoding the subunit of helicase, is involved into development replication stress and cell cycle control. The purpose of this study to increase knowledge on MCM4 gene expression, evaluate the possibility of its use in tumor therapy.

Materials and Methods: The study conducted using colorectal cancer cell line HT-29. Lipofectamine RNAiMAX was used for delivery of designed siRNA. Flow cytometry was employed for cell cycle analysis. Antibodies against AIF protein and fluorescent inhibitor of caspases-3 and -7 used for apoptosis study.

Results: It was discovered that low dose of oxaliplatin (1-5mM) up-regulates MCM4 gene mRNA expression more than 3-5 folds. The gene silencing induces apoptotic HT-29 cell death. The event is time- and dose-dependent. It was shown that MCM4 silencing lead to accumulation of cells in G1 phase after 48 hours of exposure. Apoptotic cell death reached 60%. The analysis of apoptotic pathways revealed that there is no influence of AIF. The main mechanism of cell death is associated with identified activation of caspases -3 and -7. Adding to the cell culture inhibitor of caspases-3 and -7 (Z-DEVD-FMK) significantly reduces the number of cells undergoing apoptosis.

Conclusion: Thus, the activation of caspase-dependent pathway is the main cause of cell death after MCM4 gene silencing in presence of oxaliplatin. This opens up new opportunities to create target drugs, which should help to avoid the problem of resistance during oxaliplatin treatment.

E-P12.048

Frequency of chromosomal abnormalities in patients with Multiple Myeloma

C. Aydin Acar¹, C. HanguF², O. Salim³, O. K. YuceF³, S. Berker Karazum²;

¹Mehmet Akif Ersoy University, Bucak School of Health, Burdur, Turkey, ²Akdeniz University, Faculty of Medicine, Department of Medical Biology and Genetics, Antalya, Turkey, ³Akdeniz University, Faculty of Medicine, Department of Hematology, Antalya, Turkey.

An uncontrolled proliferation of plasma cells which play a role in immune system is called Multiple Myeloma (MM). It is the second most common hematologic malignancy in the United States, and accounts for approximately 1% of all cancer cases. Currently, detection of chromosomal abnormalities is accepted as a important tool for predicting outcome in newly diagnosed MM patients (1). In this retrospective study, we aimed to determine cytogenetic findings using by conventional cytogenetics and FISH methods in 435 patients with MM. Cytogenetics analysis was successful in 367 patients (84,4%) and unsuccessful in 68 patients (15,6%). Ninety nine of 367 (27%) patients were found to have an abnormal karyotype. Of 99 patients, 19 patients (19,2%) had hyperdiploidy (>47), 40 patients (40,4%) had hypodiploidy (≤ 45), and 25 patients (25,2%) had pseudodiploidy. In addition, only the loss of Y chromosome was found in 15 patients (%15,2) and these patients were classified in as a separate group. The presence of both structural and numerical chromosome abnormalities were detected in 36 patients (36,4%); 40 patients (40,4%) had only numerical abnormalities; 23 patients (23,2%) had only structural abnormalities. In this study, specific FISH probes for t(4;14),t(11;14), t(14;16),del(11q22.3),del(17p13) and del(13q14) was applied to the slides of patients. By FISH analysis, the most frequently abnormality, del(13q14), was observed in 14,5% (33/228) and del(17p) was determined the second most frequently abnormality in 7,65% (18/235) of patients.

MYC rearrangements in diffuse large B cell lymphoma patients

B. Durak Aras¹, S. Isik¹, O. Cilingir¹, H. Uskudar Teke², M. Ozdemir¹, E. Gündüz², H. Aslan¹, S. Artan¹, M. O. Akay¹;

¹Eskisehir Osmangazi University Medical Faculty Department of Medical Genetics, Eskisehir, Turkey, ²Eskisehir Osmangazi University Medical Faculty Department of Hematology, Eskisehir, Turkey.

Diffuse large B cell lymphoma (DLBCL) is a heterogeneous disease with its clinical, immunohistochemical, morphological and molecular features. MYC rearrangements occur in 5-10% of DLBCL patients. Since we have very limited experience in patients with isolated MYC rearrangements, the prognostic significance of this cytogenetic abnormality is still unknown.

AIM: In this study, we aimed to investigate the frequency and prognostic significance of MYC rearrangements in patients with DLBCL.

MATERIAL AND METHODS: A total of 46 patients with DLBCL were included in this study. Deparaffinized samples were evaluated by FISH using MYC, BCL6 and BCL2/IGH and CCND1/IGH probes.

RESULTS: Rearrangement of MYC was found in 16 patients (34%). Of these patients, 9 were double-hit and 2 were triple hit lymphomas. When we compared the prognostic markers including stage, IPI and LDH between MYC+ and MYC- patients, we found a significant difference in stage and LDH values between the groups ($p=0,004$ and $p=0,037$, respectively). IPI score did not show any difference between isolated MYC+, two hit and three hit patients ($p>0,05$).

DISCUSSION: MYC rearrangements confer a worse effect on prognostic factors such as IPI, tumor stage, and survival. In this study, tumor stage and LDH values showed significant difference between MYC+ and MYC- patients in consistent with the previous literature. However, the presence of BCL2 and BCL6 rearrangements in MYC- patients conferred a prognostic effect. To address the prognostic impact of MYC rearrangement, we need a higher number of isolated MYC+ and three negative patients considering BCL2 and BCL6 aberrations.

The effects of a novel resveratrol analog known as DMU-212 on leukemia stem cell line

B. Ozmen Yelken, C. Kayabasi, T. Balci, A. Asik, S. Gonca, F. Sogutlu, R. Gasimli, S. Yilmaz Susluer, C. Biray Avci, C. Gunduz;

Ege University Medical School, Department of Medical Biology, Izmir, Turkey.

Myeloid leukemias results from malignant transformation of primitive hematopoietic cell and it is suggested that leukemia stem cells are malignant derivatives of normal hematopoietic stem cells. Leukemia stem cells have similar features with normal stem cells including self-renewal, differentiation and infinite proliferation. Resveratrol, which is a potential chemopreventive and chemotherapeutic agent, is found in red grape. Previous studies have shown that resveratrol has anti-tumorigenic effect in several cancer types. It has been shown that DMU-212 usually induces G2/M arrest through limited studies which are related to resveratrol analogs.

In our study, we aimed to evaluate the effects of DMU-212 on apoptosis, cell cycle and also proliferation in human leukemia stem cells.

Cytotoxicity of DMU-212 (30 μ M - 0.5 μ M) on human leukemia stem cell line (LSC) were evaluated with Cell Proliferation Reagent WST1 test. Changes of apoptosis and cell cycle in LSCs with exposure to IC50 dose of DMU-212 are detected with AnnexinV-EGFP Apoptosis Detection Kit and Cycletest Plus DNA Reagent Kit with FACS, respectively.

IC50 dose of DMU-212 was calculated as 27,97 μ M. It was shown that DMU-212 couldn't induce apoptosis during 48 hours. Beside that, LSCs accumulated in G2/M phase of the cell cycle with the exposure of 27,97 μ M DMU-212. In conclusion, our hypothesis suggests that DMU-212 may influence the cell cycle pattern of leukemia stem cell line due to G2/M arrest significantly. Therefore, DMU-212 may be considered as an additional anticancer agent in leukemia treatment.

High Content and High Throughput Single Cell mRNA Sequencing Analysis of Prostate Cancer Cells Using Fluorescence Activated Flow Cytometry Combined with Molecular Barcode Technology

M. A. Tycan;

Becton Dickinson, San Jose, CA, United States.

EpCAM, a surface adhesion protein implicated in cancerous cells gaining metastatic potential, is dysregulated, exhibiting varied expression among prostate cancer samples and cell lines. Prostate cancer cell lines PC3, DU145, and LNCaP exhibit variable EpCAM expression. While the metastatic potential of each line is understood, there is little consensus on EpCAM ex-

pression. Using single cell mRNA sequencing enables simultaneous observation of hundreds of genes, elucidating the interplay of EpCAM in metastasis. The BD FACSeq™, a new easy-to-use sorter, was employed to deliver single cells and eliminate doublets or higher order aggregates for single cell mRNA-Seq analysis. Accurate single cell delivery into 96-well plates was confirmed. Several hundred cells were examined by transcript analysis of 110 genes associated with prostate cancer using BD™ Precise encoded plates, which incorporate molecular indexing and sample barcodes to achieve high-fidelity gene profiling. For each of the three cell lines, EpCAM protein level distribution was recorded through index sorting, revealing broad distributions for PC3 and DU145. Index sorting on the BD FACSeq enabled protein expression to be tied to gene transcript count for each cell analyzed. Genes expressing differential regulation from the panel were correlated to EpCAM expression, indicating which may influence metastatic potential. The accurate delivery of individual cells by flow cytometry paired with single cell sequencing technologies can enable researchers to investigate transcriptional dynamics at the individual cellular level, disambiguating sample heterogeneities. These results aid in understanding the centrality of EpCAM, a possible therapeutic target, during the transition to androgen resistant, metastatic cancers.

The investigation of APC mutations in Russian patients with Familial Adenomatous Polyposis

A. S. Tsukanov, V. Shubin, N. Pospekhova, I. Sachkov, A. Kuzminov, V. Kashnikov, Y. Shelygin;

Ministry of Health / State Scientific Centre of Coloproctology, Moscow, Russian Federation.

Familial Adenomatous Polyposis (FAP) is responsible for 1% of colorectal cancer cases. FAP is caused by germline mutations in APC gene (mutations frequency varies between 40-75% in different populations). The aim of this investigation was to study the frequency of APC mutations in the Russian cohort of FAP patients.

We collected blood samples of 107 patients under 45 years with the presence of > 100 colorectal polyps. We also studied blood samples of 35 patient family members. Germline mutations in APC gene were analyzed by PCR, electrophoresis, Sanger Sequencing and Next-Generation Sequencing.

Germline mutations in APC were detected in 77 from 107 patients (72%). Among these 77 mutations met recurring: p.Arg232X (2 cases), p.Asp849GlufsX11 (2 cases) p.Arg216X (3 cases), p.Gln1062X (4 cases), p.Arg213X (5 cases), p.Glu1309AspfsX4 (16 cases). From 51 unique mutations 21 were nonsense, 25 - frameshift and 5 - splicing site mutations. Twenty-two mutations were described for the first time. Mutations in APC are located throughout the gene from 142 to 1492 codons, while 25 from 51 variants - in codons 900-1500. In 16 from 35 relatives germline mutations in APC were found, what led to their inclusion into the risk group.

The frequency of APC mutations in Russian patients with FAP was 72%. Twenty-two mutations were described for the first time.

E-P12.057

Peculiarities of gene expression in disseminated gastric cancer

F. Kipkeeva¹, T. Muzaffarova¹, A. Karpukhin¹, M. Narimanov², O. Malekhova²;

¹Research Centre for Medical Genetics, Moscow, Russian Federation, ²NN Blokhin Russian Cancer Research Centre, Moscow, Russian Federation.

Patients with disseminated gastric cancer have a poor prognosis. The study of gene expression is important for understanding of tumor progression and for developing predictive and prognostic markers. We studied among patients with disseminated gastric cancer the expression profiles of the genes - potential markers (VEGF, VEGFR1, VEGFR2, NRP-1, bFGF, FGFR2, TGF- β , HER2/neu, TUBB, BRCA1, Ki67, PCNA) - by quantitative real-time PCR in paired tumor - normal tissue samples. Correlations in the studied gene expression levels were also determined.

An objective response to therapy with Herceptin was observed under increased expression of HER2 gene. Tubulin gene expression was associated with the effective action of taxanes ($p = 0.036$). The FGFR2 gene is under consideration as a new therapeutic target. However, the incidence of increased expression of FGFR2 was only 5%, which corresponds to the studied elsewhere its frequency amplification at gastric cancer.

Most often elevated mRNA level in the tumor relative to the control was observed for NRP-1, VEGFR2 and TGF- β genes (32% - 41%). The correlation of these gene expression levels was found for the first time ($R=0.63$; $p=0.002$). Survival more than 1 year was associated with simultaneously increased expression level of these genes ($OR=10.6$; $95\%CI=1.48$ to 76.08 ; $p=0.018$). An inverse correlation VEGF and bFGF gene expression was revealed also ($R=-$

0.73; $p=0.005$). This effect probably reflects alternative ways to stimulate the gastric cancer development and must be taken into account in the choice of means of targeted therapy for this disease.

E-P12.059

The mRNA expression of PHD1 gene of chronic myeloid leukemia cells

A. Toylu, O. Salim, O. Altioğ Clark, I. Undar;
Akdeniz University, Antalya, Turkey.

PHD1 gene is a hydroxylase enzyme regulating the proteasomal degradation of Hif1 α transcription factor which is related with the expression of several genes responsible for the cancer development and cancer cell survival. It has been reported that PHD1 protein also regulates the expression of some other proteins related with malign cellular behavior but the expression level of PHD1 gene was remain mostly unclear. Recent studies on bone marrow stem cells showed that PHD inhibitors stimulate the hematopoietic stem cell (HSC) mobilization. Furthermore, PHD2 gene ablation was reported to increase the self-renewal of HSCs. To better understand the role of PHD1 gene on malign hematopoietic cells we performed the expression analysis of PHD1 gene of chronic myeloid leukemia (CML) cells. Patients were collected into; at the diagnosis stage, tyrosine-kinase inhibitor therapy responsive- or non-responsive groups. Peripheral blood and bone marrow samples of CML patients were obtained to investigate mRNA expression of PHD1 gene. ACTB gene was used as a reference gene. Real time quantitative PCR and REST analysis were performed to measure expression levels. PHD1 gene expression was higher in the therapy responsive group than both the diagnosis stage and the therapy non responsive groups. According to our data, the low level of PHD1 gene expression at the CML diagnosis or the therapy resistant states is most likely related with the high levels of cell survival regulatory genes. The relationship between PHD1 protein and its substrate proteins needs to be further analyzed in CML.

E-P12.060

Differential expression of genes involved in biotransformation mechanism in oral cancer

A. Russo¹, P. M. Biselli-Chicote¹, W. Chaves¹, M. M. U. Castanhole-Nunes¹, C. R. S. Silva¹, A. P. A. Gimenez-Martins¹, T. Z. Lopes¹, J. V. Maniglia², D. Santi-Neto², É. C. Pavarino², E. M. Goloni-Bertollo¹;

¹Research Unit in Genetics and Molecular Biology – UPGEM / São José do Rio Preto Medical School (FAMERP), São José do Rio Preto, Brazil, ²Department of Otorhinolaryngology and Head and Neck Surgery – FAMERP, São José do Rio Preto, Brazil.

Introduction: Differential expression of genes that encoded enzymes involved in the biotransformation mechanism of endogenous and exogenous compounds by oxidation reactions, as cytochrome P450 (CYP) family and others oxygenases enzymes, can change the activation process of toxic agents and lead to oral tumor development.

Materials and Methods: Eight tumor samples and eight adjacent non-tumor tissue samples of patients with oral cavity squamous cell carcinoma were included in this study. TaqMan® Array Human CYP450 and other Oxygenases 96-well fast plate (Applied Biosystems) was used to evaluate the gene expression pattern in oral cavity tumors by real time qPCR. For statistical analysis was performed D'Agostino & Pearson omnibus normality test, followed by One-sample T test or Wilcoxon signed rank test using GraphPad Prism v.5 program. Correction for multiple testing of Benjamini-Hochberg False Discovery Rate was applied.

Results: CYP27B1 gene was overexpressed and CYP27A1, CYP2E1, CYP2R1, CYP2J2, CYP2U1, CYP4F12, CYP4X1, PTGIS, ALOX12, CYP4B1 and MAOB were down expressed in oral squamous cell carcinoma tissue ($p<0.05$). After correction by multiple tests, PTGIS gene remained differentially expressed. Bioinformatics analyses showed that CYP2E1, CYP2J2, CYP2U1, ALOX12 and PTGIS proteins were involved in the arachidonic acid metabolism associated with important inflammatory processes in carcinogenesis.

Conclusion: Genes involved in the oxidation reactions showed differential expression in oral squamous cell carcinoma. The enzymes encoded by these genes play an important role in the arachidonic acid metabolism, which can influence the regulation of important physiological mechanisms in oral tumorigenesis process.

Sensitivity of a human glioblastoma cell line U251 to all-trans retinoic acid treatment

D. Drakulic, J. Marjanovic Vicentic, N. Kovacevic Grujicic, M. Schwirtlich, M. Stevanovic;
Institute of Molecular Genetics and Genetic Engineering, University of Belgrade, Belgrade, Serbia.

Introduction: Gliomas are the most common primary brain tumors in humans. Glioblastoma, grade IV of glioma tumors, is one of the most aggressive and deadly forms of cancer with the median survival of 15 months even though significant advances in treatment strategies. Retinoic acid (RA), an active metabolite of vitamin A, modulates the proliferation, differentiation and apoptosis in a wide variety of normal and tumor cells. It has been used in clinical trials on glioma tumors, but the efficiency of treatment was heterogeneous.

Materials and Methods: U251 cell line, one of the most widely used *in vitro* model system for studying glioblastoma pathobiology, was used to analyze the effects of RA on cell morphology (staining of microtubule cytoskeleton protein), viability (MTT test), proliferation (Ki-67 staining), migratory potential (Wound Scratch Assay Test) and adhesion ability (Cell-Matrix Adhesion Assay). Cells were exposed to 10, 20 and 40 microM all-trans retinoic acid (ATRA) and analyzed in two time points (3 and 5 days).

Results: Our results reveal that ATRA can cause changes in cell morphology, viability and migratory capabilities. On the other side, treatment with ATRA did not influence the U251 proliferation rate. Additionally, only 5-days treatment of U251 cells with 10microM ATRA changes the adhesion ability of U251 cells compared to control cells.

Conclusions: Obtain results indicate that ATRA treatment is associated with modification of some important features of U251 cells.

Fucoidan from Fucus vesiculosus inhibits proliferation and upregulates p21 level in UT-SCC-74A head and cancer cell line

E. Gunduz, K. Akbas, S. Ciftci Yilmaz, O. Hatipoglu, H. Oksuz, A. Bayatoglu, R. Bayrak, M. Gunduz;
Turgut Ozal University, Ankara, Turkey.

Head and neck cancer accounts for about 15% of all cancers, the great majority of which are of the squamous cell type and include malignant tumors of the larynx, pharynx, mouth and nasal cavity. The treatment of Head and Neck Cancer is difficult from other types of cancer if it is not early diagnosed. Thus, pursuit of finding alternative treatment methods directed scientists to investigate the potential plant and chemical sources.

Mozuku, type of moss/algae, is a commonly consumed food in Japan and is a rich source of alginic acid, carotenoid, vitamin C, vitamin K, amin acids, iron, phosphorus, calcium and fucoidan. Fucoidan, a complex sulphated polysaccharide, has been reported to have several biological activities including anti-inflammatory, anti-angiogenic and anti-tumor activities. In our presented research, we investigated the anti-tumor activity of Fucoidan on the UT-SCC-74A head and neck cancer line.

First, we investigated the anti-proliferation activity of fucoidan by using xCELLigence Real Time Cell Analysis system. Fucoidan inhibits the cancer cell proliferation compared to the control group. Afterwards, to investigate whether this inhibition was due to cell cycle arrest, we investigated the p21 level. p21 level was significantly upregulated in the cancer cell line after fucoidan treatment. Even though our preliminary result suggest that inhibition of proliferation observed was potentially due to cell cycle arrest, further experiments needed to confirm and support our findings. Nevertheless, based on our results, Fucoidan has a great potential in the head and neck cancer treatment.

This project supported by TUBITAK (Project number: 114S331)

E-P12.065

Evaluation of Genetic Mutations in BRCA1, BRCA2 and CHEK 2 Genes as Risk Factors for the Development of Breast and Ovarian Cancer

F. A. Pinarli¹, K. M. Erdogan², M. Y. Alp¹, M. K. Altundag³, Ö. Dizdar³, H. E. Tekin⁴, A. Yesilyurt¹;

¹Dişkayı Yıldırım Beyazıt Research and Training Hospital Genetic Diagnostic Center, Ankara, Turkey, ²Etlik Zubeyde Hanım Gynecology and Obstetrics Training and Research Hospital, Department of Medical Genetics, Ankara, Turkey, ³Hacettepe University Faculty of Medicine, Medical Oncology, Ankara, Turkey, ⁴Gazi University Faculty of Medicine, Medical Oncology, Ankara, Turkey.

Mutations in the BRCA1, BRCA2 and CHEK 2 genes are well-established risk factors for the development of breast and ovarian cancer. There is few studies about the spectrum and frequency of mutations in these genes in the

Turkish Population. After DNA isolation from blood samples of patients presented to our clinic with a diagnosis of familial and/or early-onset breast or ovarian cancer, BRCA1 and 2 genes were analyzed with both Sanger sequencing and MLPA, while CHEK 2 gene analysis was only performed with MLPA. A total of 169 patients with 125 index cases and 44 family members were included in the study. There were 10 males and 172 females, including 111 patients with breast cancer, 11 patients with ovarian cancer, 3 patients with both breast and ovarian cancer, and 44 relatives. Mutations were found in only 23 patients among index cases: BRCA 1, BRCA2, and CHEK2 mutations were found in 15, 7, and 1 patients, respectively. Mutations were detected with DNA sequence analysis in 20 cases and with MLPA in 3 cases. Although there are genetic markers identifying women and men with an increased risk for breast and ovarian cancers, the majority of inherited risk factors remains undetermined. Mutations in the BRCA1 and BRCA2 genes confer a substantial increase in breast cancer risk but routine clinical genetic screening is limited to the coding regions and intron/exon boundaries. Nowadays, it will be more informative and cost effective if all genes related with breast and ovarian cancer can be analyzed together.

E-P12.066

Identification of a novel variant in the MSH2 translation initiation codon

I. Wunderlich, A. Holtorf, T. Hinrichsen, O. Wachter, I. Rost, Zentrum für Humangenetik und Laboratoriumsdiagnostik, 82152 Martinsried, Germany.

HNPCC/Lynch syndrome (LS) is one of the most frequent cancer susceptibility syndromes causing an increased risk for several solid tumors, including gastrointestinal and endometrial cancers. HNPCC/LS is caused by germline mutations in the mismatch repair (MMR) genes MLH1, MSH2, MSH6 and PMS2, with MSH2 representing the second most frequent affected gene. Here we report the case of a 67 year old female with metachronous colorectal cancer without any family history of cancer. The attending physician ordered pathological analysis of tumour tissue to identify microsatellite status and immunohistochemical (IHC) status of the MMR proteins. The tests revealed highly microsatellite instability and inconsistent IHC results due to lack of both MSH2 and PMS2 proteins. Subsequent sequencing of all four MMR genes via Next Generation Sequencing and Sanger technology, as well as MLPA analysis of MLH1, MSH2, MSH6 and PMS2 was performed to identify small and larger sequence variants. We detected the heterozygous variant c.2T>G in MSH2 which affects the translation initiation codon of the gene. The variant is predicted to lack 25 amino acids at the N-terminus of the protein. Without any family history of HNPCC-associated cancers, and the cancer diagnosis made at the patient's age of 61, the phenotype appears to be not severe. Nevertheless, because tumour DNA showed highly microsatellite instability, together with in silico data this variant is supposed to reduce MSH2 protein activity and might be considered as likely pathogenic.

E-P12.067

Analysis of Ki67 and several clinical-pathological variants in Mexican patients with breast cancer

L. Plaza-Benhumera¹, M. Martin de Saro², M. Hernandez-Gonzalez³, S. Cuevas-Covarrubias⁴;

¹Department Genetics Hospital para el Niño Toluca, IMIEM, Edomex, Mexico, ²Department Genetics Hospital Materno Infantil, ISSEMYM, Edomex, Mexico, ³Patología, Facultad de Medicina, Hospital General de Mexico, Universidad Nacional Autónoma de Mexico, Mexico City, Mexico, ⁴Genética, Facultad de Medicina, Hospital General de Mexico, Universidad Nacional Autónoma de Mexico, Mexico City, Mexico.

Introduction: Breast cancer is the most common malignancy in women, with more than 1.4 million cases diagnosed each year worldwide. Ki67 is a cell proliferation marker whose expression in breast tumors has been associated with poor prognosis. The aim of this study is to evaluate the relationship between Ki67 and several clinical-pathological factors. Methods: 416 cases with breast cancer of the General Hospital of Mexico were included. Results: The most common histological type was ductal (84.1%) with a size under 2 cm (55.8%), mean-age at diagnosis was 50.78, the most frequent tumor marker was luminal B Her2+ (24.5%); Ki67 was positive in 70.9% of all tumors. Significant association was observed in Ki67 with positive familial history of cancer (p 0.002), parity (p 0.002), breastfeeding (p 0.002), postmenopausal (p 0.018), and IIIA TNM stage (p=0.003). Ki67 was found more frequently in HER2+ tumors (p <0.001). Ki67 is mainly found in Luminal B HER2+ and in triple negative, in both cases Ki67 is associated with poor prognosis (P <0.001) and with a great number of relapses (P <0.001). Conclusions: Our results indicate that there is a significant association between Ki67 and histological grade, tumor size, presence of HER2. We also detected the worse prognosis in breast cancer triple negative with high levels of Ki67. Grant DGAPA/PAPIIT/UNAM Project IN204114-2.

Gene variants in miRNAs binding site and chronic myeloid leukemia risk

H. Gutiérrez-Malacatt¹, M. Ayala-Sánchez², J. Domínguez-Rodríguez², X. Aquino-Ortega², L. Orozco¹, **E. J. Cordova**¹; ¹National Institute of Genomic Medicine, Mexico City, Mexico, ²Hospital of Specialities, CMN La Raza, IMSS, Mexico City, Mexico.

Introduction: Chronic myeloid leukaemia (CML) is a malignant hematopoietic disease, characterized by the presence of the BCR-ABL fusion gene. On Spite of its clinical importance, little is known about the genetic factors associated with CML development. The miRNAs are small non-coding RNAs that regulate gene expression by binding to the 3' UTR of the target mRNA. Gene variants altering miRNA:mRNA interaction have been described as a risk factor in cancer. The aim of this study was to evaluate the association of variants that alter miRNA:mRNA interaction with CML risk.

Materials and Methods: Identification of variants located at miRNA binding site in coding genes was performed by using public databases and bioinformatics tools. From the identified variants, 384 were genotyped in 200 CML individuals and 200 healthy donors by using custom microarrays. The top associated variants with CML were validated in 300 CML subjects and 500 healthy donors by using TaqMan probes.

Results: We identified over 59,000 SNPs in 3'UTR sequences. From the 384 variants chose for the case-control study, the SNPs rs11680458, rs11638, rs6218, rs2422976, rs6728684, rs3025053, rs1799782, rs11211037, rs4987843 and rs12194974 showed a significant difference in their allelic distribution among cases and controls. However, after increasing sample size only the rs11680458 and rs11638 SNPs, located in the genes WDR43 y HELLS, respectively showed a significant association with an increased risk of developing CML.

Conclusions: The rs11680458 and rs11638 SNPs located in the genes WDR43 y HELLS could be associated with the susceptibility to CML.

Detection of EGFR mutations and ALK rearrangements in Non-Small-Cell Lung Cancer (NSCLC) Romanian patients for TKI targeted therapy suitability.

P. Apostol¹, R. Motoc¹, F. Iordache¹, P. Gurban¹, G. Dinulescu¹, P. Iorga², A. Ungureanu³; ¹Personal Genetics - Medical Genetics Center, BUCHAREST, Romania, ²University Emergency Hospital of Bucharest, BUCHAREST, Romania, ³Radiotherapy Center Cluj, Cluj-Napoca, Romania.

In the last years, the use of tyrosin-kinase inhibitors (TKI) as targeted therapy have shown remarkable success in advanced NSCLC (adenocarcinoma-ADK) patients with genetic alterations in epidermal growth factor receptor (EGFR) and anaplastic lymphoma kinase (ALK).

Detection of EGFR mutations and ALK rearrangements in ADK patients for TKI targeted therapy suitability.

DNA was extracted from FFPE primary/secondary lesions (284/116) obtained by biopsies/resections (120/280) from 400 unrelated Caucasian patients in different ADK stage (261M:139F) age between 28-89 years old, enrolled from February 2015-February 2016. Real-Time PCR method was performed for EGFR screening (exons 18-21). Subsequently, 15 EGFR-negative patients underwent FISH analysis for ALK/EML4 rearrangements detection. EGFR mutations were detected in 63 (15.75%) samples (39 primary/24 secondary tumors) mostly TTF-1 positive, tumor cell between 3%-90%. The TKI-sensitive mutations were mostly identified in exons 19 (53.98%) and 21 (L858R-28.57%, L861Q-4.76%) and less frequently in exon 18 (G719X-3.17%) and 20 (S768I-4.76%). The TKI-resistance mutations were detected in exon 20 as insertion type - primary resistance (3.17%) or as compound mutation del19/T790M - acquired resistance (1.59%). ALK/EML4 rearrangements were observed in 1 male patient with metastatic lesions (6.66%) who received anti-ALK targeted therapy.

Our results, in accordance with international data regarding the EGFR mutations and ALK rearrangements frequency, show a low frequency of the compound mutations.

The use of combined biomarkers like EGFR and ALK mutational profile may offer an accurate, efficient and cost-effective identification of lung ADK patients suitable for TKI-targeted therapy.

Acknowledgement: We thanks to Duzen Laboratories Group, Ankara, Turkey, for FISH analyzes.

Association of miR-200b-3p and miR-1274a expressions in peripheral blood mononuclear cells with lung cancer

C. Özbayer¹, I. Değirmenci², D. Üstüner³, G. Ak⁴, F. Saydam⁵, E. Çolak⁶, H. V. Güneş⁵, M. Metintaş⁵;

¹Dumlupınar University Kütahya School of Health, Department of Midwifery, Kütahya, Turkey, ²Eskişehir Osmangazi University Faculty of Medicine, Department of Medical Biology, Eskişehir, Turkey, ³Eskişehir Osmangazi University Vocational School Health Services, Department of Medical Laboratory, Eskişehir, Turkey, ⁴Eskişehir Osmangazi University Faculty of Medicine, Department of Chest Diseases, Eskişehir, Turkey, ⁵Recep Tayyip Erdoğan University Faculty of Medicine, Department of Medical Biology, Rize, Turkey, ⁶Eskişehir Osmangazi University Faculty of Medicine, Department of Biostatistics, Eskişehir, Turkey.

Lung cancer with a poor prognosis and lower survival is a worldwide disease often accompanied by family history in around the world. The cases of lung cancer are often caused by long-term exposure to tobacco smoke, a combination of genetic factors and other forms of air pollution. Micro RNAs (miRNAs) are able to suppress the translation of mRNA into protein so have key roles in mechanisms of cancer cells. miRNAs are classified as oncogenic or tumor suppressor miRNAs depending on the functions of their mRNA targets in molecular pathways. It has reported that epigenetic mechanisms, such as DNA methylation and histone modifications, may be affected by this regulation. The miRNA group targeting the epigenetic control components called epi-miRNA. miR-200b-3p and miR-1274a are members of the epi-miRNA family. miR-200b-3p and miR-1274a target, respectively DNMT3a and DNMT3b. We aimed to determine the association of miR-200b-3p and miR-1274a gene expressions in peripheral blood mononuclear cells (PBMCs) with lung cancer. This study included 90 patients with lung cancer and 90 healthy controls. PBMCs were isolated by using Ficoll gradient centrifugation. Total RNA was extracted from these cells, and quantitative Reverse Transcriptase PCR (qRT-PCR) analysis of miR-200b-3p ve miR-1274a was performed as described in a commercial kit manufacturer's instructions. When miR-200b-3p and miR-1274a gene expression levels compared between the groups, both of them were decreased significantly in patients with lung cancer (P<0.05). Our results suggest that miR200b-3p and miR1274a-1 may be tumor suppressors in lung cancer.

Background: Mature lymphoid neoplasms are an extremely heterogenous group of malignancies with regard to biological, clinical and morphological features. The identification of recurrent chromosomal changes has a major impact on the classification of mature lymphoid neoplasms.

Patients and Methods: We investigated 649 patients (354 men, 295 woman, average age 62) with primary mature lymphoid neoplasm in years 2010-2015 of which 68 were examined repeatedly. The conventional cytogenetic analysis (CCA) was performed on bone marrow samples using short time cultivation (24-48 hours) without stimulation. If it was required, interphase fluorescence in situ hybridization (I-FISH) was performed (most often to detect IGH, BCL2 or BCL6 rearrangement).

Results: We cultivated 98 % of samples successfully. Chromosomal aberrations were detected in 20 % of patients analyzed using CCA and I-FISH. CCA revealed chromosomal aberrations in 9 % of patients with negative I-FISH results.

Conclusion/summary: Our comparison with Overview of frequent and diagnostically relevant chromosomal aberrations in mature lymphoid neoplasms (Heim and Mitelman, 2015) will be discussed in the poster. According to our results it is important to combined both cytogenetic methods (CCA and I-FISH) to characterize recurrent chromosomal changes to correct classification of mature lymphoid neoplasms and suggest appropriate therapy.

E-P12.074

Association between Glutathione S-transferase P1 Ile105Val gene polymorphisms and Ann Arbor stage in Lymphoma

G. Crauciuc¹, F. Tripon¹, A. Bogliș¹, C. Duicu^{1,2}, C. Bănescu¹;

¹University of Medicine and Pharmacy Țirgu Mureș, Țirgu Mureș, Romania, ²1st Pediatrics Clinics, Clinical and Emergency Hospital, Țirgu Mureș, Țirgu Mureș, Romania.

Introduction: Glutathione S-transferase (GST) P1, T1, and M1 are phase II enzymes involved in metabolism of chemical carcinogens, drugs and xenobiotics. Because the etiological causes are not entirely known in lymphoma,

we sought a correlation between GST P1, T1 and M1 gene polymorphism according to risk of disease and evolution using Ann Arbor classification.

Material and methods: We enrolled 99 patients with different types of lymphoma and 200 control subjects without a malignancy history. Using PCR technique we determine the presence or absence of this gene.

Results: The average age for patients group is 57.5 ±36.3 and they represent all patients diagnose in the last 10 years in central region of Romania. The distribution of GST P1 Ile105Val genotype in patients group was: 70.7%Ile/Ile, 23.2%Ile/Val and 6.1%Val/Val and for GST T1/M1: 30.3%T1/M1, 38.3%T1/T1, 10%M1/M1 and 21.4%NULL. For control group GST P1 was found in the following percentage: 58.5%Ile/Ile, 33.5Ile/Val and 8%Val/Val, and GST T1/M1 40.5%T1/M1, 41.5%T1/T1, 9.5%M1/M1 and 8.5%NULL. No difference was observed between investigated (p>0.05). We noticed a positive correlation between GST T1/M1 gene polymorphisms and Ann Arbor staging in patients with lymphoma when we compare first stage with other three stage (p=0,022; OR=1.235; 95%IC = 1.026-1.486).

Conclusion: These results suggest that GST T1/M1 and P1 polymorphism may not be considered a risk factor for occurrence of lymphoma, but GST T1/M1 may be involved in disease worsening and the absence of T1 or M1 allele can be correlated with a more advance stage of disease.

E-P12.075

BRAF V600E mutation in malignant melanoma

P. Gurban¹, F. Iordache¹, S. Dinu¹, R. Motoc¹, G. Dinulescu¹, A. Ungureanu², P. Apostol¹;

¹Personal Genetics-Medical Genetics Center, Bucharest, Romania, ²Radiotherapy Center Cluj, Cluj-Napoca, Romania.

A high proportion of human melanoma tumors harbor mutations in BRAF gene, V600E being the most frequent. Recent data confirm that BRAF V600E mutation is associated with significant clinical benefit of using BRAF-specific tyrosine kinase inhibitors.

The aim of our study was to estimate the frequency of BRAF V600E mutation in a study group of 245 patients with melanoma.

DNA was extracted from FFPE tissue samples and was amplified by PCR followed by reverse-hybridization. When detection performed by the above-mentioned method failed, samples were amplified using an in-house PCR followed by Sanger sequencing.

The mean age of the patients was 57 years old. Out of 245 patients (n =136 males and 109 females), 124 patients (50.61%) present the mutation in the BRAF gene. V600E mutation was found in 67 males (49.26 %) and 57 females (52.29%) respectively. From Fischer exact test (0.897) and of X2 square with Yates correction (0.222), no statistical significance (p<0.05) between female patients and male patients with or without the mutation was found.

The identification of mutant BRAF melanoma patients, who can benefit from BRAF-specific tyrosine kinase inhibitors treatment, is a step forward to personalized targeted therapy in metastatic melanoma which leads to improvement of the survival outcomes.

E-P12.076

The prevalence of the C677T polymorphism of methylenetetrahydrofolate reductase in acute lymphoblastic leukemia: A Tunisian experience

R. Frikha;

Laboratory of Histology, Faculty of Medicine of Sfax, Sfax, Tunisia.

Introduction: Methylenetetrahydrofolate reductase (MTHFR) is the key enzyme for folate metabolism wich play in DNA biosynthesis and the epigenetic process of DNA methylation. MTHFR gene polymorphism, mainly the C677T, have been implicated as risk factors for several types of cancers as the acute lymphoblastic leukemia (ALL). In addition, a potential impact of such variant in the efficacy of methotrexate has been reported.

In this study we evaluated the presence of the C677T variant of MTHFR in acute lymphoblastic leukemia patients from Tunisia. To provide new insights for a personalised therapy based on the human genotype.

Materials and Methods: Genomic DNA was extracted from EDTA-anticoagulant blood samples from a total of 35 patients suffering from ALL. Genotyping were carried out with restriction fragment length polymorphism (RFLP).

Results: : The allelic frequency of the C677T variant of MTHFR was 13.6% in ALL patients, with a particular history of relapse and toxicity during methotrexate therapy.

Conclusions: Our findings suggest that C677T polymorphism of MTHFR is common in Tunisian ALL and affect clinical outcome. Thus, we insist that Genotyping of MTHFR polymorphism, C677T particularly, prior to treatment for ALL is likely to be useful in order to personalize therapy and reduce the MTX-related toxicities.

Abnormalities of chromosome 1 in multiple myeloma

M. Stoklasova¹, L. Truhlikova¹, A. Strnkova¹, B. Drevojanekova¹, H. Kucharova¹, A. Burdova¹, T. Sablaturova¹, C. Bodzasova², J. Duras², J. Zuchnicka², H. Plonkova², I. Zygulova², M. Brejcha³, M. Wrobel⁴;

¹Laboratory of Medical Genetics – Department of Cytogenetics, AGEL Research and Training Institute – Novy Jicin Branch, AGEL Laboratories, Novy Jicin, Czech Republic,

²Institute of Clinical Hematology, University Hospital Ostrava, Ostrava, Czech Republic,

³Department of Hematology, Silesian Hospital in Opava, Opava, Czech Republic,

⁴Department of Hematology, Hospital Novy Jicin, Novy Jicin, Czech Republic.

Background: Multiple myeloma (MM) is a B-cell malignancy of the plasma cells characterized by complex cytogenetic aberrations. Chromosome 1 abnormalities are found in almost half of MM cases and are associated with aggressive disease. The most common structural changes that involve chromosome 1 are 1p deletion and 1q gain.

Patients and Methods: Between 2009-2014, 27 MM patients (6 women, 21 men, median age 68) showed chromosomal abnormalities by conventional chromosome banding (CCB). Bone marrow aspirates were processed using short time cultivation (24-48 hours) without stimulation. A minimum of IGH rearrangement and 13q deletion was performed in all cases by cytoplasmic immunoglobulin light chain staining (cIg FISH).

Chromosome 1 abnormalities were confirmed by CCB, cIg-FISH or FISH and multicolor FISH.

Results: Chromosome 1 aberrations were detected in 15/27 patients. Deletions were identified in 11/15 patients: 1p deletions as a result of unbalanced translocation (8/11), 1p interstitial or terminal deletions (2/11) and 1q deletion (1/11). Gains were caused by unbalanced translocation in 10/15 patients: 1q12-qter (5/10), 1q21-qter (3/10), 1q22-qter (1/10) and 1p21-qter (1/10). Trisomy 1 was presented in 1/15 patient. Deletion of 1p as well as gain of 1q were presented in 7/15 karyotypes.

Summary:

The 1p was preferentially involved in deletions that affect regions 1p11 and 1p13. The 1q gains were mostly in regions 1q12-qter and 1q21-qter. The 1q12-q23 region cover a large number of possible candidate genes. Our results support the importance of chromosome 1 abnormalities in the pathogenesis in MM.

E-P12.080

Evaluation of accompanying cytogenetic abnormalities and light chain profiles in 13q deleted MM patients

C. D. Durmaz, T. Tuncali, N. Yürür Kutlay, Ö. Türedi, H. İlgin Ruhi, A. Vicdan, H. G. Karabulut, A. Tükün;

Department of Medical Genetics, Faculty of Medicine, Ankara University, Ankara, Turkey.

Multiple myeloma (MM) is a hematological malignancy due to abnormal plasma cell infiltration in bone marrow. MM is the second most frequent hematologic neoplasm in Caucasians. The median age at onset is 66 years. Two-thirds of the patients have κ-light chain (κ-LC) type whereas the remaining one-third of the patients produces λ-light chain (λ-LC).

121 MM patients (61 men, 60 women, median age at onset 59 years) with del(13)(q) were evaluated for accompanied cytogenetic abnormalities and light chain profiles

In our study 38 patients (31,4%) had isolated del(13)(q) and the remaining 83 patients (68,6%) had additional cytogenetic abnormalities. The most frequent concomitant cytogenetic abnormality was IGH amplification (26,4%). Median survival (MS) was 4,1 years in isolated del(13)(q) group whereas was 2,8 years in the group with additional cytogenetic abnormalities. 60% of the patients' light chain was κ-LC and the MS was 3,6 years. However, the MS was 2,9 years among the λ-LC gammopathy patients (40%). In 34% of κ-LC gammopathy patients had isolated del(13)(q) and the MS was 4,3 years. The remaining patients (66%) had also another abnormalities and MS was 3,2 years. In 42% of λ-LC gammopathy patients had del(13)(q) alone and the MS was 3,8 years. The remaining patients (58%) had also another abnormalities and the MS was 2,2 years.

In our study we observed that MS was lower in λ-LC gammopathy and in the group with additional abnormalities accompanying del(13)(q).

Ph - negative myeloproliferative neoplasm syndrome with acquired trisomy 21- case report

O. Stanca¹, M. Stoian², C. Dobrea², D. Barbu⁴, A. Ciobanu⁴, I. Triantafyllidis¹, N. Berbec¹, G. Petrica-Matei⁵, A. Lupu¹;

¹University of Medicine and Pharmacy „Carol Davila“ , Coltea Clinical Hospital,

Bucharest, Romania, ²Personal Genetics-Medical Genetics Center, Discipline of Medical

Genetics, University of Medicine and Pharmacy “Carol Davila”, Bucharest, Romania,

³OncoTeam Diagnostic, University of Medicine and Pharmacy „Carol Davila“ Bucharest-Fundeni, Bucharest, Romania, ⁴Hematology Department - Coltea Clinical Hospital, Bucharest, Romania, ⁵Personal Genetics-Medical Genetics Center, Bucharest, Romania.

The myelodysplastic/myeloproliferative neoplasms (MDS/MPNs) are a category of entities with intermediate features between myelodysplastic syndromes (MDS) and myeloproliferative neoplasms (MPNs), with clonal proliferation and chronic nature. The molecular pathogenesis of MDS/MPNs is complex and the diagnostic work up requires a full evaluation of clinical and morphologic findings, as well as cytogenetic and molecular analysis. Rare recurrent balanced abnormalities in Ph-negative MPNs involve PDGFRA, PDGFRB and FGFR1 rearrangements or other recurrent secondary abnormalities, such as trisomy 8 and trisomy 21. Acquired trisomy 21 is one of the most common numerical abnormalities in acute myeloblastic leukemia (AML), MDS and MDS/MPNs, but present as sole chromosomal abnormality in only 0,4% of cases.

We report a case of 59-year-old patient who presented with anemia, leukocytosis, splenomegaly. A bone marrow biopsy revealed a MDS/MPNs. An abnormal male karyotype [47,XY,+21[18]/46,XY[12]] with 60% mosaic trisomy 21, was revealed on GTG-banded metaphases obtained from bone marrow aspirate. Molecular testing using Real Time - PCR did not identify any BCR-ABL1 fusion transcripts. Fluorescent in situ hybridization (FISH) analysis using XL PDGFRA Probe (MetaSystems) revealed no arrangement.

This case presents a challenge in terms of diagnosis, evolution and treatment options (cytoreductive therapy, tyrosine kinase inhibitors). Little is known about the pathogenic impact of the acquired trisomy 21 as a sole change in relation to disease type, morphologic subgroup, gender, and age.

Using a multidisciplinary approach, with application of cytogenetic methods and molecular analysis plays an important role in the diagnosis, treatment and prognosis, allowing targeted therapy for the patients.

Identification of the germline mutations of P53, CHEK2 and PTEN genes in non-BRCA1/2 mutation carrier high risk Turkish breast cancer families

E. Manguoglu¹, A. Moballegh¹, M. Ozdogan², C. Arici³;

¹Akdeniz University, Faculty of Medicine, Department of Medical Biology and Genetics,

Antalya, Turkey, ²Antalya Medstar Hospital, Department of Medical Oncology, Antalya,

Turkey, ³Akdeniz University, Faculty of Medicine, Department of General Surgery,

Antalya, Turkey.

Breast cancer is the most common malignancy in Turkey and worldwide. Approximately 5-10% of breast cancers are hereditary. In Turkish population BRCA1/2 mutations compose less than 10% of the hereditary breast cancer. For this reason studying the role of breast cancer susceptibility genes, in addition to BRCA1/2 is necessary. Among different breast cancer susceptibility genes P53, PTEN and CHEK2 are more stressed. In this study, 12 non-BRCA1/2 Turkish patients whose pedigrees are strong were chosen. Genomic DNA samples were isolated from peripheral blood. In P53 and PTEN genes, exons contain mutation hotspots that are exons 2, 3, and 5-8 in PTEN gene and exons 4-9 in P53 gene were amplified by PCR. In the case of CHEK2 gene whole coding exons (1-14) were amplified by PCR. All amplified exons were sequenced by capillary gel electrophoresis and screened for any possible mutation. As a result all of the 12 patients harbor the c.215C>G (p.Pro72Arg) polymorphism in heterozygous state on P53 gene. In 1 out of 12 patients c.638G>A (p.Arg213Gln) mutation in exon 6 of P53 gene was detected in heterozygous state. All patients were found to have heterozygous intronic c.802-4_802-3delTT deletion in PTEN gene. Lastly, in one patient c.470T>C (p.I157T) mutation in the CHEK2 gene was detected in heterozygous state. In conclusion, in Turkish population these mutations may take part in breast cancer predisposition. But specifying their frequency and their amount of influence on breast cancer in Turkish population and on therapy need more studies including more cases and control group.

E-P12.090

The Effect of Propolis on the Cell Proliferation of Human Melanoma Cell Line

N. Duran, G. Gulbol Duran, M. Urhan Kucuk;

Mustafa Kemal University, Hatay, Turkey.

Background and Aim: Propolis is a bee product that contain hundreds of biologically active components in the structure. It has been used for centuries for treatment in folk medicine. It has numerous pharmacological properties such as; antimicrobial, antioxidative, anti-ulserative and anti-tumor activities. We aimed to investigate the existence of antiproliferatives effects of propolis on A375(Human melanoma cell line) cells by epidermal growth factor(EGF) mRNA expression.

Materials and Methods:In study, vero cell line for cytotoxicity test as a control cells and Human melanoma cell line was selected(A375) for the study of anticancer activities were used. Non-cytotoxic concentrations of propolis were determined by the MTT method on Vero cells. Activity studies on A375 cells of propolis were investigated. The evaluation was performed as cell morphology, cell viability and mRNA expression levels. Methotrexate was selected as the standard drug(10 µg/mL).

Results:The cell viability and morphology of both Vero and A375 cells in various concentration were examined. Then non-cytotoxic concentration of propolis was determined up to 100 µg/mL on Vero cells. The growth of A375 cells was significantly suppressed in the presence of 25, 50 and 100 µg/mL of propolis. It was determined that propolis significantly reduce the mRNA expression levels at the concentration of 25, 50 and 100 µg/ml when it is compared with the control group(p<0.001).

Conclusion

In the study, propolis inhibit the proliferation of A375 cells in relation to dose-time and likewise EGF mRNA levels were significantly reduce.We think that propolis may be contain available active components in cancer therapy.

Investigation of Autophagy Gene ATG16L1 Polymorphism in Human Prostate Cancer and Bladder Cancer

S. Budak Diler¹, F. Aybuğça²;

¹University of Niğde, Faculty of Science and Letters, Department of Biotechnology, Niğde, Turkey, ²University of Niğde, Natural and Applied Sciences Institute, Department of Biology, Niğde, Turkey.

Introduction: Urological cancers (prostate cancer and bladder cancers) are the most common cancers in Western population and its rate is increasing in the Eastern World. Autophagy has appeared as a fundamental repair mechanism for degrading damaged organelles and proteins. It was clear that autophagy gene polymorphisms are correlated with development of inflammatory bowel disease and it can also be related with prostate cancer (PCa) or bladder cancer (BCa).

Aim:In this study, we aimed to determine if ATG16L1 (Thr300Ala) polymorphism is associated with an increased risk of developing PCa and BCa and to establish correlations between ATG16L1 genotypes and morphological parameters.

Method: This study included 269 healthy controls and 131 patients (62 PCa and 69 BCa) with PCa and BCa. The ATG16L1 (rs2241880) gene regions were amplified using polymerase chain reaction (PCR), detected by restriction fragment length polymorphism (RFLP).

Results: At the end we found out that the genotype AG was prevalent on patients and controls (34% vs 42%), followed by genotypes AA (35% vs 27%) and GG (31% vs 31%) in PCa. The prevalence of genotypes of AA (wild-type), AG (heterozygous mutant) and GG (homozygous mutant) profiles for the Atg16L1 Thr300Ala polymorphism were 35%, 40% and 25% respectively in BCa patients, and 32%, 40% and 28% respectively in healthy control groups. The G allele frequency was 0.53 for in BCa patients and the control groups.

Conclusion: Any association was not found for ATG16L1 (Thr300Ala) polymorphism between patients with PCa and BCa and control groups in Turkish population.

E-P12.092

Complex genetic testing of colorectal cancer

K. Zavadna¹, J. Markus¹, A. Alemayehu¹, T. Slamka¹, R. Lohajova Behulova², O. Hamidova¹, M. Konecny¹;

¹St. Elisabeth Cancer Institute, Bratislava, Slovakia, ²Institute of Genetics and Molecular Medicine. Faculty of medicine, Slovak Medical University in Bratislava, Bratislava, Slovakia.

Colorectal cancer (CRC) is one of the major causes of morbidity and mortality, representing the second most frequently occurring cancer among females and the third among males.

The presence of the RAS mutations in colorectal cancer patients correlates with lack of response to the certain EGFR inhibitor therapies. We used the SNaPshot analysis to detect somatic mutations in KRAS/NRAS (codons: 12, 13, 59, 61, 117, 146) and BRAF genes (codon 600).

The microsatellite instability (MSI) phenotype represents ~15% of all CRCs and is caused by deficient DNA mismatch repair mechanism (MMR), which is a consequence of germline mutations in MMR genes or epigenetic silencing of the MLH1 gene. We used the MSI analysis for universal colorectal tumor testing: 1. MSI-H status is a marker of favourable prognosis and not benefit from 5-fluorouracil-based adjuvant chemotherapy in stage II. 2. MSI-H status is the hallmark of HNPCC-associated tumors.

Approximately 5-10% of all CRC have hereditary background and the most common is Lynch syndrome (LS). Patients with LS are carriers of a mutation in MMR genes. Identification of a mutation is not only important for a patient, but also for his or hers relatives. We used the standard Sanger sequencing analysis to detect germline mutations in MMR genes. Currently we are using the next generation sequencing approach, we are able to test a panel of 26 genes (Illumina MiSeq).

Our complex approach to genetic testing of patients with colorectal cancer allows us to differentiate patients and provide them with personalized clinical management.

E-P12.093

Two congenital reciprocal translocations in family with hematologic diseases

S. Ransdorfova¹, J. Brezinova¹, Z. Zemanova², I. Sarova¹, H. Lhotska², M. Lauermanova¹, A. Baxová³, M. Valerianova³, K. Michalova^{1,2};

¹Institute of Hematology and Transfusion, Prague 2, Czech Republic, ²Center of Oncocytogenetics, Institute of Medical Biochemistry and Laboratory Diagnostics, General University Hospital and 1st Faculty of Medicine, Charles University, Prague 2, Czech Republic, ³Institute of Biology and Medical Genetics, General University Hospital and 1st Faculty of Medicine, Charles University, Prague 2, Czech Republic.

Acquired balanced chromosomal aberrations are associated with many types of hematologic malignancies leading to critical gene fusions or other gene alterations. However, the role of constitutional chromosomal abnormalities in hematologic malignancies has not been as yet clarified. Here we present an unusual case of two congenital balanced translocations found in members of a family with hematologic diseases.

We examined bone marrow of 58 years old woman with chronic lymphocytic leukemia with conventional and molecular cytogenetic techniques (FISH, mFISH/mBAND, aCGH/SNP). Chromosome analysis showed an abnormal karyotype 46,XX,t(2;12)(q24;q21),der(5)t(5;14)(q12;q31),der(14)inv(q21q31)t(5;14)(q12;q31) in all cells analyzed. Congenital origin of rearrangements was confirmed in peripheral blood lymphocytes. The same karyotype was demonstrated also in a 24-year-old daughter with essential thrombocythemia. Moreover, we examined constitutional karyotype of other two daughters. In 32-year-old woman we found a sole der(5)t(5;14)(q12;q31),der(14)inv(q21q31)t(5;14)(q12;q31), whereas in the 18-year-old one we proved a sole translocation t(2;12)(q24;q21). The involved genes have not been described so far in association with hematologic diseases. All four women have normal phenotype, however they are treated for endogenous depression.

The occasional observation of constitutional chromosomal abnormalities in patients with malignant disease raises a question of their potential role in cancer development. It is unclear whether the constitutional aberrations, especially reciprocal translocation, are a coincidental feature or a predisposing factor in the development of the malignant disease. Therefore, the documentation of more patients with constitutional structural aberrations and hematologic diseases could help to the identification of new specific genes/regions potentially implicated in tumorigenesis.

Association of common variants in luteinizing hormone gene and its receptor with testicular cancer: a Czech pilot study

J. Chrudimska, A. Brisuda, M. Macek jr., M. Macek sr.;

Charles University - 2nd Faculty of Medicine and University Hospital Motol, Prague, Czech Republic.

Introduction: There are two common variants in LHβ subunit gene Trp8Arg (rs1800447) and Ile15Thr (rs34349826) that form together variant β subunit of LH protein (v-LHβ) with higher bioactivity (tests in vitro), but shorter half-life in vivo. In LHCGR gene, there are common polymorphisms with an impact on receptor function - ins18LQ (rs2293275), p.Asn291Ser (rs12470652) and p.Ser312Asn (rs2293275). Testicular cancer (TC) primarily occurs in younger men with hormonal disturbances in testes. Certain polymorphisms in LHCGR and ESR1 genes were associated with a higher risk of TC. The aim of this study was to ascertain the association of selected variants in LHβ and LHCGR genes with the risk of TC.

Materials and Methods: DNA from 35 Czech patients with TC were genotyped using RFLP for detecting v-LHβ, fragment analysis for ins18LQ and TaqMan assays for p.Asn291Ser and p.Ser312Asn variants. Results were compared to 101 unrelated Czech fertile male controls without TC.

Results: The v-LHβ variant protects from developing TC: P=0,08187/ P=0,01901 (for genotype/allelic frequencies, respectively), odds ratio 0,27189 (95% CI 0,06116758-0,8030376). No difference in genotype/allelic

frequency in TC patients and in control men in LHCGR variants: P=0,3795/ P=0,5244 for insLQ; P=0,1583/P=0,1689 for Asn291Ser and P=0,6284/ P=0,7822 for Ser312Asn (P values for genotype/allelic frequencies, respectively).

Conclusions: Although our initial results should be confirmed on a larger sample, presence of v-LHβ allele protects from developing of TC, while no association with variants in LHCGR gene was found.

Supported by FNM00064203, CZ.2.16/3.1.00/24022, LD14073 and NF-CZ11-PDP-3-003-2014.

Thr241Met Polymorphism of XRCC3 Gene is not Associated with Lung Cancer Risk in Romanian Population

A. Catana¹, B. Hancu Domokos², I. Blaga¹, D. Margineanu¹, Z. Cuzmici¹, F. Petrisor¹, R. Popp¹;

¹Department of Medical Genetics, University of Medicine and Pharmacy, Cluj Napoca, Romania, Cluj Napoca, Romania, ²Department of Pneumology, University of Medicine and Pharmacy, Cluj Napoca, Romania, Cluj Napoca, Romania.

Background and Aims: DNA repair mechanisms play a critical role in protecting the cellular genome against carcinogens. X-ray cross-complementing gene 3 (XRCC3), is involved in DNA repair and therefore, certain genetic polymorphisms that occur in DNA repair genes may affect the ability to repair DNA defects and may represent a risk factor in carcinogenesis. The purpose of our study was to investigate the association between XRCC3 gene Thr241Met polymorphism and the risk of lung cancer, in a Romanian population.

Methods: We recruited 93 healthy controls and 85 patients with lung cancer, all smokers Thr241Met, XRCC3 gene genotyping was determined by multiplex PCR-RFLP.

Results: Statistical analysis (OR, recessive model), did not revealed an increased risk for lung cancer, for the variant 241Met allele and Thr241Met genotypes (p=0.138, OR=0.634, CI=0.348-1.157; p=0.023, OR=0.257, CI=0.085-6.824). Also, there were no positive statistical associations between Thr241Met polymorphism of XRCC3 gene, gender and various histopathological tumor type of lung cancer.

Conclusion: In conclusion, the results of the study suggest that the XRCC3 gene Thr241Met polymorphism is not associated with an increased risk for the development of lung cancer in Romanian patients.

E-P12.098

miRNA Expression Testing of Thyroid Fine-Needle Aspirations Could Improve Presurgical Diagnosis

D. Usaite^{1,2}, K. Suziedelis^{1,2}, L. Kunigenas^{1,2};

¹National Cancer Institute, Vilnius, Lithuania, ²Joint Life Science Center, Vilnius University, Vilnius, Lithuania.

Introduction: Discrimination between malignant follicular thyroid cancer (FTC) and benign follicular thyroid adenoma (FTA) is the most difficult aspect of thyroid pathology. Fine needle aspiration cytology (FNAC) has emerged as a successful diagnostic test and has reduced the number of unnecessary thyroidectomies. However, only 30% of patients who are reported as Follicular neoplasm/Suspicious for follicular neoplasm or Suspicious for malignancy by cytopathology and have thyroidectomy or surgical lobectomy, reported as Follicular carcinoma by postsurgical histopathology.

Material and methods: 23 patients' miRNAs were extracted from fine needle aspirations and FFPE biopsies using "miRNeasy Serum/Plasma kit" and "miRNeasy FFPE Kit" accordingly. FFPE and FNA samples were distributed into FTC and FTA. miRNA expression levels in follicular thyroid tumors and adenomas were performed by RT-PCR using miRNome miRNA Custom Assay PCR Array. All data were analysed and compared using qPCR data analysis software.

Results: 13 miRNAs whose expression increased or decreased more than 1,5-fold in in FFPE FTC compared to FFPE FTA were identified. All these selected miRNAs were run and compared in malignant and benign fine needle aspiration samples. The results showed the expression of 3 miRNAs were up- or down- regulated more than 1,5-fold in malignant FNAs.

Discussion: At present accurate presurgical thyroid follicular nodules' diagnosis is not satisfactory. We have found that 3 miRNAs were differentially expressed in FTC compared to benign nodules. Two up-regulated (miR-30a, miR-122) and one down-regulated (miR-93). These data suggest that FTA can be distinguished from FTC by miRNA expression analysis.

E-P12.099

Pharmacogenetic variants in patients with thyroid cancer

Z. A. Hammoudeh¹, D. Nikolova¹, L. Balabanski², S. Ivanov², R. Vazharova^{2,3}, S. Weidner⁴, M. Malinov², D. Toncheva^{1,2};

¹Department of Medical Genetics, Medical University of Sofia - Bulgaria, Sofia, Bulgaria, ²SBALGAR "Malinov", Sofia, Bulgaria, ³Medical Faculty, Sofia University "St. Kliment Ochridski", Sofia, Bulgaria, ⁴Department of Nuclear Medicine Inselspital, Berne University Hospital, Berne, Switzerland.

Introduction: Thyroid cancer is the most common malignancy of endocrine organs. Kinase inhibitors may be used as target therapy of thyroid cancer with mutations in EGFR and RET genes. The effect of pharmacogenetic variants on the chemotherapy of papillary thyroid cancer are not widely studied. Methods: We performed DNA analysis on 10 patients with papillary thyroid cancer. All patients provided a signed written informed consent for examination of their samples. Genomic DNA was extracted from blood samples and was sequenced by NGS instrument (Illumina-MiSeq) using the TruSight cancer panel of 94 genes and 284 SNPs. The results were analyzed using pharngkb database (<https://www.pharngkb.org/>) for SNP variants associated with sensitivity to certain drugs.

Results: Pharmacogenetic variants were found in different genes: ERCC2 (rs13181), ERCC5 (rs17655), TP53 (rs1042522) and XPC (rs2228001). These variants are sensitive to chemotherapy with the platinum compounds (cisplatin). Additional important variants in EGFR (rs227983) and RET (rs1799939) genes were found, which define thyroid cancer as sensitive to target therapy with tyrosine kinase inhibitors such as gefitinib and sunitinib.

Conclusion: Our data shows that cancer panel has future clinical application and could lead to further personalization of treatment. It has the potential to improve the therapy outcome and prognosis for thyroid cancer.

E-P12.101

MOTIEF study: identification of germline MutatiOns linked To urinary bladder cancer In Early-onset patients and Families

A. J. Grotenhuis, S. H. Vermeulen, T. E. Galesloot, R. P. Kuiper, L. A. L. M. Kiemeny; Radboud university medical center, Nijmegen, Netherlands.

Introduction: A positive family history of urinary bladder cancer (UBC) doubles the risk for UBC and suggests a role for germline genetic variants in disease aetiology. Common UBC susceptibility variants were already successfully identified through genome-wide association studies, but little is known about rare genetic variants underlying UBC predisposition. The objective of MOTIEF is to identify high-penetrance germline mutations predisposing for UBC by using a unique series of early-onset patient-parent trios and striking families.

Materials and Methods: This study consists of three parts: 1) recruitment of extremely early-onset (≤30 years) sporadic UBC patients diagnosed since 1989 and their non-affected parents (trios) based on Netherlands Cancer Registry data, and biomaterial collection (blood/tumor) of these trios and 64 known high-risk UBC families; 2) identification of novel candidate UBC-predisposing mutations and genes through whole-genome sequencing (WGS) of germline DNA of stringently selected affected relatives from high-risk families (N~145) and the trios (N~150); 3) substantiation of novel candidate UBC-predisposing genes through high-throughput mutational screening for an anticipated 100 WGS-selected candidate genes using molecular inversion probe (MIP) technology. Also, we will screen collected tumor DNA for second-hit mutations and somatic changes in the selected genes. Finally, validated UBC-predisposing genes will be studied in relation to UBC subtypes.

Expected results: a) The identification of rare, novel, high-penetrance germline mutations predisposing for familial and early-onset UBC and second-hit (somatic) mutations, b) their influence on UBC subtypes, and c) the establishment of an early-onset and familial UBC biobank for future research.

Dutch Cancer Society (KWF)-funded (KUN 2014-6695).

A novel frameshift mutation in Bulgarian patient with von Hippel-Lindau syndrome

M. Glushkova^{1,2}, I. Yordanova^{1,2}, T. Todorov², A. Todorova^{1,2}, V. Mitev¹;

¹Department of Medical Chemistry and Biochemistry, Medical University Sofia, Sofia, Bulgaria, ²Genetic Medico-Diagnostic Laboratory Genica, Sofia, Bulgaria.

Von Hippel-Lindau syndrome (VHL) is an autosomal dominant disease with incidence estimated as 1:36,000 live births. The mean age of diagnosis is 28 years. It is characterized by hemangioblastomas in the central nervous system and/or retina, renal cell carcinomas, pheochromocytomas, pancreatic tumors, endolymphatic sac tumors, epididymal and broad ligament

cystadenomas. In 80% of the cases hemangioblastomas are developed in the brain, while in the rest 20% - in the spinal cord and in some rare cases in the peripheral nerves.

Here we report seven unrelated Bulgarian patients diagnosed as VHL. The genetic testing included direct sequencing and MLPA. In four patients out of 7 (57%) the molecular defect was detected: one small deletion, one point mutation, one nonsense mutation and one novel frameshift mutation, which is indel.

The patient with a novel frameshift indel is 27 years old woman with clinical characteristics of hydrocephalus, perifocal edema of the brainstem and cerebellar vermis. The doctors suggested that the tumor formation in fourth ventricle is probable ependymoma or hemangiopericytoma. Tumor formations in other part of patient's body are absent. The detected novel molecular defect in exon 3 of the VHL gene is a complex indel c.[516_517insAGTCAAGCCT; 532_542delCTGGACATCGTinsATTG], p.Glu173Serfs*4. The possible mechanism for mutation generation involves the genetic architecture of the neighboring area rich in repeated elements.

The genetic testing provides the possibility for adequate genetic counseling and prenatal diagnostics in affected families.

The study was supported by Medical University Sofia, Project №251/2016

XPF -673C>T and XPF 11985A>G gene polymorphisms and risk of chronic myeloid leukemia

C. Banescu, V. G. Moldovan, F. Tripon, A. G. Crauciuc, C. Duicu, A. Boglis, M. Dobreanu; University of Medicine and Pharmacy Tg. Mures, Romania, Tg. Mures, Romania.

Xeroderma pigmentosum group F (XPF) genes are implicated in nucleotide excision repair (NER) system, one of the most important DNA repair system. Polymorphisms of this genes may influence the capacity of DNA repair system and therefore may predispose to malignancy, including leukemia. We performed a case-control study to investigate the relation between XPF -673C>T, XPF 11985A>G and chronic myeloid leukemia (CML) in a Romanian population. We investigated 82 adult CML patients which were Ph1 / BCR-ABL positive and 170 subjects with no history of cancer. We found no association between several prognostic factors such as blasts, basophils, additional chromosomal abnormalities and XPF -673C>T, XPF 11985A>G polymorphisms in our CML cohort. No differences were found when we examined the distribution of variant genotypes of XPF gene polymorphisms according to EUTOS score. We also looked whether there was any relation between investigated XPG polymorphisms and treatment, but no association was noticed. According to our data XPF -673C>T and XPF 11985A>G do not represent risk factors for development of CML. We consider that further study on a larger CML cohort is required to validate our observations.

De Nova 18p Deletion Syndrome that Diagnosed at Seven Years Old Boy

S. Canbek¹, A. Ayaz¹, T. Celik²;

¹Adana Numune Training and Research Hospital, Clinical Genetics Department, Adana, Turkey, ²Adana Numune Training and Research Hospital, Pediatric Neurology Department, Adana, Turkey.

Introduction: The deletion 18p syndrome is one of the most common chromosome abnormalities including variously phenotypic properties. Mental retardation, failure to thrive, round face, dysplastic ears, wide mouth and anomaly of teeth, eye, brain, heart and genital system are mostly seen clinical features. We herein report seven years old boy with dysmorphic face features, mild mental retardation, dental developmental deficiency.

Materials and Methods: Chromosome analyses and array comparative genomic hybridization (array-CGH) analyses have done. Results: Patient has diagnosed as 18p deletion syndrome by peripheral chromosome analysis. The karyotypes of the child and her parents were subjected to G-banding chromosome analysis, and array comparative genomic hybridization (array-CGH) was used for fine mapping of the aberrant region. His parental chromosome analysis were normal. Array CGH has identified a 18,4 Mb deletion at 18p11.22 region.

Conclusion: This case reported for genotype-phenotype correlations.

E-P13.02

A Case: mild clinical signs with tetrasomy 9p

B. Eroglu Kesim¹, K. Yararbaş^{2,3}, S. Kasakyan², K. Yüksek Acinikli⁴; ¹Sisli Etfal Research Hospital, İstanbul, Turkey, ²Duzen Laboratories Groups, İstanbul, Turkey, ³Maltepe University, İstanbul, Turkey, ⁴Bahçelievler Government Hospital, İstanbul, Turkey.

Tetrasomy 9p, or supernumerary isochromosome 9p [i(9p)], is a rare chromosome abnormality resulting from a supernumerary isochromosome 9p. The tetrasomy 9p phenotype varies in severity from neonatal death to mild developmental delay and minor anomalies. Abnormal genitalia were also complicated in 56% of male case, and 38% of female case. The phenotypic variability of T9p is largely unexplained. It has been suggested that the severity of the phenotype might be related to the degree of mosaicism. The influence of breakpoints position on the severity of phenotype is controversial. Our The patient, a 6 year-old girl, was child of consanguineous healthy parents. Delivery was at 41 weeks of gestation with a birth weight 3150 g, birth length 50cm, and head circumference 33cm. She had imperforate hymen. She has prominent forehead, short philtrum, downslanting corners of the mouth, micrognathia, low-set ears, incomplect cleft lip, abnormal enamel and Cardiac ECHO showed slightly mitral failure.

The patient's karyotype was 47,XX,+der 9 [90]/ 46,XX, [10]. FISH studies of lymphocytes were performed to confirm the origin of this isochromosome, using the whole chromosome 9-specific painting probe (WCP9) and the result was compatible with isochromosome 9p. We performed molecular karyotyping and patient's result was 47, XX, idic (9) (q13), arr[hg19]9p24.3q13(612,166-68,283,133)x4.

Our case has mild clinical signs, despite the high level of mosaicism and 9q13 breakpoint.

E-P13.03

Antagonistic effect of oxytocin and tacrolimus combination on adipose tissue-derived mesenchymal stem cells

B. Goker¹, G. Sir², G. Yigiturk³, T. Cavusoglu^{3,4}, C. Biray Avci¹, C. Gunduz¹, Y. Uyanikgil^{2,3,4};

¹Department of Medical Biology, School of Medicine, Ege University, Bornova, Izmir, Turkey, ²Department of Stem Cell, Institute of Health Science, Ege University, Bornova, Izmir, Turkey, ³Department of Histology and Embryology, Faculty of Medicine, Ege University, Bornova, Izmir, Turkey, ⁴Cord blood, Cell -Tissue Research and Application Center, Ege University, Bornova, Izmir, Turkey.

Introduction: In this study we aimed to eliminate the negative effects of tacrolimus (immunosuppressive drug) on adipose tissue-derived mesenchymal stem cells (AT-MSC) by using an antioxidant agent oxytocin.

Material-Method: AT-MSC cell line was obtained commercially and 5th passage of the original line was obtained. To evaluate the cytotoxic effects of tacrolimus and oxytocin on AT-MSC, WST-1 test was applied. Also Isobologram analyses were conducted to evaluate combinational effects of tacrolimus and oxytocin. After calculating the IC₅₀ values of tacrolimus and oxytocin and combination indexes, determined doses were given to cells and apoptosis analyses were conducted in 24th, 48th and 72nd period. Study groups were tested using Muse Cell Analyzer with Muse[®] Annexin V and Dead Cell Assay Kit for determining viability, apoptosis and death cell numbers. Immunofluorescence staining of Ki67 proliferation and vimentin stem cell marker in untreated AT-MSC cell line. AT-MSCs treated with IC₅₀ values of tacrolimus, oxytocin and the combination of both for 96 hours. Nuclear staining was visualized using DAPI.

Results: IC₅₀ values for oxytocin and tacrolimus were 17.44µM and 13.43µM, respectively. Combination indexes of Isobologram analysis revealed that the two agents were antagonistic. Ki67 immunopositivity of tacrolimus group significantly lower compared with negative control group but tacrolimus-oxytocin combination group similar to negative control group. Ki67 immunopositivity of oxytocin group significantly higher than the other groups. Vimentin immunopositivity of oxytocin group significantly lower than the other groups.

Conclusion: The results clearly points out that, oxytocin could be used to eliminate the cytotoxicity caused by tacrolimus.

E-P13.04

Investigation of the PTPN22 gene polymorphism in alopecia areata

S. D. Celik¹, O. Ates¹, N. Bozkurt¹, S. Sezer¹, E. Ensari¹, G. Kalkan²;

¹Department of Medical Biology, Medical Faculty, Gaziosmanpaşa University, Tokat, Turkey, TOKAT, Turkey, ²Department of Dermatology, Medical Faculty, Yıldırım Beyazıt University, Ankara, Turkey, TOKAT, Turkey.

Introduction: Alopecia areata (AA) is a common, chronic, inflammatory disease that characterized by various size and shapes of hair loss lesions on the scalp and/or body. However the cause of AA is not entirely understood in present, it is considered to be a T-lymphocyte mediated autoimmune disease. The protein tyrosine phosphatase, non-receptor type 22 (PTPN22) have important roles in the physiology of hair follicle is a gene. The PTPN22

gene encodes a lymphoid protein tyrosine phosphatase (LYP) which acts as a negative regulator of T cell signaling. The impaired function of PTPN22 in T cells may induce the production of autoantibodies and leading to development of autoimmune diseases. The aim of our study was to investigate the effect of PTPN22 C1858T polymorphism on the predisposition to AA.

Materials and Methods: The present study analyzed the genotype distribution and allele frequency for the C1858T polymorphism using the polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP) technique in 190 AA patients and 161 healthy individuals.

Results: The genotype and allele distribution of PTPN22 C1858T polymorphism have not been associated with AA ($p=0.055$ and $p=0.057$, respectively). The homozygous TT genotype was not identified in the AA patients and control groups.

Conclusions: The results do not support the hypothesis that the C1858T (R620W) polymorphism of the PTPN22 gene is an important risk factor for AA. This study was supported by Gaziosmanpaşa University Scientific Research Projects Fund.

Rare chromosomal aberrations in Iranian patients with Aplastic Anemia

B. Sadeghi^{1,2}, V. Yassaee^{1,3}, Z. Ravesh¹, M. Aghighi Rad¹, M. Ekrami¹, P. Gholami¹;

¹Genomic Research Center, Shahid Beheshti University of Medical Sciences, Tehran, Iran, Islamic Republic of, ²shahid beheshti university, Tehran, Iran, Islamic Republic of, ³Dept. of Medical Genetic, Faculty of Medicine, Shahid Beheshti University of Medical Sciences, Tehran, Iran, Islamic Republic of.

Aplastic anemia is a rare blood disease with poor prognosis. It is difficult to distinguish from myelodysplastic syndrome using conventional laboratory blood tests. Bone marrow cytogenetic studies may have an advantage for discriminating the former from the later one.

During the past five years, we examined bone marrow and blood specimens derived from over 300 blood cancer patients. Here, we report three cases with rare chromosomal aberrations.

A 27 years old female presented with thrombocytopenia, pancytopenia and her chromosomal analysis showed 46 XX and 47, XX, + 21 for blood and bone marrow respectively.

A 25 years old female manifested initial diagnosis of anaplastic lymphoma and pancytopenia. Cytogenetic study revealed 46 XX for blood and 46,XX,t(1;2)(p21.1;p12)[18]/46,XX,t(2;8;11)(p22;p23.2;q24.2)[14]/46,XX,t(4;8)(p32;q24.3)[4]/46,XX,t(13;18)(q11.2~q13:p11.3)[8] for bone marrow.

A 30 years old man with pancytopenia was clinically diagnosed for acute leukemia. Chromosomal analysis revealed 46 XX for blood and 46 XY, t(6;9)(p23;q33) in bone marrow.

None of the above cases showed any pattern of chromosome abnormality as observed in Fanconi Anemia. In this case karyotyping is beneficial for considering the best possible treatment. This approach substantially ignores the necessity of bone marrow transplantation.

Our results accentuate the advantages of cytogenetic studies of bone marrow specimens over peripheral blood of leukemia patients. An efficient diagnostic plan is paramount because time from diagnosis to treatment is critically related to outcome regardless of the elected therapeutic option.

Chromosomal Microarray Analysis (CMA) and Fluorescence In-Situ Hybridization (FISH) revealed a rare case of de novo deleted and duplicated segments of 6q25.1->q26 in an infant presented with motor delay, dysmorphic features and enlarged cisterna magna

M. L. Tan, H. J. Ee, R. S. Roch, H. Y. Yon, S. A. C. Ling, L. T. Toh, M. S. Brett, H. Y. Law, S. S.

Jamuar, M. H. Yong, A. H. M. Lai;

KK Women's And Children's Hospital, Singapore, Singapore.

Introduction: Interstitial deletions with duplications of the long arm of chromosome 6 are rare. We report an infant with motor delay, dysmorphic features, hypotonia and enlarged cisterna magna with both deletion and duplication segments in 6q25->q26.

Materials and Methods: CMA was performed on the proband using Agilent Technologies 4x180K SurePrint G3 Human CGH+SNP Platform and Cyto-genomics 2.5 software. High resolution G-banding was carried out on stimulated lymphocytes cultures. Targeted FISH was done using RP11-43B19, RP11-1112G6 and RP11-455114 BAC probes. Parental FISH and chromosome analysis were also performed.

Results: CMA on the proband revealed a pathogenic loss of 3.11Mb at 6q25.3 (hg19:157,261,472-160,368,328). This deletion affects 16 OMIM including *ARID1B*, *SEREC1*, *GTF1H5*, *SOD2* and *ACAT2*. CMA also showed a

loss of 0.48Mb at 6q25.3q26 (hg19:160,800,432-161,284,434) and a gain of 3.75Mb at 6q25.1q25.3 (hg19:152,046,289-155,794,132), which are of uncertain clinical significance. Chromosome analysis showed a female karyotype with a derivative chromosome 6 resulting from a deletion of 6q25.3->q26 and a duplication of 6q25.1->q25.3. Metaphase FISH with RP11-43B19 and RP11-1112G6 showed deleted signals while RP11-455114 showed duplicated signals on the same derivative 6. No apparent abnormality was found in both parents.

Conclusions: Interstitial deletions in 6q25 have been associated with microcephaly, developmental delay, dysmorphic features, hearing loss and agenesis of the corpus callosum. However, the clinical significance of the 0.484Mb loss and 3.74Mb gain are unclear. This case demonstrated the usefulness of FISH and karyotyping in elucidating the complex chromosomal rearrangement. FISH is also a cost-effective way to determine if the abnormality is inherited.

E-P13.07

Complex chromosomal rearrangement in a patient with periconceptional exposure to ionizing radiation

M. A. Orera, C. Rodríguez Hernandez, B. Marquez Arce, M. Moreno Domene, M. Prieto, R. Herranz Crespo;

Hospital Gregorio Marañón, Madrid, Spain.

Introduction: Ionizing radiation (IR) generates cellular damage through the interaction with DNA where the energy transfer induces structural breaks. The nonhomologous DNA end joining repair can originate chromosomal stable translocations. Periconceptional exposure to high dose of IR usually results in abortion, and lower doses, could be related to development of congenital malformations.

Materials and Methods. We present a 28 years old patient, born in Romania in 1986, 800 Km from Chernobyl. She has hypernasal speech and mild dyspraxia. She has had three spontaneous abortions before the 6th gestational week. Parents are non related. Her father has been diagnosed of hairy cell leukaemia, BRAF positive at 53 years of age.

Results: The peripheral blood karyotype revealed a complex chromosome rearrangement that required six double strand breaks: 46,XX, inv(1)(q23;q32);

del(2)(q33-q35);der(18)der(14),t(2;18;14)[18pter-q21.3::2q32-q35::14q23-qter] (14pter-q23::18q21-qter). Array CGH at 60K resolution was normal, showing no gain or losses. The mother has an inversion in the log arm of on chromosome 1, and her father's karyotype is normal. FISH based genomic translocations frequency adjusted for her individual characteristics, once the constitutional translocations are excluded, is normal.

Conclusions. The patient was conceived in the aftermath of the Chernobyl nuclear accident. Her peripheral blood shows chromosomal rearrangement, which points to a single event occurring early in the development. The probability of the appearance of the rearrangement due to three independent events is 4.2×10^{-12} . In addition, her father has a rare form of leukaemia that has been also related to exposure of ionizing radiation.

E-P13.08

Cytogenetically visible copy number variations (CG-CNVs) in banding and molecular cytogenetics of human; about heteromorphisms and euchromatic variants

T. Liehr;

(1) Jena University Hospital, Friedrich Schiller University, Institute of Human Genetics, Jena, Germany.

Copy number variations (CNVs) having no (obvious) clinical effects have been rediscovered as major part of human genome in 2004. However, for every cytogeneticist microscopically visible harmless CNVs (CG-CNVs) are well known since decades. Harmless CG-CNVs can be present as heterochromatic or even as euchromatic variants in clinically healthy persons. Here I provide a review on what is known today on the still too little studied harmless human CG-CNVs, point out which can be mixed up with clinically relevant pathological CG-CNVs and shortly discuss that the artificial separation of euchromatic submicroscopic CNVs (MG-CNVs) and euchromatic CG-CNVs is no longer timely. Overall, neither so-called harmless heterochromatic nor so-called harmless euchromatic CG-CNVs are considered enough in evaluation of routine cytogenetic analysis and reporting. This holds especially true when bearing in mind the so-called two-hit model suggesting that combination of per se harmless CNVs may lead to clinical aberrations if they are present together in one patient.

E-P13.12

Mixed gonadal dysgenesis: cytogenetic and phenotypic findings of two cases with ambiguous genitalia

E. Gokpinar¹, C. D. Durmaz², Z. Siklar², M. Berberoglu², H. Ilgin-Ruhi²;
¹Ankara University Medical Faculty, Department of Medical Genetics, Ankara, Turkey,
²Ankara University Medical Faculty, Department of Pediatric Endocrinology, Ankara, Turkey.

Mixed gonadal dysgenesis (MGD) is a sex chromosome disorder of sexual development that typically has a mosaic 45,X/46,XY karyotype, with a wide clinical spectrum from Turner-like phenotype to male with infertility. Here, we present two MGD cases that were born with ambiguous genitalia, announced as male. First case was two months old, had 2.3 cm phallus, bifid scrotum, chorda and perineoscrotal hypospadias. Only, left gonad was palpable, and ultrasound showed right inguinal hernia and atrophic right gonad. Karyotype analysis showed 45,X/46,XY mosaicism. We examined peripheral blood and buccal smear cells by interphase FISH for the evaluation of mosaicism. The rate of 45, X was high, 85% and 64%, respectively. Second case was seven months old, had no palpable gonads with 2 cm phallus and one urethral hiatus. Uterus and hypochoic gonadal structure on the left were shown with USG, but right gonad was not seen. He also had the bicuspid aortic valve. Karyotype analysis was mos 45,X/47,XXY, 95% and 5%, respectively. FISH on buccal smear cells (BSC) and urine sediment (USC) cells were performed to assess mosaicism. Three clones were found in both tissues; X/XXY/XY (93%/4%/3% in BSC and 82%/16%/2% in USC). Patients with MGD require multidisciplinary approach for gender assessment and assignment. Our patients were decided to be raised as males.

Reference: Öcal, Gönül, et al. „The clinical and genetic heterogeneity of mixed gonadal dysgenesis: does “disorders of sexual development (DSD)” classification based on new Chicago consensus cover all sex chromosome DSD?” European journal of pediatrics 171.10 (2012): 1497-1502.

E-P13.14

Rare chromosomal aberrations in Iranian patients with Recurrent Pregnancy Loss

V. Yassaeei^{1,2}, S. Kamalbeigi¹, B. Sadeghi¹, F. Hashemi-Gorji¹, S. Hosseini¹, S. Karimi¹;
¹Genomic Research Center, Shahid Beheshti University of Medical Sciences, Tehran, Iran, Islamic Republic of,
²Dept. of Medical Genetic, Faculty of Medicine, Shahid Beheshti University of Medical Sciences, Tehran, Iran, Islamic Republic of.

There are many factors contributing to Recurrent Pregnancy Loss (RPL). Some cases are diagnosable, preventive and curable; in many cases etiology remains unknown.

We examined blood specimens derived from over 200 couples diagnosed with RPL who referred to our center for genetic testing during 2012 to 2014. Here, we report three RPL cases with negative family history of RPL, normal clinical examination, normal Thrombophilic genetic testing, normal Hormonal and Spermogram analysis and rare chromosomal aberrations.

A non-consanguineous couple (female 37 and male 39 years old) with history of RPL, presented to our center. The female experienced four time abortion, three unsuccessful IVF and two unproductive IUI. Cytogenetic study ascertained 46,XY,t(1;9)(q11;q11) and 46, XX, normal female. These chromosomal regions have significant impact on zygote formation as well as recurrent abortions. In addition, this result has not been previously reported in any couple with recurrent abortions.

A consanguineous couple (female 34 and male 34 years old) with a history of three time first trimester abortion were investigated. Cytogenetic study identified 46,XY,t(6;18)(q16;q11) and 46, XX, normal female.

A non-consanguineous couple (female 34 and male 33 years old) with a history of four time first trimester abortion were examined. Cytogenetic study discovered 46,XX,t(5;19)(p12;p12) and 46, XY, normal male.

Our results suggest that chromosomal abnormalities could be one of the most important causes of RPL. Therefore, cytogenetic study of couples who suffer from recurrent abortion may prevent unnecessary treatment in which chromosomal aberration is the main cause of the disease.

E-P13.17

Familial X chromosome translocation, Xq triplication and SHOX gene deletion with short stature;Conflicting results of QF-PCR analysis for Xq segmental triplication

F. Silan, M. Urfali, O. Yildiz, B. Paksoy, A. Uludag, O. Ozdemir;
 Department of Medical Genetics, Canakkale, Turkey.

Objective: SHOX gene deletions cause short stature and related Leri Weill dyschondrosteosis(LWD), Turner syndrome, and disproportionate short stature (DSS)(3-15%). Proband and daughter with SHOX gene deletion which referred for short stature. We aimed to present SHOX gene deletion

with Xq triplication.

Methods: Double blind automated GTG banded karyotype analyses were made from mother and her daughter and diagnosed same translocation. SHOX gene deletion was determined with FISH (Euroclone). QF-PCR (An-eufast) and MLPA(P245, MRCHolland) techniques were used for identification of the the long arm of X chromosome.

Results: 46,XX,trp(X)(q11.2qter)(Xqter→Xq111.2::Xp22.32→Xqter) karyotype and SHOX deletion was detected both proband and daughter. Grandparents have no derivated X chromosome, so it was proved de novo translocation and SHOX gene deletion at proband and inherited to daughter. QF PCR shows different ratios for same duplicated region at mother and daughter, DXS8377 marker (Xq28) shows 2.10: 1 ratio at mother and 1.33:1 at daughter.

MLPA shows MECP2 (Xq28) triplication but none of the cases have neurological symptoms.

Conclusions: SHOX gene mutations is related with short stature and made-lung like deformity (wrist pain, deviation of radius, cubitus valgus). Proband has also recurrent pregnancy loss. Habituel abortion can be caused by inter-chromosomal effect of Xq translocation. Male lethality can be possible if only translocated X chromosome inherited from male fetus, because contiguous gene deletions near SHOX gene is also possible. Cut off level for triplications is 1.7:1 at QF PCR but our proband shows 2.10:1 and second case shows 1.33:1 ratio for same triplicated region.

Molecular characterization of AIPL1 gene region in the Iranian population: Application of new informative haplotypes

A. Karimi Moghadam, S. Vallian;
 University of Isfahan, Isfahan, Iran, Islamic Republic of.

Leber's congenital amaurosis (LCA) is considered as one of the main causes of congenital blindness. In view of the genetically heterogeneous nature of the disease, indirect diagnosis using comprehensive linkage analysis has proven to be useful in molecular diagnosis procedure. Mutations in AIPL1 gene are one of the leading causes of LCA. In the present study, the application of three single nucleotide polymorphic (SNP) markers related to this region, including rs7212734, rs11658369 and rs8066853 was evaluated for the first time in the Iranian population. The markers were genotyped using tetra-primer ARMS PCR in 154 unrelated healthy individuals. Haplotype frequency and other characteristics of the markers were examined by using the GENEPOP and PowerMarker software. The data indicated the presence of 6 different haplotypes in the Iranian population. Among them, three haplotypes showed highly informative with frequencies ≥ 0.05 . Among the informative haplotypes, T-A-A haplotype showed linkage to W278X mutation. Prenatal diagnosis using the markers led to the successful prediction of the fetus genotypes in the all at risk pregnancies and showed that T-A-A haplotype (rs7212734/ rs11658369 / rs8066853) could be considered as informative haplotype for linkage analysis in carrier detection and molecular diagnosis of LCA in the Iranian population.

E-P14.03

Determining and Managing Fetal Radiation Dose from Diagnostic Radiology Procedures in Turkey

M. Demir, I. Cavdar, A. Tuten, H. Ulucan, S. Mehmet;
 Istanbul University, Istanbul, Turkey.

Objective: We intended to calculate approximate fetal doses in pregnant women who underwent diagnostic radiology procedures and to evaluate the safety of their pregnancies.

Materials and Methods: Fetal radiation exposure was calculated for 304 cases in 218 pregnant women with gestational ages ranging from 5 days to 19 weeks, 2 days. FetDose software (ver. 4.0) was used in fetal dose calculations for radiographic and computed tomography (CT) procedures. The body was divided into three zones according to distance from the fetus. The first zone consisted of the head area, the lower extremities below the knee, and the upper extremities; the second consisted of the cervicothoracic region and upper thighs; and the third consisted of the abdominopelvic area. Fetal doses from radiologic procedures between zones were compared using the Kruskal-Wallis test and a Bonferroni-corrected Mann-Whitney U-test.

Results: The average fetal doses from radiography and CT in the first zone were 0.05 ± 0.01 mGy and 0.81 ± 0.04 mGy, respectively; 0.21 ± 0.05 mGy and 1.77 ± 0.22 mGy, respectively, in the second zone; and 6.42 ± 0.82 mGy

and 22.94 ± 1.28 mGy, respectively, in the third zone ($p < 0.001$). Our results showed that fetal radiation exposures in our group of pregnant women did not reach the level (50 mGy) that is known to increase risk for congenital anomalies.

Conclusion: Fetal radiation exposure in the diagnostic radiology procedures in our study did not reach risk levels that might have indicated abortion.

E-P14.04

Evaluating engraftment success by determining the proportion of donor and recipient interphase cells present in sex-mismatched bone marrow transplantation

L. Malee, V. Korkiatsakul, P. Phornsaruyth, T. Chareonsirisuthigul, B. Rerkamnuaychoke; Human Genetics Laboratory, Department of Pathology, Faculty of Medicine Ramathibodi Hospital, Mahidol University, Bangkok, Thailand.

Introduction: Bone marrow transplantation (BMT) continues to be an important treatment for patients with malignant hematologic disorders and thalassemia. The assessment of chimerism, the ratio of donor to recipient cells, is important for monitoring the engraftment of donor cells and determining the recurrence of the original disease after BMT. The aim of this study is to monitor the proportion of host and recipient cells in sex-mismatched BMT using interphase fluorescence in situ hybridization (FISH).

Materials and Methods: A total of 856 bone marrow or peripheral blood specimens were received from 170 BMT patients which were HLA-matched or partially mismatched, but had sex-mismatched donors at Ramathibodi hospital between January 2011 and December 2015. Interphase FISH analysis using dual color X/Y probes with 500 interphase nuclei were scored. Results: A total of 170 cases were diagnosed as malignant hematologic disorders (n=147), thalassemia (n=15), anemia (n=3) and others, such as Gaucher disease, neuroblastoma, adrenoleukodystrophy (n=5). These patients were divided into three age groups (1 to 20, 21 to 40 and 41 to 60 years). Patients from 1 to 20 age group had the most completed chimerism in post-BMT (123 of 137 cases, 89.78%). However, patients aged over 40 years old had the lowest complete chimerism (6 of 14 cases, 42.68%).

Conclusions: Our results suggest that young age group has the highest successful rate of BMT. FISH studies can be used to detect chimerism for XX and XY cells for evaluating successful engraftment post-BMT status.

E-P14.05

Evaluating critical performance factors between three different instruments for HRM genotyping assays

L. Papazisi, L. Jiang, R. W. Weick, F. Somanji, Z. Kabir, J. J. Huuskonen, I. T. Knight; Canon U.S. Life Sciences, Inc., Rockville, MD, United States.

Introduction: PCR followed by high-resolution melting (HRM) is a fast, reliable, and inexpensive method to perform DNA genotyping. Multiple manufacturers have added HRM capabilities to their thermocyclers. The HRM-based Novallele™ genotyping assays (Canon BioMedical) for research were developed using the CFX384 Touch™ (Bio-Rad). Our data demonstrate that carefully designed and optimized HRM assays are easily transferred between different thermocyclers, expanding the utility of these assays and HRM analysis as a method.

Materials and methods: We compared the performance of six small amplicon and six unlabeled probe Novallele genotyping assays using three different HRM-enabled thermocyclers. Assay performance, including PCR robustness and genotyping reliability, was determined for the CFX384 Touch, LightCycler® 480 (Roche) and Rotor-Gene® Q (QIAGEN®) instruments. Both genomic DNA and synthetic constructs were tested, and the data were analyzed using the HRM analysis software for each respective instrument.

Results: All 12 assays were able to detect mutations using the different instruments. The PCR amplification and melting temperature difference between the normal and mutated amplicons was maintained across the instruments. For four of the assays, minor optimization of either an annealing temperature by $\leq 1.5^\circ\text{C}$ or a change of cycle number by +5 cycles resulted in slightly improved performance. Most importantly, reliable genotyping was achieved for these assays using a wide range of starting material, approximately 6-60 ng.

Conclusion: Novallele genotyping assays perform robustly using different HRM-enabled thermocyclers, which demonstrates the successful assay design. With no or minimal optimization for each instrument, the assays can reliably genotype various targets.

E-P14.07

Efficiency of NimbleGen-based target capture for small gene panels

M. Belenikin^{1,2,3}, T. Meshcheryakova⁴, S. Zhilina⁴, G. Mutovin¹; ¹Pirogov Russian National Research Medical University, Moscow, Russian Federation, ²Lomonosov Moscow State University, Moscow, Russian Federation, ³Gamaleya Research Institute of Epidemiology and Microbiology, Moscow, Russian Federation, ⁴Research Center for Children Medical Care, Moscow, Russian Federation.

Background: Choice of target-enrichment strategy for NGS is important for design of target panels and results of sequencing. The aims of study: Testing and analysis of NimbleGen-based gene capture strategy for use with small gene panels. Methods: NimbleGen SeqCap system for targeted genomic enrichment (2-stage hybridization procedure for effective work with gene panels of small size). Results: The designed gene panel covers 34 genes (total size of exon regions ~100K bp); distribution of genes on the chromosomes was as follows: one gene is located on every chromosomes 1, 3-8, 12-15, 18, 20; two genes are located on every chromosomes 9, 11, 16; three genes are located on chromosome 19, six genes are located on every chromosomes 2 and X. We sequenced 100 samples; during every runs we studied up to 12 samples. A number of reads (454 GSJunior), relating to every chromosomes after sequencing were as follows (are listed only four mostly covered chromosomes): 28.5-49.3% on chromosome 2 (we vary a number of experimental parameters), 7.6-15.7% on chromosome 9, 5.9-12% on chromosome X, 3-7.6% on chromosome 16. Conclusions: Owing to features of NimbleGen probe design NimbleGen target-enrichment strategy is not optimal for the design of small gene panels (total size of exon regions ~100K bp), especially for genes with very different numbers of exons. So, for small gene panels the using of other target-enrichment strategies producing more uniform probe coverage is more suitable.

E-P14.08

WAVE/DHPLC technology as a promising platform for diagnostics of diseases with distinct clinical manifestation caused by contiguous genes

A. N. Voitovich¹, I. Kirsanov¹, T. Urzhumtseva¹, V. Larionova², K. Isaeva¹; ¹Academy of Molecular Medicine, Saint-Petersburg, Russian Federation, ²Center For Rare Diseases and Molecular medicine „IEM“ RAS, Saint-Petersburg, Russian Federation.

Neurofibromatosis (NF) and polycystic kidney disease are the most common autosomal dominant genetic disorders, with a frequency of 1: 3500 and 1:400 newborns respectively. Both of them are readily recognizable by clinical and clinical instrumental methods. For example, the gene of neurofibromin encompasses 61 exons. 50% of the mutations occur de novo. Problems of detection of the mutations in NF1 gene are caused by its large size, a lack of the major mutation in European populations, as well as by an interference with pseudogenes with alike structure but not function.

The modern methods developed for genetic diseases diagnostics may have different diagnostic and economic value at every particular case. The "Gold Standard" of the genetic diagnosis, ie Sanger sequencing, does not meet modern criteria of high-technology, time-, labor-, and cost-consuming method. To improve its performance, some supportive technology are in use, such as pre-mutation screening methods for selection only those samples in which the mutation is detected.

WAVE technology of mutation screening by denaturing high-pressure chromatography (DHPLC) takes the advantage of exome sequencing and NGS technologies. Exome sequencing does not allow for detection of all mutations in contiguous genes while producing an odd information difficult to be interpreted properly both legally and ethically. NGS being currently expensive itself, requires specialists experienced in bioinformatics. Moreover, all findings detected using that technologies must be verified by Sanger method. WAVE technology is the most appropriate for testing contiguous genes and may be recommended to insurance companies for looking closely at.

E-P14.09

Lack of amplification in next generation sequencing? Check for deletions

R. Bayramov, M. Ensar Doğan, M. Cerrah Güneş, K. Korkmaz Bayramov, Y. Ada, Ç. Saatçi, Y. Özkuş, **M. Dündar**; Erciyes University, Kayseri, Turkey.

Introduction: Modern methods such as Next-Generation Sequencing, leave us face to face with big data that needs specialized interpretation. In some cases, there can be a unique set of circumstances that demand unusual strategy.

Materials and Methods: Blood samples were collected into tubes containing EDTA, from the 31 male patients attended department of Medical Genetics at Erciyes University with a preliminary diagnosis of Duchenne Muscular

Dystrophy. DMD gene next generation sequence analysis was performed by using Illumina MiSeq platform after DNA isolation.

Results: Analysis of 21 patients revealed nonpathogenic variants, in 3 patient c.5637 C>A, c.4455 C>T, and c.10699 C>T hemizygous nonsense mutation variants were observed. But in 10 samples for some exons, the lack of amplification were detected. For this phenomenon, there can be several explanations. But first we decided to check for deletions by Multiplex Ligation-dependent Probe Amplification method. In the exactly same exons deletions were determined in all samples (100%). Because of a small number of cases we obtained differently but similar results described in the literature which is 90%-95%.

Conclusions: In interpretation of this experience we can say that in male patients during sequence analysis of X-linked dominant diseases such as X-Linked Hypophosphatemia, Rett syndrome, Aicardi syndrome and X-linked recessive diseases such as Hemophilia A, B, X-linked ichthyosis, X-linked agammaglobulinemia and etc. diseases which has in etiopathogenesis sequence changes and deletions in responsible genes, lack of amplification should be considered as a deletion and confirmed by adequate methods.

E-P14.10

Five years of experience from the new technological units in the Hospital Sant Pau: nucleic acid extraction and sequencing.

E. Martínez-Sánchez¹, S. Quero¹, M. Baena², M. Garí³, A. Lasa^{2,3};

¹Laboratorios. Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, ²Genetic Department. Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, ³U-705, CIBERER, Barcelona, Spain.

INTRODUCTION

Since 2011, the laboratories of the Hospital de la Santa Creu i Sant Pau have incorporated two new technological units which are available to scientists from our hospital. The aim of this project is to provide scientists with infrastructure to effectively carry out molecular diagnostic tests. Currently the core facilities are oriented on these areas: automatic nucleic acid extraction, capillary and Next Generation sequencing (NGS).

MATERIAL AND METHODS

Each technological unit has the following equipment:

- DNA extraction area: Autopure (Qiagen), Magpure (Roche)
- Sequencing area: MiSeq (Illumina) for massively parallel sequencing, and the 3500Dx and 3500XL Dx Genetic Analyzer (Applied Biosystems) for capillary sequencing.

The laboratory technician performs sample collection, preparation and manipulation procedures according to Standard Operating Procedures.

RESULTS

The following table shows the number of processed samples in both areas

Year	Results		
	DNA extraction (n° samples)	Capillary sequencing (n° samples)	NGS sequencing (n° samples)
2011	4063	38262	0
2012	5217	44032	0
2013	4228	36041	0
2014	4732	29908	366
2015	4786	28729	1280

CONCLUSIONS

The core facility described here, is a centralized, shared resource that provides clinic and laboratory investigators services and expert consultation. Next generation sequencing analysis approach allowed us to study more genes with a significant cost saving and a higher sequencing accuracy. We have also obtained a shorter turnaround time allowing a quicker molecular diagnosis and covering the demand of clinicians and patients.

E-P14.11

Benefit of using a commercial kit for prenatal non invasive testing : fetal RHD genotyping with kit jacques boy

E. Guinchard, S. Monnier, C. Marthinet;

EFS Rhône-Alpes site de Lyon-GHE, 69677 BRON Cedex, France.

Background: fetal RHD genotyping is an innovative and non-invasive method to assess the risk of fetuse's hemolytic disease of anti-D allo-immunized pregnant woman.

Patient/method: the commercial kit J Boy® for genotyping has been tested in the laboratory of Lyon-GHE: exon 5, 7, and 10 are amplified real time by PCR using TAQMan technology.

A maize's DNA is included as internal control.

The most important parameters of the method (both sensibility and the specificity) have been tested, checked and verified: the negative predictive value, detection of new variant forms of the RHD gene. Genotyping results of

pregnant women have been compared with RH1 phenotype at birth. The correlation study has allowed to establish the interpretation criteria. The residual risk analysis has allowed to understand the actual limitation of the method due to the low concentration of fetal DNA in the maternal plasma and to define criteria of biological interpretation: the negative result must be confirmed by getting the same result on another sample a few weeks later.

Conclusion:

This commercial kit very easy to use but several samples must be analysed simultaneously to reduce the unit cost for each test.

E-P14.12

Performance of the Agilent D5000 and High Sensitivity D5000 ScreenTape Assays for the Agilent 4200 TapeStation System

R. Nitsche¹, L. Prieto-Lafuente², C. MacDonald², E. Brown²;

¹Agilent Technologies, Waldbronn, Germany, ²Agilent Technologies, Edinburgh, United Kingdom.

The new Agilent 4200 TapeStation system provides automated, fast, and reliable DNA and RNA electrophoresis for up to 96 samples using prepackaged reagents and minimal manual handling. The Agilent D5000 ScreenTape and High Sensitivity D5000 ScreenTape assays have been developed for the separation and analysis of DNA fragments from 100 bp to 5,000 bp, a size range that complements and resides between the Agilent D1000

ScreenTape and the Genomic DNA ScreenTape assays. The 4200 TapeStation system

and the DNA ScreenTape assays can be used at several steps of the Next Generation Sequencing (NGS) workflow. With the emergence of methodologies, such as the use of Transposomes, NGS library sizes are tending to increase beyond 1,000 bp, even for the short-read NGS technologies. This Poster focuses on the performance of both D5000 ScreenTape assays with respect to the accuracy and precision of quantification and sizing, as well as the sensitivity of these assays. Data analysis for quantification and molarity determination was compared against the corresponding assay for the Agilent 2100 Bioanalyzer system. Additionally, performance of both the D5000 and High Sensitivity D5000 assays on the 4200 TapeStation was compared to the 2200 TapeStation system.

E-P14.13

Use of saliva and salivary DNA for comprehensive genotyping based on RealFast and StripAssays

A. Bernat, B. Hauser, C. Oberkanins, H. Puehringer;

ViennaLab Diagnostics, Vienna, Austria.

Nucleic acids extracted from blood are the most common sample types used in molecular genetic diagnostics. Blood is an abundant and reliable specimen, yielding high amounts of DNA and RNA with homogenous quality. Since drawing blood is an invasive procedure, and DNA extraction is time consuming and requires special equipment, salivary DNA and saliva direct-to-PCR represent promising alternative approaches in clinical diagnostics. Saliva is considered to represent an ultra-filtrate of blood, and thus contains in abundance a huge variety of diagnostically valuable molecules. Apart from being known to contain polymerase chain reaction (PCR) inhibitors, saliva is mucous and inhomogenous and thus often difficult to handle. Moreover, its human DNA content is by far lower compared to blood. Here we examined blood-derived DNA, salivary DNA and saliva direct-to-PCR to carry out reliable genotyping based on single-plex RealFast and multi-plex StripAssays for up to 22 mutations. Our data suggest that saliva collected and stored in dedicated devices is suitable to be used for isolating ample amounts of high-quality DNA, but also for direct-to-PCR approaches towards comprehensive molecular diagnostics.

E-P14.14

Evaluating the association of IL2RA and CTLA4 genes polymorphisms with type I diabetes mellitus in children of the northwest of Iran

M. Ranjouri¹, P. Aob¹, M. Saberi², A. Ramezani¹;

¹Zanjan University of Medical Science, Zanjan, Iran, Islamic Republic of, ²Tehran University of Medical Science, Tehran, Iran, Islamic Republic of.

Introduction: Type-1 diabetes (T1D) is caused by autoimmune-mediated destruction of insulin-secreting cells, and a variety of genetic predisposing and environmental factors are known to influence its pathogenesis. The aim of this study was to investigate the association of CTLA4 and IL2RA polymorphisms with type 1 diabetes in children of northwest of Iran.

Material and Methods: total genomic DNA was extracted by salting-out from

peripheral blood of 50 T1D patients and 50 controls. PCR and direct sequencing were used for genotyping CTLA4 (exon1) and IL2RA (intron1) genes in patients and controls.

Results: the frequency of G allele and GG genotype of the CTLA-4 (+49A/G) polymorphism in patients were significantly different from that of controls (26% vs. 11%, $p = 0.006$). Moreover, the allele frequency of the new SNP identified in exon1 of CTLA4 was significantly different was between patients and controls (14% vs. 3%, $p = 0.006$). These results suggest that the GG genotype of +49 A/G is associated with hyperglycemia in the patients ($p = 0.0067$). However, no Significant difference was observed in the frequency of IL2RA (ss52580101C/A) polymorphism between patients and controls (2% vs. 4%, $p = 0.41$).

Conclusions: The results support the association of T1D and CTLA4 +49 A/G SNP in the studied population. However, no significant relationship between IL2RA ss52580101C/A polymorphism and T1D was observed.

E-P15.06

CYP2D6 allele distribution among Macedonian, Albanian and Romani population living in the Republic of Macedonia

M. Kuzmanovska, M. Dimiskovska, I. Maleva Kostovska, P. Noveski, E. Sukarova Stefanovska, D. Plaseska-Karanfilska; Research Center for Genetic Engineering and Biotechnology "Georgi D. Efreinov", Macedonian Academy of Sciences and Arts, Skopje, Macedonia, The Former Yugoslav Republic of.

Cytochrome P450 2D6 (CYP2D6) is an enzyme of great importance for the metabolism of clinically used drugs. The CYP2D6 gene is highly polymorphic and has the most variations among the CYP450 gene superfamily, with more than 100 variants identified so far.

The aim of this study was to investigate the allele distribution of CYP2D6 variants in the Macedonian, Albanian and Romani population. A total of 300 unrelated individuals, 100 individuals from each ethnic group, were genotyped using long range PCR and multiplex single base extension (SNaPshot) method.

The most frequent variants and equally distributed in the three analyzed ethnic groups were the fully functional alleles *1 and *2. The most common non functional allele in all ethnic groups was *4, which reached the highest frequency among Albanians (22.5%) and the most common allele with decreased activity was *41, which was more frequent among Romani (23%) when compared to Macedonians (11%, $p=0.002$) and Albanians (10.5%, $p=0.0012$).

Among Albanians the percentage of poor metabolizers was 7%, 6% among Romani and 4% among Macedonians. Higher percentage of ultrarapid metabolizers (UMs) was observed among Macedonians (5%), when compared to the Albanians and Romani (1% in each group).

In conclusion, our study showed that CYP2D6 gene locus is highly heterogeneous in the three examined ethnic groups. The prevalence of CYP2D6 allelic variants and genotypes in Macedonia is in accordance with the other European populations.

E-P15.08

Cytochrome P450 2D6 (CYP2D6) polymorphisms in the drug abused postmortem subjects from South Turkey

S. Kocaturk-Seil¹, N. Daglioglu², P. Efeoglu Ozseker², H. Oksuz¹, A. Eren³, M. Gulmen², H. Luleyap¹, M. Yilmaz¹;

¹University of Cukurova Faculty of Medicine, Department of Medical Biology, Adana, Turkey, ²University of Cukurova Faculty of Medicine, Department of Forensic Medicine, Adana, Turkey, ³Council of Forensic Medicine, Adana, Turkey.

Introduction: Most patient populations show large inter-individual variability with respect to drug response and toxicity. This variation can be of physiological, pathophysiological, environmental or genetic origin. Cytochrome P450 2D6 (CYP2D6) has high relevance in drug metabolism. CYP2D6 is involved in the metabolism of 20-25% of clinically used drugs and exhibits a clinically relevant gene polymorphism that modifies the pharmacokinetics of nearly 10% of all drugs. Opiate addiction is one of the most important issues of drug dependence in the forensic toxicology in the world. Most of drug over dose related deaths are caused by opioids such as morphine, codeine, dextromethorphan, ethylmorphine and tramadol. Interestingly, an opiate addict with impaired CYP2D6 enzyme may show unexpected adverse drug reactions towards regular doses compared to controls due to poor metabolism of drugs.

Materials and Methods: In this study, polymorphisms of drug abused post-mortem samples and respected controls; CYP2D6*3 (n=38), CYP2D6*4 (n=49), and CYP2D6*6 (n=48) single nucleotide polymorphisms (SNPs) have analyzed with TagMan drug metabolism genotyping assay kit by Real-Time PCR.

Results: The genotype frequencies of CYP2D6*3, CYP2D6*4 and CYP2D6*6 yielded no significant results for both post mortem subjects compared to control groups.

Conclusion: Between people with different ethnic backgrounds the pattern of CYP2D6 polymorphisms and phenotypes differs dramatically. Although we did not obtain a significant result from our data, such studies should be done with larger sample sizes.

This study has been supported by Cukurova Research Fund (Adana, Turkey).

Pharmacogenetics as a complementary tool of medication therapy management to improve patient's outcomes

M. P. Ribate, L. Sáez-Benito, N. Berenguer, A. Sáez-Benito, C. B. García; San Jorge University, Villanueva de Gállego, Spain.

INTRODUCTION: At present a high percentage of the pharmacological treatments do not reach the wished benefits, due to the generation of adverse effects or to the lack of effectiveness. This occurs especially in polypharmacy patients. Medication Therapy Management services and pharmacogenetic approach can help to solve and prevent these problems.

MATERIALS AND METHODS: We present two kidney-transplanted males treated with Tacrolimus as immunosuppressant therapy and with Omeprazole as gastrointestinal prevention. Analyzing results of Medication Therapy Management services, one of them (patient 1) showed fluctuating Tacrolimus levels, gastrointestinal complications and muscular pain. The existence of an interaction between both drugs was suspected.

The principal genes involved in the transport and metabolism of these drugs are ABCB1, CYP3A4, CYP3A5, CYP2C19 and POR, and were studied by PCR-RFLP.

RESULTS: Genotyping results are shown in the table.

A change in antiacid therapy was proposed as solution (substitution of Omeprazole for Rabeprazole), for which there is evidence of lower incidence in its metabolism profile.

CONCLUSIONS: Pharmacogenetics and Medication Therapy Management services are raising fields that are becoming essential in the pharmaceutical area. Both of them seek to improve drug therapies effectiveness and toxicological effects. The substitution of Omeprazole for Rabeprazole stabilized plasmatic concentrations of Tacrolimus and decreased adverse effects in the patient.

VKORC1 and CYP2C9 genotypes in patients with pulmonary thromboembolism

A. Zamani¹, A. G. Zamani², S. Yosunkaya¹, M. S. Yildirim²;

¹Necmettin Erbakan University, Meram Medical Faculty, Department of Pulmonary Diseases, Konya, Turkey, ²Necmettin Erbakan University, Meram Medical Faculty, Department of Medical Genetics, Konya, Turkey.

Background: Warfarin is the most widely used anticoagulant with a narrow therapeutic index. The activity and metabolism of warfarin are regulated by vitamin K epoxide reductase complex subunit 1 (VKORC1) and cytochrome P450-2C9 (CYP2C9) genes. Genetic variability of warfarin dosing has been attributed to polymorphisms in these genes.

Objective: To investigate the impact of genetic factors on warfarin dosage requirement in patients with pulmonary thromboembolism (PTE) at the Pulmonary Diseases Department.

Methods: The VKORC1 G1639A, C1173T and CYP2C9(*1/*2/*3) allelic variants were identified by using real time-PCR in 17 (8 males and 9 females) patients with PTE.

Results: Only 4 patients were found to be normal for VKORC1 mutations, while 3 of them were heterozygous and one was compound heterozygous for CYP2C9. Eight of the remaining 13 patients were homozygous and the other 5 were compound heterozygous for both mutations. CYP2C9 gene was found normal in 4 patients(*1*1), heterozygous mutant in 9 patients(*1*3), compound heterozygous in 2 patients(*2*3) and homozygous mutant in 2 patients(*3*3). There were no wild-type genotype for mutations in both genes of patients. Warfarin dose was adjusted based on genetic testing results of the patients.

Conclusion: VKORC1 and CYP2C9 genotypes can be used to help determine the optimal starting dose of warfarin for patients with PTE. Warfarin dose management should be personalized on the basis of a patient's genetic profile.

Influence of genetic polymorphisms in the anti-TB drug-induced hepatotoxicity in an indigenous and non-indigenous population from Brazil

V. M. Zembrzski¹, D. R. Andrade², K. T. S. Moraes², M. M. Heinrich¹, R. L. F. Teixeira¹, P. H. C. Acero¹, G. M. Cunha¹, R. Souza-Santos¹, J. H. R. Croda³, P. C. Basta¹;

¹Oswaldo Cruz Foundation, Rio de Janeiro, Brazil, ²Universidade do Grande Rio, Duque de Caxias, Brazil, ³Oswaldo Cruz Foundation, Campo Grande, Brazil.

Introduction: First-line anti-tuberculosis (TB) drugs are responsible for the occurrence of several adverse drug reactions (ADR). Hepatotoxicity is one of most serious ADR and appears soon in the beginning of treatment. Although already known the main mechanisms involved in the development of hepatotoxicity, in Brazil this field is little explored, especially in vulnerable populations. Therefore, the objective of this study was to estimate the incidence

of hepatotoxicity during TB treatment and investigate the associations with genetic polymorphisms, clinical and epidemiological factors, comparing indigenous and non-indigenous patients.

Material and Methods: Clinical and epidemiological variables, serum levels of liver enzymes and polymorphisms of the genes NAT2, CYP2E1 and GSTM1 were investigated. Non-conditional logistic regression was used to identify factors associated to hepatotoxicity. Odds ratio was used as association measure.

Results: The incidence of hepatotoxicity was 19.7% for all patients, being 50% more frequent in indigenous (p=0.055). We identified 10 SNPs previously described and, in indigenous, one new nonsynonymous SNP of NAT2. 54.6% of patients expressed slow acetylation phenotype profile. The frequency of null genotype of GSTM1 was higher in non-indigenous (p=0.002) while no significant differences in relation to polymorphism of CYP2E1 were observed between the groups. Hepatotoxicity was associated to patients older than 60 years old and indigenous (OR=26.0; 95%CI:3.1-217.6; OR=3.8; 95%CI:1.3-11.1, respectively). Furthermore, hepatotoxicity was associated to slow acetylation profile in indigenous patients (OR=10.7; 95%CI:1.2-97.2).

Conclusions: Our findings reinforce the importance of develop personalized therapeutic schemes in order to avoid unfavorable outcomes.

E-P15.15

Distribution of allelic and genotypic frequencies of NAT2 and CYP2E1 variants in Moroccan population

S. Guoua^{1,2}, I. Ratbi¹, F. Laarabi², S. Elalouai Chafai¹, I. Cherkaoui Jaouad¹, A. Barkat³, A. Sebiani^{1,2};

¹Centre de génomique humaine, Faculté de médecine et de pharmacie, Mohammed V University in Rabat, Morocco, Rabat, Morocco, ²Institut National d'hygiène, Rabat, Morocco, ³faculty of medicine and pharmacy rabat, Rabat, Morocco.

Background: Several pathogenesis and genetic factors influence predisposition to antituberculosis drug-induced hepatotoxicity (ATDH) especially for isoniazid (INH). However, the major susceptibility genes for ATDH are N-acetyltransferase 2 (NAT2) and cytochrome P450 2E1 (CYP2E1). NAT2 gene determines the individual's acetylator status (fast, intermediate or slow) to metabolize drugs and xenobiotics, while CYP2E1 c1/c1 genotype carriers had an increased risk of ATDH.

Polymorphisms of the NAT2 and CYP2E1 genes vary remarkably among the populations of different ethnic origins.

The aim of this study was to determine, for the first time, the frequency of slow acetylators in Moroccan population by genotyping of NAT2 gene variants and determining the genotype c1/c1 for CYP2E1 gene, in order to predict adverse effects of Tuberculosis treatment, particularly hepatotoxicity.

Results: The frequencies of specific NAT2 alleles were 53%, 25%, 2% and 4% for NAT2*5, NAT2*6, NAT2*7 and NAT2*14

respectively among 163 Moroccan studied group. Genotyping of CYP2E1 gene, by real-time polymerase chain reaction using TaqMan probes, revealed frequencies of 98.5% for c1/c1 and 1.5% for c1/c2 among 130 Moroccan studied group.

Conclusion: The most prevalent genotypes of NAT2 gene in Moroccans are those which encode slow acetylation phenotype (72.39%), leading to a high risk of ATDH. Most Moroccans are homozygous for c1 allele of CYP2E1 gene which aggravates hepatotoxicity in slow acetylators.

This genetic background should be taken into account in determining the minimum dose of INH needed to treat Moroccan TB patients, in order to decrease adverse effects.

E-P15.16

The Impact Of CYP2C9, VKORC1, ORM1, CYP4F2, GGCX, MDR1 Gene Polymorphisms On Warfarin Dosage

H. Akar¹, L. Dinç Asarçıklı², Y. Tunca¹;

¹Gulhane Medical Military Academy, Ankara, Turkey, ²Dişkapi Yıldırım Beyazıt Training and Research Hospital, Ankara, Turkey.

Introduction: Warfarin is a widely used anticoagulant that shows a high inter-individual variability in the dose needed to achieve target anticoagulation. The main objective of this study was to identify the genetic and the environmental factors on the variabilities in warfarin dose requirements.

Methods : CYP2C9 (rs1057910, rs 1799853), VKORC1 (rs 9923231, rs 9934438), ORM1 (rs 17650) , CYP4F2 (rs 2108622), GGCX (rs2592551), MDR1 (rs1045642) polymorphisms were studied by hybridization probes in 235 patients from Turkey who had stable doses and international normalized ratios of 2-3 at their last three consecutive visits.

Results: Patients' age, weight, and height were associated with warfarin maintenance dose. VKORC1-G1639A mt and heterozygote genotype was

associated with a higher maintenance dose compared to those with the wild genotype (41.13mg/week vs.31.32mg/week). VKORC1-C1173T wild genotype was associated with a higher maintenance dose compared to those with mutant and heterozygote genotype (42,79/week vs.30,78/week). CYP2C9 *3 CC variant was related to lower warfarin dose (12,70 mg/week) requirement compared to AA genotype (35,93 mg/week). CYP2C9 *2 CC variant was related to higher warfarin dose (35,93 mg/week) requirement compared to TT genotype (32,12 mg/week). ORM1 GG variant was related to lower warfarin dose (27,76 mg/week) requirement compared to AA genotype (37,27 mg/week). There was no difference in warfarin doses with GGX, MDR1 and CYP4F2 variants. Conclusion: Age and CYP2C9*3, ORM1, VKORC1 were the most significant determinants of warfarin dosage in this preliminary study including Turkish patients.

E-P17 Epigenetics and Gene Regulation

E-P17.01

Analysis of epigenetic changes in apoptotic mechanism triggered by caffeic acid phenethyl ester (CAPE) and DNA methyl transferase inhibitor (DNMTi) zebularine in MDA-MB-231 breast cancer cell line

O. Eroglu, E. Guvenir Celik, M. Celen, E. Karacoban; Bilecik Şeyh Edebali University, Faculty of Science and Letters, Department of Molecular Biology and Genetics, Bilecik, Turkey.

High dose chemotherapeutic drugs used in cancer treatment researches may have cytotoxic effects. In this study, cytotoxic effects of the drugs were annihilated by the combined use of caffeic acid phenethyl ester (CAPE) and DNA methyl transferase inhibitor (Zebularine). Then, the regulation of genes related to apoptotic pathway in breast cancer was studied epigenetically. MDA-MB-231 breast cancer cell line was grown by culturing of cells. Drug doses were determined by MTT assay. Survival assays showed that the drugs decrease the cell viability. Colony sizes created by the cells were examined by colony formation assay and soft agar colony formation assay and found out that drugs prevent the cell growth. DNA was isolated from cells which were drugged, then bisulphite modification was made and state of methylation of TP53, caspase-9, caspase-8 and caspase-3 genes were analysed by Methylation Specific PCR (MSP). Methylation changes in the aforesaid genes gave significant results. Data obtained in consequence of MSP, in comparison with the control group, methylation changes observed at TP53 50% unmethylation ($p < 0.05$), caspase-9 70% unmethylation ($p < 0.001$), caspase-8 60% unmethylation ($p < 0.01$), and at caspase-3 60% unmethylation ($p < 0.01$).

As a result of the findings, it can be stated that cytotoxic effects disappeared after the combined therapy of Zebularin - CAPE. In the study, epigenetically significant results were obtained in the stimulation of the apoptosis through caspases by unmethylating the genes in relation of apoptosis. The findings are highly important in terms of annihilation of the cytotoxic effects through combined therapy and the fight against cancer

E-P17.02

Analysis of the effect of Zebularine on caspase-3, caspase-8 and caspase-9 in SKBR3 breast cancer cell line

O. Eroglu, M. Celen, E. Guvenir Celik; Bilecik Şeyh Edebali University, Faculty of Science and Letters, Department of Molecular Biology and Genetics, Bilecik, Turkey.

DNMT inhibitor nucleotide analogues can reorganize the expression of the genes related to apoptosis and tumour suppressor genes which are silenced by methylation. Thus, it can trigger apoptosis formation in tumour cell. Zebularine which is DNA methyl transferase inhibitor (cytidine analogue) is one of these agents. This study aimed to analyse the effects of zebularine in SKBR3 breast cancer cell line on cytotoxic and apoptotic mechanism and it is important in the sense that it is the first study on the issue in the literature. SKBR3 cell line used in the study is grown at DMEM medium. In order to evaluate the effects of Zebularine on cytotoxicity, cell viability, cell growth, MTT assay, cell survival assay, soft agar colony formation assay, wound healing assay were done respectively. At the same time, in order to understand the effects on apoptotic mechanism, Methylation Sensitive High Resolution Melting (MS-HRM) was done for the methylation analysis of caspase-3, caspase-8 and caspase-9 genes after bisulphite transformation.

As a result of the findings, it is observed that Zebularine considerably decimates the cell viability and growth ($p < 0,001$). However, Zebularine shows cytotoxic effect after 24 hours. At the same time, Zebularine causes significant change on methylation in caspase-3 ($p < 0,001$), caspase-8 ($p < 0,01$)

and caspase-9 ($p < 0,001$) genes in SKBR3 cells. These results support that Zebularine can be a new anticancer agent in epigenetic therapies in breast cancer cells.

E-P17.03

Association of HPV infection and cervical dysplasia progression with DNA methylation of genes, connected to cellular stress and oncogenesis

M. Koprinarova¹, S. Kovachev², I. Dimitrov³, D. Nikolova⁴, Z. Hammoudeh⁴, A. Todorova⁵, I. Dimova⁶;

¹Institute of Molecular biology, Bulgarian Academy of Sciences, Sofia, Bulgaria, ²Gynecology Unit, Military Medical Academy, Sofia, Bulgaria, ³SAGBAL "Dr Shterev", Sofia, Bulgaria, ⁴Department of Medical genetics, Medical University Sofia, Sofia, Bulgaria, ⁵Department of Chemistry and Biochemistry, Medical University Sofia, Sofia, Bulgaria.

Cervical cancer is tightly connected to HPV infection, but it is not yet elucidated why some of infected cases progress to cancer, but others not. Our aim was to study the role of DNA methylation in this process by analyzing HPV-infected cervical tissues from different PAP groups.

We measured unmethylated and hypermethylated fraction in promoters of 22 genes, connected to cellular stress and toxicity by real-time PCR in three groups: (i) 10 HPV positive PAP I/II cervical samples; (ii) 10 HPV positive PAP III/IV cervical samples; (iii) 10 healthy blood donors.

Overall, there was an increased average hypermethylated fraction (Fhm) for all investigated genes in cervical groups compared to controls. The highly methylated genes were DNJC15 (Fhm 31% and 32% vs 0.6% in controls), BRCA1 (29% and 13% vs. 0.8%), Tp53 (19.5% and 19.2% vs 0.8%), Gpx3 (13% and 16% vs 1.3%), ATM (11% and 15% vs 0.7%), CSTB (11% and 13% vs 0.3%) and Prdx2 (11.7% and 11.6% vs 0.5%). Comparison between high grade and low grade lesions found an increase in Fhm of more than 1.5 times for the genes Msh2 (3 times), Rara (2.1 times), Gadd45G (1.7 times), SCARA3 (1.6 times) and Mlh1 (1.5 times).

We suggest an association between HPV infection and hypermethylation (inactivation) of important tumor-suppressor genes and genes, connected to cellular stress. Dysplasia continues to progress along with further hypermethylation (inactivation) of the mismatch repair genes and genes connected to inflammation response and oxidative stress protection.

E-P17.06

DNA methylation levels in formalin induced orofacial pain

E. Abzianidze^{1,2}, E. Kvaratskhelia¹, T. Tkemaladze¹, G. Gurtskaia², N. Tsiklauri², M. Nebieridze², L. Nozadze², M. Tsagareli²;

¹Tbilisi State Medical University, Dept. of Molecular and Medical Genetics, Tbilisi, Georgia, ²IvaneBeritashvili Centre of Experimental Biomedicine, Dept of Pain and Analgesia, Tbilisi, Georgia.

Introduction: The aim of the present study was to evaluate the changes of a subset of DNA methyltransferases and global DNA methylation level in the anterior cingulate cortex (ACC) and the trigeminal ganglia (TG) neurons in formalin induced orofacial pain.

Materials and Methods: Adult rats were injected with 50 μ L of 2.5% v/v formalin subcutaneously into upper lip and consequent facial grooming behavior was monitored. All animal studies conformed to the Guidelines of International Association for the study of Pain regarding investigations. The levels of DNMT1, DNMT3a and DNMT3b were measured in nuclear extracts of the ACC and the TG neurons using DNMTs assay kits (Abcam); Genomic DNA was isolated from ACC and TG neurons using DNA isolation universal kit (Zymo Research) and Global DNA methylation was measured using the Methylated DNA Quantification Kit (abcam) in 1,5 hours after formalin injection.

Results: The 5-methylcytosine levels in rat genomic DNA obtained from the TG and the ACC neurons were decreased in the study group compared with the control group. No significant differences in global methylation level between the TG and the ACC were observed. In addition, DNMT3a and DNMT3b were overexpressed in nuclear extracts of the TG and the ACC neurons from rats with formalin induced pain compared with control sample, whereas slight increase in DNMT1 levels was detected in study group.

Conclusions: The results demonstrate that changes in global DNA methylation are correlated with DNMT3a/b levels and these epigenetic mechanisms may be involved in the development and continuation of chronic pain.

E-P17.08

Intimate Partner Violence and Post Traumatic Stress Disorder: looking for epigenetic markers associated to violence against women

S. F. M. Gaudi¹, A. A. Piccinini², E. Longo¹, A. Pitidis¹, A. Kustermann², D. A. Coviello³, C. Baldo⁴, P. Cremonesi⁵, S. Polidoro⁵;

¹Italian National Institute of Health, Roma, Italy, ²University of Milan, Milan, Italy, ³E. O. Galliera, Genoa, Italy, ⁴E.O. Galliera, Genoa, Italy, ⁵Hugef, Turin, Italy.

Introduction: violence against women is a relevant health and social problem. The interactions between genome/epigenome and environmental factors, such as Intimate Partner Violence, represent one of the major challenges in molecular medicine. The major focus of our research project, epi-REVAMP (from the Latin REpellere Vulnera Ad Mulierem et Puerum), is the characterization of the epigenetic profile of women that experienced IPV, and the identification of epigenetic biomarkers that are able to distinguish between women at high and low risk to develop Post Traumatic Stress Disorder.

Materials and Methods: we expect to study 600 subjects/year in the SINICA-IDB (Security in Domestic Environment National surveillance Project) surveillance. DNA and RNA samples will be collected in a cohort of 200 women who suffered violence and 400 matched controls of women who did not. The epigenome will be analysed using the array Infinium HumanMethylation450 BeadChip (Illumina, USA). The study protocol has been reviewed and approved by the Ethics Committee of the Italian National Institute of Health.

Results: both early detection of post-traumatic distress and the identification of epigenomic factors are the fundamental scope of this research which is focused on the resilience or not resilience to PTSD. This innovative approach represents a shift in the understanding of genetics from a gene-centric view to the phenotypic plasticity of a given genotype producing different phenotypes in response to different environmental conditions, allowing future targeted psychological and pharmacological therapies.

Interaction of prenatal maternal stress and a polygenic risk score for transcriptome response on methylation in cord blood: results from the PREDO study

D. Czamara¹, S. Iurato¹, J. Arloth¹, J. Lahti², K. Raikkönen², E. Kajantie^{3,4,5}, P. Villa⁶, H. Laivuori^{7,8}, E. Hämäläinen⁹, E. Binder¹;

¹Department of Translational Research in Psychiatry, Max-Planck-Institute of Psychiatry, Munich, Germany, ²Faculty of Behavioural Sciences, Institute of Behavioural Sciences, University of Helsinki, Helsinki, Finland, ³National Institute for Health and Welfare, Helsinki, Finland, ⁴Children's Hospital, Helsinki University Central Hospital and University of Helsinki, Helsinki, Finland, ⁵PEDEGO Research Unit, MRC Oulu, Oulu University Hospital and University of Oulu, Oulu, Finland, ⁶Obstetrics and Gynecology, University of Helsinki and Helsinki University Hospital, Helsinki, Finland, ⁷Medical and Clinical Genetics, University of Helsinki and Helsinki University Hospital, Helsinki, Finland, ⁸Institute for Molecular Medicine Finland, University of Helsinki, Helsinki, Finland, ⁹HUSLAB and Department of Clinical Chemistry, Helsinki University, Helsinki, Finland.

Introduction: It has been shown that prenatal maternal stress can have high impact on the child's development and health. These prenatal environmental conditions can often be tracked down in the child's epigenome, e.g. changing the child's methylation profile.

Materials and Methods: The PREDO study is a cohort follow-up study of Finnish pregnant women with and without risk factors for pre-eclampsia. Within these study cord blood samples of 996 children and for a subsample also placenta and mothers' DNA samples have been collected. Different metabolic and psychiatric phenotypes were assessed for the mothers including type 1 diabetes, hypertension, BMI, anxiety and depression rating scales. 996 cord blood samples were genotyped using the Illumina OmniExpress-Exome Array and DNA methylation levels were assessed using the Infinium HumanMethylation450 BeadChip.

We focused on the polygenic risk score derived from Arloth et al. (1) who showed that SNPs that alter the initial transcriptome response to glucocorticoid receptor activation also increase the risk for stress-related psychiatric disorders.

We ran an interaction analysis between this risk score and maternal stress on methylation.

Results: analysis is still ongoing at the moment of abstract submission. We aim to identify methylation sites which are modulated by both genetic and environmental factors.

Conclusion: These results as well as future analysis on the interaction pattern on whole genome and whole methylome level will give new insights into epigenetic programming.

microRNA-34b, -21 and -133a expression pattern in thyroid carcinoma

A. Plesa¹, I. V. Iancu¹, A. Botezatu¹, I. Huica¹, D. Manda², S. Vladiu², G. Anton¹, C. V. Badiu²;

¹Stefan S Nicolau, Bucharest, Romania, ²CI Parhon" National Institute of Endocrinology, Bucharest, Romania.

Thyroid cancer is a common type of endocrine malignancy and initiation and progression involves multiple genetic and epigenetic alterations (e.g. microRNA (miRNA) deregulation and aberrant gene promoter methylation). Recent studies have shown a difference in expression of certain miRNAs between normal thyroid tissue and tumors tissue and have highlighted their potential as diagnostic markers. Study aims to examine expression patterns of studied miRNAs in thyroid cancer.

Total RNA was extracted from histological confirmed cancer and non-cancer thyroid tissue from 40 patients (matched thyroid cancer tissue and their adjacent normal tissues as controls) using TriZol. miRNAs expression levels were estimated in qRT-PCR with RNU43 as reference. Statistical analysis was performed with GraphPad Prism.

miR-34b was found to be down-regulated (<-2 fold, P<0.003), the lowest expression was noted in papillary thyroid carcinoma patients (n-fold =-45.69-18.24) compared with papillary thyroid cancer- follicular (n-fold =23.54-2.650) and sclerosing variant (n-fold =-17.66-5.120). Results indicate a significantly increased miR-21 (n-fold=5.27-16.48) and miR-133 (n-fold =0.40-56.82) expression in papillary thyroid cancer subjects (P<0.001). Moreover, we observed that miR133a presented the highest expression level in papillary thyroid cancer follicular variant, whereas miR-21 displayed a high expression in papillary thyroid cancer follicular variant, but also in sclerosing variant.

The study presented a characteristic pattern for studied miRNAs gene expression in different thyroid cancer types, raising the possibility to establish specific biomarkers. Nevertheless, further studies are needed to establish the relationship between miRNAs expression and papillary thyroid carcinoma variants.

E-P17.11

Association of methylenetetrahydrofolate reductase (MTHFR) gene 677 C > T polymorphism with epigenetic changes in Georgian patients with primary hypothyroidism unspecified

T. Kvaratskhelia, E. Kvaratskhelia, K. Kankava, E. Abzianidze; Tbilisi State Medical University, Tbilisi, Georgia.

Introduction: A number of studies have demonstrated that the polymorphism 677C > T in MTHFR gene leads to decreased activity of the enzyme and its association with thyroid disorders. The aim of our study was to investigate the association between MTHFR gene 677 C > T polymorphism and DNMTs levels in patients with primary hypothyroidism.

Materials and methods: In this study 16 adult patients with primary hypothyroidism - unspecified and 14 healthy controls (mean age 29 ± 8.5 and 25 ± 9.8 years respectively) were selected. All patients were diagnosed based on serum levels of TSH, FT4, anti-TG and anti-TPO antibodies. Written informed consents were obtained from all study subjects. Genomic DNA was extracted using quick-DNA universal kit (Zymo Research). The 677C > T MTHFR polymorphism was genotyped by PCR- RELP. Levels of DNMT1 and 3a were measured in nuclear extracts of PBMC using DNMTs assay kits (Abcam).

Results: The frequency of 677TT genotype was significantly different among the patient and the control group. Genotype frequencies for the patients and controls, respectively, were: 18.75% and 7.1% for 677TT, 37.5% and 28.6% for 677CT, 43.75% and 64.3% for 677CC. In addition, individuals with TT genotype and hypothyroidism showed elevated amount of DNMT3a in nuclear extracts of PBMC compared with controls, while no significant difference in DNMT1 levels was observed.

Conclusions: This initial study indicates that the MTHFR 677TT genotype correlates with DNMT3a levels and could contribute to the development of primary hypothyroidism. However, studies with larger samples are required to confirm these findings.

Clinical and molecular findings in three Moroccan families with distal renal tubular acidosis and deafness: report of a novel mutation of ATP6V1B1 gene

L. Boualla^{1,2}, **w. jdioui**^{1,3}, **i. ratbi**⁴, **k. soulami**⁵, **a. sefiani**^{6,7},
¹Département de Génétique Médicale, Institut National d'Hygiène, Rabat, Morocco, **RABAT**, Morocco, ²Centre de Génétique Humaine, Faculté de Médecine et de Pharmacie, Université Mohammed V, Rabat, Morocco, **Rabat, Morocco**, ³Centre de génomique humaine, Faculté de Médecine et de Pharmacie, Université Mohammed V Souissi, Rabat, Morocco, ⁴Centre de génomique humaine, Faculté de Médecine et de Pharmacie, Université Mohammed V Souissi, **RABAT, Morocco**, ⁵Cabinet of pediatric Nephrology, Casablanca, Morocco, ⁶Centre de génomique humaine, Faculté de Médecine et de Pharmacie, Université Mohammed V Souissi, **RABAT, Morocco**, ⁷Département de Génétique Médicale, Institut National d'Hygiène, Rabat, Morocco, **Rabat, Morocco**.

Background: Primary distal renal tubular acidosis (dRTA) is a rare genetic condition characterized by an impaired acid excretion by the intercalated cells in the renal collecting duct. Recessive forms of this disease are caused by mutations in two major genes: ATP6V1B1 and ATP6V0A4. Causal mutations in ATP6V1B1 gene are classically associated with early sensorineural hearing loss, however cases of tubular acidosis with early deafness have also been described in patients with mutations in the ATP6V0A4 gene.

Methods: The phenotype and genotype of three Moroccan consanguineous families with dRTA and deafness were assessed. Molecular analysis was performed by PCR amplification and direct sequencing of exon 12 of ATP6V1B1 gene.

Results: A novel c.1169dupC frameshift mutation of ATP6V1B1 gene was identified in one family and the c.1155dupC North African mutation in the two other families.

Discussion and conclusion In this report, we propose first line genetic testing based on screening of these two mutations both located in exon 12 of ATP6V1B1 gene in Moroccan patients with recessive form of dRTA associated to precocious hearing loss. Molecular diagnosis of dRTA leads to appropriate treatment and prevention of renal failure in affected individuals and to provide genetic counseling for families at risk.

The influence of neonatal screening program on the early diagnosis of cystic fibrosis in Moscow Region (Russian Federation)

N. Kashirskaya¹, **V. Sherman**¹, **N. Kapranov**¹, **E. Kondratyeva**¹, **A. Voronkova**¹, **V. Nikonova**¹, **S. Krasovskiy**², **A. Cherniak**², **E. Amelina**², **N. Petrova**¹, **R. Zinchenko**¹;
¹Federal State Budgetary Institution «Research Centre for Medical Genetics», Moscow, Russian Federation, ²Research Institute of Pulmonology, Moscow, Russian Federation.

National newborn screening (NBS) program for CF was introduced all over Russia in January 2007 (in Moscow - June 2006). Currently, this is the main method of CF diagnosis in the country.

We've analyzed the data of all CF patients from the Moscow region CF Patients' Register that were diagnosed before 18 years of age. The CF patients were divided into two groups according to the different time periods: from 1999 to 2005 - Group I - 83 CF patients (before the introduction of NBS in Moscow) and from 2007 to 2013 - Group II - 228 CF patients (after the introduction of NBS).

The average age of diagnosis in Group I was 4.5 years (30% before 12 months), and in Group II - 1.8 years (74% before 12 months). The average age of CF diagnosis in the positive NBS group was 2.3 months, in the infants with false-negative NBS results - 23 months.

In Group I meconium ileus (MI) was diagnosed in 5 children (6%), and in group II - in 27 children (12%).

We assume there were much more cases of CF under-diagnosis in MI newborns before 2007. MI patients in Group I were diagnosed as having CF at the age of 1.4 years, and in Group II - 1.7 months.

Our findings demonstrate the effectiveness of NBS program. At the same time, underdiagnosed CF before NBS, false-negative results of NBS as well as some problems in the CF care still influence the diagnosis age of CF patients.

Analysis of frequent CFTR mutations in four ethnic groups from the Republic of Karachay-Cherkessia, Russian Federation

N. V. Petrova¹, **N. J. Kashirskaya**¹, **A. K. Makaov**², **T. A. Vasilyeva**¹, **E. E. Timkovskaya**¹, **R. A. Zinchenko**^{1,3}, **S. Musaeva**¹, **E. K. Ginter**^{1,4}, **S. I. Kutsev**^{1,3};

¹Federal state scientific budgetary Institution «Research Centre for Medical Genetics», Moscow, Russian Federation, ²Municipal Budgetary Health Care setting „Habezskaya central district hospital“, Habez, Russian Federation, ³Pirogov Russian National Research Medical University, Moscow, Russian Federation, ⁴Russian Medical Academy of Postgraduate Education, Moscow, Russian Federation.

Cystic fibrosis (OMIM #219700) is autosomal recessive disorder due to mutation in CFTR gene (OMIM *602421). The spectrum and frequency of CFTR mutations varies considerably in different ethnic groups and geographical regions. The aim: to study the frequency of CFTR mutations in Karachay-Cherkess Republic, the region of compact residence of four small peoples: Karachay, Cherkess, Abaza, Nogai.

Methods: The analysis of 12 common in Russia CFTR mutations was performed in 653 healthy unrelated individuals from 7 districts and Cherkessk city, representing four ethnic groups, by multiplexPCR and restriction analysis.

Results: Two carriers of 1677delTA mutation (0.003) and 6 carriers of W1282X mutation (0.01) in 300 Karachay; two 1677delTA carriers (0.01) and two F508del carriers (0.01) in 103 Cherkess; three 1677delTA carriers (0.012), one W1282X carrier (0.004) and one carrier of F508del (0.004) in 128 Abaza and three W1282X carriers (0.012) in 122 Nogai were revealed.

Conclusion: In each of the sample from different ethnic groups, the cumulative frequency of detected CFTR mutations was greater than 0.01, thus the CF incidence should be at least 1 in 10000. The 1677delta mutation is widespread among CF patients, related to the people of North Caucasus (Chechens, Ingushs) and Transcaucasia (Georgians). We found 1677delta mutation in Karachay, Abaza and Cherkess that are autochthonous ethnic groups of the North-Caucasian region of Russia, and not discovered for Nogai with a more short history of residence on this territory (since XIV century AD). This work was partially funded by RFBR grants 14-04-00525, 15-04-01859.

Ammosov North-Eastern Federal University, Yakutsk, Russian Federation, ²Yakut Scientific Center of Complex Medical Problems, Yakutsk, Russian Federation, ³Federal Research Center Institute of Cytology and Genetics, Siberian Branch of the Russian Academy of Sciences, Novosibirsk, Russian Federation, ⁴Novosibirsk State University, Novosibirsk, Russian Federation, ⁵Tyva Republican Perinatal Center, Kyzyl, Russian Federation, ⁶Institute of Chemical Biology and Fundamental Medicine, Siberian Branch of the Russian Academy of Sciences, Novosibirsk, Russian Federation, ⁷Institute of Humanitarian Research and Indigenous Peoples of the North, Siberian Branch of the Russian Academy of Sciences, Yakutsk, Russian Federation, ⁸Institute of Biochemistry and Genetics, Ufa Scientific Centre, Russian Academy of Sciences, Ufa, Russian Federation, ⁹Estonian Biocentre, Tartu, Estonia, ¹⁰Bashkir State University, Ufa, Austria.

Introduction: The c.-23+1G>A (IVS1+1G>A) splice site mutation is one of the most frequent mutations of GJB2 gene (MIM 121011) in patients with congenital deafness in some populations of Eastern Europe, Caucasus, Middle East, Central and South Asia, Southern and Eastern Siberia. In recent study, we provided evidence that high prevalence of this splice site mutation among Yakut population isolate in Eastern Siberia is due to common founder effect [Barashkov et al., 2011]. The aim of this study is to investigate the origin of the c.-23+1G>A mutation found in some Siberian and Caucasian (Russian) populations.

Materials and methods: DNA samples of four deaf patients with c.-23+1G>A mutation (GJB2) in homozygous state representing several ethnic Eurasian populations (Yakut, Russian, Tuvian and Evenk) were genotyped with Illumina 730K SNP array according to manufacturers' specifications (Estonian Biocentre, Tartu).

Results: The presence of extended homozygous region (from ~1.4 Mb in Russian to ~7.6 Mb in Tuvian) was shown for all studied patients. Moreover, we have found identical, common for all studied individuals, homozygosity track (~325 kb) flanking the region of c.-23+1G>A mutation.

Conclusions: Thus, the results of the genome-wide analysis support the hypothesis of a common origin of the c.-23+1G>A splice site mutation (GJB2) in certain populations of Eurasia. The study was supported by the RFBR grant #16-34-00234, the governmental contract #6.656.2014/K, and the grant #0324-2015-0031 from the Siberian Branch of Russian Academy of Sciences.

E-P18.11

STR polymorphism of CFTR gene in nine populations of Russia

E. E. Tymkovskaya¹, N. V. Petrova², A. K. Makaov³, T. A. Vasilyeva², S. M. Musaeva², R. A. Zinchenko^{2,4};

¹Research Center for Medical Genetics, Moscow, Russian Federation, ²Federal state scientific budgetary Institution «Research Centre for Medical Genetics», Moscow, Russian Federation, ³Municipal Budgetary Health Care setting „Habezskaia central district hospital”, Habez, Russian Federation, ⁴Pirogov Russian National Research Medical University, Moscow, Russian Federation.

Molecular genetic analysis of four STR polymorphisms in CFTR gene IVS-1CA-IVS6aGATT-IVS8CA-IVS17bCA was performed in nine populations from Russian Federation. Four Northern-Caucasus populations from the Karachay-Cherkess Republic (Karachai, Cherkess, Abaza, Nogai) and five populations from Volgo-Urals region (Mary, Udmurt, Bashkir, Tatar, Chuvashes) were included in the survey. Cherkess and Abaza are North Caucasian ethnic groups closely related to Abkhaz, Nogai and Karachai are Turkic people, Nogai descendants of various Mongolic and Turkic tribes, Karachai from the Kipchaks.

Mary and the Udmurt are Finno-Ugric peoples, Chuvashes descends from Proto Turkic people, Suars and Bulgars, Tatars - from the Volga Bulgars and Turkic tribes, Bashkir - from the different tribes of Finno-Ugric and Turkic tribes. The volume of each sample was 55-60 unrelated healthy individuals. Allele and genotype frequencies as well as indices of intrapopulation differentiation (Fst) were calculated.

The intrapopulation differentiation for all studied populations is (Fst) 0,0271. The intrapopulation differentiation among populations from Volgo-Urals region was considerably higher than that of ethnic groups from the North Caucasus (Fst 0,0072 vs 0,0179).

Analysis of genetic distances prompted us to conclude that Mary, Udmurt, and Chuvashes genetically closer to each other than to Tatar and Bashkir. Cherkess and the Abaza are genetically closer to each other than to Karachai and Nogai.

E-P18.12

Mitochondrial haplogroup H diversity in Russians based on complete mitogenome analysis

B. A. Malyarchuk, A. Litvinov, M. Derenko;

Institute of Biological Problems of the North, Magadan, Russian Federation.

Haplogroup H comprises about 50% of mitochondrial DNA (mtDNA) lineages in European populations, including Russians. This haplogroup has been difficult to subdivide based on the hypervariable segments I and II (HVS I and II) variation alone. In Russians, a number of major clades within haplogroup H were revealed on the basis of high-resolution mtDNA analysis (i.e. HVS I and II sequencing combined with analysis of some subhaplogroup-specific coding region sites) - clades H1a, H1b, H2, H4, H5, H6, H7 and H11. However, complete mtDNA analysis at higher levels of phylogenetic resolution allows revealing more than 100 distinct clades within haplogroup H. Therefore, to resolve the phylogeny of this haplogroup in Russians, we sequenced 118 complete H-mitogenomes of Russian individuals from northwestern (Pskov and Velikij Novgorod) and southwestern (Belgorod, Orel and Tula) regions of European part of the Russian Federation. Phylogenetic analysis has shown that the largest subclades in Russians are H1 (about 30% of haplogroup H pool, with lineages H1*, H1a, H1b, H1c, H1n, H1aj), H5 (about 16%, with lineages H5a, H5b, H5e, H5f, H5u), and H11 (about 10%, with lineages H11a1 and H11a2). Subclades H6, H2, H3 and H13 each comprise about 5% of haplogroup H mitogenomes, while a large number of rare mtDNA lineages (H4, H7, H10e, H13, H14a, H24, H27, H28a, H32, H35, H36a, H41a, H44b, H56a1, H79, H81 and H89) contribute substantially into haplogroup H diversity. This study was supported by Russian Foundation for Basic Research (grant 14-04-00131).

The first case of monilethrix DNA diagnosis in Russia

E. V. Degtereva¹, S. S. Amelina¹, N. V. Vetrova², N. V. Petrova², T. A. Vasilyeva³, S. I. Kutsev³, R. A. Zinchenko³;

¹Rostov State Medical University, Rostov-on-Don, Russian Federation, ²Academy of Biology and Biotechnology of Southern Federal University, Rostov-on-Don, Russian Federation, ³Research Centre for Medical Genetics, Moscow, Russian Federation.

Introduction: Monilethrix (MIM #158000) is a rare genodermatosis characterized by a hair shaft dysplasia resulting in hypotrichosis. The prevalence and incidence are not known. The three main genes are associated with monilethrix: KRT81, KRT83 and KRT86, coding the type II hair keratins Hb1, Hb3 and Hb6, and are responsible for the autosomal dominant form of the

disease.

Materials and methods: Epidemiological, PCR, sequencing.

Results: The population of twelve districts was examined to determine prevalence of hereditary disorders in Rostov Region. We examined 497460 people. Data collection and processing were done according to the protocol of Genetic Epidemiology Laboratory of Research Centre for Medical Genetics.

The study identified 5 patients from 1 family of 3 generations. All patients had the typical symptoms of the disease at an early age. Clinical examination: the hair on the scalp rare, dry, brittle, their length does not exceed 1.5-2 cm, 2 patients in the pathological process involved eyebrows and eyelashes. Direct sequencing revealed a mutation E402K in exon 4 in the gene KRT86 (HB6) in the heterozygous condition.

Conclusions: The prevalence rate monilethrix was 1.01 per 100 000 population (1:99492). The results of the study can be used for optimizing Medical Genetic Counselling in monilethrix families in the Rostov region.

This work was partially funded by RFFI grants 14-04-00525.

E-P18.17

Neurofibromatosis in Rostov Region

N. Vetrova¹, S. Amelina², T. Ponomareva², M. Amelina¹, S. Kutsev³, R. Zinchenko³;

¹Academy of Biology and Biotechnology of Southern Federal University, Rostov-on-Don, Russian Federation, ²Rostov State Medical University, Rostov-on-Don, Russian Federation, ³Research Centre for Medical Genetics, Moscow, Russian Federation.

Neurofibromatosis is the most frequent inherited disorder associated with increased susceptibility to the development of benign and malignant tumors. Penetrance is 100% but the clinical features of this disorder are highly variable, even within the same family.

The population of twelve districts was examined to determine prevalence of hereditary disorders in Rostov Region. We examined 497460 patients. Data collection and processing were done according to the protocol of Genetic Epidemiology Laboratory of Medical Centre in Moscow.

According to the research results neurofibromatosis is one of the most frequent autosomal dominant hereditary diseases in the population of the Rostov region. The study identified 54 patients from 28 families with typical clinical manifestations of neurofibromatosis type 1. The prevalence rate was 10.9 per 100 000 population (1:9212). Most families have a burdened family history (26 from 28). The tumor is diagnosed in 3 patients, in two cases there are central nervous system tumors, and one patient has benign tumor of the thorax.

Independent inheritance of two diseases neurofibromatosis and retinitis pigmentosa was determined in one family. Mother (who died from central nervous system tumor) had both diseases. There are four siblings from different marriages of the mother. One son has not inherited any of the disease, two daughters inherited both diseases, and the youngest daughter inherited only the retinitis pigmentosa.

The results of genetic and epidemiological studies enabled to determine the prevalence of monogenic hereditary diseases will help to improve the medico-genetic service.

E-P18.19

Association analysis of five genes polymorphisms in two cohorts of European athletes

V. Ginevičienė¹, A. Jakaitienė¹, S. Drozdovska², L. Tubelis³, V. Kučinskas¹, A. Utkus¹;

¹Department of Human and Medical Genetics, Faculty of Medicine, Vilnius University, Vilnius, Lithuania, ²National University of Physical Education and Sports of Ukraine, Department of Sport Biology, Kiev, Ukraine, ³Lithuanian University of Educational Sciences, Vilnius, Lithuania.

Introduction: The aim of this case-control study was to determine the association of the ACE (rs4646994 I/D), ACTN3 (rs1815739 R/X), HIF1A (rs11549465 Pro582Ser), PPARA (rs4253778 G/C) and PPARG (rs1801282 Pro12Ala) polymorphisms, with athletic status in European Caucasians cohort consisting of Lithuanian and Ukrainian. Selected polymorphisms were previously reported as associated with athlete status in different populations.

Materials and Methods: A total of 499 elite athletes (250 Lithuanian, 249 Ukrainian) and 584 non-athlete controls (healthy unrelated 266 Lithuanian, 318 Ukrainian citizens) were genotyped for mentioned polymorphisms using PCR and/or restriction enzyme digestion. The athletes were stratified into endurance-oriented, power-oriented and group of athletes with mixed endurance/power activity.

Results: The analysis of polymorphisms, except ACE (I/D) and ACTN3 (R577X), demonstrated no significant differences between populations. The ACE I allele frequency was higher in Lithuanian power-oriented ath-

letes compared to controls (51%vs.42.6%; $P=0.02$). The frequency of the *PPARG* minor C allele was significantly lower in Ukrainian than Lithuanian endurance athletes (17.2%vs.25%; $P=0.031$). The proportion of the *PPARG* Ala allele, observed in Ukrainian power-oriented athletes, was larger than in endurance-oriented athletes (24.7%vs.13.5%; $P=0.008$). Ukrainian power-oriented athletes exhibited an increased frequency of the *HIF1A* rare Ser allele (16.1%vs.9.4%, $P=0.034$) compared to controls.

Conclusions: We conclude that the *ACE* I allele determine power status for Lithuanian athletes. Likewise, *HIF1A* Ser and *PPARG* Ala alleles associated with power athlete status in Ukrainians. We confirm that variants which have a significant association with physical performance in studies of one population may not have the same association in another.

E-P18.21

Polymorphism of nine nuclear genome DNA loci in Abaza and Nogai

A. K. Makoov¹, N. V. Petrova², E. E. Timkovskaya², T. A. Vasilyeva², S. M. Musaeva², E. K. Ginter², G. I. El'chinova², S. I. Kutsev^{2,3}, R. A. Zinchenko^{2,3};

¹Municipal Budgetary Health Care setting, Habez, Russian Federation, ²Federal state scientific budgetary Institution «Research Centre for Medical Genetics», Moscow, Russian Federation, ³Pirogov Russian National Research Medical University, Moscow, Russian Federation.

The Karachay-Cherkess Republic, Russian Federation, is a region of compact residence of four different ethnic groups: the Karachai, Cherkess, Abaza, Nogai. The aim was to carry out the population genetic survey of two indigenous populations of the Karachay-Cherkessia Republic: Abaza and Nogai. The Abaza are an ethnic group of the Caucasus, closely related to the Abkhaz and Circassian (Adyghe) people. The Nogai, a Turkic ethnic group, are thought to be descendants of various Mongolic and Turkic tribes, who formed the Nogai Horde.

Methods: DNA samples of healthy unrelated individuals (110 Abaza and 122 Nogai) were examined at nine polymorphic DNA loci of nuclear genome: diallele CCR5 (del32), ACE (del/ins), D7S23 (KM19), NOS3 (VNTR), and polyallele TH01 (STR), FABP2 (STR), CFTR (IVS6aGATT), PAH (VNTR), DAT1 (VNTR) by PCR.

Results: Allele and genotype frequency distributions were obtained for both ethnic groups. Analysis of allele's frequency of autosomal DNA markers revealed genetic differentiation between populations of Abaza and Nogai. The highest levels of genetic diversity in diallele system were established at locus ACE (del/ins), Hobs=0.5963 in Abaza and Hobs=0.5333 in Nogai, in polyallele system - at locus TH01 (STR), Hobs=0.7773 in Abaza and Hobs=0.7934 in Nogai. The index of mean heterozygosity was higher in Nogai than in Abaza (0.4784 and 0.4555, correspondently). The index of mean intrapopulation differentiation (FST) was 0,0040. The highest level of intrapopulation differentiation was revealed at locus KM19 (FST=0,0122), the lowest one - at locus TH01 (FST=0,0014).

This work was partially funded by RFBR grants 14-04-00525, 15-04-01859.

E-P19.02

The novel probably casual substitution in the patient with FSGS

M. Safarikova^{1,2}, J. Reiterova², J. Stekrova¹, V. Horinova², M. Kohoutova¹, V. Tesar², S. Pospisilova¹;

¹Institute of Biology and Medical Genetics, First Faculty of Medicine, Charles University in Prague, Prague, Czech Republic, ²Department of Nephrology, First Faculty of Medicine, Charles University in Prague and General University Hospital in Prague, Prague, Czech Republic, ³Genetic Ambulance Jihlava, Jihlava, Czech Republic, ⁴General University Hospital in Prague, Prague, Czech Republic.

Focal segmental glomerulosclerosis (FSGS) is common primary glomerulopathy that often progresses to the end stage renal disease (ESRD). Several genes, such as ACTN4, CD2AP, INF2, NPHS2 and TRPC6, have been identified as a cause of autosomal dominant focal segmental glomerulosclerosis. Alpha-actinin-4, encoded ACTN4 gene, is a member of the spectrin gene superfamily that crosslinks F-actin filaments. It is nonmuscle isoform expressed in many human tissues. The structure is head-to-tail antiparallel homodimer with three main parts. N-terminal domain is composed of two calponin homologous domains with actin binding sites followed by four spectrin repeats. C-terminal domain consists of two EF-hand domains that can bind Ca²⁺ ions.

Our patient was thirty-two years old man from Italy, now living in the Czech Republic, with positive family history (mother) suffering from focal segmental glomerulosclerosis who was after renal transplantation. We screened for

mutations in genes ACTN4, INF2, NPHS2 and TRPC6 using Sanger sequencing. We identified a novel substitution Leu169Pro in the ACTN4 gene that was in the heterozygous state. According to prediction programs PolyPhen-2 and Mutational Taster this substitution has got the high probability to be casual. We also screened for the new substitution in healthy close relatives (father and brothers) but they are carriers of the wild type sequence. The DNA of the mother who also suffered from FSGS could not be analysed because she is unfortunately death. In these days we search for the novel substitution in the group of healthy controls using restriction analysis. Supported by the grant project PRVOUK- P25/LF1/2.

Genetic counselling for MELAS during pregnancy -a case report-

Y. Goto^{1,2}, C. Noji¹, K. Takahashi², Y. Ohnuki², A. Kondo³, T. Muramatsu¹, S. Izumi²;

¹Dept. of Obstetrics and Gynecology, Tokai University Hachioji Hospital, Tokyo, Japan, ²Dept. of Genetics, Tokai University Hospital, Kanagawa, Japan, ³Dept. of Obstetrics and Gynecology, Shikoku Medical Center for Children and Adults, Kagawa, Japan.

[Introduction] Mitochondrial myopathy, encephalopathy, lactic acidosis, stroke-like syndrome (MELAS) is a maternal inheritance and diagnosed by mutation of mitochondrial gene, 3243AG. Symptom varies epilepsy, head ache, vomiting, hard of hearing, mental disorder, short stature, stroke and so on. Affected pregnant women should be monitored for diabetes mellitus and respiratory insufficiency, which may require therapeutic interventions. We experienced a case of pregnancy with MELAS.

[Case] 36 y/o para 0 gravida 0 woman, who is 144cm in height and has a hard of hearing from 30 y/o, conceived by IVF-ET after 9 years infertility and came to our hospital at 9 weeks. At 21 weeks, she suddenly complained headache and dysarthria. Left temporal lobe edema and cerebellum atrophy were observed in MRI. The next day, she had strong uterine contraction which led a miscarriage. One month later, she visited our genetic clinic for asking about some influences to next pregnancy.

[Discussion] MELAS is inheritable from mother by 100%. However permeability is various. The mother of this case has only hard of hearing. The women with genetic disease sometimes confront with complications during pregnancy due to physiological changes. Possibility of prenatal diagnosis is important information, however prenatal diagnosis of MELAS is impossible. [Conclusion] Parental genetic counseling is important for women with any genetic disease before pregnancy. As infertility is not rare condition for MELAS, medical staffs at fertility clinics also should pay attention to their conditions. The patient need sufficient information about their possible problems related pregnancy before the treatment for sterility.

E-P19.05

Analysis of maternal polymorphisms of RFC1 gene and risk of Down syndrome offspring

A. Pazarbasi¹, L. Ozpak¹, N. Keser¹, S. Kocaturk-Sel¹, G. Comertpay¹, F. T. Ozgunen¹; University of Cukurova, Faculty of Medicine, Adana, Turkey.

BACKGROUND: Down syndrome (DS) is the most common trisomy in live born with a prevalence of 1 in 1000 to 1 in 1100. Enzymes involved in one carbon and transsulfuration (1C/TS) metabolism in mothers and affected individuals with Down syndrome in altering the likelihood of birth of a child with Down syndrome. An important gene located on chromosome 21 encodes the reduced folate carrier1 (RFC1), widely considered to be quantitatively one of the most significant proteins involved in uptake of reduced folates from the diet and in cellular internalisation of reduced folates. We have looked for an association of polymorphisms in the RFC gene and the risk of birth of a child with Down syndrome

MATERIALS AND METHODS: In our study, sixty-one DS mothers and fifty mothers who had no children with DS from Cukurova region of Turkey were evaluated. Genomic DNA was isolated from whole peripheral blood collected on EDTA, using salting out method. The CBS genotypes were studied by PCR-amplified products.

RESULTS: The results show that the frequencies of RFC1 alleles, as well as the frequencies of RFC1 A80G genotypes (AA, GA,GG) do not correlate with DS pregnancies, demonstrating no difference between the case and control groups.

CONCLUSIONS: In the present study, we did not find any statistically significant association between RFC-1 polymorphic genotype and history of DS pregnancies.

This study was supported by Cukurova University Scientific Research Projects Unit (Adana, Turkey) with TF2014BAP1 number.

E-P19.06

Unusual structural abnormalities of small acrocentric chromosomes-difficulties of genetic counseling

S. Popa¹, R. Popescu¹, E. Braha¹, M. Gramescu¹, E. Graur¹, V. Martiniuc², C. Rusu¹, E. V. Gorduza¹;

¹Medical genetics department, University of Medicine and Pharmacy "Gr. T. Popa", Iasi, Romania, ²Medical genetics department, "Cuza-Voda" Obstetrics and Gynecology Hospital, Iasi, Romania.

Small acrocentric chromosomes are frequently involved in genetic disorders. The majority are de novo abnormalities, but some can be inherited. In last 10 years in Cytogenetic Laboratory of Iasi, were performed 2614 karyotypes with 649 (24.8%) abnormalities in G group chromosomes: 534 (82%) cases of 21 homogeneous trisomy, 38 (6%) cases of mosaic 21 trisomy, 31 (5%) cases of Robertsonian translocations, 34 (5.3%) cases of microdeletions 22q11.2 and 11 (1.7%) cases of unusual structural abnormalities. All cases were investigated by: G banding karyotype, C banding karyotype, NOR banding karyotype, FISH with different fluorescent probes. 9 of unusual unbalanced structural abnormalities were discovered in pluriformative children: 46,XX,add(21)(q22.3); 46,XX,dup(21)(q22.3;q11.2); 46,XY,+9,dic(9;22)(q12;p11.2); 46,XY,ins(9;21)(p22;q22→qter); 47,XY,t(1;2)(p32→pter)(q37→qter),-3,-21,+der(3)rcp(3:21)(p11.1;q22.2),+der(21)rcp(3;21)(p11.1;q22.2),+21; 46,XY,der(13)(13qter→13q12:21q22.1→21pter); 47,XY,ins(21;18)(p11.2;p11.3→pter),+21; 45,XX,der(5),t(5:22)(5p15.1;22q11.1),-22/46,XX,der(5)t(5:22)(5p15.1;22q11.1); 45,XX,der(5),t(5:21)(5p15;21q)-21 and two with balanced chromosomal abnormality were discovered in couples with infertility (46,XY,ins(21;16)(q22.1;p12.1-p13.13); 45,XX,der(18)t(18,22)(q23;q12),-22). In 6 cases, we identified an inherited balanced abnormality from one parent. All cases needed genetic counseling, in order to identify the risk of next pregnancies. Our retrospective study was focused to identify cases with atypical cytogenetic rearrangements (i.e. some rare variants of chromosomal abnormalities). An important outcome of this study is directly related to couple counseling. Each case was compared with similar cases from literature data. This study was partial supported by founding of PN-II-PT-PCCA-2013-4-133 Program of UEFISCDI (National Romanian organism of research).

Incomplete Timothy syndrome secondary to a mosaic mutation of the CACNA1C gene diagnosed using next-generation sequencing

A. Baurand¹, S. Falcon Eicher², G. Laurent³, E. Villain⁴, C. Bonnet⁵, C. Thauvin¹, C. Jacquet¹, V. Probst⁶, J. Gourraud⁷, S. Schmitt⁸, S. Bézieau⁹, M. Giraud⁶, S. Dumont⁶, A. Burguet⁷, F. Kyndt^{8,9}, L. Olivier Faivre¹;

¹Service de Génétique CHU DIJON, DIJON, France, ²Cardiologie Pédiatrique et Congénitale Adulte CHU DIJON, DIJON, France, ³Centre de compétence des Troubles du Rythme Cardiaque Héritaires CHU DIJON, DIJON, France, ⁴Cardiologie pédiatrique, Hôpital Necker-Enfants Malades, PARIS, France, ⁵L'institut du thorax, INSERM U1087, CHU Nantes, NANTES, France, ⁶Service de génétique médicale, CHU Nantes, NANTES, France, ⁷Réanimation Pédiatrie, CHU Dijon, DIJON, France, ⁸L'institut du thorax, INSERM U1087, CHU Nantes, Nantes, France.

Autosomal dominant genetic diseases can occur de novo and in the form of somatic mosaicism, which can give rise to a less severe phenotype, and make diagnosis more difficult given the sensitivity limits of the methods used. We report the case of a 6-year-old female patient with a history of surgery for syndactyly of the hands and feet, who was admitted to a pediatric intensive care unit following cardiac arrest. The ECG showed a long QT interval that on occasions reached 500 ms and a wide T wave. Despite the absence of facial dysmorphism and the presence of normal psychomotor development, a diagnosis of Timothy syndrome was made given the association of Syndactyly and the electrocardiogram features. Sanger sequencing of the CACNA1C gene, followed by sequencing of the genes KCNQ1, KCNH2, KCNE1, KCNE2, were negative. The subsequent analysis of a panel of genes responsible for hereditary cardiac rhythm disorders using Haloplex technology revealed a recurrent mosaic p.Gly406Arg missense mutation of the CACNA1C gene in 18% of the cells. This mosaicism can explain the negative Sanger analysis and the moderate phenotype in this patient. Given the other cases in the literature, mosaic mutations in Timothy syndrome appear more common than previously thought. This observation shows the interest of using next-generation sequencing to identify mosaic mutations compatible with a clinical picture but not detected using classical technologies for genetic counseling and the management of patients and their families.

Association of SLC6A4 genotypes with antisocial behavior in response to childhood environment: a study in young adults supporting the hypothesis that 5-HTTLPR is a genetic marker of differential susceptibility

L. Manco^{1,2}, A. Soares², S. N. Wasterlain^{1,2};

¹Department of Life Sciences, University of Coimbra, Coimbra, Portugal, ²Research Centre for Anthropology and Health (CIAS), University of Coimbra, Portugal.

Introduction: The SLC6A4 gene encodes the serotonin transporter (5-HTT) involved in the reuptake of serotonin at brain synapses. Several studies described an association between the functional repeat length polymorphism 5-HTTLPR, with two common repeat elements (14R; S-allele and 16R; L-allele), and impulsivity, aggression, and conduct disorders. This study aims to replicate the association between 5-HTTLPR and antisocial behavior (ASB) in response to childhood environment (CE) in a general population sample of young adults.

Materials and Methods: A sample of 205 (103 males; 102 females) Portuguese healthy individuals, aged 18-37 years, was enrolled in the study. Both ASB and CE were assessed by self-reports using questionnaires. Genotyping was performed for polymorphisms 5-HTTLPR and rs25531 according to published protocols.

Results: Allele frequencies (5-HTTLPR L:0.56, S:0.44; rs25531 A:0.95, G:0.05) were similar to those previously reported for European populations and genotype distributions were in Hardy-Weinberg equilibrium (P=0.866 and P=0.431, respectively). When considering individuals exposed to adverse CE a grading tendency towards ASB was observed in carriers of S-alleles. Linear regression analysis yielded near significant association (P=0.05) between the S-allele and ASB in males. By contrast, in the group not exposed to adverse CE, individuals homozygous for the L-allele were more prone to commit ASB. The L-allele was found significantly associated (P=0.01) with ASB when testing all subjects.

Conclusions: The findings showing that the S-allele carriers are more vulnerable to childhood negative environments for ASB outcomes and profit more from positive environmental conditions support the hypothesis that 5-HTTLPR is a genetic marker of differential susceptibility.

¹North-Eastern Federal University, Yakutsk, Russian Federation, ²Yakut Scientific Center of Complex Medical Problems, Yakutsk, Russian Federation, ³Republican Hospital # 2 – Center of Emergency Medicine, Ministry of Public Health of the Sakha Republic, Yakutsk, Russian Federation, ⁴Yakutsk Branch of All-Russian Society of the Deaf, Yakutsk, Russian Federation, ⁵Institute of Chemical Biology and Fundamental Medicine, Novosibirsk, Russian Federation, ⁶Novosibirsk State University, Novosibirsk, Russian Federation, ⁷Institute for Humanities Research and Indigeneous Studies of the North, Siberian Branch of Russian Academy of Sciences, Yakutsk, Russian Federation, ⁸Institute of Biochemistry and Genetics, Ufa Scientific Centre, Russian Academy of Sciences, Ufa, Russian Federation, ⁹Bashkir State Medical University, Ufa, Russian Federation, ¹⁰Bashkir State University, Ufa, Russian Federation, ¹¹Federal Research Center, Institute of Cytology and Genetics, Novosibirsk, Russian Federation.

Introduction of a sign language in schools for deaf people led to growth of their genetic fitness, which has doubled the GJB2 gene associated deafness

in the USA over the past 200 years [Arnos et al., 2008]. High prevalence of the GJB2-deafness [Barashkov et al., 2011] and relatively recent (~60 years ago) introduction of sign language among deaf people were recorded for indigenous Yakut population (Eastern Siberia, Russia). We have performed study of fertility of deaf people living in Eastern Siberia in comparison with their hearing siblings. Fertility was determined as the average number of children born to examined groups, genetic fitness of deaf people was calculated as the ratio of the overall fertility of deaf individuals to their hearing siblings [Blanton et al., 2010]. Data on fertility of 83 deaf people (females-53, males-30) and 185 hearing siblings (females-88, males-97) aged 35-69 years were collected: deaf individuals have in total 143 children, whereas hearing siblings-422 children. Fertility of deaf people was 1.72 vs 2.28 of their hearing siblings, genetic fitness for deaf individuals was 0.75. There was no difference between genders. Our results are comparable with fitness of deaf women in Sweden - 0.76 [Carlsson et al., 2005], lower than in USA-0.88 [Blanton et al., 2010], and higher than in Mongolia-0.62 [Tekin et al., 2010]. Thus, genetic fitness of deaf people in Eastern Siberia is slightly reduced compared to their hearing siblings. The study was supported by the RFBR grants #15-04-04860_a, #16-34-00564_mol_a, and the #6.656.2014/K_MES_RF project.

Policy proposal addressing blood-borne infections at medical schools in Angola

M. M. Chimpolo, M. M. Chimpolo;

Medical School, Universidade A Neto, Luanda, Angola.

Blood borne infections such as human immunodeficiency virus (HIV), hepatitis B virus (HBV) and hepatitis C virus (HCV) are major Public Health issues throughout the world and Angola is no exception. For instance, more than 166 000 of Angolans are infected with HIV. The transmission of these blood-borne infections in health care settings and particularly amongst medical students brings considerable ethical and legal concerns. In Angola, there are currently no public policies that provides guidance on certain procedures and circumstances where a student carries a blood-borne virus. There is also no requirements for screening or immunisation programs at medical schools.

This paper aims at establishing the prevalence of infected students and providing a reasonable policy proposal that addresses important questions of public health, which may affect both students and patients and prevent the spreading of infections.

The prevalence of HIV, HBV and HCV in 160 first year Angolan medical students was analysed by serological and molecular testing. The review of literature on laws and bioethics regarding these infections were used to gather appropriate data.

The resulting work defines a set of Medical faculty requirements proposals for screening, immunisation, specialized medical assistance and compliance by students in relation to blood-borne virus infections. This policy proposal also includes professional standards and effective polices related to medical management of infections and place responsibilities on those who act negligently and fail to protect their patients

EE1 Educational Session: DTC genetic testing revisited: empowering patients -caring for consumers?

EE1.1

Shifting roles and relationships: the impact of direct-to-consumer genetic testing on healthcare delivery

E. Gordon;

23andMe, Inc., Mountain View, CA, United States.

Historically, healthcare and health information were delivered through trained medical professionals, who also recommended actions for patients to follow (e.g. undergo further tests, take a prescribed medication, etc.). Patients had some autonomy of choice, but in today's digital age, patients have become increasingly empowered to take charge of their health. One example is direct-to-consumer genetic testing (DTCGT). It has a clear public demand, but it has received a decidedly mixed reaction in the medical community.

Despite significant concerns from medical professionals and researchers, research on DTCGT has not supported the misperceptions and other concerns. As a genetic counselor working in the DTCGT industry, I support the public's right to access personal genetic information -- when it is delivered in a responsible manner. Key components and principles of any DTCGT company should include respect for consumer rights and privacy; reports written at an appropriate comprehension level; educational content to support consumers; valid test methods; and compliance with the local regulatory framework. With these in place, research supports consumers ability to comprehend their personal genetic information without evidence of psychological harm. However, the DTCGT industry is well-served to include medical professionals in its ranks. Although supporting consumers of DTCGT is very different from direct patient care, having the clinical experience to create needed resources, identify and correct for potential misperceptions among patients and create key information needed by medical professionals to effectively utilize genetic test information in patient care ultimately lead to better services. Finally, data suggests that physicians are ill-prepared to deal with DTCGT results presented by their patients and that their lack of preparedness may have a negative impact on the patient-physician relationship. DTCGT companies are working to engage and educate medical professionals; an evidence-based assessment and greater acceptance by the medical professional community is also needed.

EE1.2

The "activated patient": A fresh look at empowerment

B. Prainsack;

Department of Social Science, Health & Medicine, King's College London, London, United Kingdom.

Patient empowerment has become a buzzword. It is used to support a great variety of practices ranging from shared decision making in the clinic to self experimentation of 'citizen scientists'. In the domain of DTC genetics, the argument of patient empowerment has been used to support the idea that patients should have direct access to genetic risk information, without the involvement of health professionals. The empowerment rhetoric allows the labeling of those who oppose such ideas as paternalistic empowerment skeptics. This paper seeks to make the of the cultural and political meanings of empowerment more explicit. It suggests that these meanings are considered explicitly when analysing the societal and ethical aspects of DTC genetics. Drawing upon the work of Luca Chiapperino and others, I distinguish between three traditions of meaning of empowerment: (1) Empowerment as an expression of individual autonomy and choice (*individualistic empowerment*); (2) empowerment as liberation from paternalism and oppression (*emancipatory empowerment*), and (3) empowerment in the service of democratisation and deliberation (*democratic empowerment*). Differentiating between different calls for empowerment on the basis of its underlying political, economical and ethical goals, values, and assumptions helps us to avoid unduly simplistic and binary assessments of whether or not a particular technological practice empowers or disempowers patients. Instead it enables us to carry out a systematic analysis of how technological practices are involved in shifting power between different actors. Applying such an analysis on the field of DTC genetics shows, for example, the great extent to which battles for increasing access to information for patients also enable the types of work that patients are increasingly expected to do in order to make personalised and precision medicine possible.

EPL1 The evolution of Genetic Counseling

EPL1.1

Data sharing to support UK clinical genetics and genomics services

S. Raza¹, A. Hall², C. Rands¹, S. Deans², D. McMullan², M. Kroese¹;

¹PHG Foundation, Cambridge, United Kingdom, ²Association for Clinical Genetic Science, Birmingham, United Kingdom.

Access to high quality data on genomic variants and associated clinical information is fundamental to the delivery of clinical genetics diagnostic services. A complex interplay of practical, technical, legal and regulatory factors are currently impeding the ability of NHS clinical genetics laboratories to share and access the necessary data. Among the most significant challenges are (a) lack of a designated sustainable infrastructure or mechanism for laboratories to share data and (b) inconsistency guidance issued by local NHS Trusts to individual laboratories across the country on what constitutes acceptable practice with regards to the sharing of rare genetic variants which may be considered personally identifiable information. The

PHG Foundation in association with the UK's Association for Clinical Genetic Science, co-hosted a workshop to examine the most pressing challenges around data sharing and to identify priority areas for policy development. Our analysis highlighted that the current arrangements for sharing genomic variants within the NHS is unsatisfactory and inconsistent practices are causing significant difference in patient care and are compromising quality and safety. There is an urgent need for (i) national agreement on the legitimacy of data sharing, (ii) standardised operational processes, including a designated sustainable database or mechanism for sharing, (iii) strong leadership by the multiple relevant health organisations to demonstrate the benefits and risks associated with sharing and not sharing data. In concert these recommendations will go some way towards improving consistency in practice and building trust and confidence amongst patients, the public and healthcare professionals.

Landscapes of genetic tests worldwide: a report from the NIH Genetic Testing Registry (GTR)

A. J. Malheiro, B. L. Kattman, B. Gu, V. Hem, K. S. Katz, M. Ovetsky, R. Villamarin-Salomon, G. Song, C. Wallin, D. R. Maglott, J. M. Lee, **W. S. Rubinstein**; NCBI/NLM/NIH, Bethesda, MD, United States.

The Genetic Testing Registry (GTR; <https://www.ncbi.nlm.nih.gov/gtr/>) at the U.S. National Institutes of Health (NIH), is a freely available resource which enables centralized access to comprehensive information and improve transparency about genetic tests.

Clinical and research genetic test information is voluntarily submitted by providers worldwide. As of February 2016, GTR has 32,903 tests for 5,996 conditions offered by 462 laboratories in 41 countries. The scope includes biochemical, cytogenetic and molecular tests. There are 303 pharmacogenomic tests; 5,568 tests for neoplasms and hereditary cancer syndromes of which 622 tests have somatic targets; and 219 tests for human genome, whole exome and/or mitochondrion.

Of the 8,438 NGS tests, 79% report out only a single gene result. Panels (defined here as having > 4 targets) comprise 16.4% (1,380) of NGS tests. This shows that ordering clinicians can selectively order 1 or more genes performed as part of an NGS assay which helps avoid reporting of markers added to improve sensitivity of the assay but have unclear validity or utility.

GTR collects and distributes useful data like laboratory contact information, certifications and staff. Description of clinical tests include conditions, test targets, methods, analytical validity, clinical utility, target population and proficiency testing. Registration of research tests includes study details, methodology and test targets. Submitters must update data annually to ensure that consumers have access to the most up-to-date information. Comprehensive GTR data can be downloaded as XML using FTP or E-Utilities. GTR supplements pages with relevant information including practice guidelines from sources like ACMG and Orphanet.

EPL1.3

Informing clinical implementation of genomics by "doing" - Practitioner perspectives on integrating genomics in their practice

M. Martyn^{1,2}, E. Forbes¹, A. Kanga-Parabiah¹, I. Macciocca³, S. Metcalfe^{2,4}, L. Keogh⁵, E. Lynch¹, the Melbourne Genomics Health Alliance, C. Gaff¹; ¹Melbourne Genomics Health Alliance, Parkville, VIC, Australia, ²Murdoch Childrens Research Institute, Parkville, VIC, Australia, ³Victorian Clinical Genetics Services, Parkville, VIC, Australia, ⁴University of Melbourne, Parkville, VIC, Australia.

BACKGROUND: Health professionals' ability to incorporate genomics in practice has been recognised as a barrier to the use of genomics. Building this capability requires more than education alone. As part of a broad clinically-driven program to implement genomics, we aimed to build clinicians' capability by providing them with the opportunity to gain experience of testing patients. Clinicians' views on the impact of their participation and on future service delivery were collected.

METHODS: Clinicians offered testing to >300 patients within a demonstration project in Melbourne, Australia. Semi-structured interviews were conducted with 4 genetic counsellors, 14 geneticists and 14 other medical specialists (n = 32) participating in the demonstration project; interviews were analysed using qualitative content analysis.

RESULTS: Genetic and other practitioners reported that participating in the demonstration project gave them new insights into how and when to use genomic testing and the changes necessary to support its use in practice. The 'hands-on' learning experience provided by multidisciplinary variant interpretation meetings was particularly valued. Perspectives on future service delivery encompassed processes for patient selection, variant interpretation

and clinic organisation. Results for each will be presented.

DISCUSSION: This study confirms that the effective use of genomics in patient care depends in part on a clinical environment which supports this practice. Crucial insights have been gained into aspects of clinical practice which may need to alter to progress the transition to genomic medicine. These results are informing implementation of systems locally that meet the needs of both the workforce and patients.

EPL1.4

Genetic Counsellor training in the Genomics Era: The development of a new training scheme in England

M. Bishop¹, C. Benjamin^{2,3}, L. Boyes^{4,5}, G. Hall⁶, R. Macleod⁶, M. McAllister⁷, A. Middleton⁸, C. Patch⁹, N. Latham¹, A. Seller^{1,10}, V. Davison¹, S. Hill¹¹; ¹Health Education England, Birmingham, United Kingdom, ²UK and Eire Genetic Counsellor Registration Board Member, Preston, United Kingdom, ³University of Central Lancashire, Preston, United Kingdom, ⁴Birmingham Women's NHS Foundation Trust, Birmingham, United Kingdom, ⁵Association of Genetic Nurses and Counsellors, Birmingham, United Kingdom, ⁶Central Manchester University Hospitals NHS Foundation Trust, Manchester, United Kingdom, ⁷Cardiff University, Cardiff, United Kingdom, ⁸Wellcome Trust Sanger Institute, Cambridge, United Kingdom, ⁹Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom, ¹⁰Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom, ¹¹Chief Scientific Officer, London, United Kingdom.

A key aim of England's 100,000 Genomes Project is to create a new genomic medicine service for the National Health Service (NHS). Health Education England is responsible for the education and training of NHS staff, and its Genomics Education Programme (GEP) has been tasked to ensure NHS staff are equipped to deliver this world-leading personalised medicine service. One professional group crucial to this delivery is Genetic Counsellors (GCs). Despite the UK having a strong tradition in training GCs, there is no structured NHS training programme or formalised workforce planning. Without sustained training in place, there will be a shortfall of adequately trained GCs to cope with the increasing demand on genomic services. The GEP has worked with leaders in the GC profession to develop a new training programme in Genomic Counselling under the established Modernising Scientific Careers (MSC) framework. MSC is a UK-wide education and training strategy for the healthcare science workforce and includes diverse specialisms such as laboratory clinical scientists and bioinformaticians. This framework seems a natural fit for GCs because of the strong scientific foundation to their clinical practice. This new training programme, due to commence September 2016, comprises a three-year salaried postgraduate-level programme incorporating: an academic MSc in Genomic Counselling with a defined research component; highly structured and nationally specified workplace training emphasising clinical and counselling skills and applied scientific knowledge. By being part of MSC, GC training will be aligned to complementary scientific professions who GCs will work alongside as part of the growing genomic workforce.

EPL1.5

Ensuring patient centred care in genomics - patients' experiences of the Melbourne Genomic Health Alliance demonstration project

E. L. Lynch¹, M. Martyn^{1,2}, I. Macciocca^{1,3}, S. Metcalfe^{2,3,4}, N. Mupfeki¹, E. Forbes¹, E. Creed^{1,5}, G. Brett^{1,6,3}, E. Wilkins^{1,5}, D. Bradford¹, A. Sexton¹, L. Keogh¹, L. di Pietro¹, Melbourne Genomics Community Advisory Group, Melbourne Genomics Health Alliance, C. Gaff^{1,4}; ¹Melbourne Genomic Health Alliance, Parkville, Melbourne, Australia, ²Murdoch Childrens Research Institute, Melbourne, Australia, ³Victorian Clinical Genetics Services, Melbourne, Australia, ⁴University of Melbourne, Parkville, Melbourne, Australia, ⁵The Royal Melbourne Hospital, Melbourne, Australia, ⁶The Royal Childrens Hospital, Melbourne, Australia, ⁷CSIRO, Parkville, Melbourne, Australia, ⁸Genetic Support Network Victoria, Parkville, Melbourne, Australia.

BACKGROUND: Much research about the concerns and preferences of those having genomic testing is based on the experience of healthy individuals, with little known about patients with genetic conditions. We address this gap by investigating patients receiving genetic counselling and clinical genomic testing for one of five diverse indications.

METHODS: At recruitment to the demonstration project, patients elected whether or not to share their genomic data for further research. To explore patient understanding of and concerns about testing, patients were surveyed after a standard length genetic counselling session (<60mins), but before receipt of test results. Descriptive statistics were used to analyse scales and item lists. Content analysis was used for open-ended questions.

RESULTS: To date 62% (179/287) have responded. Only 20 (11%) expressed concerns about testing. These primarily related to the familial nature of the result, with few concerns about privacy or security. Most (98%) felt they had received enough information about genomic testing before

making a decision and the majority displayed good knowledge of the test, correctly answering questions about the numbers of genes analysed and expected types of results. Additionally, 93% of patients permitted access to their data for further research unrelated to their condition.

DISCUSSION: After genetic counselling, patients concerns about genomic testing are similar those well described for genetic testing. In contrast to healthy research participants undergoing testing, patients with a clinical indication have few concerns about privacy or security prior to receiving results. This is reflected in their decisions to share data broadly for research.

EPL1.6

Evolving genetic counselling practice in bicultural New Zealand, a case study of CDH1 testing in a large Māori whānau (family)

K. K. Gamet;

Genetic Health Service NZ, Auckland, New Zealand.

Introduction: The current generally accepted model of genetic counselling is based on a person centred approach. Although more emphasis is now placed on cultural competency for genetic counsellors, practice still incorporates a predominantly Western perspective. For this, and a number of historical reasons, there is a lack of confidence and participation in healthcare services by Māori in New Zealand. We worked with one whānau with a CDH1 mutation to address problems with patient engagement and develop a stronger relationship between Māori and the genetics service.

Method: This case study provides the opportunity to explore the evolution of a 'whānau centred' approach to genetic counselling working with Māori in New Zealand. A person centred, western model of genetic counselling includes a focus on individual autonomy and informed consent. In contrast many Māori still hold a collectivist notion of the self, and healthcare decisions are made as a group. By incorporating results of discussions with Māori elders and using the unique Māori health perspectives we developed a mutually agreed upon process of 'Whānau focused' counselling.

Results: By incorporating the Māori health elements of spiritual, psychological, physical and family into genetic counselling a respectful and reciprocal relationship has been established which has resulted in increased uptake of predictive testing. The positive outcomes of this process demonstrate the importance of building strong relationships with different cultural groups. This is a vital aspect of Genetic Counselling and will become increasingly so as genomics leads to more complex information and implications for individuals and whānau.

EPL2 The Implication for Families of Various Genetic Diseases

EPL2.1

Feedback on professional experiences on the disclosure of genetic information to family members in France

S. de Montgolfier^{1,2}, E. Rial-Sebbag³, D. d'Audiffret⁴, C. Farnos⁵, B. Derbez¹, A. de Pauw⁶, F. Galacteros⁶, D. Stoppa-Lyonnet⁷;

¹IRIS (Ehess/Inserm), Paris cedex 13, France, ²Université Paris Est Créteil, Creteil, France, ³UMR 1027 Inserm / Université Paul Sabatier, Toulouse, France, ⁴Lipha Université Paris-Est Marne-la-Vallée, Marne la Vallée, France, ⁵Institut Curie, Paris, France, ⁶APHP Hopital Henri Mondor, Créteil, France, ⁷Institut Curie, Inserm U830, Université Sorbonne-Paris-Cité, Paris, France.

The diagnosis of a serious genetic anomaly can be clinically relevant for family members when preventive measures or treatments exist. In France, the legislator introduced in 2011 a specific and original system for disclosing genetic information to family members. Patients have now a legal duty to inform their relatives about genetic risks when it is relevant for their own health. This information can be delivered directly by the patient himself, or indirectly via a procedure involving the prescribing doctor.

We propose to present the results of a survey conducted for three years on the implementation of the French procedure into practices. This was explored across juridical analyses, ethnographical study in genetic services, empirical survey with professionals and patients associations representatives. Firstly, we will present the incidence in terms of responsibility for actors of this new legal procedure; Secondly we will focus on the improvements of practices induced by this legal framework but also on the difficulties that the professionals could meet. These results underline how transmission to family members raises ethical and legal issues, particularly in light of the principles of privacy, confidentiality, autonomy and right to know or not to know in genetic field.

We will end up with some recommendations in the context of information to kin in genetics (role of actors, chronology of events, criteria of genetic

diseases involved, the relevance of information by professionals ...). Research project financed by INCa and the Canceropole Ile-de- France. "Family disclosure in human genetics" (subvention 2013-130)

EPL2.2

Co-designing an intervention to facilitate family communication about inherited genetic conditions (IGC).

A. Metcalfe¹, E. Rowland¹, I. Eisler^{1,2}, M. Ellison³, F. Flinter⁴, J. Grey⁵, S. Hutchison², C. Jackson¹, L. Longworth⁶, R. MacLeod⁷, M. McAllister⁸, T. Murrells¹, C. Patch^{1,4}, G. Robert¹, F. Ulph⁹;

¹King's College London, London, United Kingdom, ²South London and Maudsley NHS Trust, London, United Kingdom, ³Huntington's Disease Youth Organisation, London, United Kingdom, ⁴Guy's & St Thomas' NHS Foundation Trust, London, United Kingdom, ⁵AMEND - Association for Multiple Endocrine Neoplasia Disorders, London, United Kingdom, ⁶Brunel University, London, United Kingdom, ⁷Central Manchester University Hospitals NHS Foundation Trust, Manchester, United Kingdom, ⁸Cardiff University, Cardiff, United Kingdom, ⁹University of Manchester, Manchester, United Kingdom.

Introduction: Parents often want to talk to their children about an Inherited Genetic Condition (IGC) that affects their family. However they are unsure about what to say, when to say it, and are concerned about their child(ren)'s reaction. As a result, children may be given little or no information and they may be afraid of upsetting their parents by asking. The silence that occurs around the IGC can be detrimental to the long-term mental health and well-being of parents and children.

Methods: To facilitate better family communication about the IGC, we co-designed a therapeutic intervention based on Multi-Family Discussion Groups (MFDG) used in systemic family therapy. To inform the intervention's development, a series of focus groups for parents, children, young people and genetic counsellors were held. Genetic counsellors were subsequently trained in the intervention's delivery.

Findings: Training in the MFDG can extend the genetic counsellors role in delivering this intervention. Families and genetic counsellors considered MFDG important for facilitating family communication. Most parents and their children thought families with similar IGC but not necessarily the same should attend the MFDG so that they could relate to and learn from each other's experiences. The sessions should be welcoming environments that simultaneously facilitate involvement in group activities but also provide distraction from the emotionally challenging subject matter. Desired outcomes included: a happier home life, design of a communication tool kit for families' use and the development of informal networks.

Conclusion: The co-designed MFDG's effectiveness will be evaluated in a randomised controlled trial.

EPL2.3

Children's Understanding of Genetics and Inheritance: implications for Genetic Counselling

M. M. Radu, R. Moldovan;

Department of Psychology, Babeş-Bolyai University, Cluj-Napoca, Romania.

Objectives: Children have naive concepts of heredity primarily based on their daily social interactions. Research exploring children's understanding of heredity and the most adequate approach of genetic mechanisms for them is scarce. The main objective of this research was to explore children's perception of heredity; specifically, we wanted to clarify how children understand heredity and what theories they use in order to understand various genetic mechanisms.

Methods: We collected data using semi-structured interviews with 20 children (11 to 13 years old). The interview was based on 17 questions aimed at exploring their understanding and explanations of heredity. Responses were recorded, transcribed and analyzed using thematic analysis. A 3 year follow up was conducted in order to investigate the dynamic and potential changes in their understanding of heredity and genetic mechanisms.

Results: Following thematic analysis three main themes emerged: (1) inferred mechanisms, (2) inheritance, and (3) misconceptions. Overall, children in this age group have a number of naive theories and mix accurate scientific knowledge with misconceptions, but their general understanding of heredity is rather fair. Sub-themes and specific examples, as well as longitudinal changes in terms of knowledge dynamic are presented.

Discussion: Children have a good understanding of heredity which they integrate in the construct of kinship, though without being able to detail the mechanisms underlying them. The corroboration of our results with the current practice in genetic counselling highlights the implications of this study which is being detailed.

EPL2.4

Twenty years' experience conducting presymptomatic testing for late-onset neurological diseases: what have we learned?

M. Paneque^{1,2,3}, J. Félix^{1,2}, Á. Méndez^{1,2,4}, C. Lemos^{1,2,3}, S. Lêdo^{1,2}, J. Silva^{1,2}, J. Sequeiros^{1,2,3}; ¹i3S – Instituto de Investigação e Inovação em Saúde, Univ. Porto, Porto, Portugal, ²UnIGENE and Centre for Predictive and Preventive Genetics (CGPP), IBMC – Institute for Molecular and Cell Biology, Univ. Porto, Porto, Portugal, ³ICBAS – Instituto de Ciências Biomédicas Abel Salazar, Univ. Porto, Porto, Portugal, ⁴Department of Health Sciences, Univ. Aveiro, Aveiro, Portugal.

A national programme of genetic counselling and presymptomatic testing for late-onset neurological diseases was begun, in 1995, at five genetic services in Portugal. It was made accessible to adults at-risk for Machado-Joseph disease, and then extended to other hereditary ataxias, Huntington disease and familial amyloid neuropathy, following a multidisciplinary approach. We aim now at describing the consultands' profile, for a better understanding of the population seeking our services and to reflect on the protocol we have been following for 20 years.

We reviewed 1,330 records of consultands who requested presymptomatic testing at our centre. Their social-demographic profile was similar to those in other international programs. Mean age at the time of testing was 30.5 years; females (55.7%) predominated; 60.5% consultands had no offspring; and 61.4% were non-carriers. Contrarily to other international reports, withdrawals before results disclosure were only about 15%. Among the reasons for uptaking PST, the most common were: relieving uncertainty (41.7%); preparing for the disease-onset (23.2%); family planning (23.20); and informing their offspring (18.0%).

Lessons from our practice along these 20 years point out to the need for harmonization of our registers of counselling sessions, as well as the relevance of a more qualitative approach to document the consultands' experiences. For a better understanding of presymptomatic testing, as we have conducted it until now, we still need tools for quality assessment of counselling practice, as well as the study of at-risk relatives who decide not to be tested and of family-related aspects surrounding uptake of the presymptomatic protocol.

EPL2.5

Predictive testing for Huntington's disease under the age of 18 years in the UK 1993-2014.

O. W. J. Quarrell¹, R. C. Cann¹, A. Clarke², C. Compton³, A. Fryer⁴, S. Jenkins⁵, N. Lahiri⁶, R. MacLeod⁷, Z. Miedzybrodzka⁸, P. J. Morrison⁹, H. Musgrave¹⁰, M. O'Driscoll¹¹; ¹Sheffield Children's Hospital, Sheffield, United Kingdom, ²University Hospital of Wales, Cardiff, United Kingdom, ³Guy's and St Thomas' NHS Trust, London, United Kingdom, ⁴Liverpool Women's Hospital, Liverpool, United Kingdom, ⁵University Hospital of Southampton, Southampton, United Kingdom, ⁶St George's Hospital, London, United Kingdom, ⁷St. Mary's Hospital, Manchester, United Kingdom, ⁸University of Aberdeen, Aberdeen, United Kingdom, ⁹Belfast City Hospital, Belfast, United Kingdom, ¹⁰Leeds Teaching Hospitals, Leeds, United Kingdom, ¹¹Birmingham Women's Hospital, Birmingham, United Kingdom.

Background: guidelines for predictive testing for Huntington's disease (HD) were developed in the late 1980's. They became a paradigm for predictive testing in general and have been updated periodically. A consistent feature has been that minors should not be tested, this has always been <18 years in the UK.

Aim: to present information on tests which have been performed on minors in the UK since 1993.

Method: a UK HD Predictive Testing Consortium has collected data annually on the number of HD predictive tests undertaken from 23 genetic centres. The number of cases of predictive testing on minors was identified. Where possible, the circumstances of the test were categorised into broad groups. Results: 9252 tests, with age of testing recorded, were on the database of which 59 (0.64%) were reported on those <18 years. The number of tests at ages: 17, 16, 15, 14, 12, 11 and under 11 years were: 34, 12, 4, 2, 2, 1 and 4 respectively. There were records from 21 out of 23 centres. Details were available for 23 patients. Categories which could be identified included: young person close to age 18 and delay would not add anything; pregnancy in someone <18 years; not testing was judged to cause more harm; young person in a care system and more support would be available <18 years; person never going to be in a position to give informed consent.

Conclusion: we need to understand and monitor the practice of undertaking HD predictive tests on minors.

EPL2.6

'I've had to fight for everything': a qualitative study exploring the experiences of support of young people with juvenile Huntington's Disease, and their parents, in England

P. Curtis¹, O. Quarrell², R. Cann³, H. Santini²; ¹University of Sheffield, Sheffield, United Kingdom, ²Sheffield Children's Hospital NHS Foundation Trust, Sheffield, United Kingdom, ³Huntington's Disease Association, Liverpool, United Kingdom.

Background: Previous studies examining parents' experiences of caring for a child with juvenile Huntington's disease (JHD) have highlighted their isolation and their need for ongoing support. However, young peoples' own perspectives have not previously been explored and little is known about how support needs might best be met.

Aim: To explore parents' and young people' experiences of support services and their perceptions of how these might be improved.

Methods: The paper presents findings from the initial, qualitative element of a multiphase, mixed-methods study. Multiple strategies (including referrals from clinical genetics centres and from the Huntington Disease Association) were utilised to identify 14 families with a child, aged ≤ 25 years, with JHD. Eight interviews, involving ten parents and young people were undertaken and subjected to Framework analysis.

Findings: Supporting a young person with Huntington's disease requires significant physical, psychological and financial resources. Parents often feel that they have to proactively fight for services and support. Both parents and young people are concerned about professionals' lack of specialist knowledge around juvenile onset Huntington's disease. They are also concerned about the lack of social stimulation and accessible recreational activities for young people.

Conclusion: Parents and young people would benefit from ongoing contact with a knowledgeable key worker to avoid having to repeatedly initiate contact and re-establish relationships with providers as the disease progresses. [Research funded by the NHS National Institute for Health Research. Research for Patient Benefit stream. PB-PG-112-29056]

EPL3 Incidental Findings and Consent

EPL3.1

Development of a shared clinical exome sequencing consent form across multiple organisations

I. Macciocco^{1,2,3}, Z. Stark^{1,3}, D. Bruno^{1,3}, J. Taylor⁴, S. M. White^{1,3,5}, T. Y. Tan^{1,5,3}, G. R. Brett^{1,2,3}, E. Creed^{4,2}, E. Lynch², C. Community Advisory Group², A. Januszewicz⁶, C. Gaff^{2,7,5}; ¹Victorian Clinical Genetics Services, Melbourne, Australia, ²Melbourne Genomics Health Alliance, Melbourne, Australia, ³Murdoch Childrens Research Institute, Melbourne, Australia, ⁴Royal Melbourne Hospital, Parkville, Melbourne, Australia, ⁵University of Melbourne, Melbourne, Australia, ⁶Health Legal, Melbourne, Australia, ⁷Walter and Eliza Hall Institute, Melbourne, Australia.

Introduction: Informed consent for exome sequencing poses new challenges due to the complexity of the test and the many opportunities for data sharing post-test. As part of the Melbourne Genomics Health Alliance (www.melbournegenomics.org.au), a shared clinical exome sequencing consent form was developed for clinical services and testing laboratories embedded within the ten member organisations of the Alliance.

Method: A working group of representatives from laboratory genetics, medical genetics and genetic counselling from partner organisations was convened to develop the consent form. Consensus was reached on key elements of the form, following review of literature and selected local and international clinical consent forms for exome sequencing. Early consumer input was achieved through the Melbourne Genomics Community Advisory Group. The documents were refined over 10 months and subjected to independent legal review.

Outcomes and conclusion: The outcome was a single page consent form for singleton or trio analysis supported by a series of information sheets describing genomic sequencing and providing an explanation of the points that patients agree to in the consent form.

To date, the consent form has been adopted by two Alliance laboratories and one clinical department and will be used to consent more than 500 patients from five hospitals over the next two years. Up-skilling of health professionals on the use of the consent form is ongoing.

A collaborative approach to the development of an exome sequencing consent form is achievable, enabling a standardised approach to consent across multiple organisations, and facilitating data sharing in an ethically acceptable manner.

EPL3.2

Genomic investigations and incidental findings: the time for broad consent

G. Crawford^{1,2}, A. Fenwick¹, A. Lucassen^{1,2};

¹University of Southampton, Southampton, United Kingdom, ²Wessex Clinical Genetics Service, Southampton, United Kingdom.

Introduction: Rapidly declining costs and increasing availability of whole-genome analysis mean that broader explorations of the entire genome have replaced targeted approaches to testing. Many debates have been held about adaptations to consent and disclosure practices as these technologies gain widespread use. Possible results include: (a) diagnostic or informative to the clinical reason for testing, (b) diagnostic or informative findings unrelated to the clinical reason for testing (so-called Incidental Findings- IFs) and (c) results of uncertain clinical significance. Here we report the results from an empirical study exploring the challenge these results pose to the consent process.

Methods: In-depth interviews were undertaken with 32 health care professionals (HCPs) and 16 patients to explore views about consent and disclosure practices with genomic tests and in particular IFs. These were analysed thematically.

Results: Both groups:

1. Agreed that patients should be asked and given choices about the results they wish to receive
2. Realised that discrete choices were not possible since the range of possible findings was too great
3. Wanted clinical judgement to play an important role in disclosure, and were satisfied when this had been superimposed on unclear consent
4. Concluded that broad rather than specific consent was the only type of real consent possible but had concerns about how this could be applied in practice

Conclusions: Placing all choices at the consent to testing stage is neither practical nor desirable. Broad consent can provide more valid consent than long and detailed consent.

Funded by National Institute of Health Research

EPL3.3

Outcomes of a Randomized Controlled Trial of Consent Models for Genome Sequencing

B. B. Biesecker¹, P. Chrysostomou², H. Peay³, L. Nelson²;

¹NHGRI, NIH, Bethesda, MD, United States, ²NICHD, NIH, Bethesda, MD, United States, ³RTI, Chapel Hill, NC, United States.

Consent to undergo genome sequencing is more complex than consenting participants to a single gene test. The depth and scope of the results and dimensions of uncertainty exceed any prior testing. No standard for consent to participate in genome sequencing studies exists. This randomized controlled trial (RCT) compares an evidence-based streamlined consent (4 pages) to a "standard" NIH consent (6 pages). Outcomes were knowledge, informed choice and decisional conflict. Randomization to one of the models was followed by a consent discussion with a genetic counselor. Participants completed surveys at baseline, directly following the consent intervention and six weeks later. Two hundred twelve women affected with primary ovarian insufficiency (POI) and eligible for an exome study participated in the RCT; 192 completed all three surveys. The women were on average 39.2 years old (± 6.8 years), white (78.8%) and held a college (34.8%) or post-graduate (51.1%) degree. There were no statistically significant differences in knowledge between the consent models ($F=0.93$, $p=0.336$). Most participants had a greater understanding of the benefits and limitations of genome sequencing but less understanding of hereditary concepts. Patients with a family history of POI (30) had a significantly better understanding of sequencing ($r=0.16$, $p=0.031$) than those with no family history (139). If informed choice and decisional conflict complement our knowledge results, our findings suggest a streamlined consent may be as effective as a standard NIH consent process.

The UK 100,000 genomes project: views, expectations, and experiences of the first patients recruited

S. Dheensa, A. Lucassen, A. Fenwick, G. Crawford;
University of Southampton, Southampton, United Kingdom.

Introduction: The 100,000 genomes project is unprecedented and introduces several practices that are novel for the health service. As well as seeking a genetic diagnosis for the presenting rare disease, patients and families can have their genomes interrogated for additional risks amenable to intervention, such as inherited cancers and cardiac conditions. Notably, testing for autosomal-recessive carrier risk is offered solely to couples planning to

have more children and reported only if both parties are carriers. We are exploring views, expectations, and experiences of this new venture, and in particular, consent and communication practices for additional and carrier findings.

Methods: Our research design is mixed-methods, involving questionnaires and longitudinal interviews with participating patients and families; focus groups with healthcare professionals; and observations of consent and feedback consultations. At abstract submission, we had analysed 65 questionnaires and 15 interviews.

Results: Patients/families have realistic expectations about receiving a primary diagnosis. However, they also have limited understanding of the information materials provided. They are unsure what genetic and genomic tests involve; are anxious about when, how, and by whom results will be delivered; are apprehensive about the uncertain implications of primary and additional findings; and although feel privileged to have additional testing, would prefer to receive individual carrier results.

Conclusions: Patients/families speak positively of whole-genome sequencing. Nevertheless, we are identifying areas of the consent process that warrant improvement. To this end, we will design digital tools based on our ongoing research to help families understand their results and, where relevant, communicate them to relatives.

Diagnostic whole exome sequencing in pediatrics: Comparing parents' pre- and post-disclosure attitudes toward return of results

C. Cornelis^{1,2}, A. Tibben³, W. Dondorp⁴, M. van Haelst¹, A. Bredenoord⁵, N. Knoers¹, M. Düwelf⁶, I. Bolt², M. van Summeren⁶;

¹Department of Genetics, University Medical Center Utrecht, Utrecht, Netherlands,

²Ethics Institute, Utrecht University, Utrecht, Netherlands, ³Department of Clinical

Genetics, Leiden University Medical Center, Leiden, Netherlands, ⁴Department of

Health, Ethics & Society, Maastricht University, Maastricht, Netherlands, ⁵Julius Center,

Department of Medical Humanities, University Medical Center Utrecht, Utrecht,

Netherlands, ⁶Department of General Pediatrics, Wilhelmina Children's Hospital,

University Medical Center Utrecht, Utrecht, Netherlands.

Introduction: Parents' experiences, attitudes, and preferences regarding return of results from diagnostic whole exome sequencing (WES) for their child remain largely unexplored. Yet these insights are needed for morally responsible policy-development.

Method: Semi-structured interviews were conducted with parents of 16 children at two moments: parents were first interviewed after consenting to WES (trio-analyses), but prior to feedback of results; parents were then interviewed again after receiving the results.

Results: Some parents reported changes in attitudes toward disclosure of certain findings while waiting for results, but none expressed a desire to modify choices for unsolicited findings (UFs) or to revoke their decision for WES. Parents received different types of results or combinations thereof: primary results and/or UFs - some results were of unclear significance. Experiences with disclosure of results varied and depended largely on what parents' reasons were for consenting to WES and/or receiving UFs as well as on the expectations and hopes on which their reasoning was based. Sometimes results were in line with parent's expectations or positively exceeded them; sometimes expectations were only partially fulfilled, for example, this included situations in which an important reason for consenting to WES was to envision the child's future (cognitive) development, but where results only offered a general indication of what level of development the child might be able to attain.

Conclusion: These insights inform ethical theorizing on policy-development for WES and UFs in child cases.

This project is funded by ZonMw (grant 70-73000-98-047) - The Netherlands Organization for Health Research and Development.

EPL3.6

Who is my family's keeper? Professional and family ethics in the era of unsolicited findings

R. H. P. Wouters¹, E. E. Voest², R. M. Bijlsma¹, M. G. E. M. Ausems¹, J. J. M. van Delden¹, A. L. Bredenoord¹;

¹University Medical Center Utrecht, Utrecht, Netherlands, ²The Netherlands Cancer Institute, Amsterdam, Netherlands.

Introduction: as next-generation sequencing finds its way into clinical practice, ethical issues regarding disclosure of genetic information towards family members become more urgent than ever before. Who is responsible for conveying genetic risk information to family members? Unsolicited findings put geneticists and counsellors in a dilemma between (amongst others) respecting their patients' privacy and providing potentially life-saving information to probands' relatives. In this debate the focus has particularly been on professional moral duties, and patients' and family members' own

responsibilities are easily being overlooked. **Materials and Methods:** this presentation provides an ethical analysis of professionals' and patients' responsibilities towards family members at-risk for curable or preventable genetic diseases. Arguments from different ethical perspectives will be identified and critically evaluated. **Results:** the duty to warn is equally demanding to genetic professionals and patients. Yet professionals have conflicting duties such as patient confidentiality. Responsibilities that arise within a family do not play an important role in contemporary medical practice, but the current debate on unsolicited findings draws the attention towards the patient as moral agent co-responsible for his children's and siblings' health. **Conclusion:** there is a moral basis for the claim that both patients and professionals have a duty to warn relatives that are at risk for hereditary diseases. New strategies for genetic disclosure as a shared responsibility are needed. In order to achieve this, IT applications may provide a valuable contribution. This research is funded by the Dutch Cancer Society.

EPL4 Reporting the Results: Clinical and Ethical Considerations

EPL4.1

When children become adults: should biobanks re-contact?

N. A. A. Giesbertz^{1,2}, A. L. Bredenoord², J. J. M. van Delden²;

¹Department of Genetics, UMC Utrecht, Utrecht, Netherlands, ²Department of Medical Humanities, Julius Center, UMC Utrecht, Utrecht, Netherlands.

Pediatric biobanks facilitate research, which is considered important for improving (pediatric) health care by generating biomedical knowledge. However, pediatric biobank research gives rise to specific ethical issues. At the time of inclusion, many children cannot, or are legally not allowed to, consent for themselves, and typically parental permission is required. Samples may still be stored and used by biobanks when children become autonomous adults. The question arises whether children should be re-contacted to obtain their own consent, or give the opportunity to withdraw their samples, when they reach adulthood. Major guidelines do not provide sufficient guidance on re-contact and consent, and there is only very limited literature that analyses the issue in depth. Given the fact that biobanks already include pediatric samples, and in light of the rapid developments in biobank research, it is important to address the issue of re-contact and consent now. We discuss arguments in favor and against re-contacting participants at maturity and examine different re-contact policies that can be considered, ranging from a thin opt-out policy (participants can withdraw their samples, but the biobank does not re-contact the participant) to a strict opt-in (samples will be destroyed when participants do not give their consent). We suggest that biobanks adopt a thick opt-out as the default re-contact policy, which means that biobanks re-contact children at maturity and give them the opportunity to withdraw their samples.

EPL4.2

Re-contact in clinical practice: investigating the perspectives of healthcare professionals in the United Kingdom

D. Carrieri¹, S. Dheensa², S. Doheny³, P. D. Turnpenny⁴, A. J. Clarke³, A. M. Lucassen², S. E. Kelly¹;

¹Egenis, University of Exeter, Exeter, United Kingdom, ²Faculty of Medicine, University of Southampton, Southampton, United Kingdom, ³School of Medicine, Cardiff University, Cardiff, United Kingdom, ⁴Royal, Devon & Exeter Hospital, Exeter, United Kingdom.

The rapid introduction of genetic technologies in medicine is creating new information that can have implications for patients' and families' health, reproductive decisions, lifestyle choices, employment, and psychosocial wellbeing. Do healthcare professionals, such as clinical genetics specialists, have a responsibility or duty to re-contact former patients to communicate this new information? There is no professional consensus about whether and how re-contacting should happen. There is also limited empirical evidence concerning the perspectives of healthcare professionals and patients. We conducted interviews with over 30 healthcare professionals from clinical genetics, and other specialties potentially involved in re-contacting. Re-contact does take place, but generally in an *ad hoc* fashion, e.g. when clinicians happen to review a file for other reasons. Decisions about whether and how to re-contact were based on the specific patient and/or family, and the perceived utility of the result. Whilst there was uncertainty about whether more systematic re-contacting processes should be implemented, the need for a professional debate to agree in what situations re-contacting should be considered good standard of practice was highlighted. Some re-

spondents argued that the creation of re-contact guidelines may help clinical services to be allocated more resources. Others argued that this might create a legal obligation to re-contact thereby using up scarce resources. To determine whether guidelines would be useful, more empirical evidence is needed. To this aim, we will also explore the experiences and expectations of patients and other stakeholders, such as support groups. **Funder:** Economic and Social Research Council (UK) Webpage: <http://ex.ac.uk/mgc>

EPL4.3

Incidental findings derived from Next-Generation sequencing: what does actionable in childhood really mean?

A. Laberge¹, J. Richer²;

¹Medical Genetics, Department of Pediatrics, Ste-Justine, Montreal, QC, Canada, ²Children Hospital of Eastern Ontario, Ottawa, ON, Canada.

Genome-wide sequencing has been performed on a research basis for several years and now clinical diagnostic services based on these technologies are increasingly requested. Incidental findings are identified in 1-2% of tested individuals undergoing whole exome sequencing. The question of which incidental findings to return to patients has generated much discussion including formal position statements in Canada, the USA and Europe. While most agree that actionable findings should be offered to all competent adults, the discussion becomes more complex for paediatric patients with a number of organizations recommending reporting back incidental findings actionable in paediatric. In order to better understand which conditions may be actionable in childhood, we approached the question from a public health perspective, applying the WHO screening criteria to determine if a condition was a good target for opportunistic screening in the context of genome sequencing. We applied this framework to the list of 56 genes conditions considered actionable and therefore reportable by the ACMG in the context of genomic sequencing. We concluded that assessment of actionability during childhood should strongly consider issues of:

- o penetrance of treatable manifestations (not simply of any manifestation of the condition) at 18 years,
- o likelihood and severity of adverse outcome with this condition,
- o whether a clear risk-reduction intervention with proven (not simply anecdotal) benefits is available.

For incompletely penetrant conditions, the likelihood to have a deleterious impact on the patient if we wait for them to display clinical symptoms to establish a diagnosis should also be considered.

EPL4.4

Autonomy in the genomics era

A. J. Newson;

University of Sydney, Sydney, Australia.

Introduction: Genomic testing is placing unprecedented pressure on the concept of autonomy. Traditionally a paramount principle in genetic testing, autonomy is now at risk of being trumped by other considerations, such as what may be in an individual's or population's 'best interests'; or the ongoing normalisation and integration of genomic information in health care. **Materials and Methods:** This paper will use methods of theoretical bioethics (applied ethics). That is, the paper will proceed by way of analysing key concepts and case studies to build a normative ethical position on the role that considerations of autonomy should play in genomics.

Results: The paper will commence with an analysis of autonomy and how it has traditionally been employed in clinical genetics and associated disciplines. Then, using case studies, an apparent move away from presumptions of autonomy will be described. This emergent status will then be critiqued, to build an argument that autonomy should remain at the heart of genomic decision-making. However, it will also be recognised that the concept of autonomy may need refinement; in particular to account for the potential ubiquity and ongoing shared nature of genomic information. The goal is to resolve tensions between individual and collectivist approaches to information provision and decision-making. **Conclusions:** The paper will conclude by claiming that autonomy is not an obsolete concept and that it has significant relevance for genomic medicine. This will mean that emerging practices, such as an inability to opt out of receiving genomic information, may not always be ethically defensible.

EPL4.5

An exploration of reporting practices for next generation sequencing technologies with laboratory personnel

D. F. Vears¹, K. Sénécal², P. Borry²;

¹Centre for Biomedical Ethics and Law, KU Leuven, Leuven, Belgium, ²Centre of Genomics and Policy, McGill University, Montreal, QC, Canada.

Next-generation sequencing (NGS) technologies are identifying causative mutations in individuals who would have previously remained undiagnosed, influencing their treatment and providing important information to their families. However, they also have the potential to identify additional genomic information that is unrelated to their illness, such as variants in genes with unknown function (VUS) and mutations in genes causing phenotypes extraneous to the clinical question (incidental findings, or IFs). Recommendations by professional bodies outlining which findings should be reported by laboratories to the clinician requesting the test are inconsistent. Little is known about which variants laboratories are reporting and how they are using guidelines to make decisions about this.

To address these questions, in-depth interviews were conducted with laboratory staff in Europe, Canada and Australia to explore reporting practices for diagnostic NGS. Reporting of variants of uncertain significance (VUS) differed between laboratories depending on the perception of its relevance to the clinical question. There was considerable variation in the filtering strategies that participants described. While some laboratories use quite stringent filtering in order to limit the number of IFs that are identified, others are less strict, allowing identification of these variants. Whether these IFs are then reported to the clinician often involves detailed discussions, involvement of multidisciplinary committees, and consideration of factors such as actionability.

Our study highlights that laboratories are still grappling with decisions about which variants to report from NGS. These findings will assist laboratories to learn from each other's experiences and refine reporting guidelines.

EPL4.6

Informing preparation for personal genomic screening

J. Fleming¹, B. Terrill², M. Dziadel², E. Kirk², A. Roscioli^{2,3}, K. Barlow-Stewart¹;

¹University of Sydney Medical School - Northern, Sydney, Australia, ²Garvan Institute of Medical Research, Sydney, Australia, ³Sydney Children's Hospital, Randwick, Sydney, Australia.

Exploring the experience of individuals undertaking personal genome screening (PGS), offered in Australia since 2014, provides a unique opportunity to inform preparation for testing. To date 15 individuals have been interviewed: nine with genetics expertise, six without. PGS results included an autosomal dominant condition neurofibromatosis type 1 (NF1) not previously clinically identified; carrier status for recessive condition(s); a number of variants identified as likely pathogenic but many of uncertain significance; and pharmacogenetically relevant mutations.

Analysis has identified common themes between the groups: The importance of the pre-testing counselling session with positive experiences with clinical geneticists/genetic counsellors. Barriers to uptake: including skepticism of family members, medical practitioners, genetics colleagues, and privacy concerns. Genetics professionals cited rationale for testing as professional interest and/or curiosity, without anticipating personal or family impact; non-genetics professionals reported personal interest, curiosity, and interest in being an early adopter. On reflection, despite this initial objective motivation, several found the impact of the test results had unanticipated personal impact and changed over time and later recognized their relevance, as health problems developed or family history was interrogated more closely. Disclosure of results has been limited. Participants felt that expectations; residual risk; changes in interpretation with developing phenotypes; and personal and family impact and communication needed greater emphasis at the pre-test session. Some non-genetics professionals felt information provided in the report was too complex.

As saturation of data from genetic professionals has been achieved, interviewing of non-genetics professionals is continuing to further explore similarities and differences between the two groups.

EPL5 From Public Understanding to Educating Professionals

EPL5.1

Socialising the Genome

A. Middleton¹, J. Borra², K. Nevin-Ridley³, V. Parry³, A. Sanders⁴, J. Rayner⁵;

¹Wellcome Trust Sanger Institute, Cambridge, United Kingdom, ²Thin Air Factory, London, United Kingdom, ³Genomics England, London, United Kingdom, ⁴Wellcome Trust, London, United Kingdom, ⁵Wellcome Genome Campus, Cambridge, United Kingdom.

How to start a conversation about genomics with people who may know nothing about it? This is particularly relevant for patients involved in the 100,000 Genomes Project, a landmark new UK sequencing project taking place within the National Health Service. We aimed to 'socialise' genomics for participants and their families using an innovative method that combines evidence from social science with creative story telling as used by the advertising industry. We have done this through the use of animations designed to get patients talking with their families or health professionals. Through insights gained from five focus groups with membership drawn from the British public, we were able to develop core themes on which to base our animations. Using the creative skills of a senior advertising director from an established advertising company the themes were turned into six narratives. These delivered information about genomics using metaphors and cultural context, as opposed to scientific text or drawings. Feedback on each of the animations will be presented from a representative British public group of 500 people as well as from 1,000 participants and publics. The six novel, evidence-based animations will be used as part of a public engagement campaign for Genomics England. We will show our open access animations in our presentation. They are freely available for anyone to use, irrespective of where they live in the world.

EPL5.2

General public's attitudes towards genetics and genetic testing

D. Chokoshvili¹, C. Belmans¹, R. Poncelet¹, S. Sanders¹, D. Vaes¹, I. Huys¹, P. Borry¹;

¹University of Leuven, Leuven, Belgium.

As genetic testing becomes more readily available, it is important to study attitudes of the general public towards human genetics and genetic testing. To address these questions, we performed structured interviews with visitors to the annual cartoon festival in Knokke-Heist, Belgium, during the summer of 2014. The main theme of the festival was challenges and progress in human genetics and more than 100 000 visitors attended the event. The survey was completed by 1182 respondents, resulting in a demographically diverse sample with a mean age of 48.5 years (range 16-87). The majority of respondents (64.6%) were curious about their genetic predisposition to diseases, while 49.5% were interested in testing solely for treatable and/or preventable disorders. Among the respondents aged 41 or younger (n=399), 54.6% were willing to undergo carrier screening for recessive disorders before pregnancy and 54.1% would consider testing their unborn children for all serious genetic diseases during pregnancy. Almost two-thirds (64.7%) of all participants anticipated that in the near future, genetic tests will be routinely required by insurance companies for determining the insurance premium, while 23.9% indicated they were worried that genetic tests results would fall in the wrong hands. The concern over potential misuse of genetic test results was significantly greater among those who identified as religious (p<0.01). Studying the opinions and concerns of the general public is essential to ensure socially responsible adoption of new genomic technologies and identify the areas where educating the public could offer the greatest benefits.

EPL5.3

Exploring Australian public knowledge and understanding of genetic concepts and terminology in the era of personal genomics

S. A. Metcalfe¹, B. Terrill², C. Hickerton³, J. Savard³, E. Turbitt⁴, A. Newson³, C. Gaff⁵, K. Gray⁶, A. Middleton⁶, B. Wilson⁷;

¹Murdoch Childrens Research Institute and Dept Paediatrics, University of Melbourne, Parkville, Vic, Australia, ²Garvan Institute of Medical Research, Sydney, NSW, Australia, ³The University of Sydney, Sydney, NSW, Australia, ⁴Walter and Eliza Hall Institute of Medical Research and Dept Paediatrics, University of Melbourne, Parkville, Vic, Australia, ⁵Health and Biomedical Informatics Centre, University of Melbourne, Parkville, Vic, Australia, ⁶Wellcome Trust Sanger Institute, Cambridge, United Kingdom, ⁷School of Epidemiology, Public Health and Preventive Medicine, University of Ottawa, Ottawa, ON, Canada.

Personal genomic testing provides healthy individuals with access to information about their genetic makeup for purposes that include ancestry, paternity, sporting ability and health. While much of this testing has occurred within the USA, it is likely that such testing will become routine and acces-

sible to everyone.

Focus groups were conducted within a multi-disciplinary project to explore Australians' awareness of personal genomic testing. In mid-2015, 56 members of the public participated in 7 focus groups, allocated into 3 age groups: 18-25, 26-49 and ≥50 years. Three researchers coded transcripts independently and themes were generated. Here we present themes focusing on awareness of personal genomic testing and genetic literacy.

No-one had heard of the term 'direct-to-consumer' testing; most were not familiar with 'personal genomic testing' as such, but could deduce what 'personal genomics' might entail. Participants' descriptions of DNA, genetics and genomics varied according to prior experience and education. They were familiar with ideas of heredity and acknowledged genetic influences on physical characteristics. There were diverse perceptions of the relative influence of genetics and environment on health, mental health, behaviour, talent or personality. While many participants felt their own understanding of genetics was limited and did not mention specific terms, such as epigenetics, they were able to contribute to discussions using descriptive language. The focus groups highlighted challenges of using specific, jargon-laden genetic terms in public discussions. These findings can inform development of more engaging services and educational resources for the public to understand and make decisions around these marketed tests.

EPL5.4

Development of Test Ordering Recommendations for Clinicians with Minimal Genetics Background from the ClinGen Consortium Consent and Disclosure Recommendations (CADRe) Committee

K. E. Ormond¹, M. Hallquist², A. Buchanan², M. Cho³, K. Brothers³, C. R. Coughlin II⁴, L. Hercher⁵, L. Hudgins⁶, S. Jamal⁶, H. Levy⁷, H. Peay⁸, M. Roche⁹, M. Stosic¹⁰, M. Smith¹¹, W. Uhlmann¹², K. Wain¹³, W. A. Faucett²;

¹Stanford University School of Medicine, Stanford, CA, United States, ²Geisinger Health System, Danville, PA, United States, ³University of Louisville, Louisville, KY, United States, ⁴University of Colorado, Aurora, CO, United States, ⁵Sarah Lawrence College, Bronxville, NY, United States, ⁶Sick Kids Hospital, Toronto, ON, Canada, ⁷Johns Hopkins University, Baltimore, MD, United States, ⁸Parent Project Muscular Dystrophy and DuchenneConnect Registry, Research Triangle, NC, United States, ⁹University of North Carolina, Chapel Hill, Chapel Hill, NC, United States, ¹⁰Natera, San Carlos, CA, United States, ¹¹Northwestern University, Chicago, IL, United States, ¹²University of Michigan, Ann Arbor, MI, United States, ¹³Geisinger Medical Center, Danville, PA, United States.

Molecular genetic testing is increasingly ordered by clinicians in specialties beyond clinical genetics. Germline genetic testing can involve complex ethical, legal, social, medical and logistical (ELSIplus) issues; non-genetics clinicians have limited training in adjusting communication plans for patients based on these issues. Requiring all patients undergoing genetic testing to be referred for traditional genetic counseling is not scalable. Therefore, this project developed rubrics to guide non-genetics clinicians in identifying potential consent and disclosure ELSIplus issues that may inform the consent/disclosure approach and degree to which genetics clinicians may be involved for a given gene. We recruited stakeholders representing viewpoints of genetic counselors, MD geneticists, ethicists, pediatricians, policy experts, and patient advocates to join CADRe and convened multiple conference calls and an in-person meeting. We then used snowball sampling methodology to survey clinicians to assess whether the rubric was effective. We will present the rubric development and revision process, during which 14 participants enumerated many topics to consider, including: test and disease characteristics, provider/patient misinterpretation, growing cultural awareness of genetic testing in the general public, patient preferences, varying quality and availability of educational materials, necessity for a follow-up plan, cascade testing, testing context, emotional burden, and lab/clinician reporting methods. Survey results will demonstrate the rubric use for genes including HTT, DMD, OTC, GJB2, MLH1, CDH1, TP53, CYP2C9 and VKORC1. The CADRe committee expects to further revise the rubrics after focus groups are conducted in summer 2016, and plans to provide review of actionable genes using the CADRe rubric during 2017.

EPL5.5

E-learning to improve communication about cancer family history and knowledge on hereditary colorectal cancer by non-genetic health professionals

K. F. L. Douma, E. M. A. Smets, E. Dekker, P. J. Tanis, C. M. Aalfs; Academic Medical Center, Amsterdam, Netherlands.

Introduction: A recent study showed that hereditary colorectal cancer often goes unrecognized, because of inadequate discussion of cancer family history. This leads to suboptimal referral for genetic counselling and can have negative health consequences for both patients and family members. To improve knowledge and discussion of cancer genetic topics we aim to develop

an e-learning for gastroenterologists (GEs) and surgeons. Materials and methods: Through an online focus group we investigated the attitudes of 3 GEs and 5 surgeons in training towards cancer family history collecting, discussing genetic testing and their needs regarding an e-learning intervention. Subsequently, the results were discussed with a GE, surgeon, clinical geneticist, medical psychologist, an educational and an information technology expert to develop a framework. Results: GEs and surgeons in training are positive towards collecting a family history. However, they lack experience and oncogenetic knowledge and perceive this as more important than lack of communication skills. Furthermore, they perceive time pressure as well as difficulties in managing patient's reactions. Also, they lack knowledge on useful information sources (e.g. guidelines). These clinicians appreciate an e-learning, but want it to be short and case-based. Conclusions: The focus group has shown that the e-learning should be short, case-based and focus on knowledge instead of communication skills. Currently, the e-learning is tested among a group of surgeons and GEs (n=50). The e-learning and its evaluation will be presented during the conference.

This study is financially supported with a Dutch Cancer Society fellowship grant (UVA 2011-4918)

Onco-equip: Preparing healthcare professionals in cancer care for routine genetic testing

L. M. Jackson, H. Skirton;

Plymouth University, Plymouth, United Kingdom.

Genetic testing can now inform management options for individuals affected with breast or ovarian cancer and will therefore be increasingly used in cancer care settings. The aim of this project was to prepare medical and nursing staff who are involved in offering and performing genetic testing prior to making cancer management decisions. The key objective was to ensure that testing is offered safely and appropriately to patients in Europe. We used an expert advisory group consisting of clinicians, scientists and patient representatives to define the required content of an educational programme and developed a series of four online interactive modules. These are: how genes influence breast and ovarian cancer, genetic testing in patients with cancer, consent for genetic tests and explaining the result. Each module is based on a case scenario and learners must interact with the material to progress through the module. This educational programme can be undertaken free of charge and has been widely advertised using websites, Twitter, Facebook and at relevant professional conferences. A pre and post module test is part of the package, and professionals who wish to can obtain a certificate of completion after achieving a post-module score of at least 80%. Initial pre-module scores indicate that many health professionals working in these settings have poor understanding of the topic and that there are significant differences in knowledge as a result of the programme. Here we report further on the development of the educational program and the initial educational outcomes.

Introduction: Multiplex cancer testing allows for parallel sequencing simultaneously, but little is known about the psychological impact of these tests. Our aim was to analyze the patient's preferences regarding genetic counselling and the psychological impact of a multiplex cancer panel.

Materials and Methods: 210 patients who underwent panel testing (MyRisk 25-gene panel, FAMOSA study) were included (76% women, 44% with prior negative genetic result). Participants completed self-questionnaires regarding genetic counseling preferences and three psychological scales (MICRA, CWS, R-IES) at baseline, one week and three months after results disclosure.

Results: Most participants would like to be disclosed variants of unknown significance (VUS) and deleterious variants in moderate penetrance genes (72% and 78%, respectively).

At one week, mutation carriers showed higher distress compared to non-carriers and VUS carriers ($p < 0.01$). Adverse reactions were higher in those with positive results (7.56) than those with VUS (4.86) and those with negative results (3.44) ($p < 0.001$), and this difference was maintained after three months ($p < 0.01$). Participants who carried a mutation in a moderate penetrance gene showed higher cancer worry than high-penetrant mutation carriers ($p < 0.05$). No differences in uncertainty were observed, regardless of the genetic test result.

Overall, the psychological impact (IES score) decreased significantly after 3 months ($p < 0.001$).

Conclusions: Patients are willing to be disclosed all available information from panel testing. Differences in terms of family support and communication were observed among type of results at short and mid-term. Cancer worry was higher in moderate-penetrance carriers than high-penetrance carriers. Longer follow up is undergoing.

EPL6.2

The impact of predictive genetic testing for cancer on young adults

L. Godino^{1,2}, D. Turchetti², L. Jackson¹, C. Hennessy¹, H. Skirton¹;

¹School of Nursing and Midwifery, Faculty of Health and Human Sciences, Plymouth University, Plymouth, United Kingdom, ²Unit of Medical Genetics, Department of Medical and Surgical Sciences, St. Orsola-Malpighi Polyclinic, University of Bologna, Bologna, Italy.

Predictive genetic testing should involve a considered choice, which is particularly true when testing is undertaken in early adulthood. We carried out a systematic review that showed that many young adults grew up with little or no information concerning their genetic risk and that parents had exerted pressure during the testing decision-making process. However, none of the studies retrieved were conducted in Italy or other South-European countries. To address this gap, we undertook a qualitative study based on grounded theory to explore the psychosocial implications of predictive testing for hereditary cancer in young Italian adults aged 18-30 years. Interviews were conducted on three occasions: one month before genetic counselling, two weeks after counselling and six months later. Interviews were transcribed and analysed using grounded theory. To date, a total of 37 interviews with 15 participants have been conducted. Findings are reported under four themes: knowledge, genetic counselling process, decision making and dealing with test results. Although participants grew-up with little or no information about their genetic risk, none expressed regret at having the test at a young age. Pre-test counselling was appreciated as a source of information, rather than a support in decision-making. Decisions were often autonomous and sometimes conflicted with parents' wishes. Participants who have completed all three interviews to date reported changing their health behaviours after learning their genetic test result. Further analysis are required to determine how young adults conceptualise and utilise genetic risk in their daily life to inform genetic counselling practice in this client group.

How to approach all high risk members in known Lynch Syndrome families? Experiences of different contact methods and perceived challenges in passing the information to family members in Finland

K. I. Aktan-Collan¹, A. Haukkala¹, E. Koltola¹, J. Mecklin², K. Pylvanainen², H. Kääriäinen³;

¹University of Helsinki, Helsinki, Finland, ²Jyväskylä Central Hospital, Jyväskylä, Finland, ³National Institute of Health and Welfare, Helsinki, Finland.

Introduction: Identification of hereditary predisposition to cancer has limited significance if not followed by efficient cancer prevention. Of all known 3000 Finnish LS family members tested, 1500 are mutation carriers with 2110 offspring. Of these, 973 have had genetic testing while 1137 not. Most subjects have been contacted using family mediated approach (FMA) via index-patient but we have also contacted them directly (DCA) in research setting. Despite the efforts, 528 known high-risk adults have not been approached, and may be developing a fatal disease. Here, we investigated the challenges involved, and will discuss options for the future.

Methods: In DCA study we approached 286 adults with a 50% carrier risk in 102 LS families by direct letter and compared the response with 446 corresponding subjects using FMA. Furthermore, we investigated by questionnaire among carrier parents over age 40 ($n = 248$) needs and challenges in communication to offspring. Qualitative interviews were done among 10 carriers.

Results: The test uptake was 75% in FMA and 39% in DCA. One reason for

DCA higher failing may be the contact letter, being too considerate and thus vague. In family communication, informing the children about their risk was experienced most difficult, and 30% of parents reported a wish for professional help. The qualitative interviews indicated that communication did occur but had several complexities.

Conclusions: The challenge is to improve the contact and communication processes, so that all family members would get the information important for their healthcare. Possibilities of additional strategies will be discussed.

EPL6.4

Increasing awareness of lifestyle recommendations for cancer prevention among Lynch syndrome mutation carriers: results of a randomized controlled trial

A. Visser¹, A. Vrieling¹, M. Hoedjes², E. Kampman³, N. Hoogerbrugge¹;

¹Radboud university medical center, Nijmegen, Netherlands, ²Department of Health Sciences, VU Amsterdam, Amsterdam, Netherlands, ³Radboud university medical center and Wageningen University, Nijmegen and Wageningen, Netherlands.

Introduction: Lynch Syndrome (LS) carriers may potentially reduce their cancer risk by adhering to the World Cancer Research Fund/American Institute for Cancer Research (WCRF/AICR) lifestyle recommendations for cancer prevention. This study tested the effect of providing LS carriers with WCRF-NL materials on awareness of and adherence to these recommendations.

Materials and Methods: A randomized controlled trial in 218 LS carriers was conducted. Two weeks after randomization, the intervention group ($n=113$) received WCRF-NL health promotion materials. All participants were asked to fill out questionnaires at three time points: at baseline (T0), at 4 weeks (T1) and 6 months (T2) after randomization. Per-protocol analyses ($n=198$), using repeated measures ANOVAs, were performed to test differences over time between both groups on the primary outcomes: awareness of (scale 0-7) and adherence to the WCRF/AICR recommendations. Secondary outcomes were knowledge (scale 0-7), cancer risk perception, psychological distress and cancer worry.

Results: At T1, the intervention group was significantly more aware ($M_{\text{intervention}} = 5.8 \pm 1.6$; $M_{\text{control}} = 4.2 \pm 2.3$, $p < .001$) and showed a significantly improved knowledge of the recommendations ($M_{\text{intervention}} = 4.6 \pm 1.7$; $M_{\text{control}} = 2.5 \pm 1.6$, $p < .001$) compared to the control group. No effect was found on cancer risk perception, psychological distress, or cancer worry. Results on adherence and follow-up results will be presented.

Conclusions: The WCRF-NL materials are an easy-to-implement tool to increase awareness of and knowledge about the lifestyle recommendations for cancer prevention among LS carriers, without causing additional distress or cancer worry. Creating awareness is an important first step in increasing adherence to these recommendations.

Group-based patient education (GPE) courses for hereditary breast and ovarian cancer

W. Listø^{1,2}, H. Høberg-Vetti^{1,2}, G. Eide^{3,4}, C. Bjorvatn^{1,5,6};

¹Western Norway Familial Cancer Center, Haukeland University Hospital, Bergen, Norway, ²Center for Medical Genetics and Molecular Medicine, Haukeland University Hospital, Bergen, Norway, ³Centre of Clinical Research, Haukeland University Hospital, Bergen, Norway, ⁴Department of Global Public Health and Primary Care, University of Bergen, Bergen, Norway, ⁵Learning and Mastery Center in Bergen, Bergen, Norway, ⁶Department of Clinical Science, University of Bergen, Bergen, Norway.

Introduction: Women carrying BRCA-mutations are facing significant challenges, including decision making regarding risk-reduction. They often report that they are left alone with these important decisions. In order to enhance the genetic counselling session, we organized a GPE-course for women with BRCA-mutations. In the present study we investigated the characteristic of those with increased levels of anxiety and depression.

Materials and Methods: A prospective study was conducted. Two weeks before (T1) and two weeks after (T2) attending the GPE-course the participants received questionnaires by mail. We collected information on demographic- and medical variables, anxiety and depression, self-efficacy and coping style. Five courses were arranged. A total of $N = 100$ (77 %) women answered the questionnaires at baseline, and 75 (58%) completed both questionnaires.

Results: The mean level of anxiety was quite high among the participants, but was significantly reduced during the follow up period. One of the main findings was that lower levels of anxiety is associated with the time since disclosure of gene test result, higher levels of self-efficacy, and the loss of a close relative due to breast- or ovarian cancer. While lower levels of de-

pression is associated with higher levels of education, and the loss of a close relative due to breast- or ovarian cancer.

Conclusion: Overall the women in this study benefited from the course. The most vulnerable women were those newly diagnosed with a *BRCA* mutation, lower levels of self-efficacy and lower levels of education. These women need special attention.

Development of new resources to improve communication in genetic counselling practice

M. Álvarez Estapé^{1,2}, **I. Cuscó**^{2,3,4}, **L. Pérez-Jurado**^{2,3,4}, **C. Serra-Juhé**^{2,3,4};

¹Biosciences Faculty, Universitat Autònoma de Barcelona, Bellaterra, Spain, ²Genetics Unit, Universitat Pompeu Fabra, Barcelona, Spain, ³Hospital del Mar Research Institute (IMIM), Barcelona, Spain, ⁴Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), Instituto de Salud Carlos III, Barcelona, Spain.

Introduction: Genetic counselling aims to help patients and families to decide the course of action which seems more appropriate to them and make the best possible adjustment in relation to the genetic disease affecting them. This objective requires, among others, that the counsellor succeeds in communicating in a clear and appropriate manner to the patient and family the information related to the disorder. Many factors interfere in how much information do the counselees absorb and retain and being in an emotionally stressful situation might be one of them.

Methods: We identified some common weak points in counselling sessions and some concepts which genetic counsellors at two different hospitals in Barcelona consider complex and important for the families to understand their specific disease.

Results: We aimed to develop didactic materials to help counsellors improve the counselees understanding of key concepts in a genetic counselling setting. This material distinguishes the concept of what a chromosome, a gene and the DNA are in clear slides that allow counselees to easily understand these terms. We designed drawings to use in pedigrees hence the patient or family can follow the explanation without getting lost with squares and circles and an explanation of the different types of mutations has also been developed.

Conclusions: These support slides and animations offered in Catalan, Spanish and English provide a modern way of communicating genetics by using parallelisms, examples and simplifications with nice and attractive drawings and diagrams which in consequence may help improve patients and families comprehension.

EPL7.2

What determines decision making in preconception carrier screening and can it be influenced with message framing and narrative information?

J. S. Voorwinden¹, **A. H. Buitenhuis**¹, **E. Birnie**¹, **A. M. Lucassen**², **M. A. Verkerk**¹, **I. M. van Langen**¹, **M. Plantinga**¹, **A. V. Ranchor**¹;

¹UMCG, Groningen, Netherlands, ²University of Southampton, Southampton, United Kingdom.

Introduction: Next-generation sequencing made it possible to create a population based preconception carrier screening test that covers 50 severe autosomal recessive diseases simultaneously. Before this test can be offered, it is important to understand what factors are related to decision making and how the general public can be informed but not influenced in their intention to participate. This will be studied by measuring to what extent message framing and adding narrative information can influence people's intention. Materials and Methods: Data was collected by means of online questionnaires among 504 potential users. Factors were based on the Theory of Planned Behaviour and previous research about decision making. Message framing was manipulated by explaining the risk of carriership in different ways, while for narrative information half of the participants received additional narrative information next to factual information.

Results: Factors related to more intention are: more perceived benefits about testing, experience the choice to participate as easy, non-religiosity, more perceived susceptibility of carriership, more knowledge about preconception screening and being female. Message framing and narrative information have no significant effect on intention to participate, perceived susceptibility and perceived severity.

Conclusions: This research clarifies which factors are most related to decision making. Also that message framing and the addition of narrative information can inform the general public about preconception carrier screening

but will not influence their participation. As perceived benefits of testing are most related to participation, future research should try to understand how people could be made more aware of these benefits.

EPL7.3

Transparency in the marketing of direct-to-consumer genetic tests

J. A. Hall¹, **J. E. Amato**², **C. Pagliari**³;

¹Vivactiv Ltd, Bellingdon, United Kingdom, ²Post-operative Intensive Care Unit Staff, Unimed-Rio Hospital, 22775-003, Rio de Janeiro, Brazil, ³University of Edinburgh Medical School, Edinburgh, United Kingdom.

Introduction: Direct-To-Consumer Genetic Testing (DTCGT) is increasingly marketed to UK consumers, but the transparency of vendors' sales messages or terms and conditions (T&C) is unclear. We analysed information on vendors' websites to assess compliance with Human Genetics Commission recommendations (2010), and sentiments evoked amongst potential consumers.

Methods: Companies advertising in the UK were identified through web searches. Accessible T&C and privacy policies, including data re-use, were assessed against HGC benchmarks. Sentiments evoked by the marketing messages were examined through social media consultation.

Results: After excluding genealogy and paternity services, 14 companies remained, of which 10 were registered in the UK and subject to UK Data Protection laws. These tested nutri-genetics/lifestyle traits (13/14), pre-symptomatic disease (6/14), drug responsiveness (4/14) and carrier status (2/14). The scientific rationale for gene selection was absent in 9 and only 4 clearly stated all genes to be analysed.

Four companies shared both aggregated and individual-level genetic data for unspecified research. Only 2 offered a separate opt-in for research using individual-level data.

Two companies included pre-test counselling and two post-test counselling (as an upgrade). In the T&C, all companies stated information was non-medical and did not guarantee quality.

Marketing sentiments emphasised performance optimisation, self-improvement, knowledge enhancement, scientific altruism, and personalised medicine.

Conclusions: Most DTCGT companies marketing to UK customers are UK registered. Most have lengthy, legalistic T&Cs that consumers are likely to skip. Few HGC recommendations have been adopted. We provide suggestions for increasing transparency, and mechanisms to support oversight of marketing and T&Cs.

EPL7.4

Genomic Newborn Screening: Public Health Policy Considerations and Recommendations

M. C. Cornel¹, **J. M. Friedman**², **A. J. Goldenberg**³, **K. J. Lister**⁴, **K. Sénécal**⁵, **D. F. Vears**⁶, the Global Alliance for Genomics and Health Regulatory and Ethics Working Group Paediatric Task Team;

¹Section Clinical Genetics, Department of Clinical Genetics and EMGO Institute for Health and Care Research, VU University Medical Center, Amsterdam, Netherlands, ²Department of Medical Genetics, University of British Columbia and Child & Family Research Institute, Vancouver, BC, Canada, ³The Center for Genetic Research Ethics and Law, Department of Bioethics, Case Western Reserve University, Cleveland, OH, United States, ⁴Office of Population Health Genomics, Public Health Division, Department of Health, Government of Western Australia, Perth, Australia, ⁵Centre of Genomics and Policy, Department of Human Genetics, McGill University, Montreal, QC, Canada, ⁶Centre for Biomedical Ethics and Law, Department of Public Health and Primary Care, KU Leuven, Leuven, Belgium.

Genomic technologies such as genome-wide sequencing, can identify genetic causes of rare paediatric diseases much more effectively than conventional clinical and laboratory methods. However, the nature of this technology and its potential to identify additional information about the child being tested raises a range of concerns, particularly when these technologies are applied in a public health setting, such as newborn screening (NBS).

The Global Alliance for Genomics and Health is an international collaboration of more than 370 healthcare, research, disease advocacy, life science, and information technology institutions formed to promote human health through sharing of genomic and clinical data [<http://genomicsandhealth.org/>]. Within this remit, the Paediatric Task Team of the Global Alliance's Regulatory and Ethics Working Group was established to address issues of particular relevance to child health.

This Paediatric Task Team has developed the following recommendations for clinicians, clinical laboratory scientists, and policy makers regarding the use of genomic technologies for population-based newborn screening:

NBS by genomic methods should only be considered as an add-on to current screening programs, which should not be replaced unless equal or better

sensitivity and specificity is shown. Equal availability and accessibility to every infant born in the jurisdiction should be guaranteed. Data sharing is needed for interpretation of variants. Publicly-funded universal newborn screening by genomic methods should be limited to diseases that can be effectively treated or prevented early in life. A program should guarantee treatment and follow up. We conclude we are not yet ready to implement sequencing large multigene panels in NBS.

EPL7.5

Cancer genetic counselling based on electronic mega-pedigrees incorporating Cancer Registry information

V. Stefansdottir^{1,2}, O. T. Johannsson³, H. Skirton⁴, L. Tryggvadottir^{5,6}, J. J. Jonsson^{1,7}; ¹Dept. of Genetics and Molecular Medicine, Landspítali - University Hospital, Reykjavik, Iceland, ²Dept. of Biochemistry and Molecular Biology, Univ. of Iceland, Reykjavik, Ireland, ³Dept. Of Medical Oncology, Landspítali - University Hospital, Reykjavik, Iceland, ⁴Plymouth University, Plymouth, United Kingdom, ⁵Icelandic Cancer Registry, Reykjavik, Iceland, ⁶Faculty of Medicine, University of Iceland, Reykjavik, Iceland, ⁷Dept. of Biochemistry and Molecular Biology, Univ. of Iceland, Reykjavik, Iceland, Reykjavik, Iceland.

Cancer risk assessment is initially based on pedigree information. In Iceland, cancer genetic counselling is undertaken by constructing mega-pedigrees using information from a large genealogy database and the population-based Icelandic Cancer Registry. This enables rapid identification of counselees that belong to families with a known BRCA variation. Since January 2007, over 1900 individuals with concerns about familial breast and ovarian cancer have been seen.

Until recently, only two BRCA founder variations were known in the Icelandic population i.e. the *BRCA2:c.771_775del5* with carrier frequency 0.6-0.8% and the *BRCA1:5193G->A*, with unknown but low frequency. Through the cancer genetic service, three other *BRCA1* and one *BRCA2* pathogenic variations have been found in six families.

Up to eight pedigrees are made for counselees: those of the father and mother of each grandparent and their descendants. This method enables accurate tracing of any mutation. A mega-family is defined as a pedigree not sharing carrier individuals with another family. Pedigree size (mega-family) can vary from 50-4400 individuals (average 379). Up to the end of December 2015, 455 families have been traced. Sixty-two families with *BRCA2 c.771_775del5* variation and four with *BRCA1:5193G->A* variation.

In all, 1400 counselees have been tested for an alteration in a BRCA gene. Of 755 individuals tested for *BRCA2:c.771_775del5*, 339 had a positive result, while of 58 tested for *BRCA1:5193G->A*, 27 were positive. Families have a positive attitude about the use of mega-pedigrees. This approach may be useful in other countries where there is access to genealogical databases.

EPL7.6

Genetic testing for osteogenesis imperfecta on children suspected of abuse: does testing put parents at greater risk?

E. Youngblom, D. J. Bowen, P. H. Byers, P. Pecora, L. Kelly; University of Washington, Seattle, WA, United States.

Introduction: Non-accidental injury (NAI, or abuse) is a worldwide pediatric concern. The prevalence of NAI with fractures is 2.4/1,000 in the 0-3 year age. Osteogenesis imperfecta (OI), which is characterized by fragile bones, is the most common genetic condition confused with NAI (prevalence 0.1/1000). Genetic testing can be used to help distinguish OI from NAI.

Materials and Methods: To understand how genetic test results for OI are used by professionals involved in child protection, one-on-one semi-structured telephone interviews were conducted with 5 child welfare workers and 5 child abuse lawyers (dependency side) that were known to have some experience or involvement with this issue. Interviews were recorded, transcribed, and coded by two separate coders.

Results: Interview results revealed that these professionals are not typically trained about causes of skeletal injury besides NAI, and that testing might be limited by financial, policy, or guidelines limitations. When genetic testing is done, results are sometimes misunderstood and thus misrepresented in court in the hands of professionals untrained in genetic analysis.

Discussion: While genetic testing can identify children with OI among those investigated for NAI, testing could also come at some risk. Misunderstanding of genetic test results in the hands of a non-geneticist professional could result in serious ramifications for family members, and improved guidance and training may be necessary to avoid unintended adverse consequences. Further exploration of these issues will be conducted by surveying a larger population of these professionals later this year.

Improving access to genomic medicine projects by underserved populations: exemplars from USA, Australia and UK

N. Qureshi¹, S. Metcalfe², B. Julian³, M. Parker⁴, V. Bonham⁵, E. Lynch⁶, N. Khan⁷; ¹University of Nottingham, Nottingham, United Kingdom, ²University of Melbourne, Melbourne, Australia, ³University of Leicester, Leicester, United Kingdom, ⁴University of Oxford, Oxford, United Kingdom, ⁵National Human Genome Research Institute, Bethesda, MD, United States, ⁶Melbourne Genomics Health Alliance, Melbourne, Australia, ⁷Manchester Centre for Genomic Medicine, Manchester, United Kingdom.

Internationally, population-based genomic studies are being rolled out, for example, the Genome England 100,000 project. Previous studies have failed to engage underserved population, such as, minority communities and those from lower socioeconomic backgrounds.

Presenters will introduce their respective organisation's strategies to improving recruitment and retention of participants from underserved populations. Broadly, considering equality of access, reducing stigmatisation and appropriate patient information on recruitment and during the study.

Considering international experience:

USA: Community input is critical to the successful implementation of National Human Genome Research Institute's genomics research programs in clinical medicine. Through consortiums such as Implementing Genomics in Practice, Clinical Sequencing Exploratory Research and Population Architecture using Genomics and Epidemiology, NHGRI supports funding of research that includes the objective of enhancing the participation of diverse populations. These initiatives will be presented.

ENGLAND: The risk of recessive disorder is increased in consanguineous families. In these families there is little awareness of inherited disorders and research has identified that lack of knowledge, poor communication, language barriers and stigma are all factors inhibiting access. In Manchester a multidisciplinary strategy integrating clinical, educational and community engagement strands have been implemented to enhance access to genetic services. Similarly, East of England Genomic Medicine Centre have developed innovative approaches to tackling inequality of access to genomic medicine in particular access to familial cancer services.

AUSTRALIA: Melbourne Genomics Health Alliance (MGHA), comprising 10 organisations (hospitals, research institutes and a university), has a vision of integrating genomics in everyday healthcare by establishing a single shared approach to genomic information across these multiple organisations, for the benefit of patients, clinicians and researchers. English as second language (ESL) was not a barrier for recruitment to the project, with 9% of patients having ESL and at least 18 languages spoken. Genetic counsellors used either formally trained hospital interpreters or family members for the consent process. Genetic counsellors noted various issues with use of interpreters, including concerns about privacy, logistical issues, inaccurate interpretation and cultural issues.

ESY1.2

Engaging diverse populations in genomics research and reducing inequalities in the implementation of genomic medicine

V. L. Bonham; National Human Genome Research Institute, Bethesda, MD, United States.

As we advance our understanding of the interaction between gene expression and disease, genomic medicine has the potential to dramatically improve health outcomes. However, as genomic medicine becomes the standard of care and is integrated into personalized and precision treatments, the current lack of ancestrally diverse participants in genomics research creates a risk of exacerbating existing health disparities in underrepresented populations.

We will highlight three exemplary models of engagement of underserved and ancestrally diverse populations in genomics research in the United States. We will also report on the United States National Institutes of Health, National Human Genome Research Institute (NHGRI) roundtable convened in 2015 to discuss the opportunities and challenges associated with the inclusion and engagement of underrepresented populations in genomics research.

ESY1.3

Experience from Melbourne Genomics Health Alliance to improve access for underserved population

E. L. Lynch^{*}, S. Metcalfe^{*2,3}, E. Kowal⁴, M. Martyn^{1,2}, E. Forbes¹, Melbourne Genomics Health Alliance, C. Gaff^{1,3};

¹Melbourne Genomic Health Alliance, Melbourne, Australia, ²Murdoch Children's Research Institute, Melbourne, Australia, ³University of Melbourne, Melbourne, Australia, ⁴National Centre for Indigenous Genomics, Canberra, Australia.

(*Joint First Authors) A major aim of the Melbourne Genomics Health Alliance demonstration project was to understand patients' experiences of having genomic sequencing and their preferences for testing in the future. Melbourne's population is amongst the fastest growing and most culturally diverse in Australia. Overall, English was a second language (ESL) for 9% of patients enrolled in the project, speaking 18 different languages. We identified some problems accessing experiences and preferences of ESL patients regarding genomic testing, which have informed strategies to engage better with ESL patients in Phase 2 of Melbourne Genomics. Another project in Australia is the National Centre for Indigenous Genomics (NCIG) which aims to establish a national resource, under Indigenous governance, for appropriate and respectful genomic research that will benefit Indigenous Australians. NCIG has developed policies and procedures to provide a model for genomic research with Indigenous people globally and has also commissioned a short animation for Indigenous Australians explaining scientific concepts underpinning DNA collection.

An exploration of circumstances surrounding the continuation of tested pregnancies found to be at high risk of Huntington's disease - implications for clinical practice

F. Wadrup¹, S. Holden¹, A. Clarke²;

¹Clinical Genetics, Addenbrooke's Hospital, Cambridge, United Kingdom, ²Institute of Medical Genetics, University Hospital of Wales, Cardiff, United Kingdom.

In its first 20 years the UK Huntington's Disease Prediction Consortium identified 22 pregnancies at high-risk of Huntington's Disease that were continued following prenatal testing. Huntington's Disease is a severe, inherited neurodegenerative condition. Prenatal testing is available through direct or exclusion methods, but is not indicated for couples committed to completing the pregnancy if the fetus is found to be at a high-risk. This ethically complex scenario ultimately removes the child's future right to make an autonomous decision regarding predictive testing. To explore the circumstances surrounding these 22 cases the genetic centres involved were asked to review the case notes and complete a questionnaire. 14 were returned. Thematic analysis identified time pressure and external influence as two major factors contributing to the couples' decision-making. The inability to predict which couples this will affect was highlighted, as were the barriers to maintaining contact and follow-up. Most commonly the couples involved were described as long-term and committed, and their decision-making confused and emotional. This study suggests genetic practitioners must fully prepare couples for the prenatal test and possible termination of pregnancy experience, including the chance of delays and of new emotions surfacing at each stage. Effective liaison with other health professionals is also essential to ensure awareness of the complexity and implications of the situation.

EMP1.02

Diagnosed with autosomal dominant polycystic kidney disease: unmet needs and suggested support

S. T. Carter¹, M. R. Davies¹, A. Clarke¹;

¹Institute of Medical Genetics, Cardiff University, Cardiff, United Kingdom, ²University Hospital of Wales, Cardiff, United Kingdom.

Introduction: A review of the literature suggests a lack of research exploring autosomal dominant polycystic kidney disease in the field of genetic counselling. Previous studies focused on the treatment, management, pathophysiology or molecular genetics. This study focused on the affected individuals' experiences with access to genetics services, genetic risk discussions within the family and desired genetic information support.

Methods: A written questionnaire containing both open and closed questions was completed (n = 16). A subset of participants (n=9) completed a semi-structured interview using a pre-determined topic guide. The interview transcripts, and parts of the questionnaire were analysed thematically. Themes were identified if they were expressed by at least half the participants.

Medical records were also reviewed to triangulate the data collected across three different media to add rigour.

Results: Participants reported having little or no experience with genetic services. Many themes identified were unexpected, such as: (i) family history was unknown, (ii) family communication was hindered by a lack of information and knowledge about the condition and (iii) genetics support was desired. The key results were the lack of awareness about: the condition, its implications for the family and how information and guidance can be accessed from the genetics department.

Conclusion: This study reflects the findings from previous studies regarding the minimal genetic service usage, misconception of genetic information and the complexities surrounding family communication. Additionally, this study has obtained new information about the type of information this population is seeking, barriers to accessing genetic services and desired support.

EMP1.03

The role of palliative healthcare professionals in providing access to clinical genetics services: barriers and suggestions for the post-Jolie era

A. Dearing^{1,2}, N. Taverner²;

¹St George's Hospital, London, United Kingdom, ²Cardiff University, Cardiff, United Kingdom.

Introduction: Palliative healthcare professionals (PHCPs) frequently do not refer their eligible patients to the All Wales Medical Genetics Service. After the death of the affected individual, clinically relevant information for family members is lost. In previous research, PHCPs stated that the end-of-life setting is not appropriate to discuss genetic issues. It is unclear if this has changed due to increasing awareness of genetics in the media and efforts to mainstream genetics.

Materials and Methods: Semi-structured interviews of PHCPs were analysed by thematic analysis.

Results: Seven PHCPs (four nurses, two consultants, and one clinical psychologist) were interviewed. Participants reported feeling unfamiliar with the role of clinical genetics services, and did not feel confident in addressing genetic issues with their patients. A lack of scientific knowledge and unawareness of existing infrastructure to support their patients were cited. Many stated that palliative patients are interested in exploring a potential hereditary component to their disease, and acknowledged the potential for psychological benefit for their patients and their families. Most stated that addressing genetics fits within their skill set, but expressed concern about issues of consent, logistical difficulties, and ethical dilemmas.

Discussion: These perceptions differ considerably from those reported in existing literature. Importantly, each participant stated that the potential benefits of addressing genetic issues outweighed the potential for harm in most cases. These results suggest a need for clinical genetics staff to develop closer links with their local PHCPs and to provide education. Clinical psychologists may also be a helpful resource to address PHCPs' concerns.

EMP1.04

Need for multidisciplinary approach in Ehlers-Danlos syndrome: the University Hospital Ghent experience

V. Szymczak, F. Malfait;

Center Medical Genetics, Ghent, Belgium.

Introduction: Ehlers-Danlos syndrome (EDS) is a group of disorders which affect the connective tissue that support the skin, bones, blood vessels, and many other organs and tissues. The latest classification recognizes six subtypes, including the hypermobility type, which is an autosomal dominantly transmitted disorder with variable expressivity and reduced penetrance. Lifelong follow-up in a multidisciplinary team is needed since the underlying genetic defect has thus far not been identified and hence laboratory diagnosis is currently not available.

Material and Methods: The hypermobility type of EDS may affect as many as 1 in 10.000 people. In 2014, the Ghent University Hospital has launched its multidisciplinary EDS clinic. The team consists of a geneticist, a genetic counsellor, physiotherapists, an occupational therapist, podiatrists, a psychologist and a social worker. After having been diagnosed by the geneticist, patients receive appointments with members of the team, according to their needs. An individual yearly follow-up scheme is offered to each patient.

Results: Since the start of the clinic approximately 300 patients were recorded. Each patient has an individual file where the overall health status is maintained and that is evaluated in a monthly multidisciplinary meeting. Conclusion: The EDS hypermobility type comprises a clinically heterogeneous group of connective tissue diseases. Since there is no cure, a multidisciplinary approach is required to provide a preventive and symptomatic care. Organizing an EDS clinic where patients are seen on a regularly individual base, at one moment by several experienced specialists, is an added value in optimizing the care.

EMP1.05

Exploring the aspects of genetic counseling from non-medical healthcare providers in 8 Genetic Centers in Belgium

S. De Nobele¹, D. F. Vears²;

¹Center For Medical Genetics, University Hospital, Ghent, Belgium, ²Center for Biomedical Ethics and Law. Department of Public Health and Primary Care. KU, Leuven, Belgium.

Background. With the advent of new genetic technologies and the subsequent advances in genetic medicine, non-medical healthcare providers are being enlisted to assist in clinical genetics services. In Belgium, although the professional title of 'genetic counselor' was recently accepted, no formal genetic counseling courses exist. A working group of 'genetic counselors' was established in 2015 to provide support for this growing profession in Belgium. However, the scope of this new role remains unexplored in the Belgian context.

Objectives. This study aims to systematically identify the scope of non-medical healthcare providers practices in Belgium.

Methods. A survey will be administered to all non-medical healthcare providers working within the eight genetic centers in Belgium in March 2016. Questions will be based on those by Skirton et al. 2013, exploring the aspects of genetic counseling that are relevant to their current practice. We anticipate responses from all 15 non-medical healthcare providers currently working in Belgium.

Results. The analysis will focus on 1) participants' knowledge, skills and attitudes regarding psychosocial aspects, and medical and human genetics, 2) the ethical, legal and social issues they face, and 3) professional practice, education and research. Results will be compared to the European situation.

Conclusions. By understanding the scope of the genetic counseling work performed by non-medical healthcare providers in Belgium, the working group can better assist these individuals in their practice, assess the need for additional training/education programs and provide recommendations for support within the healthcare system.

EMP1.07

Family history and perceived risk of diabetes, cardiovascular disease, cancer and depression

M. Vornanen¹, H. Konttinen¹, H. Kääriäinen², S. Männistö², V. Salomaa², M.

Perola², A. Haukka¹;

¹University of Helsinki, Helsinki, Finland, ²National Institute for Health and Welfare, Helsinki, Finland.

Introduction: Family history is an inexpensive tool to assess risks of multifactorial diseases. However, better knowledge is needed on how family history is related to perceived risks of such diseases. We examined how family history relates to perceived risk of diabetes mellitus, cardiovascular disease (CVD), cancer, and depression, and whether these associations are independent of or moderated by sociodemographics, health behavior/weight status (smoking, alcohol consumption, physical activity, BMI [kg/m²]), or depressive symptoms.

Methods: Participants were Finnish 25–74-year-olds (N=6258) from a population-based FINRISK 2007 study. Perceived absolute lifetime risks (1–5) and first-degree family history of CVD, diabetes, cancer and depression, and health behaviors were self-reported. Weight and height were measured in a health examination.

Results: Family history was most prevalent for cancer (36.7%), least for depression (19.6%). Perceived risk mean was highest for CVD, lowest for depression. Association between family history and perceived risk was strongest for diabetes ($\beta=0.34$, $P<0.001$), weakest for depression ($\beta=0.19$, $P<0.001$). Adjusting for sociodemographics, health behavior, and depressive symptoms did not change these associations. The association between family history and perceived risk tended to be stronger among younger than among older adults, but similar regardless of health behaviors or depressive symptoms.

Conclusions: Association between family history and perceived risk varies across diseases. Among those with healthy and unhealthy behavior, family history contributes equally to perceived risk. Future research should seek to identify the most effective strategies to combine familial and genetic risk communication in disease prevention.

Funded by the Academy of Finland (grants 275033 and 265796).

EMP1.08

What do women want? Asking healthy Italian women about BRCA mutations and ovarian cancer risk management options

M. Franiuk¹, T. Gavaruzzi², A. Tasso³, L. Battistuzzi⁴, L. Varesco¹, L. Lotto^{2,5};

¹Unit of Hereditary Cancer, IRCCS San Martino-IST Istituto Nazionale Ricerca sul Cancro, Genoa, Italy, ²Department of Developmental Psychology and Socialization, University of Padova, Padova, Italy, ³Department of Human Sciences, University of Ferrara, Ferrara, Italy, ⁴Department of Internal

Medicine and Medical Specialties, University of Genova, Genoa, Italy, ⁵Center for Cognitive Neuroscience, University of Padova, Padova, Italy.

Introduction: Prophylactic oophorectomy in women with BRCA mutations significantly reduces their risk of developing ovarian cancer. While in countries such as the US as many as 70% of BRCA-positive women choose to have this type of preventive surgery, anecdotal evidence suggests that frequencies in Italy are much lower. Our aim was to investigate healthy Italian women's attitudes toward ovarian cancer risk management options, and to identify predictors of the preference for surgery over intensified surveillance.

Methods: Healthy women, aged 30 to 45, were asked to a) imagine they had a family history of breast and ovarian cancer and a BRCA mutation they could inherit; b) read informational material on predictive BRCA testing; c) fill out a questionnaire assessing knowledge, risk perception, preferences for cancer risk management options, and socio-demographic variables. Binary logistic regression models were used to identify predictors of the preference for surgery over intensified surveillance.

Results: Surveillance was viewed very positively and was the preferred option, whereas surgery was chosen by 24% of the 181 participants. Predictors of choice were associated with: knowledge (knowing that life expectancy is longer with surgery compared to surveillance, perceived comprehension of the consequences of testing, previous knowledge about BRCA testing), risk perception (anticipatory worry about developing cancer, feelings of risk), and childbearing intentions. Except for the latter, higher levels of these predictors were associated with a higher likelihood to choose surgery.

Conclusion: Our findings shed light on factors associated with greater intention to undergo prophylactic oophorectomy, providing useful insights for genetic counselling.

Response to Positive Cancer Genetic Testing Results -The Cyprus Experience.

E. Spanou Aristidou¹, T. Delikurt¹, G. Kallikas², G. Tanteles¹, A. Hadjisavvas³, M. Loizidou³, K. Kyriacou³, V. Christophidou Anastasiadou^{1,4};

¹Clinical Genetics Clinic, The Cyprus Institute of Neurology and Genetics, Nicosia, Cyprus, ²The Cyprus Institute of Neurology and Genetics, Nicosia, Cyprus, ³Department of Electron Microscopy, The Cyprus Institute of Neurology and Genetics, Nicosia, Cyprus, ⁴Clinical Genetics Clinic, Archbishop Makarios Medical Centre, Nicosia, Cyprus.

Social parameters, family dynamics and the general appreciation for genetic testing by wider society vary from one culture to the next. It is therefore important to consider these factors within a specific culture when hoping to maximize the effective awareness of the appropriate individuals of this culture, regarding their genetic status. In an effort to indeed consider these factors, in our paper we will examine variables such as how the patient responds to a positive genetic status, how effectively this status is communicated to the biological family, and the response of the biological family, as well as where and how misinformation may occur.

We will review the data accumulated through the patients seen at the clinical genetics clinic, with respect to their demographic data, their socioeconomic status and diagnosis. Also we will discuss how these responses have evolved over the last twelve years since the introduction of cancer genetic counselling and testing as a service offered in Cyprus. The aim of this study is to draw conclusions that will better aid professionals in their attempt to offer quality services to these families.

EMP1.10

Exploring clinicians' attitudes about using aspirin for risk reduction in people with Lynch Syndrome (LS) without personal diagnosis of Colorectal Cancer (CRC)

B. Meiser¹, Y. Chen¹, M. Peate¹, T. Wong¹, J. Kirk², R. Ward¹, A. Goodwin³, J. Hiller⁴, A. Trainer⁵, F. McCrae⁶, G. Mitchell⁷;

¹Prince of Wales Clinical School, University of New South Wales, Randwick, Australia, ²Westmead Hospital, Westmead, Australia, ³Concord Cancer Centre, Concord, Australia, ⁴Swinburne University of Technology, Melbourne, Australia, ⁵Peter MacCallum Cancer Centre Melbourne, Melbourne, Australia, ⁶Royal Melbourne Hospital, Melbourne, Australia, ⁷BC Cancer Agency, Vancouver, BC, Canada.

Background: Recent research has shown that aspirin reduces the risk of Lynch syndrome (LS)-associated cancers. Little is known about clinicians' attitudes, current practice and perceived barriers to recommending aspirin as a RRM.

Aim: To explore the attitudes of Australian clinicians towards using aspirin as a RRM.

Methods: Clinicians were invited to complete an online survey. Topics included their LS clinical experience, views and practice of recommending aspirin as a RRM, and knowledge about clinical risk management guidelines for LS. Comparison of attitudes between the professional groups: familial cancer clinic (FCC) staff vs non-FCC staff, genetics professionals vs non genetics

professionals: gastroenterologist and colorectal surgeons) was performed. Results: Data analysis is ongoing. 155 respondents: 8 medical oncologists, 7 clinical geneticists, 26 genetic counsellors, 52 colorectal surgeons, 44 gastroenterologists, 7 nurses and 11 other health professionals completed the survey. Significantly more FCC staff (85%) think that aspirin is an effective RRM, are confident about their knowledge of literature and had discussed aspirin's potential role but non FCC staff (55.1%) are more likely to recommend aspirin. Similarly, non-genetics professionals (88% of gastroenterologists and 76.2% of colorectal surgeons) are more likely to recommend aspirin despite genetics professionals (78%) reporting greater confidence in knowledge about the literature.

Discussion: FCC's staff's incongruent attitude between perception of aspirin's efficacy and actual practice of recommending aspirin warrants further research to understand the underlying reasons. Non FCC staff and non-genetics professionals' higher likelihood of recommending aspirin despite reporting lower confidence suggest possible need for training programs.

EMP1.11

The efficacy of psychosocial interventions for familial colorectal cancer: a systematic review

A. M. Ciucă, R. Moldovan, A. Băban;

Babeş-Bolyai University, Cluj-Napoca, Romania.

Introduction: Psychosocial interventions are often recommended for individuals with a personal or familial history of colorectal cancer but their impact on various outcomes has been less explored. Our objective was to investigate the impact of psychosocial interventions on cognitive (knowledge about cancer genetics, perception of risk), affective (distress, anxiety, depression) and behavioural (uptake of genetic testing, uptake of screening and surveillance) outcomes in patients diagnosed with colorectal cancer or family members at risk.

Material and Methods: An extensive search was conducted in electronic databases (PubMed, PsycInfo and Cochrane) investigating the literature published until January 2016. We included studies which investigated the efficacy of psychosocial interventions for colorectal cancer; clearly defined the psychosocial interventions; included patients diagnosed with colorectal cancer or family members at risk. Two authors independently assessed the quality of studies.

Results: Studies included in this analysis mainly explored Hereditary Non-polyposis Colorectal Cancer, Familial Adenomatous Polyposis and other familial colorectal cancers without an established genetic factor. The interventions investigated in the studies that met our inclusion criteria are genetic counselling, educational sessions and psychological interventions. Our review shows that psychosocial interventions are efficient in terms of several cognitive, affective and behavioural outcomes.

Conclusions: A number of psychosocial interventions are aimed at improving affective, cognitive and behavioural outcomes in individuals affected or at risk for familial colorectal cancer and the vast majority of them are efficient. Implications of this study are discussed in detail.

EMP1.12

Developing the Italian version of the Psychosocial Aspects of Hereditary Cancer questionnaire (I-PAHC)

M. Franiuk¹, L. Battistuzzi², E. Molinari³, E. Razzaboni⁴, D. Turchetti⁵, P. Tassone⁶, C. Chiorri⁷, L. Varesco¹;

¹IRCCS AOU San Martino-IST, Unit of Hereditary Cancer, Genova, Italy,

²Department of Internal Medicine and Medical Specialties, University of Genoa, Genoa, Italy, ³Department of Educational Sciences, University of Genoa, Genoa, Italy, ⁴Modena Cancer Center, Modena, Italy,

⁵Unit of Medical Genetics, Department of Medical and Surgical Sciences (DIMEC), S.Orsola-Malpighi Hospital, University of Bologna, Bologna, Italy,

Materdomini Catanzaro, Campus Salvatore Venuta, Catanzaro, Italy,

⁷Department of Educational Sciences, University of Genova, Genova, Italy,

Genova, Italy.

Introduction: The Psychosocial Aspects of Hereditary Cancer (PAHC) questionnaire has been recently developed in the Netherlands to assess psychosocial issues associated with cancer genetic counselling (CGC) in counselees. The PAHC includes 27 items organized into six problem domains (genetics, practical issues, family, living with cancer, emotions, and children), and has proven to be useful in improving counsellor- counselee communication and decreasing counselee distress. We aimed at developing an Italian adaptation of the PAHC (I-PAHC), as no such questionnaire is currently available in Italy. Methods: This is a prospective multicentre observational study including three stages: (i) development of the I-PAHC; (ii) pilot study aimed at testing item readability; (iii) validation study.

Results: We present here the results of stages (i) and (ii). During the translation process the research team decided to add two further domains (perceived social support and motivation to undergo genetic testing), and ex-

panded the emotions domain to include positive emotions. The I-PAHC thus comprises 49 items. Thirty participants were administered the I-PAHC and interviewed to investigate item readability. While most of the items were found to be easy to understand and to score, some required revision to improve comprehensibility, and others were deleted as irrelevant or redundant.

Conclusions: The I-PAHC seems likely to afford comprehensive content coverage of psychosocial problems related to cancer genetic counselling, and study participants have thus far reacted positively to the instrument. The next step of the project will be to test the psychometric properties of the questionnaire in a larger sample.

EMP1.13

The provision of youth friendly genetic counselling

A. Lewis, K. Thompson, L. Holland, M. Young;

Peter MacCallum Cancer Centre, East Melbourne, Australia.

Over the last 20 years the genetic counselling literature has highlighted the struggles experienced by genetic counsellors in working with young people¹. As the Peter MacCallum Familial Cancer Centre has experienced an increased number of young people (15-26) seeking information about their cancer genetic risk and predictive genetic testing, a collaboration was established with onTrac, the Victorian Adolescent and Young Adult Cancer Service, to develop a youth friendly model of genetic counselling, to overcome some of these challenges.

This evidence based model of genetic counselling, aims to support the unique needs of young people who are in the midst of a developmentally sensitive time, promote their autonomy whilst also acknowledging the needs of their parents.

This presentation will examine the increase in young people attending for cancer genetic counselling, review some of the factors influencing young people attending and discuss a new model of genetic counselling for young people.

EMP1.14

Contemplating growing older with Cystic Fibrosis(CF): The experiences of adult CF patients taking ivacaftor; a new therapy

A. B. Watford¹, M. McAllister¹, A. Prosser², C. O'Leary², S. K. Phillips³, R. I.

Ketchell², R. Belk⁴;

¹Cardiff University, Cardiff, United Kingdom, ²Cardiff & Vale University Health

Board, All Wales Adult CF Centre, Cardiff, United Kingdom, ³University

Hospitals Bristol NHS Foundation Trust, Bristol, United Kingdom, ⁴University

of Manchester, Manchester, United Kingdom.

Introduction: Ivacaftor (Kalydeco™), a CF transmembrane conductance regulator (CFTR) gene potentiator, is a treatment approved for CF patients with at least one p.Gly551Asp CFTR-mutation. It is clinically effective in short-term clinical trials and small real-world settings in CF patients. Ivacaftor's apparent potential to change clinical outcomes highlights the need for research exploring the psychosocial impact of ivacaftor for patients and implications for their care. This service evaluation explored the experiences of a group of patients on ivacaftor within two UK adult CF centres using qualitative methods.

Methods: Participants were recruited from the All Wales Adult Cystic Fibrosis Centre and the Bristol Adult Cystic Fibrosis Centre. Seven adult CF patients participated in semi-structured interviews. Interview transcripts were analysed using interpretative phenomenological analysis.

Results: Participants reported significant improvements in respiratory symptoms and a decrease in their CF treatment regimes since taking ivacaftor. All were tentatively contemplating growing older and new life choices including having children and pursuing a career. Some were experiencing anxiety about the treatment's side-effect of weight gain and reported dissatisfaction with their body image since taking ivacaftor. Ivacaftor experiences were novel for the adult with CF: patient narratives emerged of negotiation of care between the patient and service provider.

Conclusion: The changing perceptions of these patients towards their future health and ageing with CF has potential implications for how CF centres and other NHS services personalise care for this emerging cohort who are considering new challenges such as weight gain, decisions about future careers and having children.

EMP1.17

Direct-to-consumer personal genome testing: a futile search for security?

J. Savard, J. Mooney-Somers, A. Newson, I. Kerridge;
The University of Sydney, Camperdown, Australia.

Advances in genetics and genomics provide new and powerful ways for individuals to understand their past and predict their futures. These technologies are now available in the marketplace and are heavily and directly promoted to consumers. Although some may see this as an inevitable and valuable democratization and dissemination of biomedical knowledge, it is not unproblematic. Importantly, there is often a discrepancy between consumer expectations of what personal genome tests may provide and the explanatory power that they find they have.

In this paper, I present findings from a mixed methods research project that explored Australian consumers' beliefs, knowledge, expectations and experiences of direct-to-consumer personal genome testing (DTCPGT). This research involved a public survey, in-depth qualitative interviews with consumers of DTCPGT and an autoethnography.

The results of this research reveal that while DTCPGT may have value, both for consumers and for society, this is contextually dependent. Importantly, seeking DTCPGT appears to be best understood as a process of 'securitization.' That is, an individual will seek genetic knowledge about their self through DTCPGT because they believe it will enable them to confirm 'certainties' about their life and to decrease 'uncertainties'. Unfortunately, the reality is that DTCPGT instead often leads to the proliferation of uncertainty. This is because the scientific knowledge is still limited. We also lack knowledge as to what psycho-social impact test results may have. Further, gaining any form of information unavoidably reveals the gaps in that knowledge.

EMP1.19

Forum OncoGenEtica: providing Italian healthcare professionals and researchers with opportunities to discuss ethical problems that arise in the practice of cancer genetics

L. Battistuzzi¹, P. Ghiorzo^{2,3}, S. Sciallero⁴, M. Parker^{5,6}, L. Varesco^{7,8};

¹Dept. of Internal Medicine and Medical Specialties, University of Genoa, Genoa, Italy, ²Genetics of Rare Cancers, Dept. of Internal Medicine and Medical Specialties, University of Genoa, Genoa, Italy, ³IRCCS AOU San Martino-IST, Genoa, Italy, ⁴Medical Oncology Unit 1, IRCCS AOU San Martino-IST, Genoa, Italy, ⁵Ethox Centre, University of Oxford, Oxford, United Kingdom, ⁶UK Genetics Club, Oxford, United Kingdom, ⁷Unit of Hereditary Cancer, IRCCS AOU San Martino-IST, Genoa, Italy, ⁸On behalf of the Working Group on Cancer Genetics of the Italian Society for Human Genetics, Rome, Italy.

Introduction: Many decisions that healthcare professionals and researchers working in cancer genetics (HPRCGs) make in their daily practice have a moral dimension, and it is not uncommon for HPRCGs to be faced with situations involving difficult value judgements. Drawing from the experience of the UK Genetics Club, the Forum OncoGenEtica was established in 2014 to provide Italian HPCGs with opportunities to discuss the practical ethical problems that arise in their work.

Materials and Methods: The Forum OncoGenEtica meets twice yearly and is open to healthcare professionals and researchers working in cancer genetics or otherwise involved with families affected by hereditary cancer. Participants are encouraged to present ethically problematic cases. Meetings are informal and discussion is facilitated by a bioethicist, a molecular geneticist, an oncologist and a clinical geneticist. After each meeting a report is circulated among participants summarizing the cases and the salient points of the discussion.

Results: As of January 2016 the Forum has organized three meetings and a conference at the San Martino-IST Research Hospital in Genoa, Italy. Overall attendance has exceeded 200 participants, mostly from hospitals or universities in northern Italy. Eighteen cases have been discussed, with balancing conflicting interests and managing confidentiality within families being the most frequent topics.

Conclusions: The Forum OncoGenEtica has thus far met with a good degree of interest within the Italian cancer genetics community. Two meetings are planned for 2016, one of which possibly at a different location in order to reach HPRCGs from other regions of the country.

EMP1.20

Development of a scale for assessing attitudes towards cancer genetic testing among Primary Care Providers and Breast Specialists

A. Bouhnik¹, K. N'Diaye¹, G. Evans², H. Harris², A. Tibben³, C. van Asperen³, J. Schmidtke⁴, I. Nippert⁵, C. Julian-Reynier⁶;

¹INSERM-U912, Marseille, France, ²University of Manchester, Manchester, United Kingdom, ³Leiden University Medical Centre, Leiden, Netherlands, ⁴Institute of Human Genetics, Hannover, Germany, ⁵Women's Health Research, Münster Medical School, Münster, Germany, ⁶Institut Paoli-Calmettes; UMR912, Inserm, AMU, IRD, Marseille, France.

Objective: To develop a generic scale for assessing attitudes towards cancer genetic testing (BRCA1/2) and test this scale psychometrically among a

sample of French General Practitioners and Breast Specialists.

Methods: A 15 items scale was drawn up in a context of an international project (INCRISC European project), assessing perceived benefits (8 items) and drawbacks (6 items) of the process of breast/ovarian cancer genetic testing (BRCA1/2) as well as an overall indicator of agreement with the fact that expected health benefits of BRCA1/2 testing exceeded negative consequences and justified their medical prescription. These items were included in a self-administered questionnaire mailed to a sample of French doctors: 182 Breast Surgeons (BS), 275 General Practitioners (GPs) and 294 gynaecologists-obstetricians. Principal Component Analysis, Cronbach's α coefficient, and Pearson's correlations were used in the statistical analyses.

Results: 4 dimensions emerged from the respondents' responses, and were classified under the headings: "Discrimination-Stigmatisation", "Risk Information", "Prevention-Surveillance", and "Anxiety-Conflicts". Cronbach's α coefficients on the four dimensions were 0.82, 0.76, 0.62 and 0.57 respectively, and each dimension demonstrated a good correlation with the overall indicator of agreement (criterion validity). Breast surgeons scored lower on the first and fourth dimensions (both negative dimensions) and higher on the third dimension (Prevention-Surveillance). Women doctors scored higher on the fourth dimension.

Conclusions: The validation process revealed satisfactory psychometric properties for this scale that could be generic for cancer genetic testing. Confirmatory analysis for the 3 other countries involved in the project is shown in another communication.

EMP1.21

Predictive genetic testing in common complex diseases - a Delphi study on a preventive public health genomics model

M. B. Hocaoglu¹, F. Nizam², P. Savas², B. Taneri^{2,3};

¹Eastern Mediterranean University - Faculty of Medicine, Famagusta, Cyprus, ²Eastern Mediterranean University - Department of Biological Sciences, Famagusta, Cyprus, ³Maastricht University - Institute of Public Health Genomics, Maastricht, Netherlands.

Introduction: Predictive testing of any kind is of utmost importance for public health. In light of the cost reductions in sequencing technologies, predictive genetic and genomic testing is bound to become an integral part of personalized healthcare as well as public health approaches. Consequently, models that integrate gene and environment interactions are needed to be developed for common complex diseases, as both play a role in disease etiology. This work focuses on a public health genomics model with the aim of improving it via expert evaluation and validation prior to implementation.

Materials and Methods: We have previously published a public health genomics model for common complex diseases that integrates genetic testing and environmental factors for prevention of disease onset. In this study, we utilize the widely-used Delphi technique to improve and validate this particular model, and to facilitate discussion on setting associated ethical guidelines. The Delphi technique involves rounds of structured discussions of the model by an expert panel with the aim of building consensus.

Results: The expert-improved and validated model for predictive genetic testing in common complex diseases will provide a basis for development and standardization of associated healthcare guidelines and policies. In parallel, this study will provide a platform for discussion and formulation of ethical guidelines and regulations for implementation of the model.

Conclusions: The improved, validated model will present a valuable source for development of effective public health implementations and ethical guidelines for predictive testing of common complex diseases including cancers, cardiovascular conditions, diabetes and psychiatric conditions.

EMP1.22

Genetic counselling in idiopathic autism: parental knowledge and perspectives

M. Codina-Solà^{1,2,3}, M. del Campo^{4,5}, L. Pérez-Jurado^{1,2,3}, C. Serra-Juhé^{1,2,3};

¹Departament de Ciències Experimentals i de la Salut, Universitat Pompeu Fabra, Barcelona, Spain, ²Neurosciences Program, Institut Hospital del Mar d'Investigacions Mèdiques (IMIM), Barcelona, Spain, ³Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), ISCIII, Barcelona, Spain, ⁴Servicio de Genética, Hospital Universitari Vall d'Hebron, Barcelona, Spain, ⁵Division of Dysmorphology and teratology, Department of Pediatrics, University of California, San Diego, CA, United States.

Introduction: Autism Spectrum Disorders (ASD) are among the most inheritable neurodevelopmental disorders, but the aetiology remains unknown in the majority of cases. Therefore, most parents must base their reproductive decisions on empiric recurrence risk (RR) estimates. To determine factors influencing family planning and benefits of genetic counselling (GC), we studied knowledge and perceptions in parents with children with idiopathic ASD.

Materials and Methods: Parents with at least one child with ASD (n=39) answered a basal questionnaire addressing different topics, such as knowledge, perceived causes and RR or attitude towards genetics. A subset whose child

had obtained negative results in molecular karyotype and exome sequencing (n=15) received GC and a following-up questionnaire afterwards and fifteen days later.

Results: Although most parents had received information about ASD, few had seen a medical geneticist or a genetic counsellor. Genetics was the most frequent perceived cause, especially among those with affected relatives. RR was overestimated by most parents and qualitative and quantitative estimates correlated. About half of parents believed that RR affected their family planning and their risk perception was higher compared to those who did not. After GC, quantitative but not qualitative RR estimates lowered and knowledge and favorable opinion towards genetics increased.

Conclusions: Although most parents perceived genetic factors as the most common cause of ASD, few had visited a genetics service. Perception of RR affects family planning and is overestimated by most parents. GC can improve knowledge and RR estimates and is key to take informed choices.

Grant support: FI-DGR/2013.

EMP1.23

Pilot testing of an educational resource on genomic testing for breast cancer risk

T. Yanes¹, R. Kaur¹, B. Meiser¹, T. Rixon¹, M. Young², K. Barlow-Stewart³, T. Roscioli⁴, G. Mitchell², P. James²;

¹University of New South Wales, Sydney, Australia, ²Peter MacCallum Cancer Centre, Melbourne, Australia, ³University of Sydney, Sydney, Australia, ⁴Garvan Institute of Medical Research, Sydney, Australia.

Introduction: We are undertaking a prospective, mixed-method study of the psychological and behavioural impact of disclosing genomic testing results for common risk variants associated with breast cancer. An education pamphlet for women considering testing for common risk variants to assess their breast cancer risk was developed and pilot tested. Participants of an existing study: 'Common Genetic Variants and Familial Cancer' were invited to take part in this study.

Methods: The two-page education pamphlet provides a brief explanation of rare high-risk gene mutations (BRCA1 and BRCA2) and common risk variants in breast cancer. It covers a range of topics relevant to genomic testing for breast cancer risk, including meaning and implications of results, impact on family members and insurance. The pamphlet was written in accordance with health literacy guidelines and at a grade nine literacy standard (14-15 years old). The pamphlet was pilot-tested with 28 female participants of the parent study. Descriptive statistics were calculated for all responses.

Results: All women thought their understanding of the risks and benefits of genetic testing had improved. The majority of participants (68%) reported that the education pamphlet did not make them feel worried, with 71% actually reporting feeling reassured. Participants provided detailed suggestions for amendments including visual presentation, and readability. Feedback provided has since been incorporated and the final pamphlet has been reduced to a grade 8 literacy level (12-14 years old).

Conclusions: The revised pamphlet with the information on genomic testing and breast cancer risk will be used in the prospective psychosocial study.

EMP1.24

How do counselees reach decisions and how can they be adequately supported during decision-making?

T. Brouwer, H. van Spijker;

Department of Medical Genetics, Utrecht, Netherlands.

Introduction: Much research has been conducted on the outcome of couples' decision-making, when a genetic disorder runs in the family. However, the question of how couples come to decisions, or what information they need to reach an informed choice, has seldom been the subject of research.

Materials and Methods: During many years of working with couples, materials have been collected for a new booklet on strategies and supportive action plans for the decision-making process.

Results: A new booklet entitled "The desire for children and inherited genetic conditions" (in Dutch: "Kinderwens en erfelijkheid") has emerged from the practice based evidence of supporting couples struggling with reaching decisions whether or how to have children, when one or both parents has a hereditary disease. This booklet describes not only the various reproductive options available to such couples but also various strategies to facilitate their decision making. The booklet also contains tools to assist when the decision-making process threatens to get stuck. One of these tools will be presented on the poster.

Conclusions: Written information should not and cannot replace tailored counseling. However, by describing various strategies of decision-making in the field of genetics, written information can be important for both counselees, social workers and genetic counselors. This is particularly so when the genetic counselling entails delicate decisions.

EMP1.25

Communication of genetic risk information about X-linked disorders: Carrier mothers' perceptions of facilitators and barriers to talking to daughters

A. Goldman^{1,2}, R. MacLeod^{1,2};

¹University of Manchester, Manchester, United Kingdom, ²St. Mary's Hospital, Central Manchester University Hospitals NHS Foundation Trust, Manchester, United Kingdom.

Introduction: The process of communicating information about Duchenne and Becker muscular dystrophy (DMD or BMD) to girls who may be carriers has been little studied. Mothers are often the primary source of information, both about carrier risk and the nature of the condition, yet mothers' voices are notably absent in the literature. We need to understand how mothers experience this communication process in order to best support them in this task.

Materials and Methods: A qualitative study using Interpretative Phenomenological Analysis (IPA) explored how mothers described and reflected on the experience of communicating information about DMD or BMD and carrier risk to their daughters aged <18 years. 6/15 mothers invited to participate through the North West Family Register Service agreed to participate. Semi-structured telephone interviews of around 45 minutes were audio-taped with consent, and transcribed in full for IPA analysis.

Results: The six participants described how they had endeavoured to be open and honest with their daughters. Yet, all had struggled with some aspect of the communication process. Notably mothers found it harder to talk about the future, both in terms of the life limiting nature of the condition and their daughters' future reproductive options. We describe the different phases of disclosure reached, and the barriers and facilitators of communication identified.

Conclusions: Participants suggested interventions that they felt would aid the disclosure process, notably a greater involvement of Genetic Counsellors at an earlier stage.

EMP1.26

Developing a decision aid for genomic research participants notified of clinically actionable research findings in the hereditary cancer setting

A. M. Willis¹, S. K. Smith¹, B. Meiser¹, L. Ballinger², D. M. Thomas², G. Mitchell^{3,4}, J. Kirk^{5,6}, M. Tattersall⁷, M. Young^{3,4};

¹Psychosocial Research Group, Prince of Wales Clinical School, UNSW Australia, Sydney, Australia, ²The Kinghorn Cancer Centre and Cancer Division, Garvan Institute of Medical Research, Darlinghurst, Australia, ³Familial Cancer Centre, Peter MacCallum Cancer Centre, Melbourne, Australia, ⁴Sir Peter MacCallum Department of Oncology, University of Melbourne, Melbourne, Australia, ⁵Familial Cancer Service, Crown Princess Mary Cancer Centre, Westmead Hospital, Westmead, Australia, ⁶Centre for Cancer Research, Westmead Millennium Institute, University of Sydney, Westmead, Australia, ⁷Department of Cancer Medicine, Sydney Medical School, Royal Prince Alfred Hospital, Camperdown, Australia.

Introduction: Research genomic screening is increasingly used to identify genetic causes of disease, including cancer. However, there is evidence that individuals who are notified of clinically actionable research findings are ill-equipped to make decisions regarding uptake of these findings. While effective decision support for these research participants is clearly required, the broad scope of genomic screening presents unique challenges in resource development. We aimed to develop a resource to fill this decision support gap.

Methods: A decision aid booklet was developed based on a systematic review of the literature regarding cancer genetic counselling uptake, the International Patient Decision Aid Standards and the expertise of a steering committee of clinicians, researchers and consumers. The acceptability of the decision aid was assessed by questionnaire among genetic research participants who had previously accessed clinically actionable research findings.

Results: All 19 participants stated that the decision aid was easy to read and clearly presented, increased their understanding of the implications of taking up research findings and would be helpful in their decision-making. Seven participants reported low to moderate levels of distress/worry after reading the booklet; however 18 reported some level of reassurance. All participants would recommend the booklet to others considering uptake of clinically actionable research findings.

Conclusions: Results indicate the decision aid is acceptable to the target audience and has potential as a useful decision support tool for genomic research participants. The decision aid will be provided to Australian research participants notified of clinically actionable research findings by the International Sarcoma Kindred Study.

EMP1.27

Professionals' views and experiences of facilitating family communication about genetics: Findings from a qualitative study

K. Forrest Keenan, L. McKee, Z. Miedzybrodzka;
University of Aberdeen, Aberdeen, United Kingdom.

Introduction: UK guidelines advise genetics professionals to support and encourage family communication about genetic risk. We sought to explore genetics professionals' experiences in clinical practice and to identify effective elements of communication in this area.

Methods: In depth interviews with 23 genetics professionals across Scotland, UK.

Results: Whilst all participants felt that facilitating family communication about genetics was an important aspect of their role, one third reported giving limited advice and lacked confidence in this area, particularly parent/child communication. Nevertheless, we identified several 'successful' strategies and frameworks which genetics professionals draw upon, including: (1) Initiating a discussion about how/when to tell; (2) Offering to tell children directly (with or without parent present); (3) Offering access to a quick follow-up appointment e.g. after parental disclosure and (4) Accepting ambiguity as there maybe "no clear cut answers." In cases of nondisclosure professionals may: (1) "Chip away" (over months or years); (2) Undertake "emotion work" before involve children or (3) Use other relatives as "different routes" to disclosure e.g. siblings or aunts/uncles. Participants' expressed a need for child/young people focussed counselling aids, including disease specific disclosure guidance, and the time to undertake this work.

Conclusion: Genetics professionals use multiple strategies to facilitate family communication about genetics, particularly psychoeducational guidance to parents. However, this remains a challenging and sensitive area in which genetics professionals express a need for further training, resources and evidence based interventions.

KFK was funded by a CSO Fellowship, Scottish Government and the NHS Grampian Huntington's disease Research Endowments Fund.

EMP1.28

Genetic and social complexities of Non-Syndromic Hearing Loss: the importance of genetic counseling

D. Salinas, M. Borregán, L. Martínez, A. Cueto, T. Vendrell, M. Del Campo, E. Tizzano;

Department of Clinical and Molecular Genetics and Rare Disease Unit, Hospital Vall d'Hebron, Barcelona, Spain.

Introduction: Non-Syndromic Hearing Loss (NSHL) has always created a growing interest due to its genetic heterogeneity and complex social background. We present the first Spanish study that gathers together genetic and social complexities of NSHL, highlighting the importance of genetic counseling. The aims of the study were to evaluate differences in opinions, knowledge and information needs or genetic counseling among the deaf individuals and their families. Knowledge and satisfaction of those who had received genetic counseling were also analyzed.

Methods: Participants (n=50) were recruited from different centres and associations from Catalonia (Spain). An ethically validated questionnaire was distributed to the families; data was statistically analyzed with SPSS (v.20)

Results: Differences in terms of knowledge, interest in diagnostic test and opinions, defined by the level of immersion in the deaf community and hearing status of partners and relatives were found. Most of the participants (62%) were interested in genetic testing. Feelings towards genetic testing were mostly positive in comparison with previous studies in other populations. We also have seen that testing may not influence significantly on reproductive options although 33% would opt for a reproductive alternative (being PD the first option, 61%). A great increase of knowledge was evidenced between the pre- and post counseling session (37% of correct answers to 71%). The genetic counseling satisfaction score was 28.18 (out of 30).

Conclusions: This work reveals an evident need of information about genetics of hearing loss and shows a great increase of knowledge and satisfaction after receiving genetic counseling.

EMP1.29

The making, implementation and evaluation of a BRCA information web site for breast - and ovarian cancer patients

E. Siglen¹, H. Høberg-Vetti^{1,2}, M. Tveit-Haavind², C. Bjorvatn^{2,3,4};

¹Center for Medical Genetics and Molecular Medicine, Haukeland University Hospital, Bergen, Norway, ²Western Norway Familial Cancer Center, Haukeland University Hospital, Bergen, Norway, ³Learning and Mastery Center in Bergen, Bergen, Norway, ⁴Department of Clinical Science, University of Bergen, Bergen, Norway.

Introduction: As genetic testing of cancer patients increasingly will be part of the diagnostic process, due to treatment consequences, it is important to ensure that the patients receive accurate genetic information within the clinical setting. New methods to provide patients with genetic information

and counseling in the decision process are needed. Through the DNA-BONus study unselected breast-and ovarian cancer patients were offered BRCA1/2 testing and familial cancer risk assessment without prior genetic counseling. We developed and evaluated a web based patient oriented information site, and measured the efficacy of an online decisional aid in genetic testing. **Material and methods:** From April 2014 to April 2015, eligible patients were consecutively randomized into two groups, intervention group (N= 85) and control group (N= 109). They all received the same information prior to genetic testing, but the intervention group was also provided with a patient oriented web site (log in required) about hereditary breast- and ovarian cancer. The web site was built up using the Interactive Health Communication System model (ICHHS). ICHHS ensures quality assured information and increases the patient's feeling of control and contributes to involve partner in the decisional process.

Different psycho-social measures have been included in the DNA-BONus study. In the present RCT we included two outcome questionnaires; "Openness to discuss cancer in the nuclear family" and "Decisional Conflict Scale". **Conclusion:** Updated results will be presented, including the use and evaluation of the web site, and the efficacy of the online decisional aid.

EMP1.30

How do genetic counsellors give and receive feedback in the peer experiential and reciprocal supervision (PEERS) model?

H. M. Brandon^{1,2,3}, L. Stirling⁴, S. Wake^{1,2,5}, M. Kentwell^{6,7};

¹Department of Paediatrics, Faculty of Medicine, Dentistry & Health Sciences, University of Melbourne, Melbourne, Australia, ²Murdoch Childrens Research Institute, Melbourne, Australia, ³South West Thames Regional Genetics Service, St George's University Hospitals, London, United Kingdom, ⁴School of Languages & Linguistics, Faculty of Arts, University of Melbourne, Melbourne, Australia, ⁵Victorian Clinical Genetics Service, Melbourne, Australia, ⁶Department of Genetic Medicine and Familial Cancer, Melbourne Health, Melbourne, Australia, ⁷Department of Oncology, The Women's, Melbourne, Australia.

Introduction: The Peer Experiential and Reciprocal Supervision (PEERS) model is a unique supervision model developed for genetic counsellors by a single Victorian clinical genetics service. The aim of this study was to undertake further detailed analysis of PEERS model feedback session interactions to inform further development of the model, with a focus on the verbal giving and receiving of feedback. Feedback was explored for initial pair interactions in the PEERS model.

Methods: Audio recorded feedback sessions, from 2013 and 2014, for six genetic counsellors were transcribed and reviewed using discourse analysis. Five of the six participants also partook in a focus group to discuss the results with the discussion evaluated using content analysis. The results and conclusions, being derived from this small sample size, may not be considered statistically significant yet serve to provide preliminary information to inform further research.

Results: The giving and receiving of feedback was verbalised with explanations for the feedback and utilised co-occurring discourse characteristics of disfluency, hedging and epistemic markers, the latter to state that the assessment was their opinion.

Conclusions: It was concluded that feedback interactions were influenced by a participant's culture of professional practice, personal preferences and the PEERS protocol, differing from casual conversation. The manner in which feedback is given and received is to help ensure it is presented in a way which considers the needs of the listener. The findings of this study can be used to enhance participants experience in the PEERS model and provide insights to interprofessional communication.

EMP1.31

Prophylactic Mastectomy in Women Carriers of Pathogenic Mutation in Genes BRCA1/2. Has the Usage Increased as an Option for Breast Cancer Management?

M. Salinas¹, S. Iglesias¹, E. Grau², E. Darder³, A. Velasco³, A. Solanes², A. López³, A. Teulé¹, M. Navarro², G. Capellà¹, C. Lázaro¹, A. Izquierdo³, J. Brunet^{3,1,2};

¹Hereditary Cancer Program, Catalan Institute of Oncology, L'Hospitalet de Llobregat, Spain, ²Hereditary Cancer Program, Catalan Institute of Oncology, Badalona, Spain, ³Hereditary Cancer Program, Catalan Institute of Oncology, Girona, Spain.

INTRODUCTION: Risks to develop breast cancer in women carrying mutations in BRCA1/2 range between 55 and 86%.

Prophylactic mastectomy (PM) is one of the actions raised by patients to reduce the risk significantly. Until recently, population opted for a clinical follow-up and discarded to use this technique. The mixture of different circumstances, including Angelina Jolie public declaration in February 2013, have produced a notable increase for this type of surgery demand, in both - healthy and breast cancer affected women.

METHODOLOGY: In total, 1020 women carriers of mutation have been analyzed and visited in the 3 genetic counselling units of "Institut Català d'Oncologia" during 1998-2006 (618 breast/ovarian or breast and ovarian cancer affected women and 402 healthy women).

RESULTS: Until 2013, 707 patients were visited. Among the 235 healthy ones, only 4.6% performed the PM, while among the 472 carriers affected, 14.7% opted for the PM surgery.

Heretofore, the total number of carriers has risen to 1020. Overall, 10.94% of the healthy patients and 18.9% of the affected ones have chosen the PM.

In percentage terms in 2013-2016 period, PM have doubled compared the over previous 14 years.

CONCLUSION: The so call "Angelina Jolie's Effect" has influenced on the decisions of our patients: a considerable increase of PM among healthy patients has been noticed while it has remained quite stable among the affected ones.

EMP1.32

A qualitative study exploring the impact of next generation sequencing panel testing for individuals with retinal dystrophy

H. G. Jones¹, E. V. McVeigh², G. Halp³, G. Black³;

¹Nottingham University Hospitals, Nottingham, United Kingdom,

²Birmingham Women's Hospital Foundation Trust, Birmingham, United Kingdom, ³Central Manchester Foundation Trust, Manchester, United Kingdom.

Background: Inherited retinal dystrophies (IRD) are a highly genetically heterogeneous disease group causing progressive vision loss. Diagnostic testing for IRD involves Next Generation Sequencing (NGS) of a 176 IRD gene panel. NGS only identifies pathogenic variants in IRD genes in 50% of cases. Many patients remain undiagnosed. For a fraction of the patients, NGS testing produces incidental findings (IF), including variants of uncertain significance (VUS) and carrier status results. This three-armed study aimed to define the impact NGS panel testing has on patients.

Materials and Methods: Semi-structured qualitative telephone interviews investigated patient views of NGS panel testing and the impact of results. 23 participants were recruited from the Manchester Centre for Genomic Medicine. 5 participants received a pathogenic, positive result, 11 received an inconclusive, negative result and 7 received an IF result. Interviews were transcribed verbatim and analysed using Interpretive Phenomenological Analysis (IPA).

Results: Collectively, 5 key themes were identified: The Retinal Dystrophy Journey; Information from Health Care Services; Shared Impact; Uncertain Future; Disease-Specific Impact of NGS Testing.

Conclusion: Participants receiving positive or IF results value the information and have a good understanding of possible implications. Disclosure of IF had no adverse implications in this patient cohort. In contrast, participants with negative or inconclusive results were left disappointed by genetic testing. The importance of consent, the value of full discussion around results, even if uncertain, is highlighted. Clinicians need to be aware of the challenges any NGS testing results can bring and offer continual support throughout follow-up

EMP1.33

"There is a chance for me" - Interactional analysis of risk communication in Advanced Maternal Age (AMA) genetic counselling sessions in South Africa

T. Wessels¹, C. Penn²;

¹Division Human Genetics, Department of Pathology, University of Cape Town, Cape Town, South Africa, ²Health Communication Research Unit,

University of the Witwatersrand, Johannesburg, South Africa.

Providing risk information is central to genetic counselling. Many studies have examined risk communication, but the focus has been on professional and patient perspectives. Less information is available on risk communication in interactions. This study aimed to examine genetic counsellors' (GCs) risk communication in multicultural genetic counselling sessions with women of advanced maternal age (AMA).

Six GCs (2 to 20 years experience) conducted 17 AMA sessions in English (women's second language). The sessions were video and voice recorded and transcribed verbatim. Data were analysed using conversation analysis (CA). CA examines discourse as a topic, i.e. describing the turns, its functions and how these functions are accomplished.

Analysis revealed that the GCs presented the risk of having a baby with a chromosome abnormality and the risk of spontaneous abortion due to the procedure in a number of ways. They presented the risks as odds, percentages, positives, negatives and used analogies. Examination drawing on CA principles revealed that both counsellors and women orientated to an interpretation of the risk. The women's focus was on the meaning for her baby while the GC's focus was on numerical understanding.

The research showed the power of CA methodology to gain new insights into old problems. Importantly, the study revealed a mismatch between the

women and the GCs agendas related to the implications of the risks. This mismatch can result in missed opportunities in exploring patients' emotions, decisions and the implications of their choices.

EMP1.34

Adaptation in families of individuals with Down syndrome from 8 countries

M. L. Van Riper, G. Knaf;

University of North Carolina Chapel Hill, Chapel Hill, NC, United States.

Introduction: Prenatal testing for Down syndrome has become a routine part of prenatal care in many countries. Unfortunately, many expectant families find it difficult to make well-informed decisions about positive tests results because they receive limited information about life with Down syndrome or the information they receive is outdated and inaccurate. The main purpose of this study was to examine family functioning in families of individuals with Down syndrome from Brazil, Ireland, Korea, Portugal, Spain, Thailand, United Kingdom and USA.

Materials and Methods: 1358 parents completed a survey designed to assess family functioning and key dimensions of the Resiliency Model of Stress, Adjustment and Adaptation.

Results: Mean family functioning for the overall sample, as well for 6 of the 8 countries fell within the average range for family functioning. It fell within the increasing strengths range for the USA and the increasing problems range for Thailand. Family functioning got worse with increasing child's age. Family functioning was significantly better with greater ability, hardiness, mutuality when partnered, and affirmative communication and significantly worse with greater strains and incendiary communication. Over 46% of the parents viewed the fact that their child had Down syndrome as "a blessing in disguise."

Conclusions: Findings contribute to our understanding of family functioning in families of individuals with Down syndrome, as well how culture and family factors interact and shape how families respond.

EMP1.35

Treatment of hemophilia - what do mothers say?

C. von der Lippe¹, J. Frich², A. Harris³, K. N. Solbrække²;

¹Centre for Rare Disorders, Oslo University Hospital, Oslo, Norway, ²Institute of Health and Society, University of Oslo, Oslo, Norway, ³Dep. of Technology and Society Studies, Maastricht University, Maastricht, Netherlands.

Introduction: In Norway most boys with hemophilia start with prophylactic treatment around 18-24 months of age. Health professionals administer treatment initially, and parents usually provide treatment from when the child is around four years. Caring for a child with hemophilia may be demanding and stressful. Qualitative research on how parents, and especially carrier mothers, experience the treatment of their sons with hemophilia is limited. The aim of the study is to offer qualitative insights about mothers' experiences about treating hemophilia in different settings.

Materials and Methods: We have conducted a qualitative study to explore women's experiences of being a carrier of hemophilia and mother to a boy with hemophilia. We collected data through in-depth interviews with 16 women who were carriers and mothers of a child with hemophilia. We analyzed the data using an inductive thematic analytical approach.

Results: The mothers were grateful for the availability of treatment. Hospital treatment was perceived as challenging from a practical perspective. Home treatment was preferred when the boys grew older, but mothers experienced both practical and emotional challenges related to administration of treatment. Repeated venipuncture was especially difficult. The lack of competence about hemophilia displayed by health professionals was frustrating and stressful.

Conclusion: More in-depth knowledge of the experiences of mothers of boys with hemophilia, especially regarding treatment, could help health professionals better understand parents' and children's situation, and may facilitate tailored management and support.

EMP1.36

A qualitative study to explore quality of life in Brazilian families with children who have intellectual disability

D. G. Melo, V. A. Santos, R. V. V. Tomaz, S. A. Rodrigues, L. R. S. de Avó, C. M. R. Germano;

Department of Medicine, Federal University of São Carlos, São Carlos, São Paulo, Brazil.

Introduction: It is estimated that 1.4% of the Brazilian population has some degree of intellectual disability. Families with a member with intellectual disability are subject to additional stressors that can affect their quality of life. This study aimed to examine family quality of life among Brazilian mothers with children who have intellectual disability.

Methods: Individual semi-structured interviews were conducted with 30 mothers, selected by convenience. The interviews were then transcript, encoded and analyzed using categorical thematic analysis technique, considering nine precategories: family health, financial well-being, family relationships, support from others people, support from services, family values, career, recreation, and community interaction. Themes were examined in order to give a comprehensive and interpretative approach to the results.

Results: The interviews revealed that the care of disabled child is centered on the mother, who usually stops her professional career or studies, changing the family relationships. The religious coping appeared as a common strategy adjustment and many mothers believed having a disabled child as part of one's destination. The disabled children had less access to services and support than they needed in health, education and recreation. Family quality of life was also negatively affected by financial restrictions and difficulties in social interactions.

Conclusions: Emotional and psychological support for all family members, as well as social and practical support comprising income distribution and access to appropriate care, proved to be essential for the welfare of the disabled person and his family.

This survey was supported by the São Paulo Research Foundation (FAPESP, grant 13/24498-8).

EMP1.37

Evaluation of genetic counselling in clinical practice: using patient-reported outcome measures for continuous quality improvement

M. McAllister¹, A. McDermott², D. Ferrick¹, C. Thomas¹, A. Costal Tirado³, J. Harris⁴, A. Edwards⁴;

¹Cardiff University, Cardiff, United Kingdom, ²Cardiff Business School, Cardiff, United Kingdom, ³University of Barcelona, Barcelona, Spain, ⁴Cardiff & Vale University Health Board, Cardiff, United Kingdom.

The aim in this study was to explore views of genetics clinicians in Wales about usefulness and feasibility of using patient-reported outcome measure (PROM) data for continuous quality improvement in genetic counselling. PROMs data were collected using mailed self-completion questionnaires between February-July 2015. PROMs used were Genetic Counselling Outcome Scale (GCOS-24) and the generic Euroqol (EQ-5D) before and after clinic attendance, and a post-clinic audit tool. EQ-5D is the generic PROM preferred by the UK National Institute for Health & Clinical Excellence, the national agency charged with promoting clinical excellence in the UK National Health Service (NHS). Qualitative interviews with eight participating clinicians explored their perceptions following monthly team meetings to monitor progress. Paired before-after PROMs data were collected from 96 patients (response rate: 23% pre-clinic, 45% post-clinic). Quantitative data analysis demonstrated statistically significant improvement in patients' GCOS-24 scores after clinic attendance ($p > .001$), and high post-clinic scores on the audit tool but no significant change in EQ-5D scores. Monthly meetings with clinicians increasingly focused on change scores on individual GCOS-24 items and strategies the clinical team could adopt to improve these change scores over time. Qualitative analysis of interview transcripts demonstrated that participating clinicians valued use of PROMs data to inform continuous quality improvement initiatives using Plan-Do-Study-Act cycles, the NHS preferred quality improvement approach. Participating clinicians considered the clinical genetics-specific GCOS-24 the most appropriate PROM. Findings were used as a basis for discussions about quality improvement actions for the genetic counselling team.

EMP1.38

Experiences of women who had a carrier test for Becker muscular dystrophy as a teenager

R. Redmond^{1,2}, D. Scotcher^{1,2};

¹University of Manchester, Manchester, United Kingdom, ²Saint Mary's Hospital, Central Manchester University Hospitals NHS Foundation Trust, Manchester, United Kingdom.

Despite guidelines it remains unclear when it is appropriate for a minor to have genetic testing. This study explores the experiences of women who had a carrier test for Becker muscular dystrophy (BMD) as a teenager. Three research questions were investigated:

- what motivates women under 18 to request carrier testing?
- what is the impact on a young woman of having a carrier test?
- what do women think about the support and counselling they received?

Seven women were recruited from the Manchester Family Register Service who had a carrier test for BMD as a teenager. Semi-structured, qualitative telephone interviews were carried out and themes were exposed using interpretative phenomenological analysis.

The results show that the teenagers were often motivated to have a genetic test by their parents or by living and growing up with the condition, and that the majority of the participants were upset with their result but with time managed to adjust well. Some participants said that they did not fully understand the implications of their test result at the time. In general, women were satisfied with the level of genetic counselling received.

Genetic counsellors should consider a number of implications for future practice. (1) The information given should be tailored to each teenager, (2) the teenager should be made aware that prenatal options are available, (3) conversations surrounding how and when to discuss carrier status with a potential partner should be covered, (4) and follow-up should be negotiated with teenagers who are carriers and who are non-carriers.

EMP1.39

Psychological Support in Cancer Genetics: a review of Current Practice

C. Firth, V. Tripathi, S. Rose, C. Compton, E. Haque;

Guys and St Thomas' NHS Trust, London, United Kingdom.

Genetic testing for hereditary cancer conditions has many psychosocial impacts on, e.g., general emotional well-being, sense of identity and body image. The Guys' cancer genetics service offers dedicated clinical psychology input for patients at increased familial risk, such as BRCA1 and BRCA2 mutation carriers through the BRCA one-stop MDT clinic, risk reducing surgery pathways and BRCA support groups.

Objectives: The survey investigates the psychosocial needs of patients, their satisfaction with available psychosocial support and the acceptability and utility of psychological screening tools in the BRCA one-stop MDT clinic.

Methods: Over a five month period patients were asked to complete an online survey asking uptake of and satisfaction with psychosocial support received. In addition a sample of 30 patients attending the BRCA clinic were asked their views about using psycho-social screening tools including the BRCA self concept scale (Esplen et al, 2009).

Results: Preliminary data shows high satisfaction with psychosocial services in the cancer genetics service. It also shows the usefulness of psychological screening tools which are tailored to those at increased familial cancer risk.

Conclusion: So far the cancer genetics service has used the Distress thermometer and the BRCA Self concept scale. We are conducting a study to investigate the acceptability and usefulness of these tools in our BRCA one-stop multidisciplinary clinic. Preliminary data suggests that these tools are important for understanding which patients may be vulnerable after BRCA testing and which might require additional support. Recommendations for future use of these tools will be discussed.

EMP1.40

Reproductive decision making: Interviews with mothers of children with undiagnosed developmental delay

E. L. Pond¹, R. Dimond²;

¹Wessex Clinical Genetics Service, Southampton, United Kingdom, ²School of Social Sciences, Cardiff University, Cardiff, United Kingdom.

Introduction: This qualitative study explores the experiences of parents who have a child with an undiagnosed developmental disorder; focusing particularly on reproductive decisions. The research aim was to explore the reproductive decision-making process and examine the contributing factors that influence these decisions, the reasoning behind the decisions made and the emotional consequences.

Methods: Data was collected from in-depth semi-structured interviews with five mothers of children without a diagnosis. Transcripts were analysed using interpretative phenomenological analysis.

Results: Two broad themes of living without a diagnosis and the impact on reproductive decisions were identified. Participants spoke of needing a diagnosis as an explanation for their child's condition; without which they struggled with the uncertainty of their child's future. Perceptions of risk, the potential impact a child would have on their current children, expectations of a family and the desire for another child, were factors that impacted reproductive decisions.

Conclusions: Reproductive decision making for parents of a child without diagnosis is a complex and emotional task that involves weighing up both practical and emotional factors. A lack of control was an overarching issue expressed by participants, who felt that they had no control over diagnosis and an unknown future ahead. This lack of control extended to the reproductive decisions of some participants, who felt the decision had been removed from them, leaving them unable to fulfil their desires to have another child. Other participants found alternative mechanisms to manage this issue, in order to regain some sense of control or relinquish control fully.

EMP1.41

The experiences of women who have had carrier testing for Duchenne muscular dystrophy under the age of 18

H. Fraser^{1,2}, D. Scotcher^{1,2};

¹University of Manchester, Manchester, United Kingdom, ²Central Manchester University Hospitals NHS Foundation Trust, Manchester, United Kingdom.

Though carrier testing of adolescent females for Duchenne muscular dystrophy (DMD) remains an area for discussion due to ethical questions over autonomy, it is still widely practiced. The gap that exists between guidelines - some of which are arguably outdated - and practice is something that requires addressing.

Through the use of purposive, semi-structured interviews, this study endeavoured to investigate what had motivated a group of women to seek carrier testing under the age of 18, and the subsequent impact of test results. Data was analysed using Interpretative Phenomenological Analysis. Although parents were reported as having had an integral role throughout the testing process, all participants believed they had been in control of the decision to have carrier testing. Women stated that they had felt they had needed to know their carrier status during adolescence, largely as a means to alleviate uncertainty. There was on the whole a minimal negative reaction to testing. Although reproductive factors were framed as having been a key motivator prior to testing, test results appear to have had little impact on subsequent reproductive decisions. This discrepancy creates a *pregnancy paradox*. A number of women reported having not had the opportunity for genetic counselling, and having received little psychosocial input. This study is indicative that carrier testing for DMD during adolescence does not have a lasting negative impact, and that adolescent girls feel autonomous in their decision to undergo testing. The reported lack of prior psychosocial discussion is, however, something that would benefit from further research.

EMP1.42
The education pathways in clinical genetics - insight of resident

A. Pietrzyk;
Genetic Clinic/Cytogenetic Unit, Pomeranian Medical University, Szczecin, Poland.

Clinical genetics is a relatively new branch of medicine in which physicians can choose to specialize. The available residency programs vary among different countries but usually they consist of training in genetic clinic, rotations in diverse hospital departments and outpatient clinics and laboratory practice in cytogenetics, biochemical and molecular genetics. Nearly all of them are run by academic medical centres thus strong emphasis is put on research opportunities and education services. The number of physicians trained, still in training or even considering clinical genetics remains too low what is mostly connected to distinctiveness of specialty as well as economic reasons. As the field of clinical and laboratory genetics is developing rapidly, advancing both the field of diagnostic tools and therapeutic measures the need for clinical geneticists is constantly growing, outnumbering the resources. Thus the accessibility of genetic service might be limited in smaller facilities and availability of consultations within other departments. I have spent 3,5 year of residency sharing my time between various hospital department, training in genetic clinic and laboratory practice on regular basis. This balanced system has given me an enormous opportunity to create and work within interdisciplinary teams, provide genetic counseling to the groups of patients that would not be reached, quicken the right diagnosis and arrange better management and care. The benefits are shown through actual patients' reports and compared to other education systems.

EMP1.43
An evaluation of The Genetic Support Network of Victoria: A mixed methods study based on stakeholder participation

L. A. Di Pietro^{1,2,3};
¹Murdoch Childrens Research Institute, Parkville, Australia, ²Genetic Support Network of Victoria, Melbourne, Austria, ³Victorian Clinical Genetics Services, Melbourne, Austria.

Introduction: Individuals affected by genetic and rare conditions have unique support and health care needs. A necessary prerequisite for providing appropriate and accessible supportive services is to understand these needs within a rapidly developing genetics health environment. This study aims to determine the information and support needs of individuals who had previously accessed the Genetics Support Network of Victoria (GSNV) and to explore their beliefs and attitudes toward the network. Taking a participatory evaluation approach, the views of stakeholders and GSNV staff members were additionally explored to uncover avenues for organisational improvement. Materials/Methods: Participants were GSNV service users who had accessed the service within the past 12-months, (genetic/rare disease community, genetic health professionals, researchers and support group leaders), representatives from key stakeholder groups and GSNV staff members (n=40). Five focus groups were conducted with participants grouped together based on the aforementioned categories. Adopting a phenomenological approach, the focus group discussions were transcribed verbatim and coded using thematic analysis to identify major themes. Results: Preliminary data will be presented revealing important themes identified across the group discussions related to participants' understanding of the GSNV's role, beliefs and attitudes, unmet information and support needs and ideas for organisational growth and change. Conclusion: This research will provide important insight into the experiences of members of the genetics health community and their information/ support needs. Participant perspectives will be integrated to provide an overall model

of a national genetics support service that is accessible, maintains feasibility and is grounded within service users' experiences. louisa.dipietro@vcgs.org.au

EMP1.44
Swedish healthcare providers' perceptions of preconception genetic carrier screening (PCS)- a qualitative study

A. Matar, U. Kihlbom, A. T. Höglund;
Center for Research Ethics and Bioethics, Department of Public Health and Caring Sciences, Uppsala University, Uppsala, Sweden.

Introduction: preconception genetic carrier screening (PCS) is a new approach to screen couples in the general population, without priori risk and planning pregnancy, for autosomal recessive traits. A couple would be screened for many conditions via expanded screening panels at one go. This technique is currently being piloted in the Netherlands but has not been implemented in Sweden. Materials and Methods: the study explores perceptions of PCS via expanded panels among Swedish healthcare providers, with focus on ethical aspects. Eleven healthcare professionals, including clinicians, geneticists, a midwife and a genetic counselor, from academic and clinical institutions in mid-Sweden were interviewed in depth, using a semi-structured questionnaire. Interviews were recorded, transcribed verbatim and content analyzed for categories and subcategories. Results: participants expressed ethical concerns regarding discrimination, medicalization, prioritization of healthcare resources and effects on reproductive freedom. Finding resources for PCS was regarded as expensive and burdensome for Swedish healthcare system. To reach informed consent with expanded panels was also seen as a challenge. Furthermore, parents might perceive a pressure to undergo testing, if PCS was implemented. Finally, participants also expressed worries that PCS would increase medicalization and strive for control of pregnancy and parenthood. However, it was also mentioned that PCS might enhance reproductive autonomy and could reduce abortion incidence, since it allows parents to opt for reproductive decisions. Conclusion: participants nurtured many ethical and non-ethical concerns regarding PCS that may affect the uptake and use. The results give insight of ethical concerns to consider; should PCS be implemented in Sweden.

EMP1.45
Discreditable inheritance: stigma and familial amyloid polyneuropathy ATTRV30M

Á. Mendes^{1,2}, **L. Sousa**^{3,4}, **J. Sequeiros**^{1,5}, **A. Clarke**⁶;
¹i3S – Instituto de Investigação e Inovação em Saúde; UNIGENE and Centre for Predictive and Preventive Genetics (CGPP), IBMC – Institute for Molecular and Cell Biology, Univ. Porto, Porto, Portugal, ²Department of Health Sciences, Univ. Aveiro, Aveiro, Portugal, ³Department of Education and Psychology, University of Aveiro, Aveiro, Portugal, ⁴CINTESIS, Center for Health Technology and Services Research, Univ. Aveiro, Aveiro, Portugal, ⁵ICBAS – Instituto de Ciências Biomédicas Abel Salazar, Univ. Porto, Porto, Portugal, ⁶Institute of Medical Genetics, School of Medicine, Cardiff Univ., Cardiff, United Kingdom.

Research on stigma related to genetic inherited disorders, although increasing, is still scarce. Here we report accounts of stigmatisation from patients affected by familial amyloid polyneuropathy (FAP) ATTRV30M living in Portugal's northwest coast, the largest cluster worldwide. Semi-structured interviews were conducted with 11 patients, all mutation carriers at different stages after presymptomatic testing, recruited through the patients' association. Qualitative thematic analysis of the interviews was undertaken. Findings show the influence of a discrediting social context in the enactment of stigma: FAP was perceived as a source of devaluation and social distance, and permeated by beliefs of contagion in the community. The trans-generational nature of the illness was felt as a source of rejection for courtship and mating, and of devalued reproductive worth. Decisions to have children seemed to be a target of implicit negative judgment. Dealing with stigma included restraint in talking about FAP, especially outside the family, the active confrontation of others, and social withdrawal. Participants also refer a reduction in stigma over the past few decades, as medical information, potential treatments and clinical trials, are becoming more widespread. We discuss the interactional nature of stigma with individual biography, family dynamics, and societal changes. These findings may be useful to set out the social consequences of stigma towards this group, and to understand how stigma is experienced in other genetic disorders for which presymptomatic testing is available. This is of importance to genetics and other healthcare professionals in assisting individuals to effectively manage these issues.
